Release Information

This section shares the following information:

What's New in this Release

This section contains the following CA Service Management Release and Patching information regarding new features and enhancements:

CA Service Management Release 14.1.02 Enhancements

CA Service Management 14.1.02 is a cumulative patch for CA Service Management 14.1 release. It includes new features, enhancements, performance and security improvements, and bug fixes. For more information about how to install and avail enhancements for this patch, see Implement the CA Service Management Patch 14.1.02 (see page 686). You can download the patch from CA Support Online (https://support.ca.com/irj/portal/newhome).

Following are the new features and enhancements:

CA Service Desk Manager Enhancements

Environment Promotion

CA SDM Administrators can now promote customization, configuration, and application metadata changes (objects and attributes) across development, test, pre-production, and production systems. For example, you can promote the modified forms, new tables, columns, spel, majic files, object data to the production system.

For more information, see CA SDM Environment Promotion (see page 1372).

Save Search Filters

CA SDM now provides an option for analysts to save search conditions. These saved searches are displayed on the analysts' scoreboard. CA SDM search filters are available for all ticket types, announcements, contacts, workflow tasks, and Configuration Items. Search fields for such objects need not be defined every time a search is performed. Saving the search filters enable users to update search criteria values in the search form and save the filter values for further use.

For more information see, Save Search Filters (see page 2323).

User and Group Assignment

Incidents, Change Orders, Problems, and Requests details now have improved filters. The Assignee and Group filters are interdependent. If you select an assignee, the groups that are associated with this assignee are displayed in the **Group** field. Similarly, when you select a group, assignees associated with this group are displayed in the **Assignee** field.

For more information, see Incident Management. (see page 2080)

CA Asset Portfolio Management

Environment Promotion

CA APM Administrators can now promote configurations, searches, export definitions, lists, and content changes across development, test, pre-production, and production systems.

For more information, see CA APM Environment Promotion (see page 1669).

Unified Self-Service

Customize CA SDM Data Source Property

USS Administrators can now define the maximum number of CA SDM fields that a user can configure in the Unified Self-Service console.

For more information, see *Customize the CA SDM Data Source Property* in the How to Configure the CA SDM Data Source (see page 1688) section.

Configure Visibility of Communities

USS administrators can now enable or disable the **Communities** for all or specific tenants.

For more information, see *Enable or Disable the Community* in the How to Create and Manage Communities (see page 1696) section.

Manage User Password

USS users can now reset their password from the login page after it expires.

For more information, see Manage User Password. (see page 3248)

MDB Level Setting for CA Service Management

CA Service Management now provides you the capability to move MDB from the source system and configure it to work with the target system. For more information, see Move MDB Database from Source to the Target System (see page 747).

CA Service Management Common Patch Installer

Use the CA Service Management common patch installer to install CA Service Management 14.1.02 patch. For more information on how to install the patch, see Implementing CA Service Management 14.1.02. (see page 686)

SMPatchReport Utility

Use SMPatchReport utility to identify and list the CA Service Management product patches installed in your system. For more information, see Run SMPatchReport Utility to Get Installed Patches List. (see page 742)

Fixed Issues - 14.1.02

The following issues are fixed in CA Service Management 14.1.02.

- Issues Fixed in CA Service Desk Manager (see page 71)
- Issues Fixed in CA Asset Portfolio Management (see page 80)
- Issues Fixed in CA Service Catalog (see page 83)

Issues Fixed in CA Service Desk Manager

The CA Service Management 14.1 cumulative patch #2 (14.1.02) includes a number of fixes denoted by the CA Service Desk Manager component: Service Desk Server (USRD). The following table lists the defect fixes that are resolved in the cumulative patch. For more information, search the knowledge base on CA Support Online (http://support.ca.com/).

For more information about the fixes in the CA Service Desk Manager 14.1.01 patch, see CA Service Management Release 14.1.01 Patch Information (see page 104).

S. No.	Problem No.	Summary
1	USRD 432 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=432)	LDAP UPDATE NOT WORKING FOR CONTACT WITH SINGLE QUOTE
2		OUTER JOINS MISSING IN REPORTS

S. No.	Problem No.	Summary
	USRD 709 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=709)	
3	USRD 1071 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1071)	CREATION OF INCIDENT WITH INCIDENT AREA FAILS FOR EMPLOYEE
4	USRD 1638 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1638)	EVENTS AND NOTIFICATION RULES FROM SUPERTENANT DO NOT APPLY
5	USRD 1960 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1960)	UTF8 TO MULTIBYTE STRING CONVERSION ERROR
6	USRD 1977 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1977)	AHD04608 ERROR IS RETURNED WHEN DOING EDIT IN LIST
7	USRD 2122 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2122)	BLANK WEB REPORTS WHEN DATA PARTITION RESTRICTION ON IMPACT
8	USRD 2162 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2162)	CANNOT INITIALIZE STATUS FIELD FOR COPIED CHANGE ORDERS
9	USRD 2426 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2426)	SESSION COUNT MAY GO BELOW ZERO
10	USRD 2569 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2569)	IMAGES MISSING IN NOTIFICATION EMAILS
11	USRD 2723 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2723)	VIEW RISK SURVEY PAGE MIGHT NOT DISPLAY CORRECTLY
12	USRD 2842 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2842)	EXPORT BUTTON REMAINS DIMMED OR DISABLED
13	USRD 2906 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2906)	WIS 10901 ERROR WITH BOXI WEB INTELLIGENCE REPORTS
14	USRD 2908 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2908)	TABBING OUT OF ROOT CAUSE MAY NOT POPULATE UNIQUE VALUE
15	USRD 2911 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2911)	NAVIGATING TO NEXT KNOWLEDGE DOCUMENT PAGE MAY FAIL
16	USRD 2913 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2913)	SECONDARY SERVER USING UNEXPECTED HTMPL FILES
17	USRD 2917 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2917)	MISALIGNED ENTRIES IN MONTHLY VIEW OF CHANGE CALENDAR
18	USRD 2920 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2920)	LOOKUP NO LONGER WORKS AFTER AN AUTOSUGEST VALUE IS SELECTED
19	USRD 2921 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2921)	REGISTRATION ERROR WHILE UPDATING CONFIGURATION ITEM
20	USRD 2931 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2931)	KNOWLEDGE DOCUMENT TEMPLATE PAGE DISTORTS
21	USRD 2933 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2933)	SUMMARY FIELD MAY NOT WRAP FOR THE EMPLOYEE INTERFACE
22		

S. No.	Problem No.	Summary
	USRD 2936 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2936)	INCORRECT MENUBAR DISPLAYED IN QUICK PROFILE
23	USRD 2940 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2940)	LIST TITLE FONT MAY UNEXPECTEDLY CHANGE IN INTERNET EXPLORER
24	USRD 2950 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2950)	RUNNING PDM_CONFIGURE LEAVES TMP_SQL.SQL FILE IN LINUX
25	USRD 2953 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2953)	SLA TRIGGERS ON INACTIVE TICKETS
26	USRD 2954 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2954)	KNOWLEDGE SEARCH MAY FAIL WHEN CREATING A NEW TICKET
27	USRD 2960 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2960)	REDIRECTINGURL NOT PARSED
28	USRD 2961 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2961)	KD COMMENTS GET DUPLICATED
29	USRD 2963 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2963)	EXPORT BUTTON REMAINS DIMMED OR DISABLED WITH NON-IE BROWSER
30	USRD 2964 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2964)	AUTOCOMPLETE DOES NOT WORK UNDER CERTAIN CIRCUMSTANCES
31	USRD 2972 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2972)	INCORRECT NAME OF BUTTON ON REQUEST STATUS CHANGE PAGE
32	USRD 2975 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2975)	MISSING HTML MESSAGE IN TICKET NOTIFICATION
33	USRD 2976 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2976)	PDM_ISQL RETURNS ERROR WHEN PDMWEB.EXE IS RENAMED
34	USRD 2979 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2979)	VALUE OF FALSE ON EDIT IN LIST FILTER
35	USRD 2980 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2980)	INTERNAL LOGS SHOWN FOR EMPLOYEE\CUSTOMER VIA REST
36	USRD 2983 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2983)	CI BASED AUTO ASSIGN ALWAYS OVERRIDES WHILE EDITING A TICKET
37	USRD 2984 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2984)	REST DEPLOY FAILS WHEN COMMON_NAME ATTRIBUTE TYPE IS DOUBLE
38	USRD 2986 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2986)	TENANTED KNOWLEDGE ACTIVITY NOTIFICATION RULES MAY NOT FIRE
39	USRD 2987 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2987)	SHOW ENTIRE TREE BUTTON INCORRECTLY DISPLAYED
40	USRD 2988 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2988)	NOTIFICATION HISTORY NOT UPDATED FOR STAKEHOLDER CONTACT
41	USRD 2989 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2989)	INVALID NOTIFICATION RULES SHOWN FOR ACTIVITY NOTIFICATION

S. No.	Problem No.	Summary
42	USRD 2990 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2990)	INCOMPLETE DROPDOWN LIST IF CODE CONTAINS COMMA
43	USRD 2994 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2994)	NO WARNING ABOUT PENDING UPDATES ON CLOSE WINDOW
44	USRD 3000 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3000)	VISUALIZER REDIRECTS TO WRONG URL WHEN PDMWEB.EXE IS RENAMED
45	USRD 3005 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3005)	AHD04106 ERROR RETURNED WHEN RUNNING WEBI REPORT
46	USRD 3006 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3006)	TENANT VALUE CHANGED TO LOGGED IN USERS TENANT
47	USRD 3008 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3008)	BLANK DOCUMENTS MAY BE DISPLAYED ON KNOWLEDGE SEARCH
48	USRD 3013 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3013)	DISABLED CATEGORIES ARE SEEN WHEN COPYING A TICKET
49	USRD 3015 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3015)	AUTO CLOSE EVENT MIGHT NOT BE CANCELED
50	USRD 3016 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3016)	UNABLE TO ATTACH SERVICE PROVIDER CONFIGURATION ITEMS
51	USRD 3021 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3021)	EVENTS NOT GETTING TRIGGERED
52	USRD 3028 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3028)	GETOBJECTVALUES WEB SERVICES METHOD RETURNS DELETED DATA
53	USRD 3031 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3031)	WRONG EXPIRATION DATE MAY APPEAR IN REPORTS
54	USRD 3035 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3035)	SEARCH DOES NOT WORK WHEN SOME FIELDS ARE MADE DROPDOWN
55	USRD 3045 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3045)	ATTACHMENTS FAIL WHEN THE REMOTE REP_DAEMON DISCONNECTS
56	USRD 3046 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3046)	GRLOADER UPDATES LAST UPDATE DATE FIELD FOR CI
57	USRD 3047 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3047)	UNABLE TO SET CACHE-CONTROL HEADER TO DISABLE CASHING
58	USRD 3056 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3056)	CONTACT COPY MIGHT CREATE INCORECT GRPMEM RECORDS
59	USRD 3058 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3058)	SLUMP PROCESS ABNORMALLY TERMINATES ON SHUTDOWN
60	USRD 3062 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3062)	LOOKUP NOT TRIGGERING ONMOUSEOUT IN SEARCH LIST PAGE
61	USRD 3063 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3063)	UNABLE TO PERFORM ACTIONS WHEN TITLE PAGE IS REFRESHED IN IE
62		

S. No.	Problem No.	Summary
	USRD 3078 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3078)	AUTO ASSIGNMENT FAILURE REASONS TO TICKET ACTIVITY
63	USRD 3079 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3079)	INACTIVE RECORDS MIGHT BE RETURNED
64	USRD 3083 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3083)	ANALYST UNABLE TO NAVIGATE PAGES IN KNOWLEDGE SEARCH
65	USRD 3085 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3085)	EDIT IN LIST HEADER TEXT MAY DISPLAY INCORRECTLY
66	USRD 3117 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3117)	TAB SWITCH CAUSE SCROLL ISSUE WITH INTERNET EXPLORER
67	USRD 3124 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3124)	SLOW PERFORMANCE DUE TO QUEUED TRANSACTIONS ON UPDATE AGENT
68	USRD 3126 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3126)	ARGUMENT ERROR ON REWORKING PUBLISHED DOCUMENTS
69	USRD 3131 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3131)	PERFORMANCE PROBLEM WHEN VIEWING KNOWLEDGE DOCS
70	USRD 3135 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3135)	HTTP ERROR 414 REQUEST URL TOO LONG MESSAGE
71	USRD 3142 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3142)	KNOWLEDGE FILTER MAY NOT BE APPLIED CONSISTENTLY
72	USRD 3144 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3144)	UNABLE TO COPY A CHANGE CATEGORY AS A TENANT ADMINISTRATOR
73	USRD 3148 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3148)	LDAP SERVER CONTACTED WHILE LOGGING IN SSO ENVIRONMENT
74	USRD 3152 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3152)	HELP MENUBAR SUPPORT LINKS SHOW PAGE NOT FOUND ERROR
75	USRD 3161 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3161)	DELAYED SERVER RESPONSE WHEN DOING MANUAL NOTIFY
76	USRD 3163 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3163)	UNABLE TO SET PRIVATE SERVICE TYPES FOR A WF TEMPLATE
77	USRD 3167 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3167)	ARCHIVE PURGE RULE PROMPTS CONFUSING CONFIRMATION MESSAGE
78	USRD 3172 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3172)	BUSINESS_CASE COLUMN MISSING IN ISSUE TABLE
79	USRD 3173 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3173)	STORED QUERY MANGLED ON WEB INTERFACE
80	USRD 3194 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3194)	EMAIL ADDRESS CORRUPTED IN KNOWLEDGE NOTIFICATIONS
81	USRD 3200 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3200)	TWO WORKFLOW TASKS STATUS MAY SHOW PENDING
82		

S. No.	Problem No.	Summary
	USRD 3203 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3203)	MACRO SEARCH PAGE FOR EVENTS DISPLAYS BLANK PAGE
83	USRD 3206 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3206)	UNABLE TO UPLOAD FILES USING INTERNET EXPLORER 9
84	USRD 3210 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3210)	WORKFLOW TASK STAYS IN WAIT STATUS
85	USRD 3216 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3216)	INVALID SEARCH COUNT ON KNOWLEDGE SEARCH PAGE
86	USRD 3218 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3218)	KT_DAEMON MAY TERMINATE ON BACKGROUND SERVER
87	USRD 3227 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3227)	HOVERING OVER BUTTONS MAY DISTORT WEB PAGE
88	USRD 3228 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3228)	INCORRECT MESSAGE WHILE CHANGING TICKET STATUS
89	USRD 3229 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3229)	PAGE MAY HANG WHILE TRYING TO EDIT A ROLE
90	USRD 3230 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=3230)	GARBLED CHARCTERS IN TICKETS CREATED VIA EMAIL

Issues Fixed in CA Asset Portfolio Management

S. No.	Fix #.	Description
1	T5M7131	During configuration when the object level is set to read-only, the extension is editable.
2	T5GJ148	The data importer job is not using the primary and secondary lookup keys to lookup the values provided in the mappings, instead, it is changing the case-sensitivity of the values.
3	T5M7130	New extensions are unavailable for any configuration in the **Add Existing Fields** section.
4	T5M7130	Unable to create an asset import with simple and reference fields on the cost extensions.
5	T5XU059	When a data importer job fails, the exact record details that caused the failure are not displayed.
6	T5XU059	The following error message is displayed while creating a data importer job on Internet Explorer 11: TypeError: Unable to get property 'Style' of undefined or null reference.
7	T5M7130	During asset registration with CORA, the following error message appears in the registration service log: FATAL CA.Applications.RegistrationService.CORAProcessor - Error updating the usp_owned_resource record for asset XXXXXXXXXXXX."
8	T5M7130	A default configuration option is selected when the **Configuration Mode** is set to **ON**. Any change in the configuration selection returns to default if you navigate to another relationship object.
9	T5GJ146	An exception is triggered in a CA SAM-integrated environment because the query used in Common Asset Viewer (AMS) is incorrect.
10	T5XU058	The CSV file is not created for **Mass Change Jobs** when the contact's first name is listed but the value is set to blank.
11	T5UM105	The following error message is displayed when a tenant user exports the search results and tries to access the link that is mentioned in the export service email: The application cannot retrieve this file for the following reason: system.web.services.protocaols.SoapException. Server was unable to process request.
12	T5E2411	All the date formats are not specified in UTC (Coordinated Universal Time). Created Date and Last Updated Date use the UTC format, whereas Reconciliation Date and Discovery Last Run Date use the local time format.
13	T5E2411	The font of map fields required to create an import is bloated in Internet Explorer 9.
14		

S. No.	Fix #.	Description
	T5E241 1	In data importer during asset creation, the following error message is displayed when the class information is not provided for the model: Class information is required.
15	T5E241 1	Delay in data sync between CA SAM and CA APM as the time formats used in audit table and dx process are different.
16	T5M7 129	The German date format changes to the US date format when exported from an asset search result.
17	T57T002	In a tenant environment the cost page becomes unresponsive when you enter a value in the **Unit Amount** field and press Tab. The **Currency Type** drop-down expands repeatedly and the page becomes unusable.
18	T5GJ143	An environment with CA APM integrated with CA SAM, the following error is displayed on the CA APM configuration screen: FATAL CA.Common.Web - Unhandled Exception: Arithmetic overflow error converting numeric to data type numeric
19	T5M7 127	A data importer job fails when the mapping includes an extended field or a secondary lookup value.
20	T5UM 107	No criteria is defined in the reconciliation process to identify assets with the same serial number and different hostname.
21	T5XU062	Data importer displays the following error message when % is used as the input fields for mapping: No records found for Asset Family - %(Asset Asset Type) Value%
22	T5XU062	After you click **Add Fields** with the **Configure Mode** being set to **ON** for an audit history search, the asset extensions link is not listed on the Add Fields window.
23	T5GJ152	The deleted cost extension is displayed in the **Add Existing Fields** and not in the **Expose Hidden Fields**.
24	T5EM237	The following error message is displayed when you change the asset model class: **The application cannot retrieve this file for following reason - File is not accessible**.
25	T5EM237	Unable to sort the column **Log Details** in descending order in the **Import Jobs** section.
26	T5UM 110	Scroll bar is missing in some drop-down lists (for reference, Mass Change settings, and Data Importer destination field mapping).
27	T5EM238	In data importer, updating location details on an asset fails when the Main Destination Object is set to Asset (All Families).
28		

S. No.	Fix #.	Description
	T5UM109	Irrespective of the actual payment amount, the **Legal Document Payment Due** always displays zero.
29	T5UM108	When a custom relationship is added to a configuration, the relationship count is incorrect in the **Asset** menu.
30	T57T038	The events that are triggered from CA APM took long to sync with CA SAM.
31	T57T012	Unprocessed events are excluded from the **Event Service**.
32	T57T023 T57T029	System faces memory issues when huge number of records are imported on asset and contact objects using data importer.
33	T5EM242	When any user other than the UAPM admin navigates to the **Administration** tab, the following error message is displayed: An unexpected error has occurred. Length cannot be less than zero. Parameter name: length
34	T5EM242	**Hardware Asset Family** subclasses are displayed as classes.
35	T5EM241	The SSL configuration for CA SAM end-point binding is not set-up.
36	T57I127	The last character of the asset name is duplicated when you delete any character except the last character from the asset name and on pressing Tab.
37	T57I126	Unable to enter '#' and '$' symbols in the required fields in Internet Explorer 11.
38	T5EM241	ITAM login credentials are saved in the cache.
39	T5EM241	The application does not validate the permissions while accessing the **System Configuration** page in the **Administration** tab.
40	T57T033	Asset update fails when the asset creator does not exist on the CA contact table.
41		The **Role Contact** pane on the **Role Management** page displays inactive contacts

S. No.	Fix #.	Description
	T57T009	
42	T57T012	Data importer imports the records even when there is no change in the data record.
43	T5E2411	The following error message appears when you save an asset after selecting the last name for a custom legal hold blue box: Another user updated this record after it was loaded.

Issues Fixed in CA Service Catalog

S. No.	Problem No.	Summary
1.	R14.1.02	Form Designer API update: "Note that the Predefined JavaScript Functions for fields and labels will not work if used as table columns".
2.	T52W137	IXUtil is slow when importing services and forms.
3.	T52W133	Slow key events experienced in IE11 for USS catalog user search page.
4.	T52W133	Duplicate items are shown in recent requests page of USS.
5.	T52W129	Users who log in using domain name are unable to add notes (comments) and attachments to any request.
6.	T52W126	Cannot load Catalog Capabilities from Mobile Application.
7.	T52W124	Chrome browser shows an error when a SOG is saved from CA Service Catalog UI.
8.	T52W133	Progress indicator remains on a page even after acknowledgement for any validation error that occurs in a form.
9.	T52W118	When a user tries to approve or fulfill a request, all data in the request information form is lost.
10	T52W116	USS common Admin **Manage users** capability does not set admin role to the users.
11	T52W115	Progress indicator does not disappear for some requests in USS that are using the ca_reportQuery method on OnLoad of the form.
12	T52W109	Radio button is misaligned in USS.
13	T52W104	In system forms like **Request Information**, form values are appended with **-0** and **-1** at the end.
14	T52W117	Unable to submit large forms with long text in USS.

S. No.	Problem No.	Summary
15	T5JH221	Offering description is missing in the USS offering page. Offering name appears as junk character in the USS portal. Unable to expand the Feature offering tree node after two level of folder hierarchy.
16	T5JH230	UUID value appears as a junk character in the form select field. Using the Web Service call UUID appears as a junk character.
17	T5JH231	The **Requested for** field is shown as a plain text box and not as Magnify glass. The $5 character is getting appended in the Overview text. In IE11, page navigation arrow is not working.
18	T5JH235	Submit button is not greyed out upon clicking. As a result, the user can submit the request multiple times.
19	T5JH236	The **Add to cart** button is not greyed out upon clicking. Consequently, a user can add multiple requests to the cart.
20	T5JH237	SDM inactive category is shown in CA Service Catalog plug-in.
21	T5JH241	SDM analysts unable to see attachment from CA Service Catalog.
22	T52W139	USM_Request_Status entries are mixed up and status_old is set to -1 if the service option of a request in pending approval state is edited by the service designer.
23	T52W139	Request submission takes three minutes to complete.
24	T52W139	It is not possible to edit a user profile especially, the phone number field. For example, editing 123ext456.
25	T52W139	Audit Trail history is showing wrong information about the service offering.
26	T52W139	RollBack is deleting new price in invoice.
27	T52W139	Drop-down search field in a form will not display properly when searching users by first name, last name, and user ID.
28	T52W125 T6DR008	The form is not loaded on the request page, when a service offering has only a SOG and an option with form attached to it.
29	T52W133	Lookup fields must not be editable and values must only be selected from the popup window.
30	T5ES163	Unable to change the back ground color of the forms.
31	T5ES161	If a service offering has more than one SOG and if any of the SOG has a single option, there is no way to deselect this option as part of request submission as the corresponding checkbox is removed.
32	R14.1.02	Radio buttons are not aligned properly with the main label for the radio group.
33	T58S083	CA SDM change order does not open seamlessly from CA Service Catalog request using related ticket link.
34	T58S081	CA Service Catalog freezes upon tandem request submission by three or more users.

S. No.	Problem No.	Summary
35	T58S088	Request Manager is unable to approve request in USS.
36	T58S106	CA PAM Processes initiated from CA Service Catalog are not archived.
37	T58S102	CA Service Catalog widget throws a script error when used in USS.
38	T58S107	Form data is lost.
39	T58S108	CA SDM Ticket Link is not displayed for Catalog request.
40	T58S109	USS request item status is not displayed.
41	T58S113	Single-Sign On (SSO) user is stripped off domain attribute.
42	T58S114	Mobile APP fails to login in SSO.
43	R14.1.02	Request gets stuck at approval or fulfillment phase if service definition is edited after request submission.
44	T58S121	Port Form Caching and Performance Improvements.

Known Issues - 14.1.02

The following known issues are specific to the CA Service Management Release 14.1.02:

- CA Service Desk Manager (see page 85)
- CA Asset Portfolio Management (see page 88)
- CA Service Catalog (see page 90)

CA Service Desk Manager

Symptom:

The Description pop-up of Data Export does not automatically close when you log out of CA Service Desk Manager or close the browser.

Solution:

Manually close the pop-up window.

Symptom:

Save a filter with an assignee name that is different from the logged in user name. Now, edit the same filter, the Assignee field appears blank.

Solution:

There is no workaround.

Symptom:

When performing data export you may encounter a MAX DEPTH level error.

For example: Data export reached to MAX DEPTH level 20 for factory lrel_att_ctplist_macro_ntf. Increase the MAX DEPTH value in the *<NX_ROOT>/pdmconf/export.cfg* file to get data for dependent factories.

Solution:

Increase value of the MAX DEPTH parameter in the *export.cfg* file located at *<NX_ROOT>/pdmconf/*.

Symptom:

If you have done a schema change in development and production systems, but have not used the exact names between the systems, for example **zTest** vs **zTEST**. In such a scenario, the *pdm_publish* fails because of a duplicate schema name found. The environment promotion process exits.

Solution:

Ensure that level set is done on the source and target systems.

Symptom:

If the CA SDM Environment Promotion processes for export, import, or dryrun are interrupted unexpectedly, the *<export_import_path>/Promotion* folder retains the footprint of the incomplete process.

Solution:

Manually remove the following folders:

<export_import_path>/Promotion/Export/sdmp_export_yymmdd_hhmmss

<export_import_path>/Promotion/Import/sdmp_import_yymmdd_hhmmss

<export_import_path>/Promotion/Export/DB/sdmp_db_data_export_yymmdd_hhmmss

<export_import_path>/Promotion/Dryrun/Dryrunyymmdd_hhmmss

Symptom:

The BHVTPL value for WFTPL is displayed as CODE (Integer) during the import process.

Solution:

Restart the CA SDM service.

Symptom:

Multiple object selection across pages is not supported.

Solution:

Click View All, to view all the objects on the same page and select the required objects to export.

Symptom:

When you execute the command *pdm_load –r –f tucson_delete.dat* while performing the post installation steps, you may encounter an error based on your system configuration.

For example:

```
ERROR: Error 15 on deleting row.

Problem row:

Error 1 on update, insert or delete done.
```

Solution:

Ignore the errors and proceed with the post installation steps.

Symptom: You may encounter errors or may see missing links between the objects while importing.

For example, you may encounter the following error for missing link between a macro and evt objects:

```
Error: Failed to create LREL for source : [ lrel_true_action_act_t:12409 ],  and
attribute : [ macro='macro:12020' and evt is null ] .  Reason : INVALID
```

The missing link errors may occur due to the following reasons:

- Reason 1: When the link between the objects is missing on the source system.
- Reason 2: When the link between the objects exist on the source system but is missing on the target system.

Solution:

Solution 1: Ignore the error when the link is missing on the source system.

Solution 2: Manually update the link when it is missing on the target system.

Symptom: When you export an object without exporting the dependent objects, you may encounter errors while importing.

Solution: Always export the dependent objects before you export the parent object. Also, when you import, ensure that the dependent objects are imported before you import the parent object.

For example, before exporting the *chgcat* object, export the *tskstat* and *tskty* objects. While importing, ensure that you import *tskstat* and *tskty* objects before importing *chgcat* object.

Symptom: When you import the *risk_level* or *prptpl* object, you may encounter the following error:

For example:

```
Detail message : AHD04116:A duplicate record was encountered. Insert or Update failed.
SDMP10012 : Error while importing record for persistent id : risk_level:100
```

Solution:

- Navigate to the *NX_ROOT\pdmconf* folder and update the following values in these files on the source and target systems:
  - *dbpromote.uniquekey* file:
    - risk_level.uniquekey=enum
    - prptpl.uniquekey=object_type, object_attrname, object_attrval, sequence
  - *DBImport.properties* file:
    - resolve.prptpl.attributes=object_attrval
- Perform export and import again.

Symptom: O n the Non-Windows Advanced Availability server, importing the configuration or customization changes does not automatically start the CA SDM services.

You may see the following message for a while and observe that the services do not start:

Starting the CA SDM service. Please wait until the service starts completely.

Solution:

Follow these steps:

1. Interrupt the import process.
2. Start the CA SDM services manually and perform a failover.

CA Asset Portfolio Management

Symptom: During CA APM Environment Promotion Export, the contact must have a user ID that is associated with it, when the filter value is set to **Last Modified User**. If the condition fails, the search criteria ignores the **Last Modified User** filter and all the records are displayed.

Solution: There is no workaround.

Symptom: Unable to create a new event in CA APM 14.1.02. The follow error appears on the event creation screen: *The type initializer for CA.Common.Workflow.Provider.ProviderManager threw an exception.*

Solution:

Follow these steps:

1. Log in to CA ITAM application server.
2. Stop the CA Asset Portfolio Management - Event Service
3. Navigate to the *Root/Event Service* folder.
4. Open the *CA.Applications.EventService.exe.config* file.
5. Modify the Current Key with the New Key.
   Current Key:

   ```
   defaultProvider="CA IT Process Automation Manager r4.0/r4.1"
   ```

   New Key:

   ```
   defaultProvider="CA IT Process Automation Manager"
   ```

6. Modify the Current Key with the New Key.
   Current Key:

   ```
   name="CA IT Process Automation Manager r4.0/r4.1"
   ```

   New Key:

   ```
   name="CA IT Process Automation Manager"
   ```

7. Start the CA Asset Portfolio Management - Event Service.
8. Log in to the CA ITAM web server.
9. Navigate to the *Root/Web Server* folder
10. Open the *Web.config* file.
11. Modify the Current Key with the New Key.
    Current Key:

    ```
    defaultProvider="CA IT Process Automation Manager r4.0/r4.1"
    ```

    New Key:

    ```
    defaultProvider="CA IT Process Automation Manager"
    ```

12. Modify the Current Key with the New Key.
    Current Key:

    ```
    name="CA IT Process Automation Manager r4.0/r4.1"
    ```

    New Key:

```
name="CA IT Process Automation Manager"
```

13. Execute the following command to stop and restart IIS services on the web server:

```
iisreset
```

Symptom: Environment Promotion Import process fails and the following error message appears when the application server name registered in al_cdb_configurationparameters table is set to FQDN (fully qualified domain name) :

This utility can be executed only on the APM Component server. Exiting the application as the current server is not the component server.

Solution:

Follow these steps:

1. Log in to system database (MDB).
2. Run the following script:

```
UPDATE al_cdb_configurationparameters
SET configvalue = '{Component server machine name}'
WHERE componentkey='Application_Server' AND configkey='ComponentServerName'
```

3. Execute the following command to stop and restart IIS services on the application server:

```
iisreset
```

CA Service Catalog

Symptom: The offering in the **Requests** page on the CA Service Catalog UI are unavailable when the Microsoft SQL Server has a non-default MDB name.

Solution:

Scenario 1: If you are installing 14.1.02 on CA Service Management 14.1:

Follow these steps:

1. Log in to the database as sa user using MS SQL Server Management Studio.
2. Open the *USMHOME/REPLACED/CA_SLCM_r14.1.02.OLD/unconfigureMDB /configureMSSQLMDB-SP1.sql* file.
3. Copy and execute the file content in Microsoft SQL Server.
4. Open the *USMHOME/REPLACED/CA_SLCM_r14.1.02.OLD/unconfigureMDB /configureMSSQLMDB-SP2.sql* file.
5. Copy and execute the file content in Microsoft SQL Server.
6. Restart the CA Service Catalog Windows Service.

Scenario 2: If you are installing 14.1.02 on CA Service Management 14.1.01:

Follow these steps:

1. Log in to the database as sa user using MS SQL Server Management Studio.
2. Open the *USMHOME/REPLACED/CA_SLCM_r14.1.02.OLD/unconfigureMDB /configureMSSQLMDB-SP2.sql* file.
3. Copy and execute the file content in Microsoft SQL Server.
4. Restart the CA Service Catalog Windows Service.

CA Service Management Release 14.1.01 Enhancements

CA Service Management Release 14.1.01 Enhancements

The following new features and enhancements are only available if you apply the patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

CA Service Desk Manager Enhancements

Call Service Desk from Mobile

CA SDM mobile application users can use the Call Service Desk feature to contact the CA Service Management service desk or help desk. Administrators must configure or customize the service desk number using the Options Manager. To enable the options, see Call Service Desk options (see page 1308). For more information about calling service desk, see Call Service Desk from your Mobile Device (see page 3176) topic.

Show To and Cc List Recipients in the Email Notification

You can now view all the recipients of an email notification. For manual email notification, both To and Cc list recipients are displayed and for automatic email notification, only To list recipients are displayed. For this feature to be enabled, install the **mail_show_to_cc_list** option from Options Manager. If you do not install this option, you can only add recipients in the To list **.** For more information, see the Create a Manual Notification (see page 842) topic.

Note: Pager email notification method does not support the listing of all the recipients in To or CC list.

Add Attachments and URLs to a Manual Notification

Attach a local document or URL to a manual notification that is being sent to an end user. For example, the attachment can contain steps to resolve an incident. For audit purposes, the document being sent as part of the manual notification should also be attached to the parent ticket. The

attachment associated with the manual notification will be delivered as an email attachment in the inbox of the recipient. Ensure that the attachment adheres to the email server configuration of the sender and the receiver. For example, size of the file, extension of the file, and so on. If the attachment does not meet these requirements, the manual notification email may get rejected.

For this feature to be enabled, install the **mail_allow_attmnts** option from Options Manager. For more information about the considerations and how to attach the document or URL, see the Create a Manual Notification (see page 842) topic.

Attach Classic Workflow to Each Ticket Type Area

You can attach a classic workflow with each of the request, problem, incident areas. This feature also enables you to attach Request/ Incident/ Problem workflow tasks to events, macros, and notifications as the object type. The procedure to attach the workflow remains the same as attaching it to issue and change order categories. Find more information, see Attach a Classic Workflow on Define a Category or Area (see page 1054) page.

Attach CA Process Automation Workflow to Each Ticket Type Area

You can attach a CA Process Automation workflow with each of the request, problem, incident areas. Find more information, see Attach a CA Process Automation Workflow on Define a Category or Area (see page 1054) page.

Note: For the same ticket area you can attach a Classic workflow or a CA Process Automation workflow for each ticket object (Request/Incident/Problem). For example, for the same area, you can attach a Classic workflow to a request and CA Process Automation workflow to a problem or incident.

Add Attachments to a Configuration Item

Attachment tab support is available for Configuration Item (CI). This feature enables you to attach documents and URLs to a CI. Notifications are sent to the users when an attachment is attached or removed from the CI. For more information, see Attachments (see page 2476).

CA Service Catalog Enhancements

Search Forms

This feature enables user to search for a specific form in Forms Designer page. Form Display name or Folder name can be used to search the form. The search mechanism provides auto suggestion as the user types search terms in the form search text box. The search functionality is case-insensitive and the search results are displayed in hierarchical manner. For more information, see Search Forms (see page 2914).

Form Associations

The **Associations** tab in the Form Designer UI provides the list of service offerings and service option groups that are associated with the selected form. It provides the ability to view where a particular form is used in the current Business Unit and also the capability to assess the impact of modifying or deleting a form. This functionality is also available in the Form Chooser UI when attaching a form to a Service Option. For more information, see Create and Maintain Forms (see page 2986).

Configuration options for displaying or hiding SOG and Form display names

To hide or display the Service Option Group name, a check-box **Hide SOG name** is now provided in the details tab of the offering. This option is enabled only when an offering has a single Service Option Group. In case of multiple service option groups in offering, this option is disabled or greyed out by default. Checking or unchecking this option will not alter the offering preview. An option called **Display Form name** is provided in the Form Chooser UI when attaching a form to a Service Option to show or hide the form name. This option is dependent on System Configuration settings. If the administrator has disabled the form name display option at the System Configuration level, the form name is not displayed, even if the **Display Form name** option is checked. For more information, see Display or hide the Service Option Group Name (see page 2999) and Fields for Form Elements (see page)

New and Flat Icons

The Out of the Box (OOTB) Catalog content, CA Service Management Content Pack & CA Service Management Administration content pack is enhanced to include new and flat icons in the service offering definitions. The patch will re-import the OOTB content implicitly as part of the patch install, however CA Service Management Content Pack & CA Service Management Administration content pack will be imported based on the Administrator choice while installing the patch.

Email Notifications

CA Service Catalog now provides the capability to send email notification to end users and approvers when a note and/or attachment is added or modified for a request or an issue. The capability is provided based on a set of newly added Event-Rule-Actions which can be enabled or disabled as required. For more information, see Add Notes and Attachments (see page). The following are the Event-Rule-Actions:

- Notes Create (see page)
- Notes Change (see page)
- Attachment Create (see page 94)
- Attachment Change (see page)

Notes Create

This event type occurs when a note is created for a CA Service Catalog request. Rules associated with this event type are as follows:

- **When a note is added to a CA Service Catalog request**: When a note is added to a CA Service Catalog request, email notifications are sent.

- **When notes are added to a CA Service Catalog request**: When a note is added to a CA Service Catalog request, it is also synchronized with the corresponding CA Service Desk Manager ticket.
- **When a CA Service Desk note is synchronized to a CA Service Catalog request**: When CA Service Desk Manager (CA SDM) note is synchronized to CA Service Catalog request, email notifications are sent.

Notes Change

These event types occur when a Note is changed or modified for a request. The following rules are associated with this event type:

- **When note with attachment(s) is edited in a CA Service Catalog request**: When a note with attachment(s) is edited in CA Service Catalog request, E-Mail notifications are sent.
- **When note without attachment(s) is edited in a CA Service Catalog request**: When a note without attachment(s) is edited in CA Service Catalog request, E-Mail notifications are sent.

The Notes Create and Notes Change Events have the following parameters:

Event Parameter	Meaning	Example
$source_id$	The request ID of the corresponding note.	10510
$note_text$	Description of the note.	
$ignore_notification$	Value will be true in the following cases: ▪ on submission of a request that has note(s). ▪ when a note event is triggered for a comment with notes and attachments posted in Widgets.	

Attachment Create

This event type occurs when an attachment is created for a request. Rules associated with this event type are as follows:

- **When attachment is added to CA Service Catalog request**: When an attachment is added to a CA Service Catalog request, it is added as a link to the corresponding CA Service Desk Manager ticket.
- **When attachment is added to a CA Service Catalog request**: When an attachment is added to a CA Service Catalog request, email notification is sent.
- **When note and attachment(s) are added to a CA Service Catalog request**: When note (s) and attachment(s) are added to a CA Service Catalog request from Widgets, email notifications are sent.

- **When a CA Service Desk Manager attachment is synchronized to a CA Service Catalog request**: When a CA Service Desk Manager attachment is synchronized to CA Service Catalog request, email notifications are sent.

Attachment Change

This event type occurs when an attachment is changed for a CA Service Catalog request. Following rule is associated with this event type:

- **When attachment associated with a CA Service Catalog request is edited**: When an attachment associated with a CA Service Catalog request is edited, email notifications are sent.

The Attachment Create and Attachment Change events have the following event parameters:

Event Parameter	Meaning	Example
$object_id$	The request ID of the corresponding attachment.	10510
$ignore_notification$	Value will be true in the following cases: ▪ on submission of a request that has attachment(s). ▪ for the first n-1 attachments when a comment with n attachments is posted in Widgets.	Example: If a comment in Widgets has 1 note and 5 attachments, for the first four attachments (n-1=4), the value will be true.
$attachment_url$	Specifies the URL(s) of the uploaded attachment(s).	

Request Details Link for Email Notifications

By default, value for this parameter is not configured. This parameter can be configured in the following format if CA Service Catalog is configured with USS:

http://<USS HostName>:<PortNumber>/web/frontoffice/myrequest-catalog?ServiceCatalogRequestID=

If Unified Self-Service (USS) URL is configured for Request Details Link for E-Mail Notifications, clicking on the request details hyperlinks in the email notification will take to the Unified Self-Service login page instead of CA Service Catalog login page. If this parameter is not configured, clicking on the hyperlinks in email notification with request details takes to the CA Service Catalog Login page.

Edit Completed Requests

A new configuration item Edit Completed requests is added in the **Catalog**, **Configuration**, **Request Configuration UI**. For more information, see Request Management Configuration Parameters (see page 1456). The following values are applicable for this configuration item:

- True – Completed requests can be edited.
- False - Completed requests cannot be edited.

Edit Cancelled Requests

A new configuration item Edit Cancelled requests is added in the **Catalog**, **Configuration**, **Request Configuration UI**. For more information, see Request Management Configuration Parameters (see page 1456).

- True – Cancelled requests can be edited.
- False - Cancelled requests cannot be edited.

Include in Email Notification

In Form Designer, a new attribute is introduced for every form element. This element attribute is used to display a field or component value, including the label in email content. Specify the value as true or false. When the value is set to true, the field or component value is visible in the email. To set or edit this attribute, you must have admin rights. Navigate to Catalog, Forms, select the Form Component and click on the Include in Email attribute. You can use the JavaScript expressions to specify the value as a condition for the Include in Email Notification attribute too. For more information, see Include In Email Notification (see page).

When you set the **Hidden** and **Include in Email Notification element attribute** to true/false in the CA Service Catalog UI, the following is reflected in UI and email notifications:

Hidden	Include in Email Notification	Result
true	true	Form component is not displayed anywhere.
true	false	Form component is not displayed anywhere.
false	true	Form Component and value is displayed in the Form Designer and the Request Form while raising a request, and also in the email notification.
false	false	Form component appears in the Request Form UI and the Form Designer UI, but the component value is not displayed in Email Notifications.

Locale Support for Request Email Action

A new option to choose the locale or language of an Email is added to the standard out of the box Event-Rule-Action set for Request Email. It allows the Request Email Action to choose the language for sending request emails. This capability offers great flexibility as it overcomes the limitation of sending request emails in just one locale. CA Service Catalog Administrators can select the language for sending the Request Email.

- Parameter Name: Choose Email Language
- Type of UI Control: Select Box (Drop down list)
- Options: All supported languages with a special option of Browser Language.
  Browser Language option for email language ensures that the Request Email is sent in the browser language at the time the request is submitted. For example, if a Request Email action is configured with Email language set to Browser Language, the Request Email sent for request submission from a browser supporting French language will be in French.
- English
- French
- German
- Spanish
- Italian
- Chinese
- Japanese
- Brazilian Portuguese
- Dutch
- Finnish
- Danish
- Swedish
- **Browser Language**

How to Specify the Email Subject in a Localized Form

When the **Browser Language** option is chosen as the Email Language, it is apparent that the same Request Email action sends out Email notification in any of the supported locales based on requester' s browser language. This option is very useful in a multi-lingual environment with globally distributed CA Service Catalog users. Since, the same Request Email Action is used to send emails in any of the supported locale, the subject and message of an Email must be given in the locales that you require.

Both the Subject and Message fields accept the following format:

```
<Language code1> :< Language specific subject1>|! <Language code2> :< Language specific subject2>….
```

Note: The character **|!** Is the separator that separates subject line of two different languages.

Standard Language Codes

Language	Code
English	Icusen
French	Icfrfr
German	Icdede
Spanish	Icdede
Italian	Icitit
Chinese	Iccnzh
Japanese	Icjpja
Brazilian Portuguese	Icbrpt
Dutch	Icnlnl
Finnish	Icfifi
Danish	Icdkda
Swedish	Icsesv

An example of Subject Line in Multiple Languages to be used with Browser Language option for Request Email

```
icusen:Approval needed for one or more items in the request ($request_id$) for user
($req_for_user_id$)|!icnlnl:Goedkeuring nodig voor één of meer punten in het verzoek
($request_id$) voor de gebruiker ($req_for_user_id$)|!icbrpt:Aprovação necessária
para um ou mais itens no pedido ($request_id$) para o utilizador ($req_for_user_id$)|!
icdkda:Godkendelse nødvendig for et eller flere emner i anmodningen ($request_id$)
for brugeren ($req_for_user_id$)|!icdede:Zulassung für ein oder mehrere Objekte in
der Anfrage ($request_id$) für Benutzer benötigt ($req_for_user_id$)|!iceses:
Aprobación necesaria para uno o más elementos de la solicitud ($request_id$) para los
usuarios ($req_for_user_id$)|!icfifi:Hyväksyntä tarvitaan yksi tai useampia
kohteitapyynnöstä ($request_id$) käyttäjälle ($req_for_user_id$)|!icfrfr:Approbation
nécessaire pour un ou plusieurs éléments de la demande ($request_id$) pour
l'utilisateur ($req_for_user_id$)|!icitit:Approvazione necessaria per uno o più
elementi nella richiesta ($request_id$) per gli utilizzatori ($req_for_user_id$)
```

The same format is applicable for the Message field as well.

Note: You must use the multi-lingual Subject and Message field only if you use the Browser Language as the Email Language. If you are not using the Browser Language option, you are not required to provide the multi-lingual subject and message.

Note: This feature is complementary with Forms that are localized as the Forms included in the Request Email will also appear in the language of choice.

How to flip over all existing Request Email Actions to send Emails in a language other than English after installing the patch

In order to facilitate an easy flip over to send Request Emails in a language other than English with minimal work, an administrative option is added and included in **Administration**, **Configuration**, **Mail Server**. The new property is Default Request Email Language. The default value of this property is English. By changing this option to some other language, all existing Request Email actions will send out mail in the newly chosen language. This also serves as the default language when you add a new 'Request Email' action.

Limitations

This feature is not available when you are using the web service method of **sendRequestEmail**.

Request Pending Action Change

In cases, where there are multiple approvers and when pending approval actions are assigned, the 'Request Pending Action Change' event sends notifications as many number of times as per the number of approvers. In order, to identify the sequence of such event occurrences for email notification, a new parameter is added: Request Pending Action Change.

- **Parameter Name**: *sequence_id*
- **Values**: Starts with 0 and increments by 1 for every subsequent event that is part of the same Request for which a Pending Action Change has occurred.
- **Application**: This parameter could be used to control action execution based on first occurrence of this event. For e.g. A rule condition that is written by using the following condition would fire only once in spite of the number of approvers on a request *sequence_id=0*.

Addition of New objectSOE to Form Designer Standard Objects Set

This object has been added as there was a requirement to access the Service Option ID to which the form has been attached to. The new object is soe which is available exclusive to Form designer object set. This object has three properties:

- soe.item_id: Specifies the Rate item id of the service option name field
- soe.item_text: Specifies the Service option name
- soe.service_option_id: Specifies the service_option_id of this service option

These new properties could be used to build some useful regular expresssions. For example, to show a form field if the Form is attached to a Service option whose name is New Hire Onboarding:

```
Hidden = $(_.soe.item_text!=' New Hire Onboarding')
```

Pagination Feature to Approval List of Policy Designer

Pagination Feature is added to the assignees Lookup table in the CA Service Catalog Policy Designer Page. It works on the filtered set of approvers (User, Group, and Manager).

New Certifications Included with the Patch

For operating systems, hardware, and software supported by CA Service Catalog 14.1.01 patch, see the certification matrix available at https://wiki.ca.com/display/CASM1401/Supportability+Matrix. For more information, search the CA Service Catalog knowledge base available on http://ca.com/support.

Fixes Specific to the CA Service Catalog 14.1.01 Patch

The following contains the list of fixes that are specific to the CA Service Catalog 14.1.01 patch updates:

- The CA Service Catalog UI crashes when there are two users with identical userids, one active and other inactive.
- The **Requested For** field in the cart is set to default (logged in user) every time a new service offering is added to the cart.
- Built-in event for **Request Transfer** fires multiple times and sends multiple emails to requester when there are multiple approvers.
- When a **requested_for** is selected for a user and there are multiple users with the same userid, one active and others inactive, the **requested_for** is updated to the default user during the request save/submission.
- If a Business Unit (BU) contains some Swedish characters in the ID field, the roles are not populated when the user details are edited for this BU.
- A request can be edited even when it is marked as complete.
- CA Service Catalog search fails as there is an SQL exception at the back end.
- A request can be edited even when it is marked as cancelled.
- When you click the Email button for a request, the request created date is not loaded. This is noticed when there are duplicate spadmin entries, one active and others inactive.
- Folders overlap when there is a huge list of folders and sub folders in the request page.
- Request lookup for a request with 10 Forms and 10 service options takes up to 5 minutes to load.
- Request pending action fires an event each for every approver. An email event written to notify old approver results in multiple emails as that of the number of new approvers.
- LDAP Importer goes into an infinite loop when the user uses TDS (Tivoli directory server) with the **Range Retrieval** option turned off.
- Inheritance relationship of service offering breaks when the names are updated.

- In cases, where there are multiple approvers and when pending approval actions are assigned, the **Request Pending Action Change** event fires as many number of times as the number of approvers. There is a need to identify the sequence of such event occurrences for email notification purposes. In order to facilitate this need, a new parameter has been added to events - **Request Pending Action Change**.

- Clicking the CMDB/SDM test button fails on Internet Explorer (IE) 10. No such issues are noticed with other web browsers.

- Request Email sent from CA Service Catalog contains content in English (for example, General Information, Requested Services, Form Content, and so on.)

- A new object called SOE is made available in the forms designer for expression **evaluation. soe**. It contains the following properties:

  - item_id = rate item id of 'service option' name field soe.

  - item_text = Service option name soe.

  - service_option_id = service_option_id of this service option.

- Copying a service option in the SOG definition throws an error if the form rate item definition uses regular expression to control visibility of the form, and if the expression contains the Exclamation (**!)** mark in it.
  For example: *$(_.service.code != 'noservice')*

- The Email Approval Error Notification Process fails in kicking the Error Notification Process. The Error Notification Process fails triggering the POSTAlert web service method.

- Approve and Reject links in Request Email that are generated from OOTB does not work in SSO as the user is prompted to login again.

- After removing an image from a service offering, white space is seen.

- Setting the **Disable** attribute of a form by providing a JavaScript expression at a Service option level to add a form to it. In widgets, the form can be edited even if the JavaScript validation is valid. However, in the CA Service Catalog UI, it cannot be edited.

- After selecting the Perform Action for a request in which the logged in user is not assigned the pending action, the whole form becomes read only (grayed out) even if the override action is selected.

- On Internet Explorer (IE) 8, clicking the **Ok** button does not save a report to a specific folder in the Set Folder of the Report Builder.

- The **Create Inherited Copy** button does not copy Option in the same language

- There is no synchronization between widgets. Status widget does not update the open requests and cart numbers correctly on other widgets.

- Pagination feature to the approval list (of users and groups) in the policy designer page is introduced.

- For service options associated to an offering that is defined as **One-Click Submit** when the correspondent FORM is loaded, it does not hold the value of ca_fd.formId (returning undefined value). As a result, it is not able to execute the onLoad script of the form which depends on **ca_fd.formId** value in order to pre-populate form values.

  Two new parameters are added to this function:

  ```
  ca_fdFetchSelectData(FormID,DualListID,Validate,KeepExisting)
  ```

  - **Validate**
    The Validate parameter is a boolean value to validate the ToList of dualList on fetching new data into the component.

  - **KeepExisting**
    The KeepExisting parameter is a boolean value to retain the values of ToList on fetching new data into the component.
    For example: ca_fdFetchSelectData('form1','dlist','false','true');
    For details, refer to Test fix: T52W073

    

    Note: These two parameter values are optional. If the user is not using these values, the component works as per design.

- An image may be shown as the Service option name. Due to this, the HTML tags are displayed in the Service Option name in widgets.

  

  Note: For more information, refer to Test fix: T52W084

- If any regular expression is given in the pattern attribute of the field, the field is treated as a mandatory field even when it is not mandatory.

- Cross-Site scripting (XSS) vulnerability is noticed with the resetpassword UI node.

- The table data is not populating in the read-only mode when the table mode is set to data instead of selection.

- Policy conditions with external_id (for example, *$(anySoWith('external_id', eq,'111'))*) are not satisfied. This results in the corresponding policy notable to assign the respective action as desired.

- The request is approved after the first or second Overdue notification email is sent. This is noticed even when the status is successfully moved to Pending Fulfillment, and the final Overdue notification as well as the **Not Submitted – Rejected** email is sent.

- When iterating multiple items within the cart, CA Service Catalog makes the same number of calls to the EEM API method. Results are not cached, and unnecessary calls to the EEM API are made which may impact the performance.

- The **getUser** web service method does not return the group details of the user.

- When the logIn() web service is called simultaneously by multiple threads, similar message may randomly get logged in the view.log caused by:

  ```
  com.microsoft.sqlserver.jdbc.SQLServerException: Violation of PRIMARY KEY
  constraint 'XPKusm_webservice_sessions'. Cannot insert duplicate key in object
  'dbo.usm_webservice_sessions'. and the logIn method will not complete successfully.
  ```

- If the Local EEM Group with multi-domain users is made the Approver, the members do not receive email notifications.
- The Domain column of usm_request table is not updated correctly.
- Generating invoice breaks the existing requests by creating several new columns in the request details page.
- If a form contains a field that holds data of size more than 65536 bytes, the Policy based pending action assignment breaks.
- If the Service Options are selected in a quick succession, forms of few service options are not loaded.
- Opening the Service Desk Ticket link from CA Service Catalog may take time to load and open.
- Permissions assigned to a folder or service offering based on multi-domain LDAP group is not honored.
- The change order details page prompts for Authentication.
- Archived Process Status shows up as unknown in Catalog Request Tracking Tab.
- When a Service Offering is exported using the XUTIL, the resultant XML file may not contain few rate items.
- If you select a row on the first page when the **Maximum rows** attributes of a table is set to 1, selecting a row on the second page throws an error instead of deselecting first selection.
- Dual list options that have long labels are truncated and appended with **'...'**. As of now, we do not expose a horizontal scroll bar or allow for mouse over of the options to display the full label as the mouse over is controlled by the **Tool Tip** attribute of the dual list.
- When a select field has multiple options with the same value, the request will always show the first option with the selected value after added to the cart.
- Report data object throws a browser error when you try to edit it.
- In a cart page, additional offerings are shown if the description contains span elements with id value.
- List drop-down details are editable
- The **Submit** button may stop working and show a hang status in the Unified Self-Service Interface. For more information, see *Test fix: T5ES150* posted on http://ca.com/support.

CA IT Asset Manager Enhancements

Search List Items

If you have a larger number if items in your list, you need not navigate across all items to find the item you want. As a CA APM user, you now have the ability to filter your list items. The search criteria depends on the properties of the list.

For more information, see Manage List Items (see page).

Export List Item Search Results

As an Administrator, for a user-defined search, you can now view the user who created the search and when the search was last performed. This information helps you delete user-defined searches if they are not in use for long time.

List Management Access

As an Administrator, you can now define who accesses List Management. You can also determine the list items that different roles can access.

Import List Items

In List Management, you can now export the list of items that you searched for to a CSV file.

Change Cost Details of Specific Assets Using the Lookup

In the Add Asset Cost utility, you can now change cost details of specific assets using the lookup.

CA APM and CA SAM Data Synchronization Changes

CA SAM Import Driver in CA APM 14.1.01 is aligned with the latest change in CA SAM database schema related to operating system values for devices in CA SAM versions 3.6.5 and later.

If CA APM is integrated with CA SAM in your solution deployment, consider the following:

- To install/upgrade to CA SAM 3.6.5 or later, you must install/upgrade to CA APM 14.1.01 or later to be fully compatible with CA SAM.
- For older versions of CA APM (14.1 or older), you must not upgrade CA SAM to version 3.6.5 or later.

CA Service Management Release 14.1.01 Patch Information

The CA Service Management 14.1 cumulative patch #1 (14.1.01) includes a number of defect fixes for the Service Desk component, available for your download (http://www.ca.com/us/support/ca-support-online/product-content/recommended-reading/technical-document-index/ca-service-management-solutions-patches.aspx). For a smooth transition to our published patches, review the Cumulative Incidents (http://www.ca.com//us/support/ca-support-online/product-content/recommended-reading/product-related-technical-information/reported-incidents-with-first-cumulative-patches-of-ca-service-desk-r14_1.aspx).

The following table lists the individual defect fixes resolved in the cumulative patch. For more information on a particular problem, search the knowledge base on support.ca.com (http://support.ca.com) or click on the hyperlinks below.

S. No	Problem #	Summary
1	USRD 801 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=801)	LOCALIZATION CHARACTERS GARBLED IN CONSOLE DISPLAY
2	USRD 1897 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1897)	EXPORT BUTTON EXPORTS WRONG DATA
3	USRD 1927 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1927)	TRANSLATION FILE IN GRLOADER CONFIG FILE IS IGNORED
4	USRD 1939 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=1939)	AUTOFILLING OF TICKET SHOW FIELD COMPLETION IN PROGRESS
5	USRD 2113 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2113)	KT_DAEMON MAY TERMINATE WITH STRING TOO BIG ERROR
6	USRD 2133 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2133)	SUPPORT AUTOMATION LOGS ARE EMPTY DUE TO WHISPER LOGS
7	USRD 2765 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2765)	IE9 CRASHES ON OPENING MULTIPLE BROWSERS
8	USRD 2832 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2832)	BOGUS STRING ERROR WHILE PUBLISHING THROUGH WSP
9	USRD 2909 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2909)	PDM_LOAD TERMINATES DURING LOAD WITH MANY TABLE REFERENCES
10	USRD 2915 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2915)	UNABLE TO ACCESS HELP BOOKSHELF AFTER RESTART
11	USRD 2918 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2918)	IMAGE URL GETS ADDED WHEN TOGGLING BETWEEN SOURCE AND DESIGN
12	USRD 2928 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2928)	DEFAULT CHANGE TYPE NOT ASSOCIATED ON CATEGORY CHANGE
13	USRD 2938 (https://support.ca.com/irj/portal/kbproblem?productcd=USRD&problemnbr=2938)	PRINTING FORM OUTPUTS GARBAGE DATA IN INTERNET EXPLORER

CA Service Management Release 14.1 Enhancements

CA Service Management Release 14.1 Enhancements

The following enhancements provide the solution experience for the CA Service Management users. These features help reduce the time spent on installing, configuring, and administering the solution.

Simplified Install or Upgrade Experience

Single Installer to Install All or Any Combination of the Products in the Solution

You can now install all or any combination of the products in the solution using a single installer, instead of using individual installers for each product. Once you select the products that you want to install, the installer performs the prerequisite check for the selected products and lets you know the status of each prerequisite. It also prompts to install the common components that are required for the products. Common components are CA EEM, CA Process Automation, CA Business Intelligence, and the MDB.

The CA Service Management installer replaces the individual product installers. Therefore, the product-specific installers are no longer available for the products in the solution**.** The common component installers are launched directly from the CA Service Management installer except for CA Process Automation.

With this release, the name of the database (the MDB) is no longer hard-coded to “MDB”. You can now specify another unique name for the MDB, which is used by the entire solution.

Automatic Integration of Products in the Solution

If you have installed more than one product in the solution, the products are automatically integrated to a great extent right after the installation. It requires very few or no manual steps for the integration to work. In addition to the products, the common components are also automatically integrated and requires fewer manual steps after the installation. If one of the products is integrated with a common component, all the other products in the solution are also integrated with that component. This functionality helps you get started with solution faster and minimizes the manual effort and human error that is otherwise caused by manual configuration.

Automatic Upgrade for Products in the Solution

The installer detects any earlier versions of the product that you are trying to install and prompts whether you want to upgrade the same. After you confirm, it automatically upgrades the products to Release 14.1.

Shared Common Components for Products in the Solution

You can now share the common components such as, CA EEM, CA Business Intelligence, CA Process Automation, and MDB across the products in the solution. In addition to sharing a common installation, a common configuration is also now shared across these components. You no longer need to have separate instances of these common components for different products or configure the components for individual products.

Support for CA Business Intelligent 4.1 SP3

With this release, CA Service Management supports only CA Business Intelligence 4.1 SP3. If you have any other earlier version of CA Business Intelligence, you must install 4.1 SP3 and migrate the data from your earlier version for the reports in CA Service Management to work.

Important! If you want to retain any one of the CA Service Management products at an older release level, you must have two instances of CA Business Intelligence. One CA Business Intelligence instance for the older release and one CA Business Intelligence 4.1 instance for 14.1. You can then access the reports for respective releases of CA Service Management products.

Consolidated Documentation Available on a Wiki Platform

You can now access the entire CA Service Management documentation through a dynamic and collaborative Wiki platform. This Wiki space includes documentation for all the products in the solution under one umbrella. You can like, dislike, comment, and share the Wiki pages with your peers. The previous form of delivery through bookshelf has been discontinued with this release and Wiki becomes the primary mode of delivery.

Wiki Links from the Products

You can also access the Wiki from the user interface of the products. Apart from this, some of the context-sensitive links also now redirect to the Wiki. In some cases, the links take you to the CA Service Management Home Page and you can search to find the relevant content using the improved search functionality.

Integrated Administration

Single Interface to Configure and Administer Certain Aspects of the Products in the Solution

You can now manage your tenants, users, roles, and configurations for all the CA Service Management products from a single, common administration interface, as opposed to managing them individually in different products. For example, you can now add or update tenants in the common administration interface and use them in CA Service Desk Manager, CA Service Catalog, and CA IT Asset Manager.

Note: The common administration interface is exposed as a request in CA Service Catalog. So, the interface is available only when you install CA Service Catalog as part of the CA Service Management solution.

Business Value Dashboards

Business Value Dashboards provide decision makers such as, team leads, executives, and managers have additional information into life cycle of the tickets. The reports help the users analyze the following critical information:

- Cost and productivity within the organization
- Cost of service disruptions
- Service demand metrics
- Operation effectiveness of the support groups

For more information, see Business Value Dashboards (see page 783).

CA Service Management Mobile Application Enhancements

As a CA Service Management User, you can now access the CA Service Management Mobile Application. This mobile application is a common interface to access some of the core features of CA Service Desk Manager and CA Service Catalog from your mobile device. The following mobile capabilities are available in CA Service Management Mobile Application:

- Service Desk
- My Tasks
- Unified Self-Service
- Create Ticket
- Catalog

As a CA Service Management Administrator, configure the CA Service Management Mobile Application to ensure that the employees in your organization can access it. For more information, see the Mobility (see page 3156) section.

CA Service Desk Manager Enhancements

The following enhancements are available for CA SDM:

Notification Failures Logged in Ticket Activity Logs

Email notification failure is now logged in the activity log to indicate if any of the notifications were not sent to the users.

Manual Notify Check to Verify Email Address

If you try to send a manual notification to a contact that does not have an associated email address, a message is displayed.

Enhanced Security Options

To prevent a potential Session ID (SID) spoofing attack on CA SDM, you can optionally encrypt the Session ID. You enable this option in CA SDM Options Manager, Security Options. It prevents spoofing attacks by using encrypted cookies along with an encrypted SID. For enhanced security, we recommend that you use an SSL Connection with the encrypted SID option.

Multiple Files Upload Feature

You can now select multiple files simultaneously to upload for tickets, repositories, and knowledge. Maximum files that can be simultaneously uploaded is 10. This limit can configured using max_files_to_upload_simultaneously option from Service Desk Administration. For more information, see the Web Options (see page 1303).

Note: The multiple file selection functionality is not applicable for KT insert images

Cut/Copy/Paste in Context Menu

You can now right-click on a CA SDM web page and select the cut, copy, and paste options.

Note: This feature works on Internet Explorer only. On Chrome and Firefox, you are prompted to use the keyboard shortcuts such as Ctrl+x (cut), Ctrl+c (copy), Ctrl+v (paste).

xMatters and CA SDM Integration

xMatters is used for mass notifications and alerts. When a CA SDM ticket (incident, request, or problem) is created or updated, the integration mechanism sends the notification along with ticket information to the xMatters agent. The notification works only with CA SDM CR objects (incident, request, or problem). The CA SDM notification feature sends notifications to users based on the rules set for notification. CA SDM now automatically sends the Notify Log Reader information along with ticket information to the configured xMatters agent.

CA SDM administrators can enable or disable the integration with xMatters through the Options Manager xMatters options. You must install these options as these options are not installed out of the box. Restart CA SDM services after installing or uninstalling these options. On successful installation of xMatters options, a new daemon the pdm_xmatters_sync is started and can be monitored through the task manager process list. This daemon is a singleton process and runs on the primary or background server.

For more information, see Options Manager-xMatters (see page).

CA SDM and CA Process Automation integration – Retry Mechanism for Failed Events

CA Process Automation Workflows can be attached to CA SDM tickets (for example,Change Orders) through CA SDM Events and Macros. The attached events are triggered by CA SDM at the specified retry interval duration. During retry, if the CA Process Automation is unavailable, the attached event is marked as **Unknown**. CA SDM retry mechanism for failed events automatically re-triggers the attached **Unknown** events when CA Process Automation is available.

CA SDM administrators can enable the retry mechanism for failed events by installing additional options in the CA Process Automation Workflow Options Manager. For more information, see Options Manager, CA Process Automation Workflow Options (see page 1303).

- **caextwf_retry_count**: Default value is 3 and can be set in the range [1 – 20].
- **caextwf_retry_interval**: Default minimum value is set as 10 minutes in the range [10-999].

This feature can be disabled by uninstalling these options. Restart CA SDM services after installing or uninstalling these options. For more information, see CA SDM Retry Mechanism for Failed Events (see page 1250).

CA Service Catalog Enhancements

Usability Enhancements in Form Designer

As a CA Service Catalog administrator, you can now:

- Drag and drop the form elements while creating a form
- Use the Page Layout element, a new form element in this release, to create a form

> **Note:** The _id value for each form element is auto generated.

Related Documentation:

For more information about the page layout and _id value, see Elements of a Form (see page 2916).

Organizing Service Options

As a CA Service Catalog Administrator, use the **Organize Options** button in the Definition tab of the Option Groups for a service offering to arrange the service options.

Support for IN clause in Data Object queries

The IN clause in a Data Object query now supports multiple parameters. You can now choose from a list of values to create a variable.

Mobile Support for Select Plug-in

You can now use the Select Plug-in for mobile users.

LDAP Properties File Modified

You can now import users into the CA Service Catalog application using the LDAPImporter utility which comes with that application only. That is, you can import users into the CA Service Catalog application1 using the LDAPImporter utility which comes with this application only. You cannot import users into CA Service Catalog application2 using the LDAP importer utility of CA Service Catalog application1.

The following properties have been removed from the default ldapimporter_server1.properties file:

- Catalog.Hostname
- Catalog.Port
- Catalog.Context
- Catalog.SSL

Content Pack Enhancements

The following content pack enhancements are available in this release:

My Resources

The business user can perform the following tasks using this offering:

- View all the devices, software, and applications that has been assigned to the user in a single page called My Resources.
- Report an issue on a hardware or software asset from the My Resources page.
- View Warranty expiration dates from the My Resources page.

Reset Password

The business user can perform the following tasks using this offering:

- Reset application password on their own without having to raise an issue.
- Reset domain password of the user.

As a CA Service Catalog administrator, you can update and delete the table entries of the Catalog Content Configuration form of My Resources and Reset Password offerings.

Related Documentation:

The instructions for configuring and using the content packs are explained in a series of videos. To access the playlist, click here (https://www.youtube.com/playlist?list=PLynEdQRJawmxzRAWRffwpXetTc3wtIq4J).

Widgets Enhancements

Unified Self-Service is now available with the CA Service Catalog widgets out-of-the-box. You can also embed the CA Service Catalog widgets in a portal such as Liferay or Microsoft SharePoint.

As a CA Service Catalog user, you can now:

- See a "Featured" folder in the Browse widget. This folder has the featured service offerings that your CA Service Catalog Administrator has configured.
- Use the auto suggest feature when you are browsing the available offerings.

- Add comments or attachments and then view them as a conversation.

  Note: You can also edit or delete the attachments.

- See the status of your request in the Request List widget.

Related Documentation:

For more information about configuring the widgets, see Use Widgets for Request Management (see page 2176).

Change the Business Unit on the fly

As a CA Service Catalog user, you can now change the business unit without having to log out of your CA Service Catalog instance. The business unit that you see depends on your role and access rights.

Change the Locale on the fly

As a CA Service Catalog user, you can change the locale of your CA Service Catalog instance without having to log out of your CA Service Catalog instance. Specify the locale to access the localized Catalog instance as follows:

`http://hostname:port/usm/ (http://hostnameport)&locale=<locale>-<country>`

For example, to see the French UI

`http://hostname:port/usm/&locale=FR-FR (http://hostnameport)`

CA IT Asset Manager Enhancements

Add Costs to Multiple Assets

You can add a cost record to multiple assets at a time. For example, you procured 20 new laptops and want to enter cost records for these laptops.

You can choose to update an individual asset cost record or make changes to all the records at the same time. For example, all the laptops that you procured have the same Unit Amount. You enter the Unit Amount and apply the value to all the asset cost records.

For more information, see Add Costs to Multiple Assets (see page 2373).

Create Copies of Assets

You can now create multiple copies of assets from existing assets. Prior to this release, you could create only one asset copy at a time. For example, you procured 100 new laptops with the same model and same cost. To save time, you create a new asset with model name and cost and then create 99 copies of the same asset. At a later point of time you can specify other details of the assets.

For more information, see Manage Assets (see page 2357).

CA Asset Portfolio Management (CA APM) integration with CA Software Asset Manager (CA SAM) is enhanced and supports Multi-tenancy

If you implemented multi-tenancy, you now have the ability to assign a tenant to instances of SAM. Prior to this release, CA SAM did not support integration with a tenanted Service Management (i.e. CA Service Desk Manager, CA IT Asset Manager, and CA Service Catalog) environment. For more information, see How to Implement Multi-tenancy with CA SAM (see page 390).

Also, integrating CA APM and CA SAM is much simpler with configuring CA SAM Import and Export Service no longer required. For more information, see How to Implement CA SAM with CA APM (see page 382).

Payment Schedules and Recalculation

The Payment Schedule is a list of the payments due, based on the cost information you provide on a cost record. CA Asset Portfolio Management automatically generates the payment schedule in the form of a table when you define and save a cost record. Prior to this release, payments schedules were not created/updated automatically. The schedule generated depends on whether the cost is a one-time cost or a recurring cost.

For more information, see Payment Schedules and Recalculation (see page 2375).

Add Assets from Unreconciled Discovered Records

You can configure CA APM to automatically add new/un-reconciled discovered assets to your ownership repository. Prior to this release, the user was required to run a report and run an import to create newly discovered assets. This enhancement automates the process based upon the rules the user defines.

For more information, see Add Asssets from Unreconciled Discovered Records (see page 2425).

Contact Details in CA APM are Added to CA SDM Contact Quick Profile

After CA APM and CA SDM are integrated, the contacts list in CA APM is added to the CA SDM contact quick profile window. When you create asset records, the contact details are automatically reflected in CA SDM contact quick profile window. For more information, see Verify Single Sign-On (see page 3254).

Enable Single-Sign On Login for CA IT Asset Manager and CA SDM Integration

CA Service Management provides the following mechanisms to enable SSO from CA IT Asset Manager to CA Service Desk Manager.

- Web Service Access Policy File
- CA Service Desk Manager Administrator Credentials

Both the mechanisms internally use the CA Service Desk Manager SOAP Web Services to achieve the SSO from CA IT Asset Manager to CA SDM. You can configure either one or both the mechanisms to achieve SSO from CA IT Asset Manager to CA SDM.

Note: Ensure that CA IT Asset Manager and CA Service Desk Manager are installed on the same MDB.

For more information, see Enable Single Sign-On (SSO) from CA APM to CA Service Desk Manager (see page 3251) and Verify Single Sign-On (see page 3254). (https://wiki.ca.com/display/CASM/Verify+Single+Sign-On)

Unified Self-Service Enhancements

Unified Self-Service (formerly known as CA Open Space) has a new and improved user interface. There are two self-service interfaces available; one for business users and the other for administrators. You can install Unified Self-Service as part of CA SDM or CA Service Catalog products.

CA Service Desk Manager Connector Enhancements

CA Service Desk Manager Connector Enhancements

- CA Catalyst Container r3.4.1 is supported by CA SDM connector.
- CA SDM connector supports all CA SDM localized languages.
- Following new CMDB classes and families are introduced:

Family Name	Class Name
Software.WebSite	WebSite
Hardware.StorageVolume	StorageVolume
Hardware.VMDataStore	NetworkFileSystem, LocalStore, LocalStore-VMwareFileSystem
Hardware.StoragePool	StoragePool
Software.HyperVHypervisor	HyperVHypervisor
Software.ESXHypervisor	ESXHypervisor
Software.VirtualManager	VirtualManager
Enterprise.TransactionContext	TransactionContext
Hardware.EnvironmentalSensor	Intrusion, Vibration, Humidity, AirFlow, Pressure, Temperature, GasDetection, Unknown

Family Name	Class Name
Hardware.File	Volume, Directory, File, File-Exe, File-Data, File-Log, File-Cabinet, VirtualImage, VirtualImage-CDDVD, VirtualImage-Floppy
Hardware. Memory	Physical, Physical-Processor, Physical-IO, Physical-PCI, Physical-Fast, Physical-Multibus, Physical-Video, Paging, Cache
Software. NetworkServer	NetworkServer
Hardware. Processor	680x0, 80x87, x86, x86-32, x86-64, x86-64-IA64, x86-64-AMD64, s390x, MIPS, MIPS-BigEndian, MIPS-LittleEndian, Alpha, PA-RISC, PowerPC, SPARC, ARM
Hardware. DiskPartition	BFS, Xenix, Linux.EFI, FAT, FAT12, FAT16, FAT32, FAT64, IBM-Extended, AIX, HFS, HPFS, JFS, NTFS, NTFS1-3, NTFS4, NTFS5, TransactionalNTFS, OPUS, VMware, Unformatted
Software. ResourceServer	ResourceServer, SecurityServer, TransactionServer, MessageServer
Software.COTS	BackgroundProcess

For more information about the attribute mapping of these new classes, see under Type Mapping (see page 4737).

Supported Operating Environments and Languages

Supported Operating Environments

Supported operating environments include the platforms, databases, browsers, integrations, and mobile platforms that are supported by CA Service Management. For the complete list of supported operating environments, see the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

Languages Supported

Documentation Wiki is available in the following languages:

- French
- Italian
- German
- Spanish
- Japanese
- Simplified Chinese

- Brazilian Portuguese

For the list of languages supported by the products in the solution, see the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

Note: Some of the products in the solution support additional languages such as Canadian French, Traditional Chinese, Danish, and so on, which are not supported by the Wiki. Refer to the English wiki for such languages.

Supportability Matrix

The CA Service Management Supportability Matrix is a unique reference to the solution level compatibility of service management capabilities, which includes the following products:

- CA Service Catalog
- CA IT Asset Manager (CA Asset Portfolio Management and CA Software Asset Manager)
- Unified Self-Service
- Mobility

CA Service Management supports the followin g common components:

- CA EEM
- CA Process Automation
- CA Business Intelligence

Note: CA Software Asset Manager version is not specified in the supportability matrix as the information below is generic to every version of the CA SAM that is supported. The certified version of CA Software Asset Manager with CA Service Management 14.1 is 3.6.3 and we continue to support the versions above 3.6.3 .

Tip! CA Software Asset Manager version 4.0.1 is not compatible with CA Service Management MDB running on Oracle database. We recommend that you use CA SAM 3.6.7 until this incompatibility is resolved.

The CA Service Management supportability matrix encompasses the information that is related to the following:

Operating Systems Support

Consider the following points**:**

- CA Service Management will support all service packs and point releases of the following mentioned operating systems. The certified editions of above Microsoft Windows Server platforms are Standard, Enterprise, and Data Center Editions.
- If the customer configuration involves a need for Linux/UNIX server platforms, CA recommends installing the database of service management products on Linux/Unix platforms and access the web client interfaces on Windows platforms. This is applicable for all the Service Management products and can be supported by CA.
- Please refer the instructions in Operating Systems for additional details on deployment of **CA Service Desk Manager** on Linux platforms.

Database Support

All databases are certified for both 32-bit and 64-bit, unless specifically noted, and service packs of all the above databases are supported. For information about a remote Oracle 11g R2 MDB database installation on HP-UX 11i (PA-RISC) for CA Service Desk Manager, download the package from the CA SDM Product Download page on http://support.ca.com/. Refer the instructions in the Implementing section on how to deploy CA Service Management in Oracle RAC environment successfully. To know more about CA Process Automation components like Orchestrator, agent, web based UI, see the CA Process Automation compatibility matrix at http://support.ca.com (http://support.ca.com/).

Web Browser Support

Consider the following points:

- Web chat is the only feature of Support Automation that is available on Apple MAC OS 10.8.4 for desktops/laptops.
- Support Automation feature for analyst are not supported on Microsoft Edge.
- For more information about ESR releases, see https://www.mozilla.org/en-US/firefox/organizations/faq/. (https://www.mozilla.org/en-US/firefox/organizations/faq/)
- The certified versions of the browsers include Microsoft Internet Explorer 11, Microsoft Edge on Windows 10, Firefox ESR 24.0, Firefox 31.0, Chrome 34.0, and Safari 7.1.

  Note: Microsoft does not support Internet Explorer 9 and 10. We will provide limited support around the usage of these versions with CA Service Management.

- Apple Safari 7.1 support is only on MAC OS. Apple Safari is no more supported on Windows operating systems.
- CA Business Intelligence Dashboards are rendered optimally when Compatibility View display mode is enabled. Graphical glitches may appear in Dashboards if Compatibility View display mode is not enabled.
- If you use Internet Explorer 10 or 11 to view CA Business Intelligence pages, enable the Compatibility View mode to display the pages accurately.

Mobile and Tablet Support

CA Service Management mobile app is available in Apple App Store and Google Play Store. This app replaces the earlier CA Service Desk Manager mobile app. The app enables access to Unified Self-Service through mobile devices running Apple iOS or Google Android OS. The following capabilities of Unified Self-Service are most commonly used and these are made available through the mobile app including:

- Reporting an issue by users
- Browsing Service Catalog for available services
- Requesting services
- Viewing/updating/approving service requests
- Viewing My Resources (hardware and software)
- Viewing the ticket queue by analysts
- Performing basic activities on tickets like escalate, reassign, update, and so on
- Viewing My Tasks (Approve/respond/act on assigned work items created by a workflow engine)
- Posting or answering questions on communities; if the community cannot answer your questions, reporting an issue

Note: For other UI interfaces, Apple Safari browser on the Apple iPad has limited and known support boundaries. The capabilities and experience of Apple Safari browser on the Apple iPad are not fully equivalent to using Apple Safari on an Apple MAC OS X desktop /laptop.

Common Components Support

LEGEND : V - Certified (Tested and Verified); **O** - Supported (Not Tested, expected to work) ; **x** - Not Supported

CA Service Management includes common components CA EEM, CA Business Intelligence, and CA Process Automation. The supported versions of these components are as follows:

Note: CA Service Desk Manager, CA Service Catalog, and CA Asset Portfolio Management includes a limited entitlement to CA Process Automation and CA Business Intelligence. This entitlement is restricted to use within the context of Workflows associated with these products **.**

Common Components	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	CA Software Asset Manager	Unified Self-Service 14.1
CA EEM (Embedded Entitlement Manager) 12.51 CR02	V	V	V	x	V
CA Process Automation 4.2 SP2, 4.3	V	V	V	x	x
CA Business Intelligence (CA BI) 4.1 SP3, SP5 (Patch)	V	V	V	x	x

Other Components Support

LEGEND : V - Certified (Tested and Verified); **O** - Supported (Not Tested, expected to work) ; **x** - Not Supported

CA Service management products include a few additional components like JRE, Apache Tomcat, .Net Framework, IIS, and PHP.

Other Components	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	CA Software Asset Manager	Unified Self-Service 14.1
.Net Framework 4.0	x	x	V	x	x
Internet Information Server 8.0	V	V	V	V	V
Internet Information Server 7.0	V	V	V	V	V
Apache Tomcat	V	V	V	x	V
Java Runtime Environment (JRE)	V	V	V	V	V
PHP 5.4	x	x	x	V	x
Liferay Portal 6.1.2 GA3 (CE)	x	x	x	x	V

Following table lists specific versions of the common components that are used by CA Service Management products:

CA Service Management 14.1	Apache Tomcat	Java Runtime Environment (JRE)
CA Service Desk Manager 14.1	7.0.59	1.8.0_45 (32-bit)
CA Service Catalog 14.1	7.0.47	1.8.0_45 (32-bit or 64-bit)
CA Asset Portfolio Management 14.1	8.0.21 and 5.5.25	1.8.0_45 (32-bit)
Unified Self-service 14.1	7.0.40 and 7.0.59	1.8.0_45 (64-bit)

Integration and Interoperability Support

We recommend you to upgrade all CA Service Management capabilities in a customer environment using the common installer and common administration capabilities that are available with CA Service Management 14.1 solution. If you plan to upgrade product by product in a phased manner, use information in the tables below as a guideline to see the interoperability among the CA Service Management capabilities.

Unified Self-Service is an interface that is available with CA Service Desk Manager or CA Service Catalog, therefore, we recommend the following upgrades to leverage the enhanced usability improvements that are available in Unified Self-Service 14.1.

- If you are using 12.x versions of CA Service Desk Manager/CA Asset Portfolio Management and CA Service Catalog, you need to upgrade the CA Service Catalog to at least 14.1.
- If you are using 12.x version of CA Service Desk Manager/CA Asset Portfolio Management, you need to upgrade the CA Service Desk Manager to at least 14.1.

- If you are at 12.x version of CA Asset Portfolio Management and CA Service Catalog, you need to upgrade the CA Service Catalog to at least 14.1.

LEGEND : V - Certified (Tested and Verified); **O** - Supported (Not Tested, expected to work) ; **x** - Not Supported

CA Service Desk Manager interoperability/compatibility within CA Service Management capabilities are as follows:

Compatibility	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	Unified Self-Service 14.1
CA Service Desk Manager 12.9	V (Upgrade)	O	O	O
CA Service Desk Manager 12.7	V (Upgrade)	V	V	V
CA Service Desk Manager 12.6	V (Upgrade)	O	O	O
CA Service Desk Manager 12.5	V (Upgrade)	O	O	x

CA Service Catalog interoperability/compatibility within CA Service Management capabilities are as follows:

Compatibility	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	Unified Self-Service 14.1
CA Service Catalog 12.9	O	V (Upgrade)	O	x
CA Service Catalog 12.8	V	V (Upgrade)	V	x
CA Service Catalog 12.7	O	V (Upgrade)	O	x
CA Service Catalog 12.6	V	V (Upgrade)	V	x

CA Asset Portfolio Management (CA APM) interoperability/compatibility within CA Service Management capabilities are as follows:

Note: As Unified Self-Service requires either CA Service Desk Manager or CA Service Catalog, it is assumed that one of these products is available in the customer deployment along with CA Asset Portfolio Management.

Compatibility	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	Unified Self-Service 14.1
CA APM 12.9	O	O	V (Upgrade)	O

Compatibility	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	Unified Self-Service 14.1
CA APM12.8	O	O	V (Uninstall 12.8 and Upgrade)	O
CA APM 12.6	V	V	V (Uninstall 12.6 and Upgrade)	V
CA APM 11.3.4	V	V	V (Uninstall 11.3.4 and Upgrade)	O

CA Service Management integrations with other CA products is as follows:

Compatibility	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	Unified Self-Service 14.1
CA Workflow 1.1.5 SP6 Build 132	O	V	x	x
CA IT Client Automation 12.8 Fix Pack 1	V	V	V	x
CA Spectrum Automation 9.4	V	x	x	x
CA Configuration Automation 12.8 SP1, 12.8.3	V	x	x	x
CA Software Change Manager 12.5	O	x	x	x
CA Site Minder 12.5 CR01	V	V	V	V
CA Workload Automation AE 11.3.6	V	x	x	x
CA Clarity 13.3.0.286	V	x	x	x
CA Application Performance Management 9600	O	x	x	x
CA Identity Manager 12.6 SP4	V	x	x	x
CA Catalyst Connector 3.2	V	x	x	x
CA Services Operation Insight 3.0	O	x	x	x
CA Unicenter Network and Systems Management 11.2 SP2 CUM1	V	x	x	x

CA Business Intelligence compatibility with CA Service Management capabilities is as follows:

CA Service Management 14.1 requires a separate instance of CA Business Intelligence 4.1 SP3 before you upgrade or install CA Service Management capabilities. CA Service Management 14.1 is ***not*** compatible with earlier versions of CA Business Intelligence 3.3 SP1 and there is no direct upgrade from CA Business Intelligence 3.x to 4.x. For more information, see CA Business Intelligence Platform Installation. (https://docops.ca.com/display/CABI41SP3/CA+Business+Intelligence+Platform+Installation)

Compatibility with 14.1	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1
CA Business Intelligence 4.1 SP5 (Patch)	V	V	V
	V	V	V

Compatibility with 14.1	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1
CA Business Intelligence 4.1 SP3			
CA Business Intelligence 3.3 SP1	x	x	x

Internationalization and Localization Support

An Internationalized product (also referred to as a language-certified product) is an English-language product that runs on local language versions of the supported operating system and required third-party products. Internationalized products support local language data for input and output, and also support the ability to specify local language conventions for date, time, currency, and number formats.

The following list indicates the localized versions of the products that are supported depending on the operating system:

Note: IBM AIX supports English only.

Language	Operating System
German	Windows, Linux, Solaris
French	Windows, Linux, Solaris
French Canadian	Windows
Brazilian Portuguese	Windows
Italian	Windows
Spanish	Windows
Japanese	Windows, Linux, Solaris
Simplified Chinese	Windows

LEGEND : **V** - Certified (Tested and Verified); **O** - Supported (Not Tested, expected to work) ; **x** - Not Supported

Consider the following points:

- The installation of CA Business Intelligence 4.1 SP3 is supported only on English. For additional languages support, it is required to apply the language pack based on the locale as described in Full Installation (https://docops.ca.com/display/CABI41SP3/Full+Installation).
- CA Service Desk Manager 14.1 reports are localized in French, German, Italian, Japanese, Simplified Chinese, Spanish, and Brazilian Portuguese.

- CA Asset Portfolio Manager 14.1 reports are localized in French, Italian, German ,Spanish, Japanese, and Brazilian Portuguese.

- CA Service Catalog 14.1 reports are ***not*** localized.

Internationalization Support	CA Service Desk Manager 14.1	CA Service Catalog 14.1	CA Asset Portfolio Management 14.1	CA Software Asset Manager	Unified Self-Service 14.1	CA Business Intelligence 4.1 SP3

Accessibility Features

CA Technologies is committed to helping all customers, regardless of their ability, to use its products and supporting documentation to accomplish vital business tasks. This section outlines the accessibility features that are part of CA Service Management.

This section contains the following topics:

- "Skip to Main Content" Navigation (see page 136)

Product Enhancements

CA Service Management offers accessibility enhancements in the following areas:

- Display
- Sound
- Keyboard
- Mouse

Note: The following information applies to Windows-based and Macintosh-based applications. Java applications processed on many host operating systems, some of which already have assistive technologies available to them. For these existing assistive technologies to provide access to programs written in JPL, they need a bridge between themselves in their native environments and the Java Accessibility support that is available from within the Java virtual machine (or Java VM). This bridge has one end in the Java VM and the other on the native operating environment, so it will be slightly different for each operating environment it bridges to. Sun is currently developing both the JPL and the Win32 sides of this bridge.

Display

To increase visibility on your computer display, you can adjust the following options:

Font style, color, and size of items

Lets you select font color, size, and other visual combinations.

Screen resolution

Lets you change the pixel count to enlarge objects on the screen.

Cursor width and blink rate

Lets you make the cursor easier to find or minimize blinking.

Icon size

Lets you make icons larger for visibility or smaller for increased screen space.

High contrast schemes

Lets you select color combinations that are easier to see.

Sound

Use sound as a visual alternative or to make computer sounds easier to hear or distinguish by adjusting the following options:

Volume

Lets you turn the computer sound up or down.

Text-to-Speech

Lets you hear command options and text read aloud.

Warnings

Lets you display visual warnings.

Notices

Gives you aural or visual cues when accessibility features are turned on or off.

Schemes

Lets you associate computer sounds with specific system events.

Captions

Lets you display captions for speech and sounds.

Keyboard

You can make the following keyboard adjustments:

Repeat Rate

Lets you set how quickly a character repeats when a key is struck.

Tones

Lets you hear tones when pressing certain keys.

Sticky Keys

Lets those who type with one hand or finger select alternative keyboard layouts.

Mouse

You can use the following options to make your mouse faster and easier to use:

Click Speed

Lets you select how fast to click the mouse button to make a selection.

Click Lock

Lets you highlight or drag without holding down the mouse button.

Reverse Action

Lets you reverse the functions controlled by the left and right mouse keys.

Blink Rate

Lets you select how fast the cursor blinks or if it blinks at all.

Pointer Options

Lets you complete the following tasks:

- Hide the pointer while typing
- Show the location of the pointer
- Set the speed that the pointer moves on the screen
- Select the pointer's size and color for increased visibility
- Move the pointer to a default location in a dialog box

Keyboard Shortcuts

The following table lists the supported keyboard shortcuts:

Keyboard	Description
Ctrl+X	Cut
Ctrl+C	Copy
Ctrl+K	Find Next
Ctrl+F	Find and Replace
Ctrl+V	Paste
Ctrl+S	Save
Ctrl+Shift+S	Save All
Ctrl+D	Delete Line
Ctrl+Right	Next Word
Ctrl+Down	Scroll Line Down
End	Line End
CA Service Desk Manager Keyboard Shortcuts	

Keyboard	Description
CA Service Catalog Keyboard Shortcuts	
Ctrl+Shift+Z	Reach the first service offering from the category tree in the browse widget.
v (small letter)	Open the popup window when you click the links in the list widget.
Ctrl+Shift+O	Reach the first button in button area when a request form is loaded and the focus is at any place in between the form.
CA Asset Portfolio Management Keyboard Shortcuts	
Alt+Shift+Ctrl+D	Resize a Dialog Box in the Downward direction
Alt+Shift+Ctrl+U	Resize a Dialog Box in the Upward direction
Alt+Shift+Ctrl+R	Resize a Dialog Box to the Right
Alt+Shift+Ctrl+L	Resize a Dialog Box to the Left
ESC	Close a Dailog Box
Ctrl+Shift+Down	View the Contents of a Drop-Down List
Unified Self-Service Keyboard Shortcuts	
Ctrl+1	Go to Home page
Ctrl+2	Go to Communities
Ctrl+3	Ask a Question
Ctrl+4	Go to User Profile
Ctrl+5	Reply to a Question **Note:** To use the keyboard shortcut to reply to a question (CTRL+5), you must be viewing the entire conversation.
Ctrl+6	Go to Questions
F1	Display Help

"Skip to Main Content" Navigation

The user interface has a **Skip to Main Content** link that allows users to quickly navigate to the the first data field in the user interface without having to tab multiple times to get to the main content on the page.

In CA SDM, this link exists as **Skip Navigation**. This link allows the Screen Reader users to skip the in-between links and navigate to the main content page. This link is available by default for the Customer and Employee roles. For the Analyst role, the link is available only when the Screen Reader mode is enabled.

Deprecated Features

CA Service Catalog - Reservation Manager Integration Deprecated

The point-to-point integration between CA Service Catalog and Reservation Manager is deprecated.

Instead of using the point-to-point methodology, consider setting up this integration by exchanging data through web service calls from custom CA Process Automation processes. This methodology lets you set up services so that users can modify, extend, or return early their existing reservations of physical or virtual resources.

For information about how to integrate CA Service Catalog with Reservation Manager, see this section (https://support.ca.com/cadocs/0/CA%20Service%20Catalog%2012%209-ENU/Bookshelf_Files/HTML/CA_Svc_Cat_Integration_ENU/index.htm?toc.htm?IntegratingwithReservationManager.html) on the CA Service Catalog 12.9 bookshelf.

CA Workflow Deprecated

CA Process Automation is the recommended process automation tool. If you are using CA Workflow process definitions, we recommend that you create and use CA Process Automation processes instead.

Note: For more information about installing and using CA Process Automation, see the CA Process Automation documentation.

CA Workflow integrations are not documented in this Wiki.

MYSQL - Unified Self-Service Integration Deprecated

Unified Self-Service (formerly known as, CA Open Space) no longer supports MYSQL databases. You can use Oracle and SQL Server databases for installing Unified Self-Service.

Known Issues

This section contains the following articles:

CA Service Management

Note: The CA Service Management 14.1 installation media includes the following legacy documents:

- CASM r12.5 Install Guide.docx
- CASM r12.5 Readme.txt

The installation media also includes the 12.9 bookshelves.

Ignore the legacy documents because they are not required for CA Service Management 14.1 installation.

All the deliverables for CA Service Management have been completely migrated to this Wiki. Access this Wiki for 14.1 documentation.

The following known issues can also affect how you manage the CA Service Management solution:

CA Service Management Known Localization Issues

Following are the localization known issues that are applicable for CA Service Management:

Chinese and Japanese Characters Do Not Appear Correctly in the Common Administration User Interface

When you create a user or a tenant through the common administration user interface and specify the details in Chinese or Japanese characters, the details are not displayed properly.

You may experience this behavior even when the details contain upper case non-English characters like Æ, Å, Ø, Ñ, É.

Help Calls from Some of the Localized Product User Interfaces Fail

When you launch the help or the link to the wiki from the localized product user interfaces, on some pages you get an error message "Unable to render {include} The included page could not be found". We are trying to resolve this issue as soon as possible.

Note: Some of the localized product user interfaces will launch the English Wiki space, which means that the documentation Wiki will not be available in those languages. For more information, see the Languages Supported (see page 118) section.

CA Service Desk Manager

This section contains the following known issues:

CA Service Desk Manager Known CA Products Issues

This article contains the following known issues:

CA Process Automation and SSL Integration Generates Errors

Symptom:

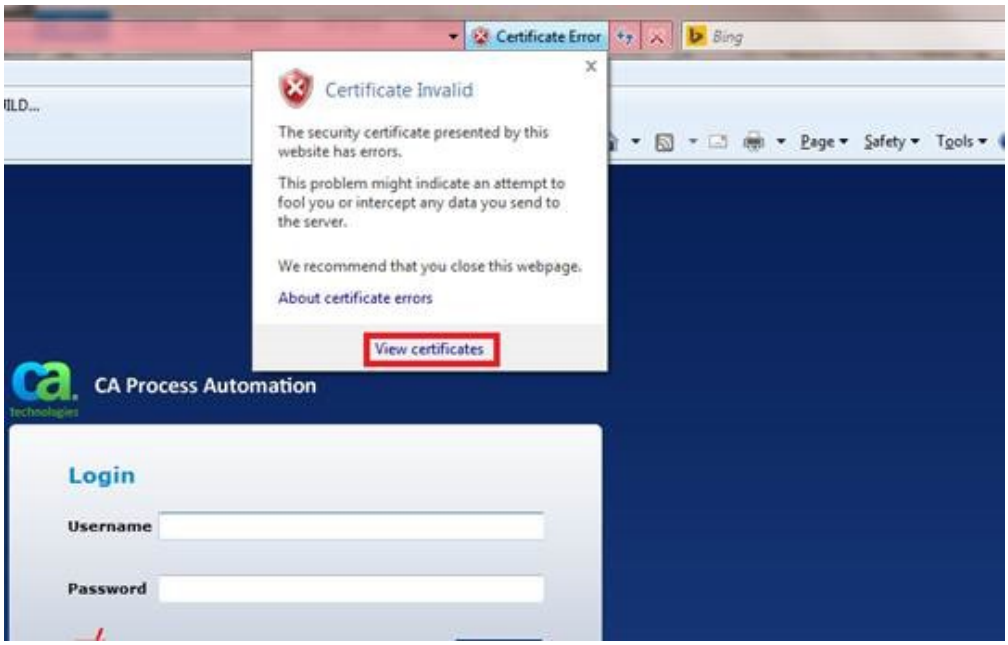
When trying to integrate CA Process Automation with SSL, the following SSL validation errors are seen during the installation:

```
2014/11/11 19.04.39.728 DEBUG [AWT-EventQueue-0] [PAMWebserviceManager] Get ITPAM
version
2014/11/11 19.04.39.752 ERROR [AWT-EventQueue-0] [PAMValidator] CA PAM validation
failed
com.ca.smsi.installcore.webservices.WebserviceException: ; nested exception is:
javax.net.ssl.SSLHandshakeException: sun.security.validator.ValidatorException: PKIX
path building failed: sun.security.provider.certpath.SunCertPathBuilderException:
unable to find valid certification path to requested target
at com.ca.smsi.installcore.webservices.PAMWebserviceManager.getITPAMVersion
(PAMWebserviceManager.java:265)
```

Solution:

This issue may occur because the Java Runtime Environment (JRE), under which the installer is running, is not able to connect to the CA Process Automation SSL URL. The needed SSL Certificates may be missing in the JRE. JRE obtains such SSL certificates from a keystore. Complete the following steps to add a CA Process Automation SSL certificate to the JRE keystore:

1. Download the SSL Certificate by accessing the CA Process Automation URL.



2. Copy this certificate file to some location. For example, *c:\ItpamCert.cer*

3. Extract the CA SDM DVD to a local drive. For example, C:\CASMDVD14\< >

4. Import the CA Process Automation SSL Certificate to a keystore file using the following command:

   ```
   c:\CASMDVD14\java\jre\bin\keytool -importcert -file c:\ItpamCert.cer -alias
   somealias -keystore c:/keystore_file -storepass somepass
   ```

5. To enter the keystore and password values to the JRE, open the C:\CASMDVD14\setup.lax file in Wordpad or a similar text editor.

   Note: It is recommended NOT to use Notepad so as to avoid any formatting issues.

6. Identify the "lax.nl (http://lax.nl).java.option.additional" property.

7. Append the reference to the JAVA keystore and keystorepass entries as follows:

   ```
   -Djavax.net (http://Djavax.net).ssl.trustStore=c:/keystore_file -Djavax.net (http:
   //Djavax.net).ssl.trustStorePassword=somepass
   ```

   After the modification, the line would look like:

   ```
   lax.nl (http://lax.nl).java.option.additional=-Djava.library.path=".\\java\\bin;
   -DGET_SD_PRESETS=true -Djavax.net (http://Djavax.net).ssl.trustStore=c:
   /keystore_file -Djavax.net (http://Djavax.net).ssl.trustStorePassword=somepass
   ```

8. Save the file and restart the setup by executing C:\CASMDVD14\setup.exe command.

GRLoader Compatibility

The General Resource Loader (GRLoader) for CA Service Desk Manager is distributed at level r14.1 and is backward compatible with all previous releases of CMDB.

Important! We recommend that you use GRLoader distributed with CA Service Desk Manager r14.1.

The following considerations apply to GRLoader:

- The GRLoader utility that is distributed with CMDB r11.x is not compatible with CA Service Desk Manager r14.1. Upgrade the utility to the version that is distributed with CA Service Desk Manager r14.1.
- For any third-party product that uses GRLoader, reinstall all the files and directories in the java\lib directory.
- Earlier releases of GRLoader, for example, GRLoader distributed with CA Cohesion ACM, may require an upgrade. Apply the appropriate patch.
- (Solaris only) When running GRLoader using pdm_task, the environment variable $NX_ROOT must not be exported from pdm_task. Prevent exporting $NX_ROOT, by doing one of the following:
  – Temporarily comment out the line where $NX_ROOT is exported.
  – Add a small script so that $NX_ROOT is not exported when pdm_task runs GRLoader.

  Note: In non-Windows operating environments, it can be useful to invoke GRLoader using pdm_task GRLoader <arguments>.

Unable to Access the Customized Tables Created from Web Screen Painter

Symptom:
I created a table using the Web Screen Painter but could not access the list page of this table from the CA Service Desk Manager Web UI.
Solution:
Customized table names must not contain the JavaScript keywords, such as alert, prompt, and confirm. For example, the customized table with the name, z_global_alert, is rejected by the CA Service Desk Manager webengine. Create the table with some other names and try again.

How to Review the Log Files

If a CA Business Intelligence installation fails, review the log files for further information. The log files contain error codes, presented as return values from certain functions. Until the installation directory is created completely, the installer dumps the installation logs in Windows temp (%TEMP%) folder.

After the installer directory is created, the installation logs are copied to <INSTALLDIR>\InstallData\logs directory with the timestamp. For more information about the CA Business Intelligence 4.1 SP3 installation,see the CABI Installation on Windows (https://docops.ca.com/display/CABI41SP3/CABI+Installation+on+Windows) topic.

CA Service Desk Manager Fails to Start after Previous Versions of eTPKI are installed after CA Service Desk Manager

Valid on Windows systems with other CA products installed after CA Service Desk Manager
Symptom:
The following message occurs while CA Service Desk Manager is starting:
Unable to connect to DB
CA Service Desk Manager fails to start when CA products with earlier versions of eTPKI are installed after CA Service Desk Manager.
Solution:
To avoid this issue, do the following:

1. Edit the system path: Move the PROGRA~1\CA\SC\CAPKI\Windows\x86\32\lib directory to the beginning of the path.

2. Start CA Service Desk Manager.

Error Adding Scoreboard to a Multi-Frame Form

Valid on all operating systems
Symptom:
When you add the Scoreboard to a multiframe form, the following error occurs:

```
Error: window.parent.scoreboard has no properties
```

For example, this problem occurs when you do the following:

1. Create a multiframe form.

2. Add the Scoreboard to one of the frames.

3. Publish the form.

4. Add the form to a tab, and the tab to a role.

5. Log in to CA Service Desk Manager using the role to which you added the tab or form. The following error message appears:

   ```
   Error: window.parent.scoreboard has no properties
   ```

   Note: For information about these steps, see the Online Help.

Solution:
Do not use the Scoreboard with multiframe forms.

Error While Launching the CA Process Automation Process Viewer

Valid on all operating systems
Symptom:
When a user tries to launch the CA Process Automation Process Viewer from CA Service Desk Manager, the following error message appears:

```
Unable to launch the application. [Client name][Publisher][From]
```

Solution:
The CA Process Automation installer uses the host name of the computer where it is installed to populate the information in the CA Process Automation configuration files. For CA Process Automation to operate properly, the host name has to be a reachable name from all computers that access CA Process Automation from CA Service Desk Manager. If there is an issue with the hostname value that is set during installation, the Administrator can change a CA Process Automation configuration file to resolve the problem.

1. On the CA Process Automation server open the %InstallationDir%\server\c2o\. config\OasisConfig.properties file.

2. Change the oasis.local.hostname to a value that is reachable from both the CA Process Automation server and from CA Service Desk Manager workstations.

   Note: Verify that the new hostname matches the CA Service Desk Manager Options Manager value set in the caextwf_processdisplay_url option.

3. Restart the CA Process Automation server.
   The user can launch the Process Viewer from CA Service Desk Manager. The host name is reachable from every computer that accesses CA Process Automation from CA Service Desk Manager.

CA Process Automation Client Launches with the Previous User Credentials

Symptom:
When I launch the CA Process Automation client, the client opens with the previous user credentials.
Solution:
CA Process Automation caches data such as for user names and passwords in the browser. This caching causes the client to open with the previous user credentials when a user clicks View Process or any process instance log under the Workflow Tasks tab of any ticket detail page.
Clear your browser cache before you log in to CA Service Desk Manager or open CA Service Desk Manager in a new browser.

404 Error is Displayed on Clicking the View Process Button

Symptom:

CA Service Desk Manager is integrated with CA Process Automation r3.1 SP1. When I click on the View Process button from CA Service Desk Manager, a 404 error is displayed.
Solution:

1. Select Options Manager, CA IT PAM Workflow.
2. Set the value of the caextwf_processdisplay_url option to the following:

   ```
   http://<wf_hostname>:<wf_tomcat_port>/itpam/JNLPRequestProcessor?
   processType=startUI&roid
   ```

3. Restart CA Service Desk Manager services.

Dependent CIs Belonging to Service Family Do Not Display on the Change Scheduler

Symptom:
Dependent CIs that belong to the CI families: Enterprise Service and Service do not display on the Change Scheduler if the Service family in the table ci_resource_family has an table_extension_name different from "serx."
Solution:
Change the table_extension_name for the Service family to "serx."

Configuration Item Reconciliation Attributes Are Not Tenant Aware

Valid on all systems with a multi-tenancy installation
Symptom:
The user cannot create a configuration item because it conflicts with another configuration item owned by a different tenant. The following reconciliation attributes are not tenant aware:

- Name
- Serial Number
- Hostname
- DNS Name
- Asset Tag

Solution:
To prevent this conflict, append the name of the tenant to one or more of the reconciliation attributes.

Support Automation Creates a Temporary Folder Named CA-SupportBridge

Symptom:
When end users and analysts use Support Automation, they cannot locate the temporary Support Automation folder. The temporary folder stores files, such as executables, from the end-user client and Support Automation Analyst Interface.
Solution:
The temporary folder created by the applications is named CA-SupportBridge, such as in the C:\Documents and Settings\All Users\Application Data\CA-SupportBridge directory.

Purge on a CA Support Automation r6.0 SR1 eFix5 Database Does Not Export Inactive Users

After running the historical data purge script on the CA Support Automation r6.0 SR1 eFix5 database, inactive users (those that have not been involved in an assistance session during the retained history time period) are not exported to the CA Service Desk Manager database.

CA BSI Metric Data Does Not Display Properly

When you integrate CA Service Desk Manager with CA BSI, users can display Metric data for Contract CIs that are associated with a CA BSI MDR. Users must specify a Contract Party (CA BSI Entity) before they submit the request. A CA BSI limitation prevents metric data from being properly displayed for Contract Parties that have certain non-alphanumeric characters within the name. We recommend that you use alphanumeric Contract Party names and avoid using any of the following characters:
reserved = gen-delims / sub-delims
gen-delims = : / ? # [ ] @
sub-delims = ! $ & ' ( ) * + , ; =

CA NSM Integration

CA Service Desk Manager customers that plan to integrate with CA NSM must apply a CA NSM patch that enables the integration using the CA Service Desk Manager r14.1 WSDL. You can download the CA NSM patch from CA Support Online (https://support.ca.com/irj/portal/newhome).

No Restriction in Multiple Selection of Same File for Upload

Applicable for tickets, repositories, and knowledge.

Example:

1. Log in to CA Service Desk Manager and choose a file to attach to a ticket.
   The file name appears in the list.

2. Again choose the same file.
   The same file appears twice in the list.

Solution:

Ensure that you do not choose the same file more than once for upload. Delete all duplicate files and then upload.

Federated Search Does not Work After CA SDM Upgrade

Symptom:

1. I installed CA SDM 12.9 and configured Federated Search.

2. I upgraded CA SDM and tried to perform the Federated Search.
   Federated search did not work ad the following error message is displayed in the jfscrawler. log file.

```
09/17 15:12:38.031 [http-bio-8040-exec-2] ERROR SearchService 181 Source name
(google) not found in configured list of search adapters

09/17 15:12:38.032 [http-bio-8040-exec-2] ERROR SearchService 303 Exception
error occurred for adapters([]) on uri(http://lodiibmsdm7:8040/cafedsearch/sdm
/search?q=testing&source=google&userid=srvcdesk&index=1&size=10&_type=json)
```

Solution:

Regenerate the following files:

- adapters-config.xml
- google.xml
- sharepoint.xml
- OpenSpace.xml
- Customized adapters xmls

Unable to Launch Support Automation Script Editor Application

Valid for Windows 8.1

Solution:

Currently no solution exists.

CIs created using the Copy (Including all Relationships) function are not displayed in the CA SOI service graph

Symptom:

You created a CI in CA SDM which is updated in the CA SOI graph. Now, you create another CI in CA SDM using File, Copy (Including all Relationships) and check the graph in CA SOI. The new CI is not updated in the graph.

Solution:

To view the added CIs, import the service graph on CA SOI again.

Incorrect TWA Update Transaction for a blank Configuration Status

Symptom:

You changed the Configuration Status of a CI in CA SOI console to production, but the Configured Status attribute is missing in TWA.

Solution:

Manually reset the service status in CMDB for the CI.

Services without alerts are not loaded in CA SOI

Symptom:

For a service, you remove the Alert option from the Exclude CI Type list of the Configuration settings. You import the service on CA SOI. The service is not loaded on CA SOI.

Solution:

Disable the alert for the service.

Follow these steps:

1. Add Alert to the Exclude_USM_CI_type property during the CA SDM Connector configuration.
2. Restart the CA SDM Connector.

Unable to rename a service CI in CA SOI

Symptom:

You edit the name of a CI on the CA SOI console. The CI is not renamed and a new service CI is created with the edited name.

Solution:

CA SOI does not handle decorrelation of some type of CIs, for example, USM:Service. When such CIs are renamed, CA SOI sends a new CI to be created in CA CMDB, while the old one still exists.

CA Service Desk Manager Known Client Issues

This article contains the following known issues:

Unable to Launch the Support Automation Web Chat Client Session

Symptom:
The web chat client session can only be launched after closing the existing browser and opening a new browser. You encounter the following problems when you configure the supportautomation_url with an IP address:

- The web client end user does not launch after the first web client end-user session is closed. The Post Logout page displays the following message: Your Live Assistance Session is complete.

- Different web client end-user consoles are merged with the existing web client session when you try to launch a different web client end-user console on the same computer in the same browser window.

Solution:
If the supportautomation_url configuration uses an IP address which has an existing host name mapping, the HTTP request processing resolves to this host name. You can change the configuration of supportautomation_url to the host name or you can remove the mapping of the IP address to host name to resolve the issue.

Unable to Run the Support Automation Agent Installer Silently

Valid on Windows 8 with UAC enabled or disabled, Windows 7 with UAC enabled. Vista with UAC enabled
Symptom:
I am unable to perform silent install or silent uninstall on the Support Automation Agent installer.
Solution:
To run the installer silently, user must be using a built-in administrator account. If the user is a created administrator (non-built-in administrator), complete the following steps to install or uninstall silently:

1. Open the command prompt, as the administrator.
   The UAC window is displayed.

2. Click Yes on the UAC window, go to file location of silent installation bat file and run the batch program.

Unable to Perform Some Support Automation Tasks (Chat, Automation, File Transfer, Remote Registry, and so on)

Valid on Windows XP 64 bit machine with pre-installed Support Automation agent.
Symptom:
Remote control and screenshot functionalities are working, while the remaining functionalities (for example, Chat, Automation, File Transfer and Remote Registry, and so on) are not working.
Solution:
Currently no solution exists.

Unable to Use the Remote Control Functionality

Valid on Windows 8 machine with pre-installed agent
Solution:
Make the following registry changes on the end-user machine:

- Hive: HKLM
- Path: SYSTEM\CurrentControlSet\Control\Windows
- DWORD: NoInteractiveServices
- Change value "1" to "0"

We also recommended that when an analyst tries to do Remote Control with the end user, the end-user machine must be accessed as a console session and not by any other remote desktop protocols.

Unable to Create Registry keys Under HKEY_LOCAL_MACHINE, Software

Valid on Windows 7, 8 and Vista with UAC enabled
Symptom:
SA analyst has initiated a Live chat session with a SA end user. Both SA analyst and SA end user are on different machines and the SA end user has logged in to Support Automation as a created administrator. SA analyst tries to create a registry key under HKEY_LOCAL_MACHINE, Software on the SA end user machine (Windows 7, 8 and Vista with UAC enabled). An error message is displayed.
Solution:
Use the impersonate feature, and impersonate as the built-in administrator to work with registry keys.

Support Automation Analyst Cannot Use Remote Control During the Assistance Session

Valid on Windows Vista, Windows 7, Windows 8, and Windows 8.1

Symptom:
When I use Remote Control during an assistance session, I try to run an application as Administrator and I use the provided Administrator credentials in the User Account Control window. I do not have control on an opened application in the Remote Control session on the end-user computer.
Solution:
Windows Vista, Windows 7, and Windows 8 do not display the User Account Control (UAC) window or any Secure Desktop window for the Support Automation Analyst during the web launch. You can only switch between the Desktops to display the secure Windows window when the end-user computer runs the CA Support Automation Agent Service.

Unable to View the HKEY_LOCAL_MACHINE\SOFTWARE Sub Registry Keys

Valid on Windows 64-bit computers
Symptom:
When the end user uses a 64-bit client computer, the registry key behaves as the following cases:

- During an assistance session, a user creates, modifies, or deletes registry keys under HKEY_LOCAL_MACHINE\SOFTWARE on the end-user computer from the Support Automation Analyst Interface. These keys display under the HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node on the end-user computer.

- A user creates, modifies, or deletes registry keys under HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node on the end-user computer and starts the assistance session. The keys display under the HKEY_LOCAL_MACHINE\SOFTWARE in the analyst session.

- A user creates, modifies, or deletes registry keys under HKEY_LOCAL_MACHINE\SOFTWARE on the end-user computer and starts the assistance session. The keys do not display under the HKEY_LOCAL_MACHINE\SOFTWARE in the Analyst assistance session.

Note: The HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node key is transparently presented to 32-bit applications by WoW64 as HKEY_LOCAL_MACHINE\SOFTWARE. For more information, see the MSDN article titled Registry Keys Affected by WOW64.

Error Message Appears When Launching the Support Automation Analyst or End-User Clients

Valid on Internet Explorer 9, 10, and 11
Symptom:
For the Support Automation end-user client, if your CA Service Desk Manager site is in an Internet zone (or any other zone) with a security level higher than Medium-Low, Internet Explorer blocks pop-up windows and the end user is not able to launch the Support Automation client.
For the Support Automation analyst client, if your CA Service Desk Manager site is in an Internet zone (or any other zone) with a security level higher than Medium-Low, Internet Explorer blocks downloads and launches from IFRAME, and the analyst is unable to launch Live Assistance.
Solution:
For the Support Automation end-user client, move the CA Service Desk Manager site to the Trusted Sites Zone and set the security level to Medium-Low, or allow pop-up windows from the CA Service Desk Manager site.
For the Support Automation analyst client, move the CA Service Desk Manager site to the Trusted Sites Zone and set the security level to Medium-Low. You can also set a Custom security level by setting the Enable for Downloads and Automatic prompting for file downloads options.

Submenu Does Not Disappear from the Page in iOS

Valid on the Apple iPad
Symptom:
When I click the File Menu on the Service Desk tab, the submenu does not disappear until I select any links from the submenu or any other tab. If I click a different link on the form, the submenu does not disappear.
Solution:
The iOS has a limitation that causes this behavior because the iPad does not use a mouse.

Cygwin Environment Causes Application Problem

Symptom:
I can launch CA Service Desk Manager Java applications from a Cygwin environment using an AIX server, but the application buttons are not operable.
Solution:
This behavior is a problem with the Cygwin environment. Use a different emulator.

Functionalities in Change Calendar Are Not Accessible

In the Change Calendar tab, if you click the back button in Internet Explorer, you cannot access the functionalities of the change calendar. The object that does not support the error displays. Log out from CA Service Desk Manager to access the Change Calendar tab again.

iOS Crashes when Selecting a Contact During Ticket Creation

Valid on iOS
Symptom:
When I create a ticket and want to add a contact, the browser crashes. The auto-correction feature of iOS and the search-as-you-type feature of CA Service Desk Manager retrieve results and the user selects the contact that CA Service Desk Manager retrieves.
Solution:
Disable the auto-correction feature on iOS.

Child Windows Do Not Close After Logging Out on the iPad

Valid on iPad iOS 5
Symptom:
After I log out of CA Service Desk Manager on the iPad, the child windows do not close. For example, I click File, New Change Order. I log out of CA Service Desk Manager and the New Change Order window remains open and I can still enter data.
Solution:
The iOS 5 operating system has an issue when you close the window using the handle (close() API). For more information, use an internet search engine to look for "iPad Safari IOS 5 window.close()."

PDA Interface Displays Error Message when Creating a Ticket

Valid on the PDA interface
Symptom:
If two or more contacts have the same first name, last name, and middle name combination and I add the user to the End User, Requester, or Assignee fields, I cannot create tickets from the PDA interface.
The PDA interface displays one of the following error messages:

- Multiple Matches - Affected End User: XXXX
- Multiple Matches - Requester: XXXX
- Multiple Matches - Assignee: XXXX

Solution:
Use the regular CA Service Desk Manager user interface which does not display these errors.

CA Service Desk Manager Known Knowledge Management Issues

This article contains the following known issues:

Unable to Batch Import Knowledge Documents Using the keit_daemon Command

Valid on Linux

Solution:

The problem may occur while importing SampleData by using ImportSampleData script. Import the packages individually using pdm_kit command.

Comma Not Supported in Name Fields

Valid on all operating systems
Symptom:
A comma in a name field can cause unexpected results in the display of the combined user name. For example, entering a name such as the following while creating or updating a contact record causes the combined name to display incorrectly:

- Last Name: Smith, Jr
- First Name: John
- Middle Name: <blank>

The comma causes "Jr" to appear in the first name position and "John" not to appear.
Solution:
Avoid using the comma character in a name field.

Searching for a Document That Has White Spaces in the Title Causes Failure

Valid on all operating systems
Symptom:
You create a Recommended Document from Knowledge, Search, Recommended Documents, Create New. The Title text (as displayed in Edit mode) contains a leading space or double spaces between title words.
When I type the title words and use the auto-completion feature in the Knowledge Document text field, the Knowledge Document Lookup page opens with no results found.
Solution:
You must invoke the Knowledge Document Lookup Form by clicking the link on the Create New Recommended Document page. From the Knowledge Document Lookup Form, do the following:

1. Enter the title text.
2. Search for the document.
3. Select the correct record.

Note: If you fail to do this solution and enter the title words into the text field (without observing correct white-space), auto-completion is invoked, and the Knowledge Document Lookup page opens with no results found. If no results occur, clear the search filter on the Knowledge Document Lookup page, manually enter keywords in the title into the Keywords for Advanced Search field, and click Search.

Wrong Number of Documents Are Returned in Search Results

Symptom:
The incorrect number of knowledge documents are returned in search results.
Solution:
To resolve this issue, run pdm_k_reindex +f from the command line. The correct number of documents appears in the search results.

Unable to Export Documents from Templates

Symptom:
I am unable to export a document using the export or import template. I click the Export button from Documents, Export/Import Templates, but the action does not initiate the exporting function.
Solution:
Incorrect handling of embedded links that reference CA Service Desk Manager objects instead of files in a repository cause this error. A warning message displays when you click the Export button, similar to the following example:
02/17 15:55:05.30 hostname keit_daemon 4088 WARNING export.c 645 The link 'New Request from a template - 400002'' which references a Service Desk object was encountered. The target object will not be exported. As a consequence, if the link is invalid or incorrect on the server where the document is re-imported the document will need to be altered to reference the correct object.
Using Insert, New Ticket Link lets you automate part of the request or automate another ticket type creation process for users. However, during export while the text in the resolution field exports as is, the linked ticket template cannot export with it.

1. Reimporting the document to the same CA Service Desk Manager cluster (as defined by a shared backing data store) that it was exported from works correctly.
   The reimport works if the referenced ticket still exists.

2. If you want to export the document to a different CA Service Desk Manager cluster, modify the resolution to verify that the linked ticket template actually references a ticket template.

3. Verify that the template references the correct ticket template.
   This issue affects all links to CA Service Desk Manager objects within Knowledge Documents.

CA Service Desk Manager Known Localization Issues

This article contains the following known issues:

Installer and Component Installers Translated Incorrectly

Valid in all localized versions
Symptom:
The installer and some of the component installers display strings that are not translated correctly. For example, minor spelling or grammar problems can occur in the title bar, on buttons, or in dialogs.
Solution:
The errors have no impact on the functionality of the product.

Unable to View the CA Service Desk Manager Reports in Localized Languages

Solution:
CA Service Desk Manager reports support all CA Service Desk Manager supported languages, except Brazilian Portuguese, and French Canadian, with the following exceptions:

- CA Service Desk Manager reports content will be in Brazilian Portuguese and CABI will be in English when Brazilian Portuguese is integrated with CABI multilingual installation.

- CA Service Desk Manager reports content will be in French Canadian and CABI will be in French when French Canadian is integrated with CABI multilingual installation.

To view the CA Service Desk Manager reports in the required languages (for example, Japanese, French, German, and so on), complete the following steps:

1. While installing BO, install required language packs to get the localized strings that are part of BO.

2. Install Arial Unicode MS (True Type) font on the server where BIAR file will be imported.

3. The font files have to be copied to the Fonts folder of windows.

4. Add the following code to fontalias.xml and i18n.xml files:

Note: Find the fontalias.xml file in the <BO Installation Path>\BusinessObjects Enterprise 12.0\win32_x86\fonts directory.

Find the i18n.xml file in the <BO Installation Path>\BusinessObjects Enterprise 12.0 \win32_x86\scripts directory.

```
<FONT NAME="Arial Unicode MS">
<FONTFAMILY PLATFORM="ttf" NAME="Arial Unicode MS">
<FONTATTRIBUTE BOLD="false" ITALIC="false" LOGICAL="Arial Unicode MS"
PHYSICAL="ARIALUNI.TTF"/>
</FONTFAMILY>
<FONTFAMILY PLATFORM="win" NAME="Arial Unicode MS"/>
<FONTFAMILY PLATFORM="java" NAME=" 'Arial Unicode MS', 'Arial Unicode MS'"/>
<FONTFAMILY PLATFORM="html" NAME=" 'Arial Unicode MS', 'Arial Unicode MS'"/>
</FONT>
```

When the user opens the reports document, Business Intelligence Launch Pad tries to display content in the user's Preferred Viewing Locale (PVL).
If no visible translation is available in the PVL, Business Intelligence Launch Pad tries to display the translation in the Substitution language.
If no visible translation is available in the substitution language, Business Intelligence Launch Pad tries to display the translation in the Dominant locale of the user's PVL.
If no visible translation is available in the dominant locale, Business Intelligence Launch Pad displays the Original content language.

Note: Following are the localization limitations:

- Localization of crystal reports prompts are not supported.
- Localization of chart labels are not supported.
- Localization of reports folder structure (tree control), report titles, and descriptions in the List view of Business Intelligence Launch Pad are not supported.

- Group Tree labels cannot be localized in Crystal Reports when a Group Name is based on a conditional Formula.
- Y-Axis chart labels in Crystal Reports are shown horizontally in Firefox browser, while they are shown vertically in IE browser.
- Dashboards are partially localized. Tabs within the Dashboards and charts are not localized.
- Timestamp is not displayed by default in new Webi Reports.
- Date format does not change based on the browser locale because all the date formats are hard coded in CA Service Desk Universe as "mm/dd/yyyy hh:mm:ss AM/PM". By removing the date format, there is an Impact on Webi Reports. By default, only date part will be displayed in new Webi Reports.You can change the date format in Webi Report to display the correct timestamp.

CA EEM Install Fails on Windows 2008 SP2

Valid on all languages
Symptom:
The CA EEM install fails on Windows 2008 SP2 with the following message:
Windows 2008 sanity testing failed.

Note: The message appears in English for all languages.

Solution:
Before you install the CA EEM Server on Windows 2008, do the following:

1. Run the netsh-> interface-> ipv6-> show-> address command from the command prompt.
   All the interfaces in the computer that use the IPv6 link-local addresses starting with fe80 are listed.
2. Delete the link-local address starting with fe80.
   The link-local address is removed.

Note: For more information about how to remove the interface, see the Microsoft Support website and refer to KB article 929852.

Two Windows Menu Shortcuts for the CA EEM Documentation and UI Items

Valid on all localized versions
Symptom:
After upgrading CA EEM for a Non-English language OS environment, two Windows menu shortcuts for the CA EEM Documentation and UI items can appear. One item displays in the local language, and

the other item in English.
Solution:
Delete the unwanted duplicate menu item.

Hot Keys Not Working in Context Menus

Valid on Japanese and Chinese localized versions
In the Japanese and Chinese localized versions, most right-click context menus do not include a hotkey character that works for each menu item. Typically, the hotkey character is placed between parentheses after the translated characters of the menu item; (_) is placed instead. In some cases, where the menu text includes English, the hot key is designated with an underscore and it works.

Some Values in the Option List Are Not Translated

Valid in all localized versions
Symptom:
The string "Auto Issue Event" is not translated in the "Value" Column of the Option List.
Solution:
Most of the fields on the Option List and Options Detail Web form with the exception of the Description field, certain Value fields such as Yes/No, and drop-down lists are not localized and appear in English. The Option List is found by navigating the left pane menu on the Service Desk Manager Administration tab to the Options Manager node and select any child node.

Language Valid Character Range Does Not Display Correctly

Symptom:
When I try to view kt_admin_parse_settings.htmpl, the Language Valid Character Range does not display correctly.

Solution:
No solution is available.

Localized Noise Words

Valid in all localized versions
Symptom:
Noise words for your language do not display.
Solution:
Each language has its own set of noise words that are delivered with the product.
To see the noise words for your language, run pdm_k_reindex in the same manner as when you want to add a noise word.
The noise words for your language appear.

Alias Name is not Localized

The alias name data that appears on the Attributes Alias List and the Attributes Alias Detail pages is not localized. For example, when you select Service Desk, Application Data, Codes, Attribute Aliases and click Search, the data that appears in the Alias Name column appears only in English.

8.3 File Name Creation and Extended Character Support

Valid in Japanese and Chinese localized versions
Symptom:
8.3 file name creation and extended character support are not supported.
Solution:
Perform the following steps:

1. Modify the NtfsAllowExtendedCharacterIn8dot3Name registry key to "0".

   Note: The value is set to "1" as default; manually change this setting.

2. Restart your computer.

3. Start the install.

Command-Line Utilities Cannot Display Special Characters

Valid in all localized versions
Symptom:
All CA Service Desk Manager command-line utilities that run from a DOS command prompt do not correctly display data that is returned. In particular, Japanese characters, Chinese characters, and special Latin characters with accents such as a German umlaut or a French accent grave are not displayed correctly.
Solution:
The output of command-line utilities, for example, pdm_extract can be redirected to a file, and then successfully read using any tool that supports UTF-8 encoded characters, for example, Microsoft Notepad.

Command-Line Tools Output Strings Incorrectly on Windows

Valid in all localized versions on Windows
Symptom:
Command line utilities display incorrect characters in output.
Solution:
Use the pdm_cmd.exe program to run all command line tools. The pdm_cmd utility converts output strings of the command line tool from UTF8 to UNICODE, so it can display the output strings in a foreign language. For example, to display output characters for pdm_webcache correctly, run the pdm_cmd pdm_webcache command. If the command line file name does not end with .exe, use the full file name on the command line.
For example, use the pdm_cmd pdm_publish.cmd command to publish Web Screen Painter schema changes. Use the pdm_cmd pdm_odbc_start.bat command to start the ODBC driver.

Note: Any command line tool that displays incorrect characters must run pdm_cmd.

Spell Check Not Working as Expected

Valid in all localized versions
Spell Check is not supported in the Japanese and Chinese localized versions.
Symptom:
Spell Check suggests almost every word in Latin localized versions.
Solution:
Perform the following steps:

1. Set the lex_lang option to the correct language in the Options Manager.
2. Restart the Service Desk Service.

Only U.S. States and Canadian Provinces Display for All Localized Versions

Valid in all localized versions
Symptom:
The State list selection in the CA Service Desk Manager web client only displays U.S. states or Canadian provinces regardless of the country selected.
Solution:
CA Service Desk Manager includes a database table for states and provinces. The product delivers data for this table consisting of only U.S. states and Canadian provinces. States or provinces for other countries are not included in the data provided, but you can modify the ca_state_province table to include additional states for other countries.

Characters Not Displayed in Linux SuSE Installation and Configuration

Valid in Japanese and Chinese localized versions on Linux SuSE
The CA Service Desk Manager installer and configuration program (pdm_configure) cannot display Japanese and Chinese Korean characters.

Hot Keys Defined as Dollar Signs

Valid in Japanese and Chinese localized versions
The dollar sign ($) is used as the hotkey in all forms when there is no other hotkey character available. In previous versions, the hotkey was picked from a list in the alphabet. In this release, CA Service Desk Manager determines the hotkey character from the corresponding English label.

Characters Not Translated During Upgrade

Valid in all localized versions on Linux and Solaris
All characters are displayed in English during the Migration step of an upgrade from Unicenter Service Desk r11.2.

CA CMDB Visualizer Date Helper Does Not Translate the Month and the Day

Valid in all localized versions
The name of the month and days of the week are not translated in the Date Helper in the Maintenance section of the scoreboard in the CA CMDB Visualizer.

CMDB Visualizer Date Format Cannot Be Localized in Japanese and Chinese

Valid in Japanese and Chinese localized versions
Symptom:
The date format in Maintenance section of the CMDB Visualizer Web Client cannot be localized.
Solution:
The CMDB Visualizer Web Client displays dates in the format dd/mm/yyyy. The preferred format for Japanese and Chinese is yyyy/mm/dd.

CMDB Visualizer Date Helper Does Not Translate the Month and the Day

Valid in all localized versions
The name of the month and days of the week are not translated in the Date Helper in the Maintenance section of the scoreboard in the CMDB Visualizer.

CA CMDB Visualizer Date Format Cannot Be Localized in Japanese and Chinese

Valid in Japanese and Chinese localized versions
Symptom:
The date format in Maintenance section of the CMDB Visualizer Web Client cannot be localized.
Solution:
The CMDB Visualizer Web Client displays dates in the format dd/mm/yyyy. The preferred format for Japanese and Chinese is yyyy/mm/dd.

CA CMDB Visualizer Does Not Support Login with Non-English User Credentials

Valid in all localized versions
CA CMDB Visualizer does not support login with Non-English User credentials.

Process Definitions in the CA Workflow IDE Appear in English

Valid in all localized versions
CA Workflow IDE process definitions are not localized and appear in English.

Support Automation End-User Assistance Session Pages Display in English

Valid in all localized versions
Symptom:
Support Automation Live Support: Assistance Session Web Page displays in English.
Solution:
All default Support Automation end user interface pages are not localized, such as the On Hold, In Session, Post-Launch, and Post-Logout pages. You can customize these pages and configure custom localizations from the Support Automation node on the Administration tab.

The Support Automation Adaptations Page Does Not Show the Localized Language Name

Valid in all localized versions
Symptom:
When I migrate a non-English CA Service Desk Manager from a previous release (r11.2, r12, or r12.1), the following areas display in English:

- Administration tab: Support Automation, Branding, Adaptations list page, shows the English row (in the respective localized language) instead of showing the actual localized language name.
- Click Live Chat on the Employee Home page, and the Localization list box shows English (in the respective localized language) instead of showing the actual localized language name.
- Support Automation Tab: From View Preferences, Support Automation Analyst UI, the Localization list box shows English (in the respective localized language) instead of showing the actual localized language name.

For example, in the Brazilian Portuguese localized SDM, after migration displays "Inglês" instead of "Português do Brasil."
Solution:
On the Administration tab, Support Automation, Adaptations, Localization Admin, enable the installed localized language name so that it is available with English.

Note: You cannot disable the English language when you migrate a non-English localized CA Service Desk Manager from r11.2, r12.0, r12.1.

Knowledge Search Parse Settings Set to English in Localized Versions

Valid on all localized versions
Symptom:
From the Search node in Knowledge Administration, the Language Type setting on the Parse Settings page is set to English by default in localized versions of CA Service Desk Manager. The product parses search text according to the language specified.

Web Screen Painter Shows English Strings While in Design Mode

Symptom:
When Web Screen Painter is in design mode, notebook tabs, buttons, menus, and the menu items appear only in English.
Solution:
To view a form in another language, do the following:

1. Open the form in Web Screen Painter.
2. If you are creating a form or updating an existing form, add the new localized strings to the $NX_ROOT/sdk/scripts/msg_cat.js file.
3. Click Preview.

Positions of Month and Day Options are Not Switched

Symptom:
I select the Yearly option when creating a Change Window for a Change Order. The Month and Day options appear in a different order.
Solution:
Customize the form in WSP to modify the positions of the Month and Day options.

Workshift Schedule Data Can Only Be Entered in English

Valid on all localized versions
Symptom:
If I use localized Workshift data, an error message appears when scheduling the Workshift.
Solution:
CA Service Desk Manager only supports English text for workshift schedule data, including days of the week, dates, and morning (am) and afternoon (pm).
The following examples display Workshift data in the correct formatting:

- Mon - Fri {8:00 am - 5:00 pm}
- Sun {9:00 - 12:00 2:00 pm - 4:00 pm}
- Sat 12/24/08 - 1/1/05 {8:00 - 12:00 14:00 - 4:00 pm}
- 7/4/09

Note: This restriction only applies to the Workshift schedule data. You can specify the Workshift display name in any localized language.

CA Process Automation Does Not Process Japanese Character Values Correctly

Valid on Japanese localized versions
Symptom:
I am able to install and run CA Process Automation and display characters correctly, until I run a CA Process Automation process that requires Japanese values being sent to CA Service Desk Manager. This action causes the process monitor to display question marks (??) in the values and CA Service Desk Manager rejects input by displaying ?? errors in stdlog.

Solution:

Important! This information supersedes the instructions in the CA Process Automation documentation.

For SQL Server

Your SQL Server database uses an incorrect collation, such as SQL_Latin1_General_CP1_CI_AS. You cannot change the collation after creating the SQL Server database.

1. Install SQL Server with the ability to create databases with Japanese codepages.
2. During the CA Process Automation installation, complete one of the following tasks:
   - Create the database with Japanese codepages manually.

- Select the Japanese codepage within the CA Process Automation installer and create the database.

Note: If you manually create the database, match the codepages from the CA Process Automation installer drop-down list with the database codepages. The installer does not detect this option or change the default codepage from Latin. CA Process Automation does not warn you about incorrect settings.

For Oracle

1. Verify that you created and started the CA Service Desk Manager database instance with the locale set correctly. For Japanese, set the locale set to ja_JP.UTF-8.

2. Verify that CA Process Automation database also started in the Japanese locale.

CMDB r11.2 German and Japanese Upgrade Detects French Locale

Valid on German and Japanese Versions
Symptom:
When upgrading CA CMDB r11.2 German or Japanese versions, the Installer upgrade program automatically detects the French locale instead of the German or Japanese locale. When the French version is detected an error message appears and the installation fails. The user cannot switch to the German or Japanese locale from the Installer.

Solution:
To resolve this issue, do the following:

1. On the CA Service Desk Manager server, navigate to the NX_ROOT directory.

2. Open the .GENLEVEL file for editing.

3. Replace 12611053G900 with 11209045R4

4. Navigate to the NX_ROOT/Site directory.

5. Open the install.properties file for editing.

6. Replace locale.current=en-US with one of the following:
   locale.current=ja-JP (Japanese)
   locale.current=de-DE (German)

7. Save your changes and run the upgrade.

The correct locale is detected.

GRLoader Does Not Identify Non-English Spreadsheet Sheet Names

Valid on all English Operating Systems

Symptom:

GRLoader does not identify non-English spreadsheet sheet names when I use the -sss option on an English OS.

Solution:

Specify the non-English spreadsheet sheet names in a configuration (.cfg) file with the grloader. spreadsheet.sheetname=name option if you run GRLoader on an English OS.

Installer Does Not Auto-Detect Local Languages

Valid on Windows 2008

Symptom:

The Setup Language screen in the CA Service Desk Manager Installer does not automatically detect the local language on Windows 2008. To proceed with the installation, the end user must select a language in this screen. The problem occurs when the format, system locale, and location options are not specified correctly in Regional and Language Options. Additionally, the product displays misplaced special characters (commas and periods) when the Format tab in Regional and Language Options is not set to the correct language.

Solution:

Set the format, language, and system locale for your environment as follows:

1. From the Control Panel, select Regional and Language Options.
2. Specify a language in the Format and Location tabs.
3. On the Administrative tab, select the Change system locale button, and specify your current system locale.
4. Click OK.

The format, location, and system locale are set.

Error Message May Appear After Installing or Migrating on a Non-English Windows Computer

Valid on all non-English Windows computers

Symptom:

The installation or migration displays an error message such as "Can not find the install directory." When I click OK, the migration or configuration window does not appear.

Solution:

This error can display on non-English Windows computers during installation or migration. Open the C:\Windows\paradigm.ini file and update the CA Service Desk Manager installation directory in the NX_ROOT and NX_LOCAL variables, such as in the following example:

```
[PARADIGM]
NX_ROOT=C:/PROGRA~2/CA/SERVIC~1
NX_LOCAL=C:/PROGRA~2/CA/SERVIC~1
```

Spelling Errors Appear in Translated CMDB Data Values

Valid on Spanish, Italian, Japanese, Brazilian, Portuguese, Simplified Chinese language systems

Symptom:

After data is loaded into CMDB, unexpected spelling and grammatical errors appear in the translated values for class names, family names, and relationship types.

Solution:

In CA Service Desk Manager, the GRLoader utility provides a set of .rul files with the new translation values for CMDB. GRLoader .rul files appear by default in the following directory:

$NX_ROOT\java\lib\GRloader

If you moved the GRLoader .rul files to a different directory (or server) in a previous release, then modify the .rul files to reflect the new translation values.

CA Service Desk Manager provides the following new translation values for CMDB:

Object Type	English Strings	Language	Previous Translation Values	New Translation Values
class	Pager	Spanish	Localizador	Buscapersonas
class	Portfolio Asset	Spanish	Activo de cartera	Activo de la cartera
family	Cluster.Resource Group	Spanish	Clúster.grupo de recursos	Clúster.grupo de recursos
family	Cluster.Resource	Spanish	Clúster.recurso	Clúster.Recurso
relationship	is monitored by	Spanish	está controlado por	está monitorizado por
relationship	is served by	Spanish	está proporcionado por	está servido por
relationship	authors	Spanish	autores	es autor de
relationship	monitors	Spanish	controla	monitoriza
family	Facilities.Furnishings	Italian	Attrezzature.Mobili	Attrezzature.Mobilio
relationship	is governed by	Italian	è regolato da	dipende da
relationship	runs on	Italian	esegue su	viene eseguito su
relationship	is serviced by	Italian	è fornito da	è servito da

Object Type	English Strings	Language	Previous Translation Values	New Translation Values
relationship	is served by	Italian	è servito da	è assistito da
relationship	governs	Italian	regola	governa
relationship	is administered by	Japanese	管理される	処理される
relationship	administers	Japanese	管理する	処理する
class	Portfolio Idea	Brazilian Portuguese	Idéia do Portfolio	Ideia do Portfolio
family	Investment.Idea	Brazilian Portuguese	Investimento.Idéia	Investimento.Ideia
relationship	is administered by	Simplified Chinese	的管理方是	的控制者是
relationship	is governed by	Simplified Chinese	的管理方是	的治理方是
relationship	is regulated by	Simplified Chinese	的管理方是	的调整方是
relationship	administers	Simplified Chinese	管理	管控
relationship	governs	Simplified Chinese	管理	治理
relationship	serves	Simplified Chinese	服务	提供服务
relationship	regulates	Simplified Chinese	管理	调整

Note: All data values must be encoded using UTF-8 encoding.

Missing Exclamation and Colon Characters from the Final Installation Page

Valid on French, Brazilian, Portuguese, and German versions
Symptom:
The final installation page displays text that is missing a colon (:) or exclamation point (!).
Solution:
This behavior relates to a third-party software issue and does not affect the product functionality.

Japanese Version of Online Help Does Not Open in Internet Explorer

Valid on Japanese versions
Symptom:
When a Japanese Internet Explorer is used with the Japanese version of CA Service Desk Manager, the role-based Online Help does not display in the web interface as expected. This problem occurs for the following reasons:

- The order of statements in the SDHelp_index.htm file is incorrect.
- The Japanese IE browser defaults to the native JIS encoding instead of the Unicode (UTF-8) signature.

Solution:
To resolve this issue, update the SDHelp_index.htm file as follows:

1. Navigate to the SDHelp_index.htm file in the $NX_ROOT/bopcfg/www/wwwroot/help/web directory.
2. Create a backup copy of this file.
3. Create a new SDHelp_index.html file (named tmp.htm in this example) by running the pdm_uconv --add-signature -f utf8 -t utf8 -i SDHelp_index.htm -o tmp.htm command at the command prompt.
4. Replace the original SDHelp_index.htm with the new file.
   The SD_Help_index.htm file with the UTF-8 signature is updated.
5. Launch the web-based Online Help.

xMatter Integration is Supported on CA SDM English Language Only

Currently no solution exists.

CA Service Desk Manager Known Reporting Issues

This topic contains the following known issues:

Unable to Run the Crystal Reports

Symptom:

I integrated CA Business Intelligence Release 4.1 SP3 with CA SDM. Sometimes, I cannot launch the crystal reports (CA SDM reports) and the following error message is displayed:

The viewer could not process an event. Your request could not be completed because a failure occurred while the report was being processed. Please contact your system administrator. [RCIRAS0546]
---- Error code:0 [CRWEB00000119]

Solution:

Follow these steps:

1. Locate and find the following lines in the ivoa25.ini (32 bit Client ODBC) file located at C:\Program Files (x86)\CA\Service Desk Manager\add-ons\oaodbc72.

   Note: If CABI is installed on different machine from CA SDM find the file at C:\Program Files (x86)\CA\SC\CASD_ODBC.

   ```
   ;[WorkArounds]
   ;UnloadICUMessagesDLL=0
   ```

2. Remove the semicolon (;) from both the lines. For example,

   ```
   [WorkArounds]
   UnloadICUMessagesDLL=0
   ```

3. Save the file and test your report.

Symptom:

The following error occurs when the 64bit ODBC client did not install correctly when CABI was running and the DLL file was already in use.

Failed to open Connection and a driver architecture mismatch error on WEBI reports.

Solution II:

Follow these steps:

1. Stop the CABI server.
2. Close the Universe Design Tool.
3. Start the CABI server.
4. Execute the CABI configuration for SDM routine to install the 64 and 32bit ODBC drivers again.
5. Update the .ini file with the changes in Solution I (see page).

Unable to Generate Reports for the CIs that contain dot (.) in the CI names

Valid on MS SQL
The following reports (to find the relationship between the CIs) are not generated for the CIs containing dot (.) in the CI name:

- All Change Impact Report
- CIs Relationship Report
- CIs Root Cause Analysis Report
- Direct Change Impact Report

CA Business Intelligence Web Report Options

In Options Manager, the following options listed on the Web Reports List page are no longer relevant when configuring CA Business Intelligence to work with CA Service Desk Manager and can be safely ignored.

- bo_server_auth
- sec Enterprise
- secLDAP
- secWinAD
- secExternal

Progress OpenEdge DSN and ODBC Driver are Not Visible in ODBC Data Source Administrator

Valid on Windows 2008 R2
Symptom:
When configuring the OA server, I create a Project OpenEdge DSN named casd_servername. I use this DSN with pdm_isql and CA Business Intelligence. After I create the DSN, I cannot view it in the 64-bit ODBC Data Source Administrator.
I cannot edit the DSN or create a DSN using the ODBC Data Source Administrator. I am unable to point CA Business Intelligence to a different server. The 64-bit ODBC Data Source Administrator control panel does not show 32-bit drivers and configurations.
Solution:
Use the 32-bit ODBC Data Source Administrator to view the ODBC drivers by executing the %windir% \SysWOW64\odbcad32.exe file.

CA Service Desk Manager with CA Business Intelligence Upgrade

If you configured CA Service Desk Manager as a data source for CA Business Intelligence, shut down all CA Business Intelligence services before upgrading.

CA Business Intelligence ODBC Server Fails to Start on Non-Windows

For CA Business Intelligence reporting, if you experience problems with the startup of your ODBC server, uninstall, and then reinstall the ODBC server.

Follow these steps:

1. Export the library path as follows:
   - (For AIX) Export LIBPATH=$LIBPATH:<CA_SharedComponent>/lib:<NX_ROOT>/lib
     Example: Export LIBPATH=$LIBPATH:/opt/CA/SC/lib:/opt/CAisd/lib
1. - (For Solaris/Linux) Export LD_LIBRARARY_PATH=$ LD_LIBRARARY_PATH:/opt/CA/SC/lib:<NX_ROOT>/lib
     Example: Export LD_LIBRARARY_PATH=$ LD_LIBRARARY_PATH:/opt/CA/SC/lib:/opt/CAisd/lib
2. To uninstall the ODBC server, run the oa72_server_uninstall command from the command prompt.
3. To reinstall the ODBC server, run the oa72_server_setup command from the command prompt.

CA Business Intelligence ODBC Server Fails to Start on Windows

For CA Business Intelligence reporting, if you experience problems with the startup of your ODBC server, uninstall, and then reinstall the ODBC client and server.

Follow these steps:

1. To uninstall the ODBC client and server, run the following commands from the command prompt:
   - oa72_client_uninstall
   - oa72_server_uninstall
2. To reinstall the ODBC client and server, run the following commands from the command prompt
   - oa72_server_setup
   - oa72_client_setup

CA Business Intelligence Integration Fails after Upgrade

Symptom:

I upgraded CA Business Intelligence and downloaded the TrustedPrincipal.conf file from the Central Management Console. But the integration between CA SDM and CA Business Intelligence failed.

Solution:

After the CA Business Intelligence upgrade, copy the downloaded TrustedPrincipal.conf file at $NX_ROOT\bopcfg\www\CATALINA_BASE\webapps\CAisd directory.

Report Details are not Displayed Correctly After Export to CSV

Symptom:
When I export reports to CSV, the data does not display correctly. For example, the header displays multiple times in the CSV without showing the appropriate content.

Solution:

Export the report in Excel format, which is available in Crystal Reports 2013 and save the file as a CSV.

Configure Business Intelligence Launch Pad Log On Page

Valid on Windows
Symptom:
The Business Intelligence Launch Pad Log On page is not configured to prompt users for their authentication type or CMS name.
Solution:

1. Copy the properties file from C:\Program Files (x86)\SAP BusinessObjects\tomcat\webapps\BOE\WEB-INF\config\default directory to C:\Program Files (x86)\SAP BusinessObjects\tomcat\webapps\BOE\WEB-INF\config\custom directory for modification.

2. Specify the default authentication types (secEnterprise, secLDAP, secWinAD, secSAPR3) here. For example, authentication.default=secEnterprise.

3. To prompt users for their CMS name, locate the cms.visible parameter and change its <param-value> from false to true. For example, <param-value>true</param-value>.

   Important! To ensure that your changes are preserved and not lost the next time the WAR files are deployed (typically during patch upgrades), follow SAP Note 1615492 (http://service.sap.com/sap/support/notes/1615492) and copy the custom files to the <BOE_HOME>\SAP BusinessObjects Enterprise XI 4.0 \warfiles\webapps\BOE\WEB-INF\config directory.

4. Save and close the file.

5. Restart Tomcat.

CA Service Desk Manager Known Security Issues

This articles contains the following known issues:

Antivirus Software Can Delay CA Service Desk Manager Startup

Valid on Windows
Symptom:
In some situations, antivirus software running on the same computer as CA Service Desk Manager can delay CA Service Desk Manager startup by 2 minutes or more. Typically, after a few minutes, the startup continues.
Symptoms include messages in the stdlog indicating a network connection cannot be made and CA Service Desk Manager appears suspended for several minutes.
If the delay occurs during migration, the migration can fail as the migration process times out waiting for services to start.

Solution:
Disable the antivirus software before you start CA Service Desk Manager. If the problem resolves, try configuring the antivirus software to relax restrictions on opening network ports, upgrade the antivirus software, and contact the vendor.
To complete migration, temporarily disable the antivirus software during the entire migration process.

LDAP Using TLS on a Windows AD Server Stalls or Fails

Valid on Windows
Symptom:
A Microsoft bug causes LDAP client applications that use more than one connection to stall or fail while using TLS encryption. When the server uses TLS encryption with LDAP groups enabled, CA Service Desk Manager can use a second connection in each LDAP Agent process. CA Service Desk Manager encounters one or more of the following symptoms:

- LDAP queries, synchronizations, or imports stall. A time-out can also occur with one or more ldap_agent.exe processes running continuously at or near 100 percent usage of one CPU core.
- LDAP queries, synchronizations, or imports fail with Server Down errors.
- LDAP queries, synchronizations, or imports return no errors and no results.

Solution:
If you use TLS encryption for LDAP, we do not recommend using LDAP groups with Windows Active Directory servers. You can either disable TLS or LDAP groups.
To disable TLS encryption or LDAP groups, do the following:

1. Terminate all ldap_agent.exe processes that are continuously using a large portion of CPU time
2. If you are unable to log in to CA Service Desk Manager to access the Options Manager, stop the CA Service Desk Manager service. In the $NX_ROOT/NX.env file, set one of the following options to No, and then stop and restart the CA Service Desk Manager service:
   - NX_LDAP_ENABLE_GROUPS (LDAP Groups)
   - NX_LDAP_ENABLE_TLS (TLS Encryption)
3. In Options Manager, disable either the ldap_enable_groups (LDAP Groups) option or the ldap_enable_tls (TLS Encryption) option.
4. If the CA Service Desk Manager service is running, stop the service.
5. Restart the CA Service Desk Manager service.

Automatic Login to Business Intelligence Launch Pad Fails

Valid on all operating systems with a CA Business Intelligence installation
Symptom:
During the CA Business Intelligence installation, a CA Technologies web cookie is installed by default that lets you automatically access Business Intelligence Launch Pad from the CA Service Desk Manager Reports tab without logging in. If access is restricted through your web browser privacy settings, the application fails to execute, and a login prompt appears on the Reports tab.
Solution:
If you encounter this issue, adjust your web browser Internet Options, Privacy settings so that CA Technologies web cookies are allowed on your system.

Warning Messages Appear When Generating Stub Classes

Valid on all operating systems
Symptom:
When using the AXIS tool WSDL2JAVA to compile stub files, warning messages appear.
Solution:
These warning messages are common when using AXIS 1.4 and cannot be avoided. The stub files are still created successfully.

Online Help Error Messages

Symptom:
Some context-sensitive online help pages produce a script error, although the online help topic displays correctly.

Solution:
The script errors can occur when script error notification is enabled in your browser. You can ignore these error messages, or you can disable script error notification on the Tools, Internet Options, Advanced tab.

CA Workflow Process Definitions Are Not Imported Automatically

Symptom:
The CA Workflow process definitions and actors are not imported automatically when starting CA Workflow due to incorrect locale variable settings on UNIX/Linux.
Solution:
After installing CA Workflow, use one of the following methods to resolve this issue:
To import CA Workflow process definitions and actors

1. Set the environment variables of LANG and LC_ALL to UTF-8 in a prompt for your operating system environment. For example, on Oracle Solaris the environment variable appears as: LANG=en_US.UTF-8.

2. Stop and then restart the CA Workflow Tomcat server as follows:

   - Run pdm_tomcat_nxd -d STOP -t CAWF.

   - Run pdm_tomcat_nxd -d START -t CAWF.
     The CA Workflow process definitions are imported.

To import the CA Workflow process definitions and actors manually

1. Use the IDE client to open CA Workflow.

2. Note: The IDE client is only available on Windows and Linux operating systems.

3. Locate the process definition and actor xml files, for example: $NX_ROOT/site/Workflow/data /actors and $NX_ROOT/site/Workflow/data/process directories.

4. Select File, Import, Process Definition, select all the XML files for import, and click Open.

5. Select all the definitions and click Import.
   The process definitions are imported.

6. Select File, Import, Actors, select all the XML files for import, and click Open.
   The actor xml files are imported.

7. Select all the actor files and click Import.
   The CA Workflow process definitions are imported.

CA Workflow IDE Login as User Other than Root Sets Incorrect URL

Valid on Linux

Symptom:

When a nonprivileged user launches CA Workflow IDE on Linux, the URL is set incorrectly to https://servername:8443/pm. Java errors appear on screen, and the login to CA Workflow is unsuccessful.

Solution:

1. Launch the CA Workflow IDE client.
2. Change the URL to: http://servername:8090/pm.
   Login is successful.

Duplicate Definition Messages

Symptom:

Because CMDB automatically creates the attributes and triggers for your customized extension tables, the stdlog can include the following harmless message for extension tables that were created in previous releases:

Ignoring duplicate definition

Solution:

To eliminate these messages, remove the following attributes from your custom extension tables:

- id SREL nr;
- version_number INTEGER { ON_CI INCREMENT 1; };
- creation_date DATE { ON_NEW SET NOW ; };
- creation_user STRING { UI_INFO "AUDITLOG"; ON_NEW DEFAULT USER ; } ;
- last_mod_dt last_update_date DATE { ON_NEW SET NOW ; ON_CI SET NOW; } ;
- last_mod_by last_update_user STRING { UI_INFO "AUDITLOG"; ON_NEW DEFAULT USER ; ON_CI SET USER ; } ;
- delete_flag del SREL actbool { ON_CI DEFAULT 0; };
- mdr_name LOCAL STRING;
- mdr_class LOCAL STRING;

Errors Occur When CA Wily Data is Loaded into CA CMDB

Symptom:

The GRLoader.log file produces errors when CA Wily data is loaded into CA CMDB as CIs.

The following is an example of the log entry:

```
11/07 00:44:52.662 ERROR grCI 504 Error trying to insert CI. Error setting at
```

Solution:

CA Wily integration includes an older version of GRLoader. Use the version of GRLoader that ships with CA Service Desk Manager to import the data successfully.

Multi-Tenancy and Visualizer

The Visualizer uses the Administrator role for impersonation purposes. A user with this role must have rights to see *ALL TENANTS*. If this user does not have ALL TENANTS rights, then Visualizer launch (stand-alone or in context) can fail.

Example: Visualizer Session Error

When Visualizer is launched in context for a CI, the following Visualizer session error appears:

Authentication failed for user

Symptom:

Tenant Access for the impersonation role is set to *Single Tenant*.

Solution:

To launch Visualizer in context without this error, set the Administrator role to *Tenant Access to All Tenants*.

Visualizer Relationship Performance

CMDB Visualizer can process approximately 2500 relationships on its graphical canvas. If a Visualizer request contains more than 2500 relationships, then Visualizer performance can degrade.

Set Browser Locale for Visualizer

CMDB Visualizer adapts itself to the client-browser locale, which can display a different language from your localized CA Service Desk Manager. To view the same language in Visualizer, set the browser locale to the CA Service Desk Manager language.

To set the browser locale in Internet Explorer

1. Select Tools, Internet Options, General tab, Languages.
2. Add the language you want and move it to the top.
3. Open the new IE browser window (or refresh the browser).

   Visualizer displays the language of the localized CA Service Desk Manager.

To set the browser locale in Firefox

1. Select Tools, Options, Content tab, Languages section.
2. Add the language you want and move it to the top.

3. Open the new Firefox browser window (or refresh the browser).

   Visualizer displays the language of the localized CA Service Desk Manager.

CA Service Desk Manager Known Miscellaneous Issues

This article contains the following known issues:

Upgrade to JRE 1.8 Causes PDM_CONFIGURE to Throw an Error

Valid on AIX

Symptom:

Running pdm_configure after upgrading CA SDM JRE to version 1.8 throws the following error in the AIX operating system:

```
"ERROR: xawt path is not a valid directory: [$XAWTPATH]"
"Please export proper JAVA_HOME/lib/ppc/xawt into LIBPATH"
```

Solution:

Follow these steps:

1. Take a backup copy of the $NX_ROOT/local/pdm_configure file.

2. Open the file $NX_ROOT/local/pdm_configure and search for the following information:

   ```
   echo "ERROR: xawt path is not a valid directory: [$XAWTPATH]"
   echo "Please export proper JAVA_HOME/lib/ppc/xawt into LIBPATH"
   exit 1
   ```

3. Comment those lines (Add # to start of each line).

4. Save the file and exit.

Auto Refresh Does not Work When an Existing Attachment or URL is Deleted or Detached From a Configuration Item

> **Note:** This known issue is only applicable for CA SDM Release 14.1.01

Valid on all browsers
Solution:
Manually refresh the Activities Tab of the Configuration Item to view the updated activities.

Values in Money Fields Truncated at Decimal Point

Valid on all operating environments
Symptom:
Including a decimal point in a money amount causes truncation of the value. This behavior applies to all fields intended to hold currency values, such as Purchase Amount and Maintenance Fee. For example, if you enter 265.50 in the Purchase Amount field, the value is saved as 265.
Solution:s
Although the name of some fields implies that they are money fields, they are implemented as integers. To avoid truncation, do not use a decimal point in integer fields.

pdm_ident command Returns an Empty Output

Valid on Linux
Running the pdm_ident command on any CA Service Desk Manager executable, returns an empty output.

Xlib Error Messages Appear While Uninstalling CA Service Desk Manager

Valid on Linux and UNIX
Symptom:
I am using third part remote management tool to uninstall CA Service Desk Manager. Xlib error messages appear during the uninstallation.
Solution:
CA Service Desk Manager will be uninstalled successfully, even though the error messages appear. To stop these error messages from coming, export DISPLAY variable and execute xhost + command before you begin the uninstallation.

Unsuccessful Failover on Standby Server

Valid on AIX
Symptom:
Both standby server and background server are installed on AIX. You want to perform failover and promote the standby server as the new background server. You used the pdm_server_control -b command on the standby server. You get the following error message:
This server is not a STANDBY server and cannot use the -b option.
Solution:
This issue occurs when you use XManager. Export CASHCOMP=/opt/CA/SC on Xmanger and try to run the command on the standby server again.

Pop-up Windows on CA Service Desk Manager web UI Shows Blank Page

Valid on Internet Explorer 10
Symptom:
You opened a pop-up window (for example, Create New Incident page) from the CA Service Desk Manager web UI. The page is blank or has only few control with blank sections. If you resize the window, then the contents appear properly.
Solution:

1. On your IE browser, go to Internet Options, Security, Local intranet.
2. Click Sites.
3. Add the CA Service Desk Manager URL to the intranet zone.
4. Close the browser and try to launch the CA Service Desk Manager web UI on a new IE browser.

Library Errors Occur When Running Command-Line Utilities

Valid on AIX, Linux, and Solaris
Symptom:
The following library errors similar to the following occur when I run command-line utilities:

```
ld.so (http://ld.so).1: pdm_pki: fatal: libetpki2.so (http://libetpki2.so): open failed:
No such file or directory
Killed
```

Solution:
Add the etpki library directory to your library path. The etpki library path is typically located at /opt /CA/SC/ETPKI/lib.

CA Spectrum Infrastructure Manager Integration with CA Service Desk Manager

Valid on all platforms
Symptom:
Integrating CA Spectrum Infrastructure Manager 9.2 (hotfix H03 applied) with CA Service Desk Manager produces the following issues:

- When an alarm is triggered through CA Spectrum, the associated service desk ticket is not automatically created in CA Service Desk Manager as expected. A solution has not been found.
- (Solaris only) When a user closes or transfers a service desk ticket in CA Service Desk Manager, the ticket is not propagated to CA Spectrum as expected.

Solution:
To resolve the ticket closure issue on Solaris, do the following:

1. Navigate to the $NX_ROOT/bin directory.
2. Open the OCNotify.jar file for editing.
3. Change the permission value to 777.
   The value is set.

4. Update a service desk ticket (Incident, for example) in CA Service Desk Manager.

5. Save your changes.
   The ticket is propagated to CA Spectrum.

SiteMinder Integration with CA Service Desk Manager

Symptom:
Single Sign-on (SSO) with the CA Service Desk Manager and SiteMinder integration is not working.
Solution:
Due to known issue with SiteMinder, SiteMinder is not able to send REMOTE_USER in HTTP Header which is required for default SSO for CA Service Desk Manager. Complete the following workaround steps to enable SSO until there is a fix from SiteMinder:

1. Set RemoteUserVar as REMOTE_USER under Agent Configuration in SiteMinder Policy Server.

2. Create a response with Attribute “WebAgent-HTTP-Header-Variable” and Variable Name as “REMOTE_USER” on SiteMinder.

3. Add @NX_ACCEPT_HTTP_REMOTE_USER=1 in the Service Desk Manager NX.env file.

4. Restart CA Service Desk Manager Services.

Exported Excel File Contains Errors and Does Not Open

Symptom:
When I click Export on a CA Service Desk Manager form, the exported Excel file displays XML PARSE ERROR and does not open correctly. I used the character 0xB (0013 base 8 and 11 base 10).
Solution:
The export utility does not support certain characters. According to the World Wide Web Consortium (W3C), XML does not permit all characters below 0x20, except 0x9, 0xA, and 0xD.

Wild Character Search Does Not Work for Federated Search

Symptom:
Wild character search such as %, ?, _, [], [^] does not work for Federated Search.
Solution:
CA Service Desk Manager wild character search is applicable only to EBR search.

CA Service Desk Manager Known Browser Issue

This section contains the following known issues:

IE 9 Browser Does not Support Multiple File Selection

Valid for IE 9 browser

Applicable for tickets, repositories, and knowledge.

Example:

1. Log in to CA Service Desk Manager with the administrator access type.
2. Open any existing ticket and try to attach multiple files using the Ctrl button.
   Unable to select multiple files using Ctrl button.

Solution:

Currently no solution exists.

Firefox Limitations in Knowledge Management

Valid on Windows and Linux
When using Firefox browsers, you can experience the following limitations in Knowledge Management:
Symptom:
From the Design Tab in the HTML Editor, you cannot delete previously saved text entered in the Resolution field of a knowledge document.
Solution:
You can delete previously saved text from the Source tab in the HTML Editor.
Symptom:
In Knowledge Management, a Firefox security setting can prevent you from using Cut, Copy, and Paste functions.
Solution:
To enable Cut, Copy, and Paste functions, modify your browser security preferences.

Note: For more information about configuring browser preferences, see mozilla.org (http://mozilla.org/).

Chrome Does Not Display Page Titles Correctly

Valid on Windows Server 2008
Symptom:
When I use Google Chrome, some title pages do not display correctly. For example, the detail_in. htmpl contains the title as untitled.
Solution:
Upgrade to the latest version of the browser.

Unable to Navigate to the Main Page of CA Service Desk Manager

Valid on Internet Explorer 9, 10, and 11.
Symptom:
I am unable to go back to the main page of CA Service Desk Manager when I click List All Windows from the menu driven option and then click Main Page.
Solution:
The problem occurs when you open multiple tabs on the Internet Explorer. You must close all the other tabs and then click Main page option. This behavior is a known issue in Internet Explorer 9, 10, and 11.

JAWS Does Not Read Header Associated with a Link on Read-Only Detail Forms

Symptom:
JAWS does not read the header associated with a link on a read-only detail form.
Solution:
Complete the following steps:

1. Open IE.
2. Press the Insert key + V to open the JAWS options.
3. Click Link Options, Text Link show Using - Screen text.
4. Press the spacebar until the option changes to Text Link Show Using - Title.
5. Close the options dialog.

Search-As-You-Type Works Differently for Japanese Language with Firefox

When Firefox is used with the Japanese version, the analyst must commit characters (such as exiting the IME process) to see matching results with Search-As-You-Type. Japanese characters in Firefox are not processed until the characters are released (no longer underlined or highlighted) by the Japanese Input Method Editor (IME).

Web Interface Renders Incorrectly in Internet Explorer

Valid on Windows
Symptom:
I experience any of the following problems:

- The web interface does not render correctly when I log in to the Analyst interface
- I cannot log on as a customer or employee.
- The guest login link is not on the page or the button is incorrect.
- Internet Explorer is using the Enhanced Security Configuration and the Internet zone does not allow you to run any script.

Solution:
Complete one of the following tasks:

- Create a custom security level in IE to enable most entries or add the server hostname to the Local Intranet zone.
- Log on as Administrator and disable the Enhanced Security Configuration in Internet Explorer.

Unable to Export Schedule on Internet Explorer

Valid on Windows
Symptom:
Exporting the Change Order Schedule does not function correctly when Enhanced Security is enabled in Internet Explorer (IE). The Enhanced Security option prevents IE from displaying the download prompt that the Export button creates for the user. The Enhanced Security option is only available on server installations of Windows.
Solution:
Disable the Enhanced Security option in IE.

Support Automation Clients Do Not Open on Chrome, Safari, or Firefox

Symptom:
When I open the Support Automation Analyst Interface or end-user client from Chrome, Safari, or Firefox, the Support Automation client opens in IE. The client only opens in IE, even if I set Chrome, Safari, or Firefox as the default browser. For example, you click on any link on the Support Automation Analyst Interface, such as an Incident. The Incident opens in Internet Explorer, instead of opening in Chrome, Safari, or Firefox. If I disable IE, the links do not work.
Solution:
No solution exists.

JavaScript Updates Cause Pages to Appear Incorrectly in Internet Explorer

Valid on Internet Explorer 9, 10, and 11.
Symptom:
I upgraded CA Service Desk Manager or modified CA Service Desk Manager by updating the JavaScript files. The updates do not display in the web interface correctly. JavaScript errors may also appear.
Solution:
A setting in Internet Explorer prevents the deletion of Temporary Internet Files from favorite sites and you must clear the browser cache.
Follow these steps:

1. Click Tools, Internet Options.
2. Click Delete in Delete Browsing History.
3. Disable the Preserve Favorites website data option and verify that the Temporary Internet files check box is selected.
4. Click Delete.
   The browser deletes the files.
5. Click OK on the Internet Options dialog.

CA Service Desk Manager Known Database Issues

This article contains the following known issues:

Oracle and CI Name Search

On Oracle 11g r1, if you search for an existing CI Name that is longer than 67 characters, the search fails. This problem does not occur on Oracle 11g r2.

Oracle RAC Failover

Few delay response pages are not converted to proper CA SDM pages during the failover of Oracle 11g r2 RAC Node. Errors are logged in the std log file.

For more information, see Deploy Oracle RAC with CA Service Management (see page 745).

Search Operations Do not Fetch any Results

Symptom:

I tried to perform search in CA Service Desk Manager based on data partitions. No search results are displayed and I get a DB error in the stdlog file.

Solution:

Upgrade your Oracle server version to release 11.2.0.3.0 and try again.

pdm_isql Utility is not Working on the Background Server

Symptom:

I logged in to the background server and executed the pdm_isql command. I am getting the following error message:

```
Unable to connect to the database.Since ODBC Services are not running on BG S
```

Solution:

The pdm_isql utility works only on the application server and you cannot run it on the background server.

Oracle 11g Release 1: Enable Case-Sensitive Search Capabilities within CA Service Desk Manager

Valid on all operating systems

Symptom:

When using CA Service Desk Manager with Oracle 11g Release 1, unexpected results can occur due to a case-sensitivity issue. For example, the following problems can occur:

- Documents can be associated with the wrong categories.
- Data partitioning may not work as intended.
- The Web UI may become unresponsive when a list of relationships is displayed.

Solution:

To *resolve* this issue, use Oracle 11g, Release 2. You can download Oracle 11g Release 2 from the Oracle Metalink Support page.

To *avoid* this issue, enable case-sensitive search capabilities within CA Service Desk Manager. In the NX.env file, set the NX_ORACLE_CASE_INSENSITIVE=variable to 0 instead of the default, 1, and restart services.

Note: For problem resolution, BUG ID No. 7335665 has been assigned to the Oracle development group.

CA Service Desk Manager Services Do Not Run After Configuration

Valid on Oracle on UNIX/Linux

Symptom:

After I complete the CA Service Desk Manager configuration, the CA Service Desk Manager services do not run by default.

Solution:

For configuring a 64-bit Oracle 11g database on a 64-bit computer, you *must* also install the Oracle 32-Bit Client on the server. Complete the following steps when you configure the database:

- The system library path (LD_LIBRARY_PATH on Oracle Solaris and Linux, and LIBPATH on AIX) must point to the 32-bit Oracle libraries.
- The ORACLE_HOME variable *must* point to the 32-bit Oracle libraries.
- The system PATH variable should include the 32-bit client bin folder: $ORACLE_HOME/bin.
- Create a net service name on the Oracle client to point to the Oracle database server instance. Use Administrator as the Oracle 32-bit client installation type.

Incorrect Search Results When Using Wildcards on Oracle

Valid on Oracle 11g R2

Symptom:

I use the underscore (_) and question mark (?) wildcards in a search and an incorrect number of results appear.

Solution:

Avoid using an underscore or question mark when you want the number of returned records to be accurate. These wildcards work on SQL Server searches.

SQL Server Limitation When Using Required Fields Which Do Not Allow Duplicate Values

SQL Server may not accept more than 900 bytes when you update the required fields which does not allow duplicate values. These fields can contain unique indexes and SQL Server has a known limitation. When you click Save, this limitation causes CA Service Desk Manager to display an error message such as the following example:

Operation failed. The index entry of length %d bytes for the index '%.*ls' exceeds the maximum length of %d bytes.

CA Service Desk Manager Known Documentation Issues

This article contains the following known issues:

Help On CA Service Catalog Options Opens the Online Help Home Page

Solution:

For more information about the CA Service Catalog options, navigate to Options Manager, CA Service Catalog from the Online Help Home Page or you can also see Options Manager (see page 1303) topic.

Help On This Window Option Does Not Work on the iPad

Valid on the Apple iPad

Some online help forms display the main CA SDM *Online Help* home page instead of specific topics. If this topic appears, use the search in the *Online Help* to find the appropriate content.

If the Help On This Window option does not work on the iPad, use the following actions:

- If you have an open help page and click Help On This Window on the other form, the new help form does not appear. Instead, the form updates to the already opened help form. The focus does not go to the help form and you have to click the form.
- If you open the help from another form, for example the Incident or Problem detail form, a prompt appears on the CA SDM home page. Click Accept from th home page to view the required help form.

Help on Server Configuration Wizard Shows Incomplete or Incorrect Information

- The following fields are not added in the help documentation of MS SQL Database Config wizard:
  - Database Admin User
  - Database Admin Password
- The following fields are stated as Read-only in the help documentation of Oracle Database Config wizard:
  - Data Tablespace Name
  - Index Tablespace Name
- Tablespace Path in DB server is written as Tablespace Path in the help documentation of Oracle Database Config wizard.

For correct information about these fields, see Server Configuration Utility (see page 869) topic.

Online Help Does Not Include the Documentation of Newly Introduced Options

The following options are not explained in the CA SDM online help:

- caextwf_retry_count
- caextwf_retry_interval
- force_browser_to_send_cookie_only_in_ssl_connection
- use_encrypted_sid_and_cookie
- max_files_to_upload_simultaneously
- xmatters_cr_attr
- xmatters_retry_count
- xmatters_retry_interval
- xmatters_url

For more information about these options, see the Options Manager (see page 1303) topic.

CA Service Desk Manager Known Sharepoint Issues

This article contains the following known issues:

Incident Modified Date is not Correct in the SharePoint 2010 Search Result

Valid on all operating systems

Symptom:

I created and modified an incident. Then I created the content source and crawler rule for CA Service Desk Manager. When I do Federated Search for the incident in SharePoint 2010, I find that the modified date of the incident is displaying the crawling time and not the modified date.

Solution:

There is no solution for this problem.

SharePoint 2010 does not Index PDF Files

Valid on all operating systems

Symptom:

When I perform the knowledge search through the Federated Search crawler, the PDF files that the crawler sends to the SharePoint 2010 does not get indexed.

Solution:

SharePoint 2010 does not have a PDF filter and cannot process the PDF files. So, you do not get the content of these PDF files in the search results. Install the fix that is mentioned in the KB_Article (http://support.microsoft.com/kb/2293357).

Total Search Count Varies When I Navigate Through Search Result Pages

Valid on all operating systems

Symptom:

I searched the knowledge database using the Federated Search mechanism (SharePoint 2010). As I navigated through the results pages, the total search count varies from one page to the other page. Though the total count must be consistent through out the pages.

Solution:

This is a known behavior in SharePoint 2010. For more information, use the following URL:

`http://social.technet.microsoft.com/Forums/sharepoint/en-US/10638572-9240-44f`

CA Service Desk Manager Known Migration Issues

This article contains the following known issues:

Errors are Displayed in the ITIL Content After the Migrating

Symptom:

I migrated from CA SDM Release 12.9. After the migration, the ITIL content schema files are missing and errors are displayed in the std log file.

Solution:

Install the ITIL Content for CA Service Desk Manager (see page 4819) to rectify this issue.

Migration Failure on Oracle 10g

Valid on Oracle 10g

Symptom:

The migration fails with the following error messages in the log file:

```
"STDERR: Error in dbcallback. event:4 err:15"
"STDERR: Error fetching data:15"
"ERROR: (54 of 54) Tables Failed Schema Validation!"
```

Solution:

Before starting the migration on Oracle 10g, verify that SQLPlus and Oracle DB are able to communicate. If communication fails, verify that Oracle is configured with the loopback adaptor using Oracle-supplied utilities and diagnostic techniques.

Migration Failure on SUSE 10 Machine

Valid on SUSE 10 machine

Symptom:

I click on Migrate to upgrade CA SDM. An error message is displayed.

Solution:

You are required to apply a patch to fix this problem. Contact CA Support Online (http://support.ca.com/) and find out the patch details.

Migration Does Not Back Up xlate Files

Symptom:

When you migrate from CA SDM r12.1, the GRLoader translation "xlate" files located in <nxroot>/java /lib/GRLoader are not backed up.

Solution:

If you made edits or created GRLoader translation "xlate" files located in <nxroot>/java/lib/GRLoader for any user-defined class, family, or relationship, back them up before migration.

Inactive Support Automation Users Set to Employee Access Type After Migration

Symptom:

Inactive Support Automation users, such as deleted Technicians, appear as Employees after migration.

Solution:

If you deleted users in CA Support Automation 6.0 SR1 eFix5, login and role associations were deleted, and the users were set to inactive. After migration, these inactive users have the Employee access type. You can delete these inactive users.

Data in Support Automation Reports Cannot Be Grouped by CA SDM Ticket Category After Migration

Symptom:

After I migrate Support Automation data, I cannot group or filter CA Business Intelligence reports by using the CA SDM ticket category. The Support Automation Assistance Sessions, Support Automation Assistance Sessions Metrics, and Support Automation Tool Usage Summary reports are impacted.

Solution:

The Support Automation migration script does not migrate relationships between Support Automation assistance sessions and CA SDM ticket categories. After migration, the Support Automation assistance session associates with the CA SDM ticket reference number. Additionally, you *must* manually associate the assistance session to the CA SDM ticket category.

Migration Does Not Remove WorldView Class Options

Symptom:

If the installation of a previous release of CA SDM included the Change Impact Analyzer integration, the WorldView context menu includes the ManageObject and UBMClass WorldView Class options.

Solution:

Because Change Impact Analyzer is deprecated in this release, delete theses menu options manually.

To delete the menu options

1. Start WorldView.
2. Right-click any object on the WorldView map and select Edit Class.

The Unicenter Class Wizard opens.

3. On the Class tab, select Modify Existing Class, and select the ManagedObject class.
4. On the Menu tab, select ManagedObject from the Menu Name drop-down list.
5. Scroll down in the middle field, select Impact Analyzer Sep, and click Delete.
6. Select Read Impact Analyzer in the middle field.
7. Click Delete.
8. Save and close the dialogs by clicking OK and Yes as appropriate.

   The ManagedObject class is removed from the WorldView context menu.
9. Repeat Steps 1 through 8 for the UBM Class and delete the same entries for the UBMClass Menu.

   The UBMClass is removed from the WorldView context menu.

Incorrect Path Causes Migration Failure on UNIX/Linux

Valid on UNIX/Linux

Symptom:

When I try to migrate from CA SDM r12.1 migration fails with missing file or directory errors in configure.log:

```
ERROR InstallTomcatTask.java 150 catalina.policy: /opt/CA/ServiceDesk/bopcfg/www
/CATALINA_BASE/conf: A file or directory in the path name does not exist.
ERROR InstallTomcatTask.java 150 context.xml: /opt/CA/ServiceDesk/bopcfg/www
/CATALINA_BASE/conf: A file or directory in the path name does not exist.
```

Solution:

The CATALINA_BASE path begins with the /opt/CA/ServiceDesk directory incorrectly. This path was replaced in CA SDM r12.5 with /opt/CA/ServiceDeskManager.

Execute the following command to fix the link to the required path:

```
ln -s /opt/CAisd /opt/CA/ServiceDesk
```

Tenant Cache Error Appears When Migrating from CA SDM r12.1

Symptom:

After I migrate from CA SDM r12.1 with multi-tenancy enabled, I try to create a Request/Incident /Issue and assign a tenanted user as a contact. When I tab out of the contact field, the following error message appears:

getCandidateTenants(cr:83274874,3986928649836438928346) failed - tenant cache is not correctly initialized

Solution:

Complete the following steps after you migrate:

1. Open web.cfg in the $NX_ROOT\bopcfg\www\ directory.
2. Go to the line that defines SelListCachePreload.
3. Add the following factory and attribute at the end of the line:

   ```
   tenant(name subtenant_group supertenant_group) tenant_group_member(tenai
   ```

4. Restart CA SDM services.

CA Service Desk Manager Known Upgrade Issues

This article contains the following known issues:

Modify Tomcat Delivered with Unicenter Service Desk r11.2

If you are upgrading from Unicenter Service Desk r11.2 and are using a version of Tomcat other than the default (4.1.31), follow these instructions before upgrading.

For Windows:

1. Modify the following line in the NX_ROOT\NX.env file to specify the path of the version you are using:

   ```
   @NX_TOMCAT_INSTALL_DIR= C:\Program Files\CA\SharedComponents\Tomcat\4.1.31
   ```

2. Modify the following lines in the NX_ROOT\site\config.properties file:

   ```
   web.tomcat_home= C:\Program Files\CA\SharedComponents\tomcat\4.1.31
   web.tomcat.service_name=Apache Tomcat 4.1
   web.tomcat.version=4.1.31
   ```

3. Install CA SDM.

Note: Any customizations made to the NX_ROOT\bopcfg\www\CATALINA_BASE\conf server.xml have to be manually updated to the server.xml (5.5.25) after configuration is run. An example would be SSL setup for Tomcat.

For UNIX:

1. Modify the following line in the NX_ROOT/NX.env file to specify the path of the version you are using:

```
@NX_TOMCAT_INSTALL_DIR=/opt/CA/SharedComponents/tomcat/4.1.31
```

2. Modify the following lines in the NX_ROOT/site/config.properties file:

```
web.tomcat_home=/opt/CA/SharedComponents/tomcat/4.1.31
web.tomcat.service_name=Apache Tomcat 4.1
web.tomcat.version=4.1.31
```

3. Install CA SDM.

Note: Any customizations made to the NX_ROOT/bopcfg/www/CATALINA_BASE/conf server.xml have to be manually updated to the server.xml (5.5.25) after configuration is run. An example would be SSL setup for Tomcat.

MDB Patch 17261861 Oracle for Windows

Symptom:

MDB patch 17261861 Oracle for Windows has an error that prevents an upgrade to MDB r1.5.

Solution:

MDB patch 17615776 includes the fix for this problem. Install patch 17615776 before upgrading to MDB r1.5 (CA CMDB r12.0 and CA CMDB r12.1 use this MDB version).

Note: CMDB-UAP Integration Patches RO2252 and RO02288 both include MDB patch 17261861 Oracle for Windows. If you have installed RO2252 or RO02288, and you are using an Oracle database, contact CA Technical Support for information about how to obtain the MDB patch and how to install it.

Upgrade Fails from Unicenter Service Desk, CA CMDB r11.2, and Visualizer

Valid in all languages

Symptom:

The following error message displays when you upgrade your Unicenter Service Desk, CA CMDB r11. 2, and Visualizer installations.

The environment variable CMDBVISUALIZER_HOME has been detected. This system appears to have CMDB Visualizer installed. This installation cannot continue. Cancel this installer. Remove CMDB Visualizer by 1) executing the Uninstaller separately; 2) Reboot the Operating System; 3) then run this installer again.

Solution:

Manually uninstall CA CMDB Visualizer before you perform the upgrade.

Live Assistance, Live Chat, and Join Analyst Now Links Are Missing

Symptom:

After upgrading from Unicenter Service Desk r11.2 with CA Support Automation r6.0 SR1 eFix5, the Support Automation Live Chat and Join Analyst Now links on the Employee page do not appear.

Solution:

After you upgrade CA SDM, remove the home.htmpl file from the NX_ROOT\site\mods\www\htmpl\web\employee\Employee directory so that the folder does not contain any files

Symptom:

After upgrading from Unicenter Service Desk r11.2, CA Service Desk r12, or r12.1 without CA Support Automation r6.0 SR1 eFix5, the following Support Automation options do not appear:

- The Live Assistance button on the Assigned Queue list page.
- The Live Chat and Join Analyst Now links on the Employee or Customer home pages.

Solution:

Support Automation uses the Analyst and End User default access levels. Because you upgraded from a CA SDM release that did not include Support Automation, assign the access level manually after upgrading.

CA SDM Upgrade Fails if the UTF-8 Locale is Not Installed

Valid on UNIX and Linux

Symptom:

The CA SDM upgrade fails when the UTF-8 locale is not installed before upgrading.

Solution:

CA SDM must run on the UTF-8 locale on UNIX and Linux operating systems. Before upgrading CA SDM, verify that you have installed the UTF-8 locale.

Printed Knowledge Documents Contain Large Spaces After Migration

Valid on all operating systems

Symptom:

Customers upgrading from Unicenter Service Desk r11.2 experience a printing problem for Knowledge Documents. Printed documents display a large space after the Resolution section when the documents contain embedded images.

Solution:

Complete the following steps:

1. On the Administration tab, navigate to Knowledge, Documents, Document Templates.
2. Open a Knowledge Document template.
3. Locate the <TD> tag in the HTML section and add the following code:

   ```
   <TD vAlign=top><SPAN class="clsTextBlackXXsmall"><SPAN>{TAG_RESOLUTION}
   ```

4. Repeat this change for all default Document Templates.

CA Service Desk Manager Known Configuration Issues

This article contains the following known issues:

pdm_configure Fails When MDB is Copied From Another Environment

Symptom:

1. Copied MDB from one machine to another machine and run pdm_configure.
2. During the configuration, entered the database information, and clicked Next.
   The following message is displayed.

   ```
   Database was previously configured by the server name of application server in
   the environment in which
   MDB was copied from.
   ```

3. Clicked OK and the dlgsrv table is automatically updated.
   The following message is displayed

   ```
   Already following servers are using the same database:<server name>. Make
   these servers as Inactive
   to proceed.
   ```

4. Clicked OK.
   pdm_configure fails to continue.

Solution:

To resolve this issue, add the @NX_SWING_BOX_MIGRATE variable. If this variable is set to Yes, the active server checks are ignored.

Note: For each CA SDM advanced availability server, manually add or update the NX variable in the $NX_ROOT/NX.env file and recycle CA SDM.

1. Run the following command from the command prompt on the primary server:

   ```
   pdm_options_mgr -c -s SWING_BOX_MIGRATE  -v Yes -a pdm_option.inst
   ```

2. Set the value of NX_SWING_BOX_MIGRATE to **No** after pdm_configure is successfully completed using the following command:

   ```
   pdm_options_mgr -c -s SWING_BOX_MIGRATE  -v No -a pdm_option.inst
   ```

3. To retain the changes made when you run pdm_configure, run the following command:

   ```
   pdm_options_mgr -c -s SWING_BOX_MIGRATE  -v No -a pdm_option.inst -t
   ```

Note: You may need to make additional changes to the database and/or CA SDM configuration to prevent duplicate notifications, and so on. For more information, see TEC578669 (https://support.ca.com/irj/portal/anonymous/kbtech?searchID=TEC578669&docid=578669&bypass=yes&fromscreen=kbresults).

Functionality Failures After Configuring the CA SDM Secondary Server with a Different Tomcat Port

Valid on all operating environments

Symptom:

I configured the CA SDM Secondary server with a different Tomcat port than the Primary server port. This configuration causes some functionality to fail when accessed from the Secondary server web URL. For example, GRLoader, and Process Viewer.

Solution:

Access the functionality from the primary server URL because they do not work on the secondary server. Use the –s parameter to specify host name and port number while running GRLoader from the secondary server.

Configuration Failure on 64-bit Oracle

Valid on 64-bit Oracle 11g R1 and 11g R2

Symptom:

The configuration fails and the following error messages appear on 64-bit Oracle:

- In the stdlog: "Unable to connect to Oracle database mdbadmin on server"
- In the checkdb.0 log: “Unable to load the OCI library or DLL. Cannot continue!”

Solution:

Install the latest 32-bit Oracle client, and do the following:

- On Windows, verify that the path includes the directory for the 32-bit Oracle libraries.
- On UNIX, set the library path variable so it points to the 32-bit Oracle library.

> **Note**: The problem can also occur when migrating from a previous release of CA SDM. If the error occurs during migration, install the client and run the migration.

bopauth_nxd Does not Run When Moved from Background Server

Symptom:

I have setup advanced availability configuration for the CA SDM environment. I logged in to the background server and navigated to Options Manager , Security from the Administration tab. I changed the bopauth_host value from default to point to an application server. I restarted all the CA SDM servers. bopauth_nxd is not running on the application server.

Solution:

When bopauth_nxd is moved from background server to any other server (such as the application server) complete the following steps:

1. Restart the background server after changing the default value of bopauth_host.
2. Start version control as a client on the application server using the following command:

   ```
   pdm_ver_nxd -c
   ```

3. Restart the application server.

Configuration Fails After CA SDM Installation

Valid on Windows 2008 SP2 and Windows 2008 R2

Symptom:

I logged in as an Administrator on Windows 2008 with enabled User Access Control (UAC) settings and installed the CA SDM application. When I try to configure CA SDM from the Start menu, the configuration fails either during the launch of the Configuration window or in the Database Configuration screen of the Configuration window.

Solution:

To configure CA SDM successfully, click Start, All Programs, CA, Service Desk Manager, then right-click Configure and select Run As Administrator.

Warning Message Appears When Implementing CA SDM

Valid on SuSE 11 only

Symptom:

During the CA SDM installation, configuration, or uninstallation procedures, the following warning message appears:

libxcb: WARNING! Program tries to unlock a connection without having acquired a lock first, which indicates a programming error. There will be no further warnings about this issue.

Solution:

Disregard the warning; it has no impact on the installation, configuration, or uninstallation procedures.

Error Messages Appear in pdm_tomcat_REST.log During REST Web Services Deployment

Symptom:

On rare occasions, the following error message may appear in the REST Tomcat logs (pdm_tomcat_REST.log) during REST Web Services application deployment.

```
SEVERE: Exception fixing docBase for context [/caisd-rest]
java.util.zip.ZipException: error in opening zip file
Feb 27, 2012 3:44:57 PM org.apache.catalina.core.StandardContext resourcesSta

SEVERE: Error starting static Resources
java.lang.IllegalArgumentException: Invalid or unreadable WAR file : error in

Feb 27, 2012 3:44:57 PM org.apache.catalina.core.StandardContext startInterna

SEVERE: Error in resourceStart()
Feb 27, 2012 3:44:57 PM org.apache.catalina.core.StandardContext startInterna

SEVERE: Error getConfigured
Feb 27, 2012 3:44:57 PM org.apache.catalina.core.StandardContext startInterna

SEVERE: Context [/caisd-rest] startup failed due to previous errors
Feb 27, 2012 3:45:07 PM org.apache.catalina.startup.HostConfig checkResources

INFO: Undeploying context [/caisd-rest]
```

Solution:

Sometimes the WAR file for the REST Web Services application is not accessible at the time Tomcat tries to deploy the application. You can ignore this error message because Tomcat fixes the error automatically. Tomcat retries the deployment which succeeds usually.

IPV6 Address Fails to Connect

Valid on all operating systems

Symptom:

A primary or secondary server is configured for either mixed mode or IPV6-only mode and the browser or standard logs show connection failure messages.

Solution:

Verify that the primary server, secondary server, or client can resolve the IPV6 address by name. Verify that the CA SDM address is a valid IPV6 address. For example, the IPV6 address is a routable IPV6 global address instead of an unrouted FE80 address.

To resolve IPV6 address connection issues on the servers or clients, do the following:

1. On the primary or secondary server, run the following CA SDM Java 1.7 command-line utility:

   ```
   java -cp $NX_ROOT/java/lib/checkprotocols.jar com.ca.ServicePlus.ipv6.t
   ```

   ```
   For example, to obtain IPV4 addresses for the Sd16 node, enter java –cp
   ```

   address/nodeSpecifies the named address/node name of the primary or secondary server (either local or remote).slump portSpecifies the TCP slump port number. For example, 2100. protocol(Optional) Specifies the IPV4 or IPV6 protocol. When you omit the protocol, the default supplies both IPV4 and IPV6 addresses.

   The utility lists information for the specified server node.

2. Use the data from the command line utility to verify that the routable CA SDM addresses are correct and are the same addresses that are on the DNS or name resolving servers entries.

3. If the addresses still do not resolve, specify the local and remote addresses for the CA SDM servers in one of the following files:

   - (Windows) <system drive>:\windows\system32\drivers\etc\hosts
   - (UNIX/Linux) /etc/hosts

   > **Note:** Use the server information from the command line utility to update the *hosts* file. Follow the instructions in the hosts file to add the CA SDM server node names.

4. If remote clients cannot connect to CA SDM, do one or more of the following:

   - Verify that the DNS name servers have the correct addresses.
   - Enter the IPV6 address directly into the browser.

PKI Login Fails with CA Workflow Configuration on AIX

Valid on IBM AIX

Symptom:

When I configure CA Workflow on AIX, the PKI login fails.

Solution:

After you install CA Workflow on AIX, you can configure CA Workflow for PKI login if necessary. IBM AIX requires additional security policy files for this login to work successfully.

Follow these steps:

1. Verify that you configured CA Workflow successfully.
2. Go to the IBM website and download the *Unrestricted Policy Files* (version 1.4.2 or later) from the Unrestricted JCE policy files page.

   Note: Register on the IBM website to download the policy files.

3. Replace the local_policy.jar and US_export_policy.jar files in your Shared Components JRE directory with the policy files that you downloaded from the IBM website.

   By default, these files are located in the /opt/CA/SC/JRE/1.7.0_04/lib/security directory.

4. Stop and start CA Workflow using the following commands:

```
pdm_tomcat_nxd -c STOP -t CAWF
pdm_tomcat_nxd -c START -t CAWF
```

LDAP Virtual Database Does not Run When Moved from Background Server

Symptom:

I have setup advanced availability configuration for the CA SDM environment. I logged in to the background server and navigated to Options Manager , Security from the Administration tab. I changed the ldap_virtdb_host value from default to point to an application server. I restarted all the CA SDM servers. LDAP Virtual Database is not running on the application server.

Solution:

When LDAP Virtual Database is moved from background server to any other server (such as the application server) complete the following steps:

1. Restart the background server after changing the default value of ldap_virtdb_host.
2. Start version control as a client on the application server using the pdm_ver_nxd -c command.
3. Restart the application server.

Uninstall CA SDM Manually

Symptom:

During uninstall, a message informs me to refer to the *Release Notes* for manual uninstall instructions.

Solution:

The installvariables.properties file is missing from the NX_ROOT/SDUninstall folder, however, the file is required to uninstall CA SDM. Perform the following procedures to resolve this problem.

To uninstall CA SDM manually on Windows operating environments

1. Shut down CA SDM.
2. Execute the following instructions:

   ```
   oa60_client_uninstall
   oa60_server_uninstall
   ```

3. Remove the file %WINDIR%\paradigm.ini.
4. Remove the CA SDM installation folder. For example, the default folder location is C:\Program Files\CA\Service Desk Manager.

   Important! Verify if both the ODBC services (CA SDM ODBC Data Access and CA SDM ODBC Agent) are removed or shut down before deleting the installation directory.

5. Remove the CA\Service Desk Manager folder from % ALLUSERSPROFILE%\ Start Menu\Programs.

   The product is uninstalled.

   Note: To uninstall the CA SDM Server service, run the instruction pdm_d_mgr -u.

To uninstall CA SDM manually on UNIX operating environments

1. Shut down CA SDM.
2. Remove the symbolic link /opt/CAisd.
3. Remove the CA SDM installation folder. For example, the default folder location is /opt/CA /ServiceDeskManager.

   The product is uninstalled.

CA CMDB Visualizer Fails to Start on Secondary Server

Valid on all operating systems

Symptom:

When CA CMDB Visualizer is configured on a secondary server, the following error message appears on the Visualizer login screen:

```
Loading application configuration data. Application is not ready to use. Plea
```

Solution:

Stop and then restart CA CMDB Visualizer tomcat on the secondary server as follows:

1. Run the following commands at the command prompt:
   - pdm_tomcat_nxd -d STOP -t VIZ
   - pdm_tomcat_nxd -d START -t VIZ
2. Log on to Visualizer.

   The Visualizer application opens.

CA Service Desk Manager Known Installation Issues

This article contains the following known issues:

Installation Issue in a non-Windows Environment

Valid on Non-Windows (RH Linux, AIX, and Solaris)

Symptom:

I cannot install CA Service Desk Manager in a non-Windows environment if root directory '/' has less than 10 GB.

Solution:

The CA Service Management installer checks the ‘/’ drive always for the required free space. When the disk space is less than 10 GB in the root directory, the installation fails because the threshold for the disk space is set to 10 GB in the installer.

Follow these steps to disable the disk-space validation:

1. Copy Non-windows DVD to a folder.
   For example, /DATA/CASM_DVD

2. Edit the common_config.properties under <DVD>/config/
   For example, the file is at DATA/CASM_DVD/config/common_config.properties path.

3. Set the following properties values to 0 to disable validation:

   - diskspace.sdm=0
   - diskspace.osop=0
   - diskspace.error.limit=0
   - diskspace.warning.limit=0

4. Save this config file and relaunch setup.

Supported Characters in Installation Path

Valid on operating systems with a CA Business Intelligence installation

Symptom:

The installation fails with an error regarding the characters specified in the installation path.

Solution:

The CA Business Intelligence installation supports only alphanumeric, spaces, dashes, and underline characters in the installation path. Modify the installation path to include these character types only.

Unable to Enter Credentials for the Privileged User During the CA SDM Installation

Valid on Non-Windows (RH Linux, AIX, and Solaris)

Solution:

Type the password on a notepad on your computer or any terminal, and then copy and paste it using the mouse.

Unable to Install or Configure CA SDM When the Install Directory Contains Spaces

Valid on UNIX/Linux

Symptom:

The install directory name contains spaces and you are unable to install or configure CA SDM properly on UNIX/Linux.

Solution:

Do not specify spaces in the installation media path and folder name.

CA EEM Installation Fails on Solaris or Linux

Valid on Solaris and Linux

Symptom:

The CA EEM installation fails with the following errors if you did not configure IPV6 correctly:

- CA iGateway installation failed
- Error message: Performing sanity test for system ip configuration for localhost: fail is displayed in igwinstall.log.

Solution:

Execute the following commands:

```
ifconfig lo0 inet6 plumb ifconfig lo0 inet6 up Add ::1 in /etc/hosts
```

CA Service Desk Installation Fails on a Pure IPV6 Environment

Symptom:

The **Installation Progress** screen reports an issue during **Integrating the Products** and an error message is displayed.

Solution:

1. Exit from the CA Service Management installer.
2. Open NX.env file from $NX_ROOT directory.
3. Ensure that the NX_PROTOCOL_ONLY variable is set to IPV6.
4. Restart CA SDM services.
5. Re-launch the CA Service Management installer.
6. On the **Select the required Installer** screen, select **Integrate pre-installed solution components** option (last in the list) and complete the installation.

CA Service Catalog

This section contains the following known issues:

CA Service Catalog Installation Known Issues

This section contains the following CA Service Catalog installation known issues:

Installation, Upgrade, and Migration Issues

After JRE1.8.0 is Upgraded, JRE Version is not Updated

Post JRE upgrade, while mentioning JRE version in the ANT upgrade-jre command, build failed error message is shown. This happens because the build.xml file is not getting updated with the correct JRE version after an upgrade is performed. To resolve this, you must locate the following lines in the build. xml file and manually change the JRE version to the upgraded JRE version:

```
<condition property="new.jre.is (http://new.jre.is).supported">
 <matches pattern="^(1.8.0_)([1][2-9]|[2-9][0-9])$" string="${new.jre.version}" />
 </condition>
```

Upgrade Requires Several Hours for Oracle

If you are using Oracle, the upgrade can require several hours. For example, the upgrade can run for five hours for all CA Service Catalog components.

Restart Computer After Migration

After migrating to CA Service Catalog from an earlier release, restart your computer and verify that all installed CA Service Catalog Windows services are started. The services are CA Service Accounting and CA Service Catalog.

Issue with Yearly Fiscal Periods After Migration

After migrating to CA Service Catalog from an earlier release, if you are using yearly fiscal periods, recreate them after migration. You do not need to recreate monthly fiscal periods after migration.

Actions Disabled After Upgrade

If an action whose type is JAVA, Command Line, or HTTP Post has a status of Disabled before you upgrade CA Service Catalog, the type of the action changes to Unknown during the upgrade. If you enable the action after the upgrade, CA Service Catalog prompts you to specify the type again.

Uninstall not Clean

When you uninstall CA Service Catalog, some folders and files can remain. For example, the USM_HOME\catalog folder can remain after you uninstall. Typically, the cause is that files in the USM_HOME folder were modified or new files were added.

To work around this issue, if any folders or files are left over after the uninstall, delete them manually.

Database Issues

Case Sensitivity for Searches

In CA Service Catalog, you can search for requests, users (including attributes), accounts, and other items. The case sensitivity of all searches in the product depends on the case sensitivity or collation settings in the database used for MDB, as follows:

- Microsoft SQL Server is typically set up using case-insensitive collation. Therefore, searches are typically case-insensitive.
- Oracle is typically set up using case-sensitive collation. Therefore, searches are typically case-sensitive.

If necessary, verify the case sensitivity settings for your database by testing or by consulting your database administrator.

Case Sensitivity for Assigning Actions to Groups

You can assign requests pending action to an CA EEM group that corresponds to a group with the same name in CA Process Automation. In such cases, the group names in CA EEM and CA Process Automation must match exactly, including case, if either of the following conditions exist:

- The CA EEM database is configured to use case-sensitive group names.
- The external directory (such as Active Directory) that populates the CA EEM database is configured to use case-sensitive group names.

Otherwise, the request is not assigned to the group.

Test the settings by requesting services and verifying that the requests pending action are assigned to the groups that you specified.

Content Pack Issues

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Issue with Importing Content Packs when 'Business Unit ID' and ‘Business Unit Login ID’ are different

You cannot import content packs when the ‘Business Unit ID’ and ‘Business Unit Login ID’ are different.

To work around this issue, update the 'Business Unit Login ID’ with the value of ‘Business Unit ID’ and then import the content pack. When the import is completed, revert 'Business Unit Login ID' to its original value.

CA Service Catalog Localization Known Issues

This section contains the following CA Service Catalog Localization Known Issues:

Issue with Display of Units of a Cost Element in Localized UI

For all languages, CA Service Catalog displays the units that comprise a cost element using the following fixed sequence. This sequence is customary for English and other languages, but not for all languages.

<Billing Cycle> + <Charge Type> + “of” <Currency> +<Unit Cost>+<Display Unit Type>

Examples include the following cost elements:

- One Time Charge of $3 each
- Recurring Credit of €199 each
- Installment Charge totaling 10 x £199 for 10 items

System Alert Messages and Dashboard Builder not Localized

System alert messages always appear in English, even when CA Service Catalog is installed on non-English operating systems. System alert messages appear for individual requests when you view their request details. An example is selecting Home, Requests.

Similarly, certain text strings in the GUI elements and published content of the Dashboard Builder of CA Service Catalog always appear in English, even when CA Service Catalog is installed on non-English operating systems.

Double-byte Numerals not Supported

The numeric fields on localized operating systems support only single-byte numerals that are used on English-based operating systems.

CA Service Catalog Reporting and Form Designer Known Issues

This section contains the following known issues:

Values Missing from Reports

This issue applies only if you are integrating CA Service Catalog with CA Service Desk Manager and CMDB.

The predefined CA Business Intelligence report named Requests _Change Orders_CI Association does not display any value for the following columns:

- CI Resource Name
- CI Family Name
- CI Class Name

Cannot Drag and Drop Table Row in the Preview Pane

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

In the Forms Designer you cannot drag and drop the table row to the table in the Preview pane. To work around this issue, drag and drop the table row to the table in the Components pane.

CA Service Catalog Integration Known Issues

This section contains the following CA Service Catalog reporting known issues:

CA EEM Application Installation Fails

The CA EEM application installation may fail for one or more of the following reasons:

- The length of the application name is more than 50 characters.
- The application name contains a double quote (“), comma (,), forward slash (/), back slash (\), number sign (#), ampersand (&), or plus sign (+).

To work around this issue, correct the error, and try again to install the CA EEM application.

Issue with the Use of CA EEM Global Groups

This issue applies if both the following conditions exist:

- The user store is configured as External LDAP Directory.
- The Configuration Type is configured as Multiple Microsoft Active Directory.

To work around this issue and use CA EEM global groups with CA Service Catalog for permission control, use user-defined groups.

CA EEM Application Installation Fails

The CA EEM application installation may fail for one or more of the following reasons:

- The length of the application name is more than 50 characters.
- The application name contains a double quote (“), comma (,), forward slash (/), back slash (\), number sign (#), ampersand (&), or plus sign (+).

To work around this issue, correct the error, and try again to install the CA EEM application.

Issue with the Use of CA EEM Global Groups

This issue applies if both the following conditions exist:

- The user store is configured as External LDAP Directory.
- The Configuration Type is configured as Multiple Microsoft Active Directory.

To work around this issue and use CA EEM global groups with CA Service Catalog for permission control, use user-defined groups.

CA Process Automation action Disabled after Installation

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

If you are have integrated CA Service Catalog with CA Process Automation, the CA Process Automation actions for CA Service Catalog rules are enabled or disabled by default, as follows:

- The actions are disabled by default for CA Service Catalog upgrades
- The actions are enabled by default for new installations of CA Service Catalog.

However, even for new installations, the CA Process Automation action is disabled by default for the rule named *When Category is Software and Status is Pending Fulfillment*. Therefore, to use this action, enable it manually.

CA Service Catalog Request Processing Known Issues

This section contains the following CA Service Catalog Request Processing Known Issues:

- Issue with Suspension of a Subscribed Service (see page 211)

Issue with Suspension of a Subscribed Service

If you suspend a subscribed service, the suspension works properly as long as the Period Start Date for the suspension remains set to the default value. However, the suspension fails if the value for the Period Start Date field is changed to a non-default value.

Retrying Failed Actions Does Not Work

When an action fails while a request is being processed, the request can become stuck. Stuck requests cannot move to the next state of the request life cycle without manual intervention by you or another user. Stuck requests are marked with an alert status. By default, the alert is a yellow warning icon in the Status column of several request windows, including the Open Requests window.

If you are unable to retry the failed action successfully, override (push through) the alert to move the request to the next state.

Email Notifications not Sent

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

This issue applies if you have configured email notifications for requests. Requestors occasionally do not receive email notifications when their requests are assigned, approved, or rejected.

Notes and Attachments Deleted

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

This issue applies when both of the following conditions exist:

- A request includes two or more instances of the same service.
- The catalog user deletes one or more instances of the service after submitting the request.

In such cases, the Catalog system can inadvertently delete notes and attachments from the remaining instances of the service in the request.

To work around this issue, inform catalog users of this behavior and advise them to perform the following actions:

- Verify that these notes and attachments still exist in the remaining instances of the service.
- Create any notes and attachments again, if necessary, that were inadvertently deleted.

Oracle RAC Failover

During the failover of Oracle 11g r2 RAC nodes, error message is displayed instead of requests list on the CA Service Catalog requests page.

For more information, see Deploy Oracle RAC with CA Service Management (see page 745).

Browser Known Issues

This section contains the following known issues:

Batch Printing Fails with Mozilla Firefox

In Service Catalog Accounting component, batch printing can fail when you use the Mozilla Firefox web browser.

To work around this issue, use Microsoft Internet Explorer for batch printing.

Display Issue for CA Service Catalog Widgets on Safari

The CA Service Catalog Widgets are not displayed correctly in Unified Self-Service on the Apple Safari browser on an Apple iPad or an Apple desktop/laptop.

To work around this issue, go to the Privacy settings of the browser and set "Block Cookies" to "Never".

Display Issues for CA Service Catalog on Internet Explorer 10 and 11

CA Service Catalog is not displayed correctly on Internet Explorer 10 and 11, if the Security is Medium or High,

To work around this issue, follow these steps:

1. Open Internet Explorer.
2. Click **Internet Options, Privacy**, **Advanced**.
3. Check **Override automatic cookie handling** and **Always allow session cookies** options.

Display Issue for CA Service Catalog Widgets on Internet Explorer and Microsoft SharePoint 2010

The following issues occur for widgets, when users access them through Internet Explorer and when Microsoft SharePoint 2010 is the portal server:

- Catalog forms in requests do not render correctly in Internet Explorer.
  Microsoft SharePoint 2010 enforces XHTML standards and Internet Explorer complies with these standards. However, GXT does not support XHMTL and hence the forms are not rendered correctly in Internet Explorer.

- "Communication error" messages appear intermittently.

To work around this issue, access the widgets through Mozilla Firefox or Google Chrome when Microsoft SharePoint 2010 is the portal server. Else, use Microsoft SharePoint 2013 if your browser is Internet Explorer.

ActiveX Controls Do Not Run With Mozilla Firefox

In CA Service Catalog, objects that require Microsoft ActiveX controls do not appear when you use the Mozilla Firefox web browser, because of a limitation in Firefox. Examples include certain functions in the Dashboard Builder and the Report Builder.

To work around this issue, use the Microsoft Internet Explorer for actions that require ActiveX.

CA IT Asset Manager

This section contains the following known issues:

CA Asset Portfolio Management Installation Known Issues

The following known issues can affect how you install CA APM.

Restart the Server After Installation

Valid on all supported operating environments.

After you complete the product installation, restart each server on which you installed the product and the associated components. When you restart the servers, some of the services that the product requires to operate are started. However, you must manually start some services. You can then successfully log in to and use the product.

Note: For more information about the services the product uses, which services need to be started manually, and how to verify the installation, see Verify CA APM Installation (see page 317).

Installation of CA EEM Certificate Fails

Valid on all supported operating environments.

Symptom:

The CA EEM installation fails to create the authentication certificate.

Solution:
Complete the following steps:

1. Log in to the server on which you started the CA APM installation.
2. Use the following command to change from the current directory to the EEMSetup directory:

   ```
   CD "[ISO Root Path]\Setups\EEM
   ```

3. Use the following command.

   a. **For SQL:**

```
[ISO Root Path]\Setups\EEM\AppLauncher.exe -ProductName=EEM -
EEMParameter='-EEMBackend="[EEM Host]",-EEMAdminPass="[Eiamadmin
password]",-EEMUapmPassword="[uapmadmin password]",-EEMCasmPassword="
[casmadmin password]",-DatabaseType="SQL Server",-DBServer="[MDB
Hostname]",-UserID="sa",-DBName="[mdb name]",-Port="[mdb port number]",-
DBOwner="dbo",-DBPassword="[sa password]",-MdbAdminPassword="[mdbadmin
password]",-BundleVersion="14.1"'
```

When the command is finished, the command displays a log from the CA EEM SDK. You can safely ignore the log.

[EEM Host]
Server where CA EEM is installed.
APM
CA EEM application name. Do not change this value.
EiamAdmin
CA EEM superuser ID. Do not change this value.
[EiamAdmin Password]
CA EEM superuser password specified during the installation.
uapmadmin
Uapmadmin user password specified during the installation. If you changed the default uapmadmin password during the installation, use the same password when logging in to CA APM.

b. **For Oracle:**

```
[ISO Root Path]\Setups\EEM\AppLauncher.exe -ProductName=EEM -
EEMParameter='-EEMBackend="[EEM Host]",-EEMAdminPass="[EEMAdminPass]",-
EEMUapmPassword="[EEMUapmPassword]",-EEMCasmPassword="[casmadmin
password]",-DatabaseType="Oracle",-DBServer="[Server Name]",-UserID="
mdbadmin",-DBName="[Net Service Name]",-Port="[mdb port number]",-
DBOwner="mdbadmin",-InstanceName="[Oracle SID]",-DBPassword="[Sys
Password]",-MdbAdminPassword="[MdbAdminPassword]",-BundleVersion="
14.1.0.57"'
```

When the command is finished, the command displays a log from the CA EEM SDK. You can safely ignore the log.

[EEM Host]
Server where CA EEM is installed.
APM
CA EEM application name. Do not change this value.
EiamAdmin
CA EEM superuser ID. Do not change this value.
[EiamAdmin Password]
CA EEM superuser password specified during the installation.
uapmadmin
Uapmadmin user password specified during the installation. If you changed the default uapmadmin password during the installation, use the same password when logging in to CA APM.

4. Verify that the command has successfully processed by completing the following steps:

a. Log in to the MDB using mdbadmin as both the User ID and password.

b. Use the following query:
SELECT CERTIFICATE FROM AL_PROCESS_ACCOUNT

If you see BLOB value, the utility has successfully processed. Log in to CA APM using uapmadmin as the user ID and your uapmadmin password.

CA APM Does Not Work When Windows Encryption Is Applied

Valid on all supported operating environments.

Symptom:

When I encrypt the CA APM installation folder, the product does not work.

Solution:

The default CA APM application pools process using the Network Service account, which has minimal system privileges. To work in an IIS environment in which the CA APM installation folder is encrypted, the CA APM application pools must process under the Administrator account.

When the CA APM installation folder is encrypted, use the Administrator account to configure the application pool (ITAM application pool on Windows Server 2008).

Follow these steps:

1. Click Start, Run.
2. Enter the following command:
   `inetmgr`
   The Internet Information Services (IIS) Manager appears.
3. (Windows Server 2008) Complete the following steps:
   a. On the left, expand Application Pools, select ITAM, and select Advanced Settings.
   b. Navigate to the Process Model section of the dialog.
   c. In the Identity field, click the ellipses and select Custom Account.
   d. Enter the Administrator user name and password and click OK.
   e. Restart the application pool.

Component Installation Fails

Valid on all supported operating environments.

Symptom:

During the installation and configuration of the CA APM components, one or more component installations fail.

Solution:

When another process (for example, an antivirus product) is locking the files that are necessary for the product component installation, the component installation fails. In this situation, temporarily disable the product that is locking the files. Then, click Retry Install. The Installation Manager retries only the component installations that failed previously and displays the setup summary.

Installation of CA Client Automation Fails

Valid on all supported operating environments.

Symptom:

After I install CA APM, the CA Client Automation installation fails.

Solution:

The CA Client Automation installation fails when compatibility mode for the MDB is enabled.

Follow these steps:

1. Start the CA Client Automation installation.
   A wizard appears to install the CA Client Automation.

2. When prompted, do not enable compatibility mode for the MDB.

3. Continue with the CA Client Automation installation.

4. CA Client Automation is installed successfully.

Note: If enabling compatibility mode for the MDB is required, contact CA Support at http://ca.com/support.

Installation Fails with Insufficient Tablespace

Valid on Release 11.3.4 Oracle database environment.

Symptom:

The CA APM database installation fails on a Release 11.3.4 Oracle environment when the Data tablespace size is insufficient. Subsequent installation attempts on the same database also fail, even if you increase the tablespace size.

Solution:

Before you install CA APM, verify that the following recommended default tablespace sizes are set:

- Data tablespace = 400 MB
- Index tablespace = 100 MB

Upgrade to SQL Server 2008 Does not Update Compatibility Level when Attaching a Database

Valid on SQL Server database environments.

Symptom:

I upgraded from SQL Server 2000 to SQL Server 2008 by attaching the database, and the correct Compatibility Level was not set.

Solution:

The minimum supported version of SQL Server is SQL Server 2005. If you upgrade from a version before 2005 by attaching the database, update the Compatibility Level manually after the upgrade.

Execute the following command on the SQL Server 2008 database:

```
ALTER DATABASE mdb SET COMPATIBILITY_LEVEL = appropriate_compatibility_level
```

For information about this command, refer to the Microsoft Developer Network (MSDN) using the following steps:

1. Access the MSDN site at the following URL:
   http://msdn.microsoft.com

2. Search for the following article number:
   ms191137

3. Select the Database Compatibility Level Option article with the following version (for SQL Server 2008):
   v=SQL.105

Note: You can also upgrade from a lower version of SQL Server to SQL Server 2008 by backing up the lower version database and then restoring it on SQL Server 2008. With this method, there is no issue with the Compatibility Level.

Location of CA EEM Installer

Valid on all supported operating environments.

Symptom:

I need to locate the CA EEM installer on the CA APM installation media to install CA EEM Server 12.51.0.4.

Solution:

CA APM does not install CA EEM automatically. However, CA EEM is a prerequisite for the CA APM installation. If you have CA EEM installed already on an existing server, you can use the existing CA EEM. If you do not, install CA EEM before you install CA APM.

Follow these steps:

1. On the server where you are installing CA EEM, access the following location on the CA APM installation media:
   [ISO Root Path]\EEMSetup\

2. Execute the following:
   EEMServer_12.51.0.4_win32.exe

Apache Tomcat Log File Shows Unregistration Error

Valid on all supported operating environments.

The Apache Tomcat Common Asset Viewer service causes an error with Apache Tomcat version 6.0.24 or 6.0.26. This error is displayed in the Tomcat log file as an unregistration error. However, the error does not affect the functioning of the Apache Tomcat Common Asset Viewer, and corrective action is not required.

Business Objects and CASM Do Not Run on the Same Computer

Valid on all supported operating environments.

Symptom:

When you start the CASM service on a computer where CA APM and Business Objects Tomcat server are installed, the service starts and stops immediately.

Solution:

By default, Business Objects Tomcat Server and CASM Tomcat Server use the same shutdown port. To avoid this scenario, you must change the Tomcat Server shutdown port to another available port.

Follow these steps:

1. On the computer where CA APM is installed, navigate to one of the following folder locations, depending on your server:
   C:\Program Files\CA\SharedComponents\CASM\Tomcat\conf\ (for 32-bit operating system)
   C:\Program Files (x86)\CA\SharedComponents\CASM\Tomcat\conf\ (for 64-bit operating system)

2. Select and open the server.xml file.

3. Navigate to the following section:

   ```
   <Server port="8005"
   shutdown="SHUTDOWN">
   ```

4. Update the Server port with any available port number other than 8005.

5. Save and close the server.xml file.

6. Restart the CASM service.

CA APM Installation and the CA Business Intelligence Tomcat Port

Valid on all supported operating environments.

Symptom:

The installation assumes that the CA Business Intelligence Tomcat port is 8080. However, my environment uses port 8080 for CA Service Desk Manager and a different port for CA Business Intelligence. The installation wizard does not allow me to specify another port for CA Business Intelligence. Thus, the installation fails because the CA Business Intelligence connection is not available on port 8080.

Solution:

You can use the following workaround to resolve this issue.

Follow these steps:

1. Log in to the CA Business Intelligence server as the administrator.
   Note: If you have a product or service using Tomcat port 8080, stop that product or service first.

2. Open a command prompt window and execute the following command:

   ```
   netsh interface portproxy add v4tov4 listenport=8080 connectaddress=cabi_server
   connectport=cabi_tomcat_port
   ```

   Replace cabi_server with the hostname and cabi_tomcat_port with your CA Business Intelligence Tomcat port number.
   This command creates a port proxy on the CA Business Intelligence server that forwards all traffic for port 8080 to your CA Business Intelligence Tomcat port.

3. Complete the installation.

4. Log in to CA APM.

5. Navigate to Administration, System Configuration, Web Server.

6. Change the Reporting Server Port from 8080 to your CA Business Intelligence Tomcat port number.

7. Restart Internet Information Services (IIS) by performing the following steps:

   a. On the CA APM web servers and application servers, open a command prompt window.

   b. Execute the following command:

      ```
      iisreset
      ```

8. Execute the following command on the CA Business Intelligence server:

```
netsh interface portproxy del v4tov4 8080
```

This command removes the port proxy that you used during installation.

Note: If you previously stopped a product or service using Tomcat port 8080, restart that product or service now.

Changing the CA EEM Server after Installing CA APM

Valid on all supported operating environments.

Symptom:

I finished installing CA APM, and I now want to change the CA EEM server.

Solution:

Use the following procedure to change the CA EEM server. For more information, see Integrate CA Asset Portfolio Management with CA EEM Manually (see page 3481).

CA EEM Integration Error While Installing CA APM

Valid on all supported operating environments.

Symptom:

While I install CA APM, the installation process fails with a CA EEM integration error while configuring CA APM.

Solution:

You can ignore the error message.

On the error dialogue box, click Ok. Then click Retry Install. The installation completes successfully.

CA Asset Portfolio Management Starting Known Issues

The following known issues can affect how you start CA APM.

- Tenancy Management Page Cannot Be Displayed Browser Error Appears (see page 221)
- Tenancy Management Page Does not Display with Google Chrome Browser (see page 222)
- Change the Web Site Port (see page 222)
- CA APM Home Page Links Do Not Work (see page 224)
- Login Fails with Service Model Activation Error (see page 225)

Tenancy Management Page Cannot Be Displayed Browser Error Appears

Valid on all supported operating environments.

Symptom:

The following browser error message appears when I click Administration, Tenancy Management:

Page cannot be displayed.

Solution:

When CA APM, including Tenancy Management, is accessed from a network that is outside of the computer on which you installed CA APM, the URL for Tenancy Management (the CASM service) becomes inaccessible. The URL for CASM cannot be accessed because the URL that is stored in the CA MDB uses an internal host name for the computer on which CASM is installed.

Follow these steps:

1. Log in and connect to the CA MDB database as the user who owns the MDB database (mdbadmin).

2. Execute the following script on the CA MDB database:

   ```
   UPDATE CA_APPLICATION_REGISTRATION
   SET product_specific_data='http://[EXTERNALHOSTNAME]:[CASMPORT]/
   itam/itam.html' WHERE product_code=2070
   ```

   The following fields require explanation:
   [EXTERNALHOSTNAME]
   Public host name or public IP of the computer on which the CASM service is installed, which can be accessed from an outside network.
   [CASMPORT]
   Port number on which the CASM service operates. The default port number is 9060. You can obtain this value by reviewing the existing CASM URL.

3. Restart the web server.
   The updated URL to access Tenancy Management (the CASM service) is accessible.

Tenancy Management Page Does not Display with Google Chrome Browser

Valid on all supported operating environments with Google Chrome browser.

The following browser error message appears when you try to access the CA APM Administration, Tenancy Management page using the Google Chrome browser.

Page cannot be displayed.

The Common Administration for Service Management (CA CASM) component provides multi-tenancy administration for CA APM. CA CASM does not support the Google Chrome browser. If you plan to perform Tenancy Management in CA APM, use a browser other than Google Chrome.

Change the Web Site Port

Valid on all supported operating environments.

Symptom:

As the administrator, I cannot use the default CA APM web site port number because another application in my environment is using that number.

Solution:

The default product web site port number is 80. You can change this default number to use a different number.

Follow these steps:

1. From the Start menu, select Run.
2. Enter inetmgr in the Run dialog.
   The Internet Information Services dialog opens.
3. Select the user-provided web site name on the Connections pane.
4. Click Bindings in the Actions pane.
   The Site Bindings dialog appears.
5. Click Add.
   The Add Site Binding dialog opens.
6. Enter the new port number for http and click OK.
7. Click Close on the Site Bindings dialog.
8. (Single Server Installation) Update the web site port number.
   Follow these steps:
   a. Log in to CA APM.
   b. Navigate to Administration, System Configuration, Application Server.
   c. Change the Server Port and the Component Server Port to the new values.
   d. Log in to the product database as the administrator.
   e. Execute the following command:

      ```
      Update al_cdb_configurationparameters set configvalue=New Port where
      configKey='ServerPort' and componentkey='Web_Server' and machineName='WEB
      SERVER NAME'
      ```

      Replace New Port with the new port value.
      Replace WEB SERVER NAME with the name of the web server in all upper case.
9. (Multiple Server Installation) Update the web site port number.

   Follow these steps to change the web site port for the web server (if required):

   a. Log in to the product database as the administrator.
   b. Execute the following command:

```
Update al_cdb_configurationparameters set configvalue=New Port where
configKey='ServerPort' and componentkey='Web_Server' and machineName='WEB
SERVER NAME'
```

c. Replace New Port with the new port value.

d. Replace WEB SERVER NAME with the name of the web server in all upper case.

Follow these steps to change the web site port for the application server (if required):

a. Log in to CA APM.

b. Navigate to Administration, System Configuration, Application Server.

c. Change the Server Port and the Component Server Port to the new values.

10. Notify product users that they need to update the port number in the CA APM browser URL address. Users need to perform this update each time that they access CA APM from the Start menu shortcut.
The following URL shows the default CA APM browser URL address:
http://localhost/ITAM/Pages/UserLogin.aspx
Users need to change this URL to the following URL address:
http://localhost:port/ITAM/Pages/UserLogin.aspx (http://localhostport)
Replace port with the new web site port number.

CA APM Home Page Links Do Not Work

Valid on all supported operating environments.

Symptom:

When I log in to the CA APM home page, none of the links on the page works. I receive the following error message:

Error: (System.InvalidOperationException: Unable to generate a temporary class

Solution:

Correct this problem by following the instructions from Microsoft.

Follow these steps:

1. Open a browser and navigate to http://support.microsoft.com.
2. In the Search field, enter 908158.
3. In the results list, select the article with the following title:
Error message when ASP.NET 2.0 is configured to run with a user account: "Unable to generate a temporary class".
4. Follow the instructions in the article.

Login Fails with Service Model Activation Error

Valid on all supported operating environments.

Symptom:

After I upgrade from a previous release to release 14.1, I receive the following error message when I try to log in to the product:

Could not load type System.ServiceModel.Activation.HttpModule

This message indicates an error with the ASP.NET registration with Internet Information Services (IIS).

Solution:

Follow these steps:

1. From the Start menu, open a command prompt.
2. Navigate to the appropriate Microsoft.NET framework folder. The following folders are examples:
   C:\Windows\Microsoft.Net\Framework64\v4.0.30319
   C:\Windows\Microsoft.Net\Framework\v4.0.30319
3. Run the following command:

   ```
   aspnet_regiis.exe -iru
   ```
4. Restart IIS by running the following command:

   ```
   iisreset
   ```

CA Asset Portfolio Management Configuration Known Issues

The following known issues can affect how you configure CA APM.

Adding Costs to Multiple Assets Fails on Oracle 12c Database

Symptom:

On an Oracle 12c database, I cannot add costs to multiple assets at the same time using the **Add Asset Cost** mass change utility or the data importer.

Workaround:

Update the cost record of each asset separately.

Configuration Changes and User Roles

Valid on all supported operating environments.

When you make configuration changes such as defining a configuration, defining an extended field, defining a hierarchy, granting security, and so forth, and then add user roles or assign a configuration to a role, verify that you shut down IIS on all but one application server in your web farm before you start configuration mode again. Complete your configurations, and then start the IIS instance on the remaining application servers in your web farm. You can then continue using the product.

Inactive Items Available When Defining Objects

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Valid on all supported operating environments.

When you define an item and make it inactive, the item still appears and can be selected when defining an object.

Default Reference Field Searches Include Inactive Items

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Valid on all supported operating environments.

Symptom:

When defining an object, you can use a reference field search to select a related object (for example, to select the model for an asset). The default reference field search results include both active and inactive records, and the search dialog does not indicate which records are inactive.

Solution:

When you use a reference field search to select an object, first change the Inactive drop-down list to No and click Go, so that only active records appear in the search results. You can then select an active record for the object.

Renaming Configurations

> **Note:** This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Valid on all supported operating environments.

After you save a global or local configuration, you cannot rename it. Delete the configuration and add it again with the new name. When you delete a configuration, all configuration changes that you saved, such as hiding fields and buttons, moving fields, and defining extensions, are deleted.

Common Administration for Service Management (CASM) and Multi-Tenancy

Valid on all supported operating environments.

Symptom:

When CA APM is configured to support the Secure Socket Layer (SSL) protocol and the Common Administration for Service Management (CASM) is not configured to support SSL, you receive a message similar to the following when you click Administration, Tenancy Management:
You do not have required privileges to perform the action.

Solution:

Complete the following steps to configure CASM to support the SSL protocol:

1. Configure CASM to support the SSL protocol.
   Note: For more information about configuring CASM to support the SSL protocol, see the CASM documentation.

2. Complete the following steps on the CA APM database:

   a. Log in to the CA APM database using a client interface.

   b. Execute the following SQL statement:

```
UPDATE CA_APPLICATION_REGISTRATION SET PRODUCT_SPECIFIC_DATA = 'https://<
hostname>:<ssl-port>/itam/itam.html' WHERE PRODUCT_CODE = 2070;
```

3. Restart the IIS server on the CA APM web server.
   You can use CA APM with CASM with both products using SSL, and you can use CA APM with CASM with both products using non-SSL.

Hierarchy List Management

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Valid on all supported operating environments.

You can define a multiple level hierarchy that begins with a new field, and then navigate to List Management to define the items that appear in the hierarchy fields. For any level in the hierarchy, a row of blank list items, and duplicate rows (that is, rows with identical values in all items) can be successfully saved. The product should not save the rows and should provide an appropriate message.

Adding Extended Fields and Existing Fields

Valid on all supported operating environments.

Symptom:

When I configure the user interface, the Add Extension and Add Existing Fields hyperlinks do not appear.

Solution:

The Add Extension and Add Existing Fields hyperlinks are only available for a global configuration. After you add an extended or existing field, the field is available to all users in both global and local configurations. If the field should not be available to users in a local configuration, update the local configuration and remove the field.

Tenant Drop-Down List Does Not Appear

Valid on all supported operating environments.

Symptom:

After I enable multi-tenancy, a tenant drop-down list does not appear when entering information for objects and when generating reports.

Solution:

Restart Internet Information Services (IIS) on the CA APM web server using the iisreset command.

Contacts and Locations Do Not Appear

Valid on all supported operating environments.

Symptom:

After I define a contact or location using Administration, Tenancy Management, the contact or location is not available when entering information for objects.

Solution:

Restart Internet Information Services (IIS) on the CA APM web server using the iisreset command.

Adding Existing Fields for Software Assets

Valid on all supported operating environments.

In an integrated environment with CA Software Compliance Manager, you can configure the user interface and add an existing field for a software asset. When adding existing fields to either the Basic or Additional parts of the page, the product displays. You can select to add the Software License or SwCM License fields. When adding an existing field to the Basic or Additional parts of the page, do not select the SwCM License fields. However, you can add the Software License fields to any part of the page (License, Basic and Additional parts).

Database IDs are Required for Reference Field Event Definition

Valid on all supported operating environments.

When you define an event for a reference field on the Events page, you can select Old Value for the Value Changed From drop-down list and New Value for the Value Changed To drop-down list. When you make these selections, you can then specify the values in the Value fields. The values that you specify must be in the form of database IDs or UUIDs, not text entries. Locate the IDs or UUIDs in the database and enter the information in the appropriate Value fields on the Events page.

Note: For more information about defining an event, see Events and Notifications (see page 2376). For more information about reference fields, see Reference Field Configuration (see page 1551).

Family Field

Valid on all supported operating environments.

When defining a configuration for an asset, model, and legal document, the Family field appears. The Family field is different from the Asset Family field. The Asset Family field (previously named Asset Type) is used to organize and classify assets to track specialized information about products, services, or equipment used in your organization. The Asset Family field determines the information that you see on the page when you define an asset.

In contrast, the Family field is a simple indicator for the attribute to classify the current primary object. For example, Asset Family appears by default in the Family field for assets and models, and Legal Template appears by default in the Family field for legal documents. You define the configuration for the asset, model, and legal document based on the value in the Family field.

Restricting Users from Creating and Assigning Global Configurations

Valid on all supported operating environments.

Symptom:

I created a role for members of my team and assigned each user to the role. I did not assign a local or global configuration to the new role. A user in this role created a configuration and assigned the configuration globally to all users, even when I did not grant any security permissions to the user or role.

Solution:

When you do not assign a local or global configuration to a role, all users in the role are assigned the default permissions from global configurations. Global configurations are intended for administrators only. To restrict users from creating and assigning global configurations, complete the following steps:

1. Create local configurations and limit the security permissions based on your requirements.
   Important! To restrict a user from performing any configuration and not allow the user to create a configuration, create a local configuration and deny all configuration permissions for all objects. To deny all configuration permissions, deny a user the ability to define an extension, manage events, change a field label, move a field, make a field required, hide a field, and secure objects.

2. Save the local configurations.

3. Create roles and assign the local configurations to the roles.
   Each user in the roles cannot create and assign global configurations.

Defining a Hierarchy for a Software Model

Valid on all supported operating environments.

Symptom:

I defined a global configuration for a software model and selected to define a hierarchy. When defining the hierarchy levels, I selected the existing Capacity Units field as the top-level field for the hierarchy, completed the wizard, and saved the hierarchy. I then defined the list items for the hierarchy. After defining the hierarchy and the list items, I cannot search and select the hierarchy values when defining a software model.

Solution:

When defining a software model, the Capacity Units field is not available. Therefore, do not select the Capacity Units field as the top-level field in the hierarchy levels when defining a hierarchy for a software model.

Incorrect Data Appears for Hierarchy Fields

Valid on all supported operating environments.

Symptom:

At the end of the wizard to define a hierarchy that is based on an existing field, I clicked Save and New, canceled the wizard, and saved the global configuration. The hierarchy fields are not added to the global configuration and the hierarchy fields do not appear on the page. However, I can add values for the hierarchy fields using List Management. How can I add the hierarchy fields to the global configuration that I previously saved?

Solution:

To add the hierarchy fields to the global configuration, select the global configuration and click Add Existing Fields. In the wizard, select the same part of the page to add the hierarchy fields that you selected when you defined the hierarchy. If you select a different part of the page for the hierarchy fields, the data represented by the hierarchy fields does not match the values you specified using List Management. You can also define a new hierarchy.

Audit History and Extended Fields

Valid on all supported operating environments.

Symptom:

I defined an extended field for an object with a specific subtype (for example, an asset has a subtype of hardware). When a user defines an object with the subtype and views the audit history, the extended field that I added does not appear.

Solution:

Extended fields that are added for a subtype are not available in the default audit history for object records having the same subtype. To see the extended fields for the subtype, define a new audit history search that includes the missing extended fields for the specific subtype.

Removed Relationships

Valid on all supported operating environments.

The following relationships will be removed and will not be supported. We recommend that you do not use these relationships.

Object	Removed Relationship
Model	▪ Dependencies ▪ Product Evolution
Asset	▪ Budget Managers ▪ Product Upgrades ▪ Support Contacts ▪ User Allocations ▪ Contacts User

Object Relationships

Valid on all supported operating environments.

For the company allocation, contact allocation, location allocation, and legal asset relationships, you can see the relationship when you view both objects. For example, you can have a legal asset relationship between an asset and a legal document. When you view the asset, you can see the relationship to the legal document. When you view the legal document, you can see the relationship to the asset. For all other relationships, you can only see the relationship from the parent object. For example, when you view an asset, you can see the relationship to the image partitions. However, when you view the image partitions, you cannot see the relationship to the asset.

Audit History Displays Extended Field IDs Instead of Names

Valid on all supported operating environments.

You can define an extended field to help ensure that you capture all data in your repository that is critical to your asset management program. For example, define a reference field extension for an asset named Chipset so that users can enter and manage the chipset information (for example, Intel 5520). When a user views the audit history for an object, the internal field ID appears for the reference field extension (for example, 1000000) instead of the name (for example, Chipset). The product should display the extended field name instead of the internal field ID.

User Receives an Error when the Administrator Changes the Configuration

Valid on all supported operating environments.

Symptom:

If an administrator changes or deletes an object configuration while a user who is assigned to that configuration is creating an object, the user receives an error.

Solution:

The user can refresh the current page and continue working. The administrator can also plan to make configuration changes when users are not working.

Assets Allocated Page does not Display Assets Allocated to a Contact

Valid on all supported operating environments.

Symptom:

The Assets Allocated page does not display assets allocated to a contact in the following scenario:

In CA SDM you create a Model without a Family or Class and then assign the model and a primary contact to a new CI. When you access the assets allocated to the primary contact in CA APM, the page does not list the CI you created in CA SDM.

Solution:

CA APM displays the assets allocated to a contact only when the asset's family/class are the same as the model's family/class. Ensure that the model's family/class and the asset's family/class are the same.

CA Asset Portfolio Management Security Known Issues

The following known issues can affect how you secure CA APM.

- Deleted Users and Roles Can Access the Product (see page 233)
- Common Home Page Links Prompt for Credentials (see page 233)

Deleted Users and Roles Can Access the Product

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online

Valid on all supported operating environments.

When I delete a user or role, the deleted user, or the users in the deleted role, may be logged in to the product in another session. In this situation, the deleted user, or users in the deleted role, can still access the product until the session expires. When a user or role is deleted, the product should shut down the session for the user and not allow the user to access the product.

Common Home Page Links Prompt for Credentials

Valid on all supported operating environments.

Symptom:

The Common Home Page provides a single web-based home page for accessing the functions in both CA APM and CA SAM, including CA Business Intelligence reporting. However, when I click the links for CA SAM and CA Business Intelligence, I am asked to provide authentication credentials.

Solution:

You can eliminate the authentication prompts by configuring CA SAM and CA Business Intelligence.

Follow these steps:

1. (CA SAM) Configure CA SAM to Token authentication.
   Note: For more information, see the CA Software Asset Manager Administration Manual.

2. (CA Business Intelligence) Configure the CA Business Intelligence Windows Active Directory for either Kerberos or CA SiteMinder.

Note: Release 14.1 does not support CA Business Intelligence Trusted Authentication with CA APM.

CA Asset Portfolio Management Import Known Issues

The following known issues can affect how you import data into CA APM.

- Error When Trying to Import a Large Number of Users (see page 234)
- Error When Trying to Import Large number of Users from CA EEM Integrated with CA SiteMinder (see page 234)

Error When Trying to Import a Large Number of Users

Valid on all supported operating environments.

Symptom:

When importing and synchronizing users from an active directory or another CA EEM source such as an LDAP server, and the import list contains over 30 thousand users with the name beginning with the same letter, you receive the following message:

EE_POZERROR Repository Error. Problem with EEM connected Repository. Please try after some time.

Solution:

Import users in batches having less than 30 thousand users in each batch.

Error When Trying to Import Large number of Users from CA EEM Integrated with CA SiteMinder

Valid on all supported operating environments.

Symptom:

When importing a large number of users using LDAP Import Sync from CA EEM that is integrated with CA SiteMinder, you may experience an error.

Solution:

No known workaround.

User Name Appears as the Last Name for a User

Valid on all supported operating environments.

Symptom:

After importing users from CA EEM, the user name displays in the last name field in CA APM.

Solution:

The last name was not specified when the user was created in CA EEM. The last name is not a required field in CA EEM, but because a last name is required for CA APM, the user name is set as the last name. Verify that you specify a last name when creating a contact in CA EEM.

Importing Data for Extended Fields

Valid on all supported operating environments.

Symptom:

When you configure the data import process and use extended fields as part of the object lookup, you receive an error message similar to the following:

No keys specified for class <class name> Exception thrown! Return without creating object for class <class name>.

Solution:

Replace the extended field with a non-extended field in the lookup criteria.

Importing Secondary Objects for a Tenant

Valid on all supported operating environments.

When you import dependent secondary objects for a tenant to which you have access, the Data Importer creates the objects in the same tenant that you selected for the primary destination object. The product should create the object in the tenant that you select.

Extended Fields Do Not Appear for Subtype-Specific Secondary Objects During Column Mapping

Valid on all supported operating environments.

When you use the Data Importer to map your source columns to CA APM data fields, you select a main destination object that has a specific subtype. For example, when importing assets, the main destination object Asset(Hardware) indicates that the asset object has a subtype of hardware. During the column mapping process, you then select a destination field for each source column. The destination fields that you select are based on the main destination object and subtype that you selected (for example, you can select model fields with a subtype of hardware). Any extended fields that you defined for the selected secondary object subtype do not appear when mapping the columns and cannot be selected.

Submitting the Import Does not Validate the Data Importer Engine Status

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Valid on all supported operating environments.

Symptom:

When I submit a Data Importer job for processing, I receive a message about a successful job submission. However, if the Data Importer Engine service is not running, my import job is not processed. CA APM does not check to verify that the Data Importer Engine service is started when I submit a job.

Solution:

Verify that the Data Importer Engine service is running. If not, start the service or contact your system administrator.

Object Names Beginning with Numbers Cause Errors

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Objects imported from the Data Importer that have names beginning with numbers cause errors when you try to link to them in CA APM. For example, a company name that begins with a number causes an error when you try to create a cost center for the company. A similar error occurs if you try to create a company relationship for a company acquisition. If the acquired company name begins with a number, an error results and you cannot save the relationship.

https://wiki.ca.com/display/CASM/.CA+Service+Catalog+Installation+Known+Issues+v14.1

CA Asset Portfolio Management Search Known Issues

The following known issues can affect how you search for objects in CA APM.

Asset Searches for the CI and Asset Check Boxes

Valid on all supported operating environments.

When you configure an asset search in which you specify Yes or No for the CI and Asset fields, the search results return either 1 (true) or 0 (false). The search results should return Yes and No.

User-Defined Searches with Asset Families or Legal Templates

Note: This issue is resolved in CA Service Management patch 14.1.01. Find the patch and the download details from CA Support Online.

Valid on all supported operating environments.

Symptom:

When creating a user-defined search, I can select an asset family or legal template, or a group of asset families or legal templates for the primary object. When I select a related secondary object for the search, the product requires me to select an asset family or legal template for the secondary object. For example, I create an asset search and select both the hardware and computer asset families. I select the model object as the secondary object, and the product requires me to select an asset family for the model. The product should maintain the asset family or legal template from the primary object and not require me to select an asset family or legal template for the secondary object.

Solution:

Select the same set of asset families or legal templates for both the primary and secondary objects in the user-defined search.

Search Selection Dialog Appears (Firefox)

Valid on all supported operating environments.

When you define an object, you can enter part of a value in a search field, select the value, and press the Tab key or click another field. In this situation, the Search Selection dialog appears with the value that you previously selected. The product should save the value you previously selected and the Search Selection dialog should not appear.

Adding Fields to User-Defined Searches

Valid on all supported operating environments.

Symptom:

When selecting asset families or legal templates for a user-defined search, the product displays a long list of available fields in the Add Fields dialog. However, I cannot scroll down in the list to select the field.

Solution:

Scroll down in the Add Fields dialog using the scroll bar to the right in the product window. You can then select the asset families or legal templates for the user-defined search.

Selected Asset Families or Legal Templates

Valid on all supported operating environments.

After you create a user-defined search and select asset families or legal templates, the selected asset families or legal templates do not appear in the product user interface. For example, you create an asset search in which you select the hardware and computer asset families. You then open the search. The selected asset families for the search do not appear. The product should display the asset families that were selected when you created the search.

Inconsistent Behavior Restricting Service Provider and Supertenant Group Data

Valid on all supported operating environments.

In a multi-tenancy environment, CA APM and CA Service Desk Manager do not consistently restrict the display of service provider and supertenant group data when you search.

Note: The supertenant group is the group of the parent record's tenant.

The following information describes this known inconsistency:

- (CA Service Desk Manager) Referenced objects can be designated as SERVICE_PROVIDER_ELIGIBLE. When enabled, the data for the service provider and supertenant group appears, even when the supertenant group does not include the service provider tenant. When disabled, only data for the supertenant group appears. The data for the service provider only appears if the service provider is a member of the supertenant group.

- (CA APM) Referenced objects can be designated as SERVICE_PROVIDER_ELIGIBLE. When enabled, the data for the service provider and supertenant group only appears when the service provider is a member of supertenant group. When disabled, data for the service provider does not appear, even when the service provider is a member of the supertenant group.

Note: By default, the only SERVICE_PROVIDER_ELIGIBLE enabled attributes are available for the contact and organization objects.

Performance Can Be Slow for Some New Audit Search Functions

Valid on all supported operating environments.

With a high number of users (for example, 100), system performance can be slow when performing the following new audit search functions:

- Add fields for a new audit search

- Refresh an asset audit history

- View an audit history.

Users Cannot Create New Audit Searches for Objects with Extensions

Valid on all supported operating environments.

Symptom:

As a non-administrator user, I receive errors when I attempt to create a new Audit Search for an object that has an extension. The extension can be any type–Simple, Reference, or Hierarchy.

Solution:

Correct the problem by executing a database stored procedure.

Follow these steps:

1. Execute the following database stored procedure:
   al_build_security_hierarchy

2. Restart Internet Information Services (IIS) by performing the following steps:

1. a. On the CA APM web servers and application servers, open a Command Prompt window.

   b. Execute the following command:
   iisreset

CA Asset Portfolio Management Integration Known Issues

The following known issues can affect how you integrate CA APM with other products.

CMDB Model Consistency between CA Service Desk Manager and CA APM

Valid on all supported operating environments.

If CA APM is integrated with a compatible version of CA SDM on the same Database and you create a Model in CA Service Desk Manager and you then update the Class value, the corresponding Family is automatically added to the Database. The same Model is now visible in CA APM.

Note: The Administrator must ensure that the Models and assets belong to the same family because of this auto update feature. Also, if the Model created in CA SDM does not have Family, it is not visible in CA APM.

For example, if the user has created a Model with Class as "Hardware" and then the user updates this value to "License", the Family of CA APM now is automatically changed to "Software" from the initial value of "Hardware". Now, you have the Asset as Hardware even though the Model is changed to "Software". To overcome this inconsistency, use the Change Asset Family wizard in CA APM.

CA Software Compliance Manager and CA APM in a Multi-Tenancy Environment

Valid on all supported operating environments.

Do not use CA Software Compliance Manager in an environment that includes a tenanted release of CA APM. If you do, a CA Software Compliance Manager user may be able to view and update tenanted CA APM data to which they should not have access.

Oracle MDB in an Integrated Product Environment

Valid on all supported operating environments.

When you create or use an Oracle MDB in an integrated product environment, verify that tablespace values for data and indexes are consistent among the integrated products. Consider the following information:

- CA APM and CA Service Desk Manager allow the product administrator to select the tablespaces for data and indexes during the CA MDB installation.
- CA Service Catalog uses fixed values of MDB_DATA and MDB_INDEX for the data and index tablespaces, respectively. The fixed values are contained within the installation and the product administrator cannot change the values.
- CA Client Automation uses fixed values of mdb_data and mdb_index for the data and index tablespaces, respectively. The tablespace values are contained within a script and the product administration can manually change the values.

When installing in an integrated product environment, plan your installation accordingly. Make the necessary changes to the data and index tablespace values so they are consistent (including uppercase and lowercase formatting) across the products.

Asset Families Not Completely Defined

Valid on all supported operating environments.

Symptom:

When using CA APM, the following product behavior occurs:

- Hardware reconciliation does not complete as expected.

- You experience incorrect behavior and fields on the Asset and Model pages.
- You receive incomplete search results for asset searches that you configure to include the Asset Family, Is Software and Reconcile Hardware fields. The incomplete search results include assets from CA Service Desk Manager and CA Service Catalog.

Solution:

CA Service Desk Manager and CA Service Catalog do not assign a value to the Asset Family, Is Software and Reconcile Hardware fields. If CA Service Desk Manager, CA Service Catalog, or both products are installed before CA APM, verify in CA APM that the Is Software and Reconcile Hardware fields for Asset Family (Computer, Hardware, Other, Projects, Service, and Software) are correctly set. Click the Directory tab, List Management and select Asset Family to verify these field settings.

User-Defined Searches and the Is Software Field

Valid on all supported operating environments.

When you integrate CA Service Catalog and CA APM, you can create and successfully save a user-defined search in which the Is Software field is set to Yes. If you then update the user-defined search and change the Is Software field to No, a message appears indicating that the search is successfully saved. However, the product does not save the Is Software field update for the search.

Legal Document Records from the CA CMDB Asset Viewer Do Not Appear

Valid on all supported operating environments.

Symptom:

In an integrated environment with CA Service Desk Manager or CA CMDB, the Common Asset Viewer may not display data as expected. For example, when you select an asset in CA APM, the Common Asset Viewer displays one or more legal document records. However, when you select the same asset in CA Service Desk Manager or CA CMDB, the Common Asset Viewer does not display the legal document record. The legal document record may not appear because insufficient privileges are assigned to the CA Service Desk Manager or CA CMDB database user in the Common Asset Viewer. properties file (by default, C:\Program Files\CA\Service Desk Manager\bopcfg\www\CATALINA_BASE\webapps\AMS\WEB-INF\classes).

Solution:

Complete the following steps to assign the correct privileges to the database user:

1. Assign the user explicit SELECT grant privileges to the tables used by the Common Asset Viewer, or assign the user to a group having explicit grant privileges to the tables.
   Note: If you receive an error about a table not being found, you can safely ignore this error.

2. Restart the appropriate service in CA Service Desk Manager, and the Apache Tomcat Common Asset Viewer service in CA APM.
   The same legal document records appear from both the CA Service Desk Manager or CA CMDB Asset Viewer, and the CA APM Asset Viewer.

Tables Used by the Common Asset Viewer

Gold Brick Icon in CA Service Catalog Fails to Fulfill with an Access Denied Error

Valid on all supported operating environments.

Symptom:

When I click the gold brick icon in CA Service Catalog to fulfill an asset request, CA APM starts but I receive an Access Denied error. I have verified that I'm a member of the System Administrator role and I have access to asset fulfillment.

Solution:

Complete the following steps to resolve this known issue:

1. Open a browser and navigate to http://support.ca.com.
   The CA Support Online page appears.

2. Log in to CA Support Online.

3. Enter TEC536192 in the Search text box and click Search.
   The search results appear.

4. Click the appropriate knowledge base article in the search results.

5. Complete the instructions that are documented in the knowledge base article.

Object Deletion Fails from an Integrated CA Software Compliance Manager Environment

Valid on all supported operating environments.

Symptom:

When I delete an object in CA Software Compliance Manager that has an extended field defined in CA APM, I receive an error in CA Software Compliance Manager.

Solution:

When CA APM and CA Software Compliance Manager are integrated, you can access and manage the following objects from both products:

- Company
- Contact
- Location
- Site
- Organization

However, if you define extended fields for one of these objects in CA APM, you can no longer delete the object in CA Software Compliance Manager. Delete the object in CA APM.

Cannot Assign CA APM Models to Service Option Groups in CA Service Catalog

Valid on all supported operating environments.

Symptom:

With an integration between CA APM and CA Service Catalog, CA Service Catalog sends requests to CA APM for models. These requests are in XML format. The Microsoft .NET Framework fails these requests with the following error message:
A potentially dangerous Request.Form value was detected from the client.

Solution:

Correct the problem by changing the request validation mode so that http requests are not validated.

Follow these steps:

1. On the application server where you installed CA APM, navigate to the Application Server folder under the ITAM installation directory.
2. Open the web.config configuration file.
3. Locate the following XML tag:
   httpRuntime
4. Add the following new attribute value to this tag:
   requestValidationMode="2.0"
5. Save the web.config file.

6. Restart Internet Information Services (IIS) by performing the following steps:

    a. On the CA APM web servers and application servers, open a command prompt window.

    b. Execute the following command:
    iisreset

Cannot View CA Business Intelligence Reports after Upgrading to CA APM Release 14.1

Valid on all supported operating environments.

Symptom:

I upgraded to CA APM Release 14.1 from a previous release. I can now no longer view CA APM reports in CA Business Intelligence. One of the following error messages appears when I open the reports from CA Business Intelligence launch Pad:

A Database error occurred. The database error text is : (CS) SSO failed in CMS, contact sysadmin for details: Single Sign-On failed. Contact your system administrator for details. (FWB 00020). (WIS 10901)

A Database error occurred. The database error text is : (CS) Specified RDBMS is invalid. (WIS 10901)

Solution:

Use the following procedure to correct the problem.

Follow these steps:

1. Click Start, All Programs , CA, CA Business Intelligence 4.1 Client Tools, Universe Design Tool and open the CA IT Asset Manager universe.
2. Click Tools, Connections and select the CA ITAM connection.
3. Click Edit.
4. Enter the password for the database user.
5. Verify the connectivity by clicking Test connection.
6. Click Next to complete the wizard.
7. Save the universe and close the universe.
8. Click Import and provide the details for the previously saved universe.
9. Click OK to import the universe.
10. Save the universe and exit the CA Business Intelligence Universe Design Tool.

Database Replication Does not Work after Migration

Valid on all supported operating environments.

Symptom:

I have an integration between CA APM Release 11.3 and CA Service Desk Manager. I have unique asset extension database tables for each product. For example, CA APM uses the ucapme_asset table and CA Service Desk Manager uses the usp_owned_resource table. I have fields in both tables that represent the same data (for example, the ucapme_asset table includes the mycustomfield column and the usp_owned_resource table includes the zmycustomfield column). A replication process keeps the fields in both tables synchronized. However, the replication process will not work after I migrate data from Release 11.3 to Release 14.1.

Solution:

You can resolve this issue before or after you upgrade and migrate your data.

Resolve before Migration (Recommended)

Follow these steps:

1. Disable your replication process.
2. Log in to http://support.ca.com.
3. Enter the following document file name in the Search field:
   CA_ITAM_Integrations_Best_Practices
4. Click the ITAM Integrations PDF link for the most recent update.
5. Search for the scenario about Sharing Global Extension Fields.
6. Follow the instructions to move to global tables and fields in your Release 11.3 environment.

Resolve after Migration

Follow these steps:

1. Disable your replication process.
2. Identify the shared fields between the legacy CA APM table and the CA Service Desk Manager table.
3. In CA APM Configuration, hide the CA APM fields.
4. In CA APM Configuration, expose the CA Service Desk Manager fields.

CA Asset Portfolio Management Normalization Known Issues

The following known issues can affect how you normalize data using CA APM.

- Normalization Lists with Removed Values (SQL Server) (see page 245)
- Map Button is Disabled for Normalization Rule Mapping (see page 246)

Normalization Lists with Removed Values (SQL Server)

Valid on all supported operating environments.

Symptom:

After I initially map the items in a normalization list (for example, nonauthoritative collected companies to normalized authoritative companies), the normalized value is removed from the list. The value is no longer available for mapping additional items.

Note: When a normalized item appears multiple times in the list for different tenants, each normalized item having the same value is removed from the list.

Solution:

To map additional items to the normalized value, complete the following steps:

1. Delete the existing items from the mapping.
2. Map the items again, with any additional items.

Map Button is Disabled for Normalization Rule Mapping

Valid on all supported operating environments.

You define a company, operating system, or system model normalization rule in the product (Directory, List Management, Normalization) by mapping a collected (discovered) object with an authoritative normalized object. The normalization pages display lists of collected objects and normalized objects. When you select the objects that you want to map, you must select the normalized object first and then the collected object to enable the Map button. If you select the collected object first and then the normalized object, the Map button is disabled. You cannot map the objects until you select the objects in the correct order.

CA Asset Portfolio Management Data Validation Known Issues

Data Validations for Currency Fields

Valid on all supported operating environments.

CA APM performs prevalidations of the format and content for currency fields. As a result, when you define a data validation for a currency field, do not include validations for the currency symbol, grouping symbol, and grouping limit. The prevalidations validate these items.

Important! Use the following regular expression to define currency field data validations. If you specify a different expression, CA APM overrides your expression with the following expression.

The following regular expression is the valid expression for CA APM currency field data validations:

^\d+(\<decimal_separator_symbol>\d{1,2})?$

The *decimal_separator_symbol* can vary depending on the locale, but the default is a period (.).

Examples of Valid Currency Values: 4555, 455.66, 455.5

CA Software Asset Manager Known Issues

The following known issues can affect software asset management.

Deletion Change Events Do not Work for Extended Fields

Valid on all supported operating environments.

A CA APM change event lets you monitor a CA APM field and receive a notification when a change occurs to the field value. You can define a deletion change event that processes and sends a notification when a record is deleted. If you define the deletion change event for an extended field of an asset, model, or legal document object and then you delete the object, the event does not occur. As a result, you do not receive notification that the object was deleted.

Field Validation Errors during Automatic Data Synchronization

Valid on all supported operating environments.

During automatic data synchronization, errors can occur as a result of differences between CA APM and CA SAM field validations. For example, CA APM allows a maximum of 20 characters for the Location Zip field. However, CA SAM allows a maximum of ten characters for that field. If CA APM sends Location Zip data with more than ten characters to CA SAM, CA SAM rejects the data.

To troubleshoot and resolve these field validation errors, review the error messages in the CA SAM log file and correct the CA APM data.

CA SCM Fields Are Displayed in CA APM after CA SCM Uninstallation

Valid on all supported operating environments.
If you have an environment with CA APM integrated with CA SCM, you see software-related fields from CA SCM displayed in CA APM. When you want to enable SAM capabilities in CA APM, you uninstall CA SCM. However, just uninstalling CA SCM does not remove the CA SCM fields from CA APM. You must also enable the SAM capabilities in CA APM (Administration, System Configuration, Software Asset Management). Then CA SCM fields are removed from CA APM.

Intermittent Error Occurs with Multiple Workflow Providers

Valid on all supported operating environments.

If you have implemented CA SAM with CA APM, the following message appears intermittently in the CA APM Event Service log file:

```
ERROR CA.Applications.EventService.EventService - Web Service threw
exception
CA.Common.Utilities.Exceptions.ValidationException: Another user
updated this record after it was loaded.

at CA.Common.Data.Persistence.Persister.Save(IEntity entity)at CA.
Common.Business.BusinessEntityImp.Save()at CA.Applications.Business.
FiredEvent.Save()at WebService.Service.
Save_WithoutInjectedLogging3619502461923(Byte[]RequestStream)
```

This message indicates that multiple workflow providers (for example, CA Process Automation and the CA SAM Workflow provider) attempted to update the status of the same event. The update failed. However, the event is updated successfully during the next Status updater processing cycle of the Event Service.

CA APM Components Fail when IIS 7 is Installed on Windows 2008

Valid on Windows 2008 operating environments.

Symptom:

When I have Microsoft Internet Information Services (IIS) 7 installed on Windows 2008, the WCF Services do not work. CA APM uses a WCF Service to implement the web services function.

Solution:

This problem occurs because the service file types are mapped incorrectly or the Windows components, including IIS 7, were installed in an incorrect order. To correct the problem, verify and change (if necessary) the IIS settings. Microsoft provides information and solutions for the problem.

Follow these steps:

1. In a web browser, open the Microsoft website (http://www.microsoft.com) and search for "IIS Hosted Service Fails".

2. Follow the instructions in the article.

Common Asset Viewer Does not Display Device Details with Certain Special Characters

Valid on all supporting operating environments.

Common Asset Viewer fails to display Device details when the details in CA SAM contain straight quotation marks followed by a semicolon (";).

The following error message is displayed:

There was an error when attempting to connect SAM web service. Please see the log for more details.

Software Asset Management Configuration Page Displays Incorrect Message

Valid on all supported operating environments.

If you implemented CA SAM with CA APM in a previous release, you need to enter some additional CA SAM configuration parameters after you upgrade to release 14.1. On the product user interface, you navigate to the Administration tab, System Configuration, Software Asset Management page. Fields are available for single sign-on (SSO) and CA SAM web services. After you complete these fields and click Save, you should receive the following message:

The save has completed successfully.

Instead, the following message appears:

You cannot undo this action. Are you sure you want to enable CA APM with SAM capabilities?

This message should not be displayed because CA SAM is already implemented with CA APM.

Cannot Save Zend Server Configurations during CA SAM Installation with Internet Explorer 8

Valid on all supported operating environments with Internet Explorer 8.

Symptom:

During the CA SAM installation, I install and configure the Zend server. (For more information about installing and configuring the Zend server, see the CA SAM product documentation.) However, while configuring the Zend server with Internet Explorer 8, I cannot save the configurations. The Save button is disabled on the configuration page.

Solution:

To configure the Zend server, use one of the following browsers and versions:

- Firefox 10 or higher
- Chrome 17 or higher
- Internet Explorer 9 or higher
- Opera 11
- Safari 5

CA Asset Portfolio Management Web Services Known Issues

The following known issues can affect how you use web services with CA APM.

- Objects with Negative Key Values (see page 250)
- CA Process Automation Does not Load the CA APM Web Services WSDL Correctly (see page 250)

Objects with Negative Key Values

Valid on all supported operating environments.

You can use the web services to create CA APM objects from your external client application. When you use the web services, do not create CA APM objects in which you set the key with a negative value. If you create an object with a negative key value, the object is successfully created in certain circumstances and the key value is available in the database. However, the key value does not appear in the product user interface.

CA Process Automation Does not Load the CA APM Web Services WSDL Correctly

Valid on all supported operating environments.

Symptom:

The CA APM web services allow you to download a WSDL (.wsdl) file. You open the WSDL file in CA Process Automation and set the values for the web service parameters. However, CA Process Automation encounters some problems with the SOAP message format and structure of the CA APM WSDL. As a result, CA Process Automation may not load the WSDL correctly.

Solution:

Create each SOAP message that you need and use it in CA Process Automation as a preformatted SOAP message file. Create a separate SOAP message for each operation (on each object) that you want to perform.

Complete the following steps to create and implement preformatted SOAP messages:

1. Navigate to Administration, Web Services and download the WSDL (.wsdl) file to your local computer.

2. Open the WSDL file in your preferred SOAP message tool.

3. Create a SOAP message XML file for each method and operation that you want to perform in web services.
   Note: You must create a SOAP message file for the Login method.

4. Save the SOAP message files on a server that CA Process Automation can access. The following example shows a path and file name for a SOAP message file that is named SearchContact.xml:
   C:\Program Files\CA\ITAM\SOAPS\SearchContact.xml

5. Open CA Process Automation and create or open the required CA Process Automation process.

6. Use the saved SOAP messages as preformatted messages with the SOAP operator in CA Process Automation.

7. Modify the data and settings for the SOAP message files, if required.

8. Start the process.
   Note: After the Login method has run and you receive the authentication ticket ID, save the ID in a temporary variable or data set in the process.

Example: SOAP Message for Logging in to CA APM

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
    <soap:Body>
        <ns3:Login
        xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays"
        xmlns:ns2="http://schemas.datacontract.org/2004/07/CA/ITAM/Service/Core"
        xmlns:ns3="http://www.ca.com/ITAM/APIService"
        xmlns:ns4="http://schemas.datacontract.org/2004/07/CA/ITAM/Service/DataModel
/BAAAAAA"
        xmlns:ns5="http://schemas.microsoft.com/2003/10/Serialization/">
        <ns3:UserName>uapmadmin</ns3:UserName>
        <ns3:Password>uapmadmin</ns3:Password>
        </ns3:Login>
    </soap:Body>
</soap:Envelope>
```

Example: SOAP Message for Searching for a Location by Name

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
    <soap:Header>
        <ns2:ITAMHeader
        xmlns:ns5="http://schemas.microsoft.com/2003/10/Serialization/"
        xmlns:ns4="http://www.ca.com/ITAM/APIService"
        xmlns:ns3="http://schemas.datacontract.org/2004/07/CA/ITAM/Service/DataModel
/BAAAAAA"
        xmlns:ns2="http://schemas.datacontract.org/2004/07/CA/ITAM/Service/Core"
        xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays">
        <ns2:TicketID>Xkgz1GAcxkyFqyQQt/CAqw==</ns2:TicketID>
        </ns2:ITAMHeader>
    </soap:Header>
    <soap:Body>
        <ns3:Search
        xmlns="http://schemas.microsoft.com/2003/10/Serialization/Arrays"
        xmlns:ns2="http://schemas.datacontract.org/2004/07/CA/ITAM/Service/Core"
        xmlns:ns3="http://www.ca.com/ITAM/APIService"
        xmlns:ns4="http://schemas.datacontract.org/2004/07/CA/ITAM/Service/DataModel
/BAAAAAA"
        xmlns:ns5="http://schemas.microsoft.com/2003/10/Serialization/">
        <ns3:searchDefinition xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="ns2:SearchDefinition">
        <ns2:FieldstoNull xsi:nil="true" />
        <ns2:Criteria>
        <ns2:FieldstoNull xsi:nil="true" />

```

CA Asset Portfolio Management Migration Known Issues

Migration Toolkit Shortcut is not Removed after Uninstallation

Valid on all supported operating environments.

Symptom:

During the uninstallation of CA APM, the Migration Toolkit is also uninstalled. However, the Migration Toolkit shortcut still displays on the Start menu after the uninstallation.

Solution:

To delete the shortcut, select it from the Start menu (Start, Programs, CA, Asset Portfolio Management, CA APM Migration Toolkit). You receive a prompt to remove the shortcut. Click Yes.

CA Asset Portfolio Management Events and Notifications Known Issues

The following known issues can affect how you manage events and notifications using CA APM.

- Notifications Are not Sent for Change Event with Record Deleted Only (see page 252)
- Event Service Does Not Process Events When Components Are not Working (see page 253)
- Notification Process Files Are not Available on the CA APM Installation Media (see page 253)
- CA APM Notifications Do not Occur if CA Process Automation Is not Installed (see page 254)

Notifications Are not Sent for Change Event with Record Deleted Only

Valid on all supported operating environments.

CA APM events are associated with configurations. Therefore, for Asset, Model and Legal Document, you can define different events for each family (asset and model) or legal document template. When an event is evaluated for one of these objects, the product tries to match the configuration and family or template of the event with the object. With expected product behavior, if there is no match, the event workflow is skipped and the notification is not sent.

However, this issue occurs even when the asset family or legal template matches the object. This issue happens with most Asset, Model, and Legal Document relationship objects when the Event Type is Change Event and the Event Cause is Record Deleted Only.

Event Service Does Not Process Events When Components Are not Working

Valid on all supported operating environments.

Symptom:

When I configure the Event Service (Administration tab, System Configuration), I set the following values:

- Provider URL (for example, CA Process Automation URL)
- SMTP server (email server)

During processing, the Event Service lost communications with the Provider URL or the SMTP server. As a result, the Event Service does not process events, including CA Process Automation events and CA SAM data synchronization events.

Solution:

To resolve this situation, verify that the Provider URL and the SMTP server are working. Then restart the Event Service.

Notification Process Files Are not Available on the CA APM Installation Media

Valid on all supported operating environments.

Symptom:

I am implementing events and notifications in CA APM. I want to import the default notification process files into the workflow provider (for example, CA Process Automation). The Implementation information states that these files are available in the ITAM.xml file, which is found in the following path on the installation media:

CD1\SetupFiles\ITPAM

However, I cannot find this path on the installation media.

Solution:

The ITAM.xml file is not available on the CA APM installation media. You can download this file from CA Support Online.

Note: The ITAM.xml file is available on the installation media for previous releases.

Follow these steps:

1. Click the following link:
   ftp://ftp.ca.com/pub/ca_itam/ca_apm/apm12_9/ITAM.xml.zip

2. Save ITAM.xml.zip in the desired directory.

3. Extract the contents of ITAM.xml.zip.
   The contents of ITAM.xml.zip include one file, ITAM.xml. The ITAM.xml file incorporates the default notification process files.

4. Continue with the procedure Import the Workflow Provider Notification Process Files (see page 3490).

CA APM Notifications Do not Occur if CA Process Automation Is not Installed

Valid on all supported operating environments.

CA APM allows you to define and configure notifications that occur after specific events take place. CA Process Automation, which is the workflow provider for CA APM notifications, must be installed for the notifications process to work. If CA Process Automation is not installed, you cannot define and configure notifications and notification alerts are not produced.

You can install CA Process Automation by selecting the Install Event Service option during the CA APM installation.

CA Asset Portfolio Management Audit History Known Issues

Audit History Displays Entries for Deleted Relationship Objects

The CA APM audit history lets you view a list of all changes that were made to an object record. These change entries are removed from the audit history when the object is deleted. However, for some relationship objects (for example, legal document for an asset), the audit history retains the change entries even after the relationship object is deleted.

For example, you delete an existing asset legal document object. At a later time, you create a new legal document object for the same asset. When you look at the audit history for the new asset legal document, you see the history of changes for the deleted object and the new object.

CA Asset Portfolio Management Multi-tenancy Known Issues

Users with No Tenant Can Log In

Valid on all supported operating environments.

Symptom:

If I enable multi-tenancy after I create users or user roles, the roles and users are not updated with the correct tenant settings. As a result, users can log in and access tenant data when they do not belong to a tenant.

Solution:

To reset the tenant settings for the users and roles, complete the following steps:

1. Navigate to the Role Details page for each role that you created before you enabled multi-tenancy.
2. Verify that the tenant permissions are correct and click Save.
3. Navigate to the Contact Search page and delete each user that you created before you enabled multi-tenancy.
4. Create each user again (New Contact), assign the correct tenant, and click Save.

CA Asset Portfolio Management User Interface Known Issues

The following known issues can affect how you work with the CA APM user interface.

- Currency Symbol Does not Match the Currency Type (see page 255)
- Attachment File Name with Spaces is Truncated in Firefox (see page 255)

Currency Symbol Does not Match the Currency Type

Valid on all supported operating environments.

Some currency types do not have associated currency symbols in CA APM. In this situation, a CA APM currency field (for example, Unit Amount) displays the currency symbol that is associated with the browser locale. This symbol may not match the selected currency type. The Currency Type field displays the correct type even if the currency symbol is incorrect.

Attachment File Name with Spaces is Truncated in Firefox

Valid on all supported operating environments with Firefox.

Symptom:

With the Mozilla Firefox browser, I see that a file attachment file name with spaces is truncated after the first space. The attachment content is displayed correctly.

Solution:

You can install a fix for the Firefox browser so that the entire file name displays.

Follow these steps:

1. Open a Firefox browser window.
2. Access the following URL address:
   http://www.polarcloud.com
3. Click Firefox at the top of the page.
4. Scroll to the article that is titled "TruncFix 1.04" and click the article.
5. Follow the instructions to download and install the fix.

6. When the installation is complete, open the file attachment again.
   The attachment opens and the file name displays correctly.

CA Asset Portfolio Management Upgrade Known Issues

The following known issues ca affect how you upgrade CA APM.

- CA APM User Interface Displays Error Message after Upgrade (see page 256)
- Error Message During CA APM Upgrade (see page 257)
- CA EEM Integration with CA APM fails on Oracle Database during Upgrade (see page 257)

CA APM User Interface Displays Error Message after Upgrade

Symptom:

After I upgrade CA APM from release 12.9 to release 14.1 and open the CA APM interface, an error message is displayed.

Solution:

This issue can be seen in any environment where you modified the web.config file manually after CA APM 12.9 installation. Installing release 14.1 does not replace the file, as the file was manually edited and thus retains the changes made to the file.

Follow these steps:

1. Open the web.config at [ITAM Root Path]\Web Server folder file in notepad.

2. Find the following entries:

```
<add assembly="BusinessObjects.DSWS.Session, Version=11.5.4100.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS.ReportEngine, Version=11.5.4100.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS, Version=11.5.4100.0, Culture=neutral,
PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS.BIPlatform, Version=11.5.4100.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS.QueryService, Version=11.5.4100.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
```

3. Replace the entries with the following entries:

```
<add assembly="BusinessObjects.DSWS.Session, Version=14.0.2000.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS.ReportEngine, Version=14.0.2000.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS, Version=14.0.2000.0, Culture=neutral,
PublicKeyToken=692FBEA5521E1304"/>
<add assembly="BusinessObjects.DSWS.BIPlatform, Version=14.0.2000.0,
Culture=neutral, PublicKeyToken=692FBEA5521E1304"/>
```

4. Save and close the file.

Error Message During CA APM Upgrade

Symptom:

While trying to upgrade CA APM from an earlier release version to CA Service Management 14.1, I encounter the following error message:

The specified service does not exist as an installed service. Unable to delete AMS service.

Solution:

This error has no impact on the upgrade process. Click okay to continue and proceed with upgrade process.

CA EEM Integration with CA APM fails on Oracle Database during Upgrade

Symptom:

CA EEM integration fails if you are upgrading CA APM and you have selected **Redo Integration** on an Oracle Database. Integration does not happen successfully if you have given different names for Oracle Net Service and Oracle System ID (SID).

Solution:

Create a new Oracle Net Service Name with the same name as the Oracle SID and click **Retry** to proceed with the upgrade process.

CA Asset Portfolio Management Known Database Issues

This article contains the following known issues:

Application Login

Attempt to login to the application when a node is shutting down, will cause CA Asset Portfolio Management to generate an error message. For example:

Unable to establish a connection with the database. Oracle Error: ORA-03113: end-of-file on communication channel.

Object Creation

Attempt to create a core object when a node is shutting down, will cause CA Asset Portfolio Management to generate an error message. For example:

Unable to establish a connection with the database. Oracle Error: ORA-01089: immediate shutdown in progress - no operations are permitted.

Export CSV

Attempt to export CSV when a node is shutting down, will cause CA Asset Portfolio Management to generate an error message. For example:

The export request could not be completed. No output results were created.

CA Service Management Mobile Application Known Issues

This section contains the following Known Issues:

Unable to Open the Survey Form

Symptom:

You opened a CA Process Automation work item and clicked on the survey link. It opens the CA Service Desk Manager login page. When you enter your credentials, the survey form is not displayed.

Solution:

For using the survey and other CA Service Desk Manager related links, open the link on your desktop Internet Explorer or Mozilla Firefox web browser. In general hyperlinks located inside the CA Process Automation forms do not open, subject to any network limitations and limitations of launching the URL on the mobile device web browser.

Unsupported Form Fields

The *My Tasks* capability does not support the following:

- Lookup fields, select fields, and radio groups. If you have used a form with any of these fields in CA Process Automation or to create a work item, these fields are not displayed in the *My Tasks* capability when you view the work item.
- CA Process Automation form features which were introduced in CA Process Automation 4.1, such as java script form manipulation.
- Minimum and maximum length for string input fields in CA Process Automation.

Slow or No Response from Workflow Engines

Symptom:

I am facing slow or no response from the associated workflow engines.

Solution:

This problem occurs if there is an overload of work items (for example, for more than 500 work items). Performance may be improved if you increase the cache for the associated workflows. The LRUBUFFERISIZE is an approximate number of pending tasks that are actively being referenced by CA Process Automation or CA Service Desk Manager. The default value is 1000.

Alternately, disabling SDMLOOKUP can also improve performance at the expense of reducing some functionality.

Note: After you disable SDMLOOKUP, restart the CA Service Desk Manager server.

Follow these steps:

1. Log in to the CA Service Desk Manager server.
2. Set NX_MOBILE_WFM_ITPAM_LRUBUFFERSIZE and NX_MOBILE_WFM_SDM_LRUBUFFERSIZE variables to an appropriate value. The default is 1000 entries.
3. Set the NX_MOBILE_WFM_ITPAM_DISABLE_SDMLOOKUP variable to YES. This action disables the extended information (such as start time, priority, and change order number).
4. Run the pdm_options_mgr command to update each variable. For example, run the pdm_options_mgr command to increase MOBILE_WFM_SDM_LRUBUFFERSIZE, as follows:

   ```
   pdm_options_mgr -c -a pdm_option.inst -s  MOBILE_WFM_SDM_LRUBUFFERSIZE -v 2000
   ```

5. Restart the CA Service Desk Manager server.

Data Partitions Created in CA Service Desk Manager not Supported

My Tasks capability does not take into consideration the data partition constraints that are created in CA Service Desk Manager. For this reason, the logged in user can see all the tasks and the related information, irrespective of the data partition. If a task is assigned to an authenticated user, the user can see the task.

Unified Self-Service Known Issues

The following known issues can affect how you use Unified Self-Service:

Integration Issue with Unified Self-Service

Symptom:

You might run into an issue during integration with Unified Self-Service and the install.log can contain the following errors:

```
2014/11/18 16.57.48.809 INFO  [DeployThread: Validating Unified Self-Service
Configuration] [VerifyOSOPConfig]  Verifying whether the Unified Self-Service is up
and running
2014/11/18 16.57.48.810 DEBUG [DeployThread: Validating Unified Self-Service
Configuration] [CommonUtil] Checking response from URL (http://USS_HOSTNAME:8686)
2014/11/18 17.00.45.991 DEBUG [DeployThread: Validating Unified Self-Service
Configuration] [CommonUtil] Response : 404
2014/11/18 17.15.38.518 DEBUG [DeployThread: Validating Unified Self-Service
Configuration] [CommonUtil] Retry after 10000 millis, Retry count 90 of 90
2014/11/18 17.15.38.519 ERROR [DeployThread: Validating Unified Self-Service
Configuration] [VerifyOSOPConfig] Unable to connect to Unified Self-Service on server
USS_HOSTNAME
2014/11/18 17.15.38.520 ERROR [DeployThread: Validating Unified Self-Service
Configuration] [VerifyOSOPConfig] Unable to connect to Unified Self-Service on server
USS_HOSTNAME
```

Solution:

1. Restart Unified Self-Service using Windows Services Control Panel. Unified Self-Service normally takes about 1.3 GB memory for java.exe process to start properly.

2. Log in to Unified Self-Service manually.

3. Check Unified Self-Service logs to ensure that there are no abnormal Tomcat or Unified Self-Service errors.

4. Retry the integration option through the CA Service Management installer again.

Apple Safari Browser on Windows Operating System is Not Supported

Valid on Windows

Unified Self-Service is Not Supported on Apple Safari Browser on Windows Operating System.

Unable to log in With the Special Character in Screen Name

Unified Self-Service only supports dot (.), hyphen (-), and underscrore (_) in the Screen Name. Ensure that you do not enter any other special characters.

Unable to Deploy Unified Self-Service

Symptom:

I am unable to deploy Unified Self-Service. Some of the database tables are not getting created or some of the war files are still present in the OSOP\deploy folder of the Unified Self-Service installation directory.

Solution:

Follow these steps:

1. Stop the Unified Self-Service services.
2. Log in to the Unified Self-Service server and open the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory.
3. Take a backup of the encrypted jdbc.default.password.
4. Modify the jdbc.default.password value with the password that you entered during the Unified Self-Service installation.
5. Set the jdbc.default.encrypted.password value to false.
6. Modify (for example, add a space and remove the space) and save the web.xml file located in the OSOP\tomcat-7.0.23\webapps\ROOT\WEB-INF\ folder.
7. Restart the Unified Self-Service services.
8. If the OSOP\deploy folder is empty, then Unified Self-Service has been deployed successfully.
9. Open the portal-ext.properties file and complete the following actions:
    a. Modify the jdbc.default.password value with the password that you backed up in step 3.
    b. Change the jdbc.default.encrypted.password value to true.
10. Save the file.

Attachment Does not Work for the Employee Access Type

Solution:

1. Inactivate the Pre-Update data partition constraint for the Employee role.
2. Set the Function Access level to Modify for the following functions for the Employee role.
    - Reference
    - Administration

Incorrect Priority Calculation When APC is Enabled or Disabled in CA SDM

Symptom:

I configured the CA SDM Data Source with ticket type as Incident. I created an incident in Unified Self-Service with a default priority, for example, 3. I observed the following incorrect changes:

- When APC is disabled in CA SDM, the urgency value of the incident is changing instead of assigning the priority to 1.
- When APC is enabled in CA SDM, the default priority field is not disabled in Unified Self-Service. Also the urgency and impact fields are not added.

Solution:

Currently no solution exists.

Unable to Re-Install Unified Self-Service

Valid on Windows

Symptom:

I am unable the install Unified Self-Service after uninstallating it. Uninstallation does not remove Unified Self-Service Related Entries in Installanywhere Registry XML

OR

I try to install Unified Self-Service and I get an error that the product is already installed (though the product does not exist in my computer).

Solution:

If the uninstaller does not remove the Unified Self-Service related entries in the InstallAnywhere registry XML file, you can change this registry file manually.

Modify the file.com.zerog.registry.xml under the directory C:\Program Files\Zero G registry after Unified Self-Service is uninstalled. Zero G Registry can be a hidden folder, so you have to enable the Show Hidden Folder option on Windows. Remove the following node <product name="Unified Self-Service"> and two other components nodes that are related to Unified Self-Service:

```
<registry install_date="2014-10-21 17:52:05" version="1.1" last_modified="2014-10-21
18:05:56">
<products>
<product name="Unified Self-Service" id="409328f9-1f0a-11b2-941e-b9699e36f638"
version="14.1.0.182" copyright="2014" info_url="" support_url="http://support.ca.com/"
 location="C:\Program Files\CA\Self Service" last_modified="2014-10-21 17:52:05">
<![CDATA[Unified Self-Service]]> <vendor name="CA, Inc." id="de0206eb-1ee1-11b2-84f1-
ce0895af55c4" home_page="www.ca.com" email=""/> <feature short_name="Open Sp" name="Op
en Space on Premise" last_modified="2014-10-21 17:52:05">
<![CDATA[This installs the Open Space on Premise Framework to support Service Desk
applications and features.]]> <component ref_id="409328f7-1f0a-11b2-941d-b9699e36f638"
 version="4.0.0.0" location="C:\ProgramData\Microsoft\Windows\Start
Menu\Programs\CA\Unified Self-Service\Change Unified Self-Service Installation.lnk"/>
```

```
<component ref_id="409328fa-1f0a-11b2-941d-b9699e36f638" version="4.0.0.0" location="C
:\Program Files\CA\Self Service\Unified Self-Service_installation\Change Unified Self-
Service Installation.exe"/>
</feature>
</product> </products>
<components>
<component id="409328fa-1f0a-11b2-941d-b9699e36f638" version="4.0.0.0" name="InstallAn
ywhere Uninstall Component" location="C:\Program Files\CA\Self Service\Unified Self-
Service_installation\Change Unified Self-Service Installation.exe" vendor="CA, Inc."/>
<component id="409328f7-1f0a-11b2-941d-b9699e36f638" version="4.0.0.0" name="Common
Folder" location="C:\ProgramData\Microsoft\Windows\Start Menu\Programs\CA\Unified
Self-Service\Change Unified Self-Service Installation.lnk" vendor="CA, Inc."/>
</components>
</registry>
```

After removing the Unified Self-Service and components, you get to see the following code with no reference to Unified Self-Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<registry install_date="2012-12-05 14:12:12" version="1.1" last_modified="2012-12-05
14:15:47">
<products></products>
<components></components>
</registry>
```

Starting of Tomcat Gives BeanLocator Exception

Symptom:

When I start the Tomcat, I get the following message:

[ServiceLocator:56] com.liferay.portal.kernel.bean.BeanLocatorException: BeanLocator has not been set for servlet context openspace-portlet in Tomcat Window.

Solution:

You can continue working as this error does not affect the Tomcat functionality.

Ignore the Error Table osop.Lock_does not Exist in Liferay Log

Symptom:

When Tomcat starts while installing Unified Self-Service, I get the following message in the Liferay. log:

Table osop.Lock_ does not exist.

Solution:

You can continue working as this error would not impact any Unified Self-Service functionality.

CA EEM Errors in FIPS Mode

Symptom:

When I work with FIPS mode supported Unified Self-Service, CA EEM API displays the following logs messages:

log4j:WARN Continuable parsing error 1 and column 20
log4j:WARN Document root element "EiamConfiguration", must match DOCTYPE root "null".
log4j:WARN Continuable parsing error 1 and column 20
log4j:WARN Document is invalid: no grammar found.
*log4j:ERROR DOM element is - not a <log4j:configuration> elemen*t.

Solution:

Unified Self-Service does not have a control over these logs and it does not affect any functionality of CA EEM.

Onboarding a Tenant Throws Tomcat Error

Symptom:

When I onboard a tenant, Liferay log shows the following error:

No theme loaders are deployed.

Solution:

This is a Liferay error, which you can see at the link: http://issues.liferay.com/browse/LPS-18614?page=com.atlassian.jira.plugin.system.issuetabpanels:all-tabpanel

You can continue working as this error would not impact any Unified Self-Service functionality.

Uninstallation does not Remove Unified Self-Service Related Entries in Installanywhere Registry XML

Valid on Windows

Solution:

For Windows Operating System, if the uninstaller does not change the InstallAnywhere registry XML file, you can change the registry manually. After Unified Self-Service is uninstalled, navigate to C:\Program Files\Zero G registry and modify the file.com.zerog.registry.xml file.

Zero G Registry can be a hidden folder, so you have to enable the Show Hidden Folder option on Windows. Remove the following node <product name="Unified Self-Service"> and two other components nodes that are related to Unified Self-Service:

```
<product name="Unified Self-Service" id="409328f9-1f0a-11b2-941e-b9699e36f638"
version="2.0.176.0" copyright="2012" info_url="" support_url="http://support.ca.com/"
location="C:\Program Files\CA\Self Service" last_modified="2012-12-05 14:12:12">
```

Unable to Open the Attached Files

Symptom:

I am unable to open the attached files of the Request and Incident in Unified Self-Service. When I click the attached file link of the request or incident in Unified Self-Service, the Service Desk Manager login page opens instead of the file.

Solution:

The name of the SERVER HOST NAME that is mentioned in CA Service Desk Manager Data Source configuration page (Administrator, Data sources, CA Service Desk Manager) of Unified Self-Service Server must match the name of the Server that is mentioned in Service Desk Repository (Administrator, Attachments, Library, Repositories, Service Desk).

Unable to Add Tags to a Question in Internet Explorer 9 Compatibility View

Symptom:

In Internet Explorer 9, when I create a new question, I do not see the option to add tags and hence cannot add tags to the question.

Solution:

No known workaround.

Accessibility Known Issues

This section contains the following known issues:

- Issue with Date and Table Components in CA Service Catalog Widgets (see page 265)

Issue with Date and Table Components in CA Service Catalog Widgets

The tab / arrows keys do not work correctly when you open a date control in the CA Service Catalog widgets because of a limitation with GXT. You cannot access some of the icons such as icons for today' s date, next month, previous month.

To work around this issue, use:

- Space bar to select **Today**
- Control + Right, Control + Left to change the month
- Shift+Up/Down to change the year

The general navigation techniques in a table also do not work correctly because of a limitation with GXT.

To work around this issue, use tab / arrow keys to navigate within the table.

CA SDM Connector Known Issues

This topic contains the following information:

Update on Service Relationships Does Not Work Properly

Symptom:

I update a relationship, affecting the scope of that relationship. A new relationship is created in Catalyst with the changed scope while the old relationship with the old scope still exists.

Example: I create a provider-dependent relationship between a portfolio application, PA1 and a service, S1. I modify the relationship by replacing S1 with another service, S2. Catalyst creates the relationship between PA1 and S2, but does not delete the relationship between PA1 and S1. This issue also occurs when I update the provider-dependent relationship between two services.

Solution:

We recommend that you delete or deactivate the relationship that you want to modify and then create the new relationship.

CA SDM Connector Does not Support High Availability

Symptom:

If the CA SDM server (on which this connector is installed) goes down, then the CA SDM connector service will also go down. As a result Service Asset and Configuration synchronization between CA SDM-CMDB and CA SOI, and CA Configuration Automation will stop working till CA SDM server is again up and running.

Solution:

Currently no solution exists.

CA CMDB and CA Confinguration Automation Integration Known Issues

This topic contains the following information:

Delay in Publishing Large Number of CIs

Symptom:

The CA Configuration Automation Connector handles data in batches. The CA Configuration Automation Connector pauses between sets of CIs before publishing to CA Catalyst. When CA Configuration Automation discovers a larger number of components, a considerable delay in publishing CIs to CA Catalyst can occur.

Solution:

You can configure the priming utility of CA Catalyst for CA Configuration Automation and can execute it. The primer tells CA Catalyst to plan the synchronization again.

Existing CA Configuration Automation Data Not Synchronized

Symptom:

If you run a CA Configuration Automation job before the CA SDM connector is configured and running with CA Catalyst, the data is not pushed to CA SDM from CA Catalyst. When a new connector is plugged in, CA Catalyst does not synchronize with the new CA SDM connector.

Solution:

No solution currently exists.

Number of Relationships in CMDB and the ServiceDesk-CMDB Projection Sheet in CA Catalyst May Differ

Symptom:

USM enforces a constraint that relationships are correlated using source, target, semantic and scope. Scope is an attribute which represents the service object that this relationship affects. When CA Catalyst sends relationships to CMDB for creation, the CA SDM Connector creates the CI and traverses the CMDB network of CIs to find its scope. If the scope is not found, the CA SDM Connector publishes the unscoped version of the relationship to CA Catalyst. Later, if the CA SDM connector finds the scope due to some update activity on the relationship, it publishes the scoped relationship to CA Catalyst. The scoped and the unscoped relationship does not correlate and results in extra relationships in the CA Catalyst database. However, there are no side-effects of these relationships in the CA Catalyst database, but they tend to persist in CA Catalyst, until they are removed from CMDB. When the relationship is removed from CMDB, it deletes the scoped, as well as the unscoped relationships from CA Catalyst.

Solution:

No solution currently exists.

CA SDM Contact Details are Updated if Business Owner/IT Owner Details are Changed in CA Configuration Automation

Symptom:

Change the Business Owner/IT Owner information of the service or server in CA Configuration Automation. Run the Catalyst Job again and view the contact information in CA SDM. User ID gets updated in CA SDM and not in the CI details of the contact.

Example:

CMDB obtains two users, User-1(username: User 1) and User-2 (username: User 2) from the CMDB import. User-1 is modified to contain the same username as User-2 in CA Configuration Automation. Both the users have different MDR element IDs. Once they are published to the Catalyst, the correlator correlates both user-1 and user-2, puts them under the same notebook, and removes the User-1 projection from the original notebook.

Solution:

No solution currently exists.

CIs and Relationships are Not Synchronized after Restarting the CA SDM Service

Symptom:

If CA SDM is restarted, the CA SDM Connector stops synchronizing both inbound and outbound CIs and Relationships. The same behavior is observed when the CA SDM Connector is restarted using the CA Catalyst Admin UI.

Solution:

Restart CA Catalyst Container service on the CA SDM Connector host.

All the Relationships are Not Deleted When the Data is Loaded through TWA

Symptom:

Some relationships are not removed from CMDB when the data is loaded through TWA.

To perform the root cause analysis and impact analysis in CMDB, CMDB must contain the relationships between the Enterprise Service and software.COTS family that the other MDRs do not provide. For example, CA Configuration Automation. The CA SDM Connector creates these relationships from the scope of the incoming relationship. When the relationships are deleted, it does not contain any information about the scope of the relationship and the CA SDM Connector has no knowledge to clean up those relationships from CMDB.

Solution:

Manually identify those relationships in CMDB and delete.

Implementing

Audience: As an Implementation Consultant, you can refer this page to help you get started with CA Service Management and to plan, install, and upgrade the product.

Getting Started

About CA Service Management (see page 270)

What's New in this Release (see page 69)

Supported Installation and Upgrade Scenarios (see page 274)

Getting Started with Installation (see page 274)

CA Service Desk Manager

Plan your Installation (see page 450)

Install the Product (see page 479)

Upgrade the Product (see page 399)

Configure the Product for First Use (see page 505)

CA Service Catalog

Plan your Installation (see page 564)

Install the Product (see page 590)

Upgrade the Product (see page 579)

Configure the Product for First Use (see page 596)

CA IT Asset Manager

Plan your Installation (see page 304)

Install the Product (see page 309)

Upgrade the Product (see page 325)

Configure the Product for First Use (see page 319)

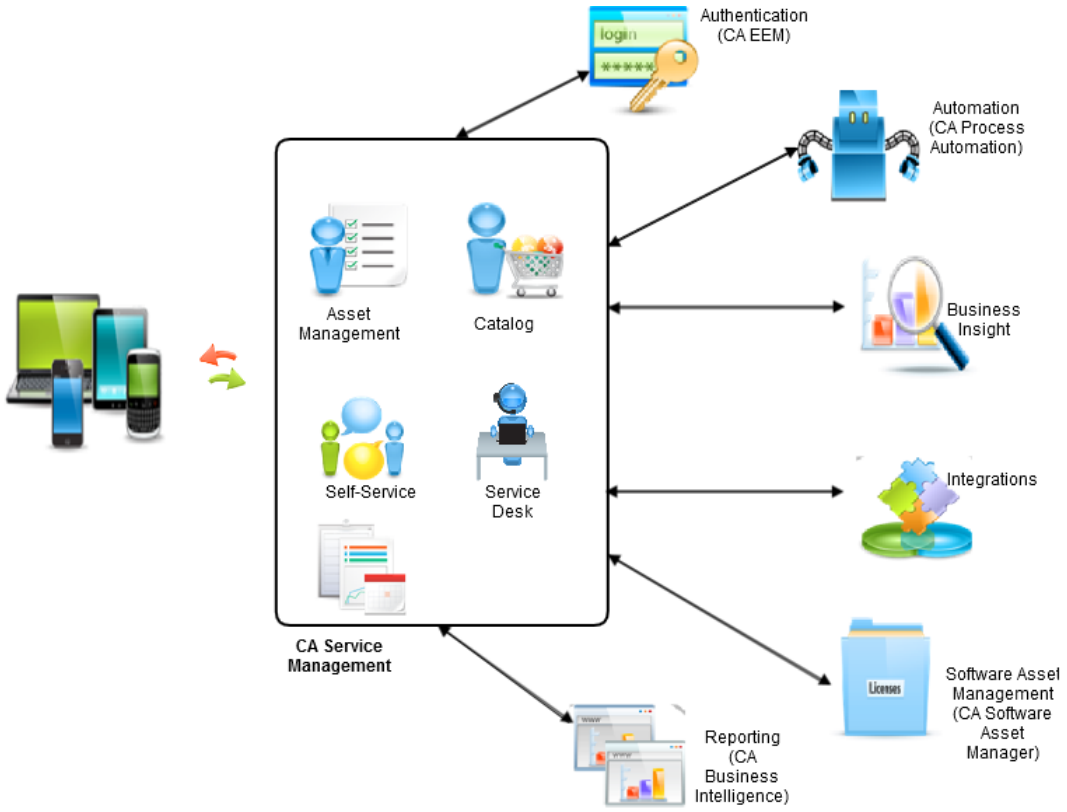
Implementing CA Service Management 14.1

CA Service Management is a seamless integration of three products namely, CA Service Desk Manager, CA Service Catalog, and CA IT Asset Manager. The solution also consists of a collaborative platform called Unified Self-Service, that lets you connect and share knowledge with the people in your organization. Unified Self-Service also offers self-service functionalities for your business users and administrators.

CA Service Management helps you do the following:

- Deliver efficient IT service management to consumers, IT teams, and management.
- Increase the value that IT provides to the business by communicating service offerings in terms that users can understand.
- Manage IT assets to deliver proven ROI and control IT spending, enable regulatory and policy compliance and improve service delivery.

The following diagram illustrates the capabilities that CA Service Management offers:



Products or Capabilities in the Solution

CA Service Management lets you leverage several capabilities that you earlier implemented by manually integrating individual solutions. For example, you can associate CA APM assets with assets requested through CA Service Catalog without having to manually integrate CA Asset Portfolio Management and CA Service Catalog.

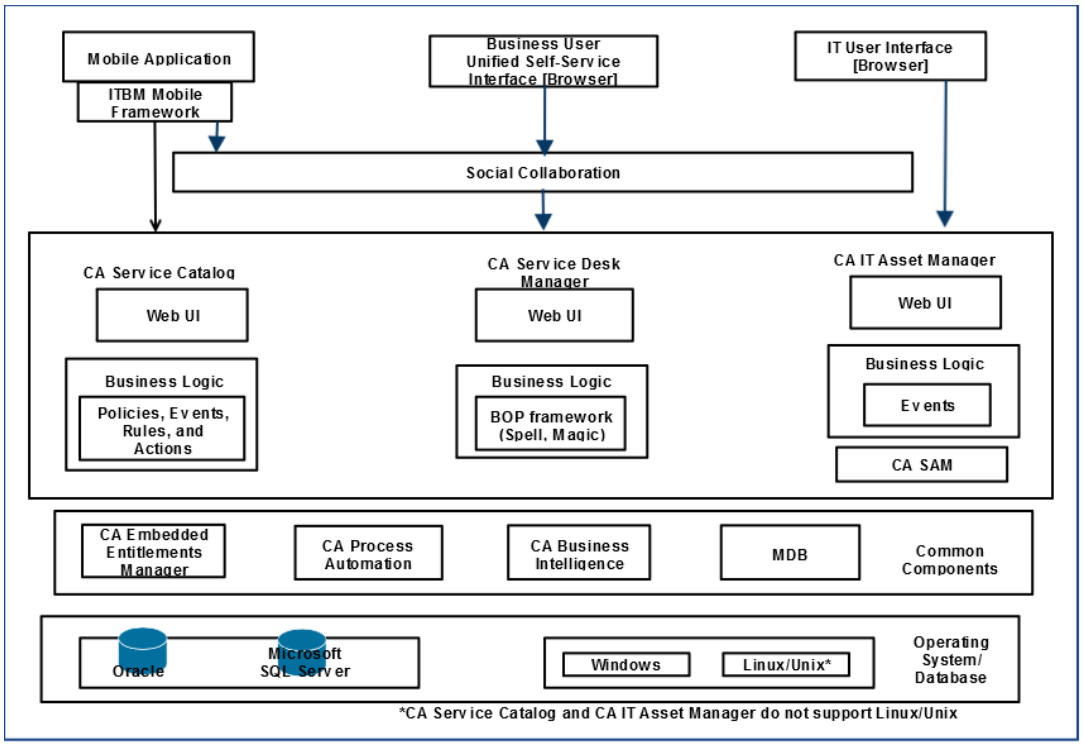
Through CA Service Management you can implement:

- CA Service Desk Manager capabilities such as Ticket (incident, problem, request, issue) Management, Change Management, Configuration Management, Knowledge Management, Support Automation
- CA IT Asset Manager capabilities such as Contract Management, Financial Management, Hardware Asset Management, Software Asset Management, Vendor Management. CA IT Asset Manager is a combination of CA Asset Portfolio Management (CA APM) and CA Software Asset Manager (CA SAM).
- CA Service Catalog capabilities such as Service Catalog Management, Service Accounting
- Unified Self-Service capabilities such as collaborating through communities, reporting issues, and requesting hardware or software services.

Note: Unified Self-Service can now be integrated with either CA Service Desk Manager or CA Service Catalog only.

Solution Architecture

The following diagram represents the CA Service Management Architecture:



Hardware and Server Requirements

The hardware requirements for each of the CA Service Management products are in the following sections.

- CA Service Desk Manager Hardware Requirements (see page 452)
- CA Asset Portfolio Management Hardware Requirements (see page 304)
- CA Service Catalog Hardware Requirements (see page 573)
- Unified Self-Service Hardware Requirements (see page 273)

For information about the supported Operating Systems, databases, and browsers, see the CA Service Management Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

Server Requirements

The following table lists the different components in the solution and the minimum number ofserveryou will requireforeach of them:

Component	Number of Servers (Minimum)	Description
CA Service Catalog	1	

Component	Number of Servers (Minimum)	Description
		CA Service Catalog and the accounting component are installed on the same server.
CA Service Desk Manager (Conventional Configuration)	1	One Primary Server
CA Service Desk Manager (Advanced Availability Configuration)	3	One Background Server, one Standby Server, one Application Server **Recommended:** 4 servers. One Background Server, one Standby Server, two Application Servers
CA IT Asset Manager	1	Web and Application Server can be installed on the same server. **Recommended:** 2 servers; one each for Web and Application servers.
CA EEM	Cluster: 2 Standalone: 1	
CA Business Intelligence	1	
CA Process Automation	1	
MDB	1	

Unified Self-Service Hardware Requirements

If you plan to install Unified Self-Server on a different server other than where you installed CA SDM or CA Service Catalog, you must meet the specified hardware requirements.

You must meet or exceed the following requirements to successfully install and run Unified Self Service:

Hardware	Requirements
CPU	Dual Processor 2.0 GHz preferred
RAM	Minimum 4 GB
Disk Space	4 GB

You must meet or exceed the following requirements to successfully access Unified Self-Service Web Client computer with better performance:

Hardware	Requirements
CPU	Dual Processor 2.0 GHz preferred
RAM	Minimum 2 GB available free memory
Disk Space	4 GB

You must meet or exceed the following requirements based on the size of your Unified Self-Service environment, to successfully install and run Unified Self-Service:

Database Size	Hardware	Requirements
Small—Used for installing Unified Self-Service in a test environment.	CPU	Minimum Dual Processor 2.0 GHz
	RAM	Minimum 4 GB
	Disk Space	Minimum 4 GB minimum. This will increase over time to accommodate database growth
Medium—The Unified Self-Service default. The recommended setting for most Unified Self-Service installations.	CPU	Dual Processor 2.0 GHz
	RAM	Minimum 8 GB
	Disk Space	Minimum 8 GB. This will increase over time to accommodate database growth
Large—Used for large Unified Self-Service installations.	CPU	Quad Processor 2.0 GHz
	RAM	Minimum 16 GB
	Disk Space	Minimum 8 GB. This will increase over time to accommodate database growth

Step 1 - Identify your Installation or Upgrade Scenario

You can install any combination of the products in the solution. Use the CA Service Management installer to install or upgrade the following:

- Any product in CA Service Management (CA Service Desk Manager, CA Service Catalog, and CA Asset Portfolio Management).
- Any combination of products (CA Service Desk Manager, CA Service Catalog, and CA Asset Portfolio Management)
- The entire solution with all the products.

Note: You can install Unified Self-Service only with CA Service Desk Manager or CA Service Catalog or if either of these products are already found in the environment. We recommend that you install Unified Self-Service with any combination of the products to manage the solution administration through Unified Self-Service.

Ensure that the CA Service Management products that you want to integrate share the same MDB. For example, if you have CA Service Desk Manager on non-Windows and the other products on Windows, you can integrate only if the two products share the same MDB.

You can also use the CA Service Management Installer to install and integrate any of the common components (CA EEM, CA Business Intelligence, and CA Process Automation) with the CA Service Management products. If you have an existing set up of these products, you can use them with CA Service Management, provided that the versions are supported. For information on supported versions, see the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

Some of the installation and upgrade scenarios that CA Service Management Installer supports are as follows:

- Scenario 1: New Installation of one of the CA Service Management products and integrating with a common component (see page 275)
- Scenario 2: New installation of two or more CA Service Management products (see page 276)
- Scenario 3: New installation of one or more products in an existing CA Service Management 14.1 environment (see page 276)
- Scenario 4: Upgrading an existing version of the product to CA Service Management 14.1 (see page 277)
- Scenario 5: Upgrading the existing version of two or more non-integrated CA Service Management products (see page 277)
- Scenario 6: Upgrading the existing version of two or more integrated CA Service Management products (see page 278)
- Scenario 7: Upgrading the existing version of a CA Service Management product and installing another new product (see page 279)
- Scenario 8: Upgrading the existing version of a CA Service Management product when the common components are not the same (see page 279)

Scenario 1: New Installation of one of the CA Service Management products and integrating with a common component

Example: Installing CA Service Desk Manager and integrating with a common component

1. Plan your CA Service Desk Manager implementation (see page 450).

2. Install the common components (see page 283). Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

3. Install CA Service Desk Manager (see page 479) with the required configuration on each CA Service Desk Manager server. Use the "Configure Common Components" to integrate CA Service Desk Manager with any of the common components.
   The installer installs CA Service Desk Manager 14.1 and integrates it with the common component.

Note: The flow applies for CA Service Catalog and CA Asset Portfolio Management too.

Scenario 2: New installation of two or more CA Service Management products

Example: Installing CA Service Desk Manager, CA Service Catalog, and CA Asset Portfolio Management

1. Plan your CA Service Desk Manager implementation (see page 450).
2. Plan your CA Service Catalog implementation (see page 564).
3. Plan your CA Asset Portfolio Management implementation (see page 304).
4. Install the common components (see page 283) according to your requirement. Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

   Note: Ensure that you have at least one CA EEM in your environment because CA EEM is mandatory for CA Service Catalog and CA Asset Portfolio Management.

5. Install CA Service Desk Manager (see page 479) with the required configuration on each CA Service Desk Manager server.
6. Step 2 - Install CA Service Catalog (see page 590) with the required configuration on each CA Service Catalog server.
7. Install CA Asset Portfolio Management (see page 309) with the required configuration on each CA CA Asset Portfolio Management
   The installer automatically detects that CA Service Desk Manager 14.1 is already installed in the environment and integrates both CA Service Catalog 14.1 and CA Asset Portfolio Management 14.1 with each other and also with CA Service Desk Manager.
8. (Recommended) Use the common administration interface (see page 763) from the Unified Self-Service interface (if Unified Self-Service is installed) foruser, role, and tenancy management of CA Service Desk Manager and CA Service Catalog.

Scenario 3: New installation of one or more products in an existing CA Service Management 14.1 environment

Example: Installing CA Service Catalog in an environment that already has CA Service Desk Manager 14.1

1. Plan your CA Service Catalog implementation (see page 564).
2. Install the common components (see page 283). Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

Note: Ensure that you have at least one CA EEM in your environment because CA EEM is mandatory for CA Service Catalog.

3. Step 2 - Install CA Service Catalog (see page 590) with the required configuration on each CA Service Catalog server.
   The installer automatically detects that CA Service Desk Manager 14.1 is already installed and integrates CA Service Catalog with CA Service Desk Manager. Any new component that is selected for CA Service Catalog is also integrated with CA Service Desk Manager.

4. (Recommended) Use the common administration interface (see page 763) from the Unified Self-Service interface (if Unified Self-Service is installed) foruser, role, and tenancy management of CA Service Desk Manager and CA Service Catalog.

Scenario 4: Upgrading an existing version of the product to CA Service Management 14.1

Example: Upgrading CA Service Desk Manager 12.9 to 14.1

1. Plan for the upgrade of CA Service Desk Manager (see page 399).

2. Install the common components (see page 283), if required. Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

3. Upgrade CA Service Desk Manager (see page 399) on each CA Service Desk Manager server. The installer detects the version of CA Service Desk Manager and upgrades it to 14.1.

Note: The flow remains the same for Catalog except that the upgrade can be done using the traditional upgrade or migration-model upgrade.

Scenario 5: Upgrading the existing version of two or more non-integrated CA Service Management products

Example: Upgrading CA Service Desk Manager and CA Service Catalog from 12.9 to 14.1 but the products are not already integrated

1. Plan for the upgrade of CA Service Desk Manager (see page 399).

2. Plan your CA Service Catalog Upgrade (see page 580).

3. Install the common components (see page 283). Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

> **Note:** Ensure that you have at least one CA EEM in your environment because CA EEM is mandatory for CA Service Catalog.

4. Upgrade CA Service Desk Manager (see page 399) on each CA Service Desk Manager server.

5. Upgrade CA Service Catalog (see page 586) on each CA Service Catalog server.
   The installer automatically detects the existing versions of the products. It upgrades the productsto 14.1 and integrates them. Any common component integrations selected for CA Service Desk Manageris also integrated with CA Service Catalog. Also, ifany new integration is selected for CA Service Catalog, existing CA Service Desk Manager is integrated with the new common component.

6. (Recommended) Use the common administration interface (see page 763) from the Unified Self-Service interface (if Unified Self-Service is installed) foruser, role, and tenancy management of CA Service Desk Manager and CA Service Catalog.

Scenario 6: Upgrading the existing version of two or more integrated CA Service Management products

Example: Upgrading CA Service Desk Manager and CA Service Catalog from 12.9 to 14.1 and the products are already integrated

1. Plan for the upgrade of CA Service Desk Manager (see page 399).

2. Plan your CA Service Catalog Upgrade (see page 580).

3. Install the common components (see page 283). Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

> **Note:** Use the same common components for both the products.

4. Upgrade CA Service Desk Manager (see page 399) on each CA Service Desk Manager server.

5. Upgrade CA Service Catalog (see page 586) on each CA Service Catalog server.
   The installer detects the existing versions of the products and upgrades the productsto 14.1. No changes are made to existing integration. Any new component selected is integrated with both CA Service Desk Manager and CA Service Catalog.

6. (Recommended) Use the common administration interface (see page 763) from the Unified Self-Service interface (if Unified Self-Service is installed) foruser, role, and tenancy management of CA Service Desk Manager and CA Service Catalog.

Scenario 7: Upgrading the existing version of a CA Service Management product and installing another new product

Example: Upgrading CA Service Desk Manager from 12.9 to 14.1 and installing CA Service Catalog 14.1

1. Plan for the upgrade of CA Service Desk Manager (see page 399).
2. Plan your CA Service Catalog installation (see page 564).
3. Install the common components (see page 283). Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).

   Note: Use the same common components for both CA Service Desk Manager and CA Service Catalog.

4. Upgrade CA Service Desk Manager (see page 399) on each CA Service Desk Manager server.
5. Install CA Service Catalog (see page 590) with the required configuration on each CA Service Catalog server.
   The installer automatically detects that CA Service Desk Manager is already installed in the environment and integrates CA Service Catalog with CA Service Desk Manager. Any new component selected is integrated with both CA Service Desk Manager and CA Service Catalog.
6. (Recommended) Use the common administration interface (see page 763) from the Unified Self-Service interface (if Unified Self-Service is installed) foruser, role, and tenancy management of CA Service Desk Manager and CA Service Catalog.

Scenario 8: Upgrading the existing version of a CA Service Management product when the common components are not the same

For example, upgrading CA Service Desk Manager12.9 integrated with CA EEM Server 1 and CA Service Catalog integrated 12.9 with CA EEM Server 2. In this scenario you can also change the common component during the upgrade process.

1. Plan for the upgrade of CA Service Desk Manager (see page 399).
2. Plan your CA Service Catalog Upgrade (see page 580).
3. Install the common components (see page 283). Alternatively you can use an existing supported version of these products as listed in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix).
4. Upgrade CA Service Desk Manager (see page 399) on each CA Service Desk Manager server.

5. Upgrade CA Service Catalog (see page 586) on each CA Service Catalog server.
   The installer detects the existing integrations and auto populates the information about the existing integration during the upgrade. Because the CA EEM server (CA EEM Server 2) discovered during the second upgrade is different from the CA EEM Server 1 detected in the environment already, the conflict is highlighted in the integration screen. The installer recommends using the CA EEM Server 1 used in the solution.

   - If you select to use the new common CA EEM server for integration, both the CA Service Catalog servers are integrated with the value of CA EEM Server 1,
   - If you select to not resolve the conflict, then the integration settings are not changed.

   The installer upgrades both the CA Service Catalog servers to 14.1.

6. (Recommended) Use the common administration interface (see page 763) from the Unified Self-Service interface (if Unified Self-Service is installed) foruser, role, and tenancy management of CA Service Desk Manager and CA Service Catalog.

Step 2 - Plan your CA Service Management Installation

Before proceeding with CA Service Management installation, ensure that you have reviewed the following installation planning considerations and completed the prerequisite checks for the products.

Note: CA Asset Portfolio Management App Server uses the reserved port 9080 and CA Service Catalog uses the reserved port 7777. Reserved ports are set internally and are not configurable during CA Service Managementproducts installation. You must not configure any other services on these reserved ports.

Customization

Perform Customization

Any “modifications” or “adaptions” or “configurations” that are done administratively through the interface (web browser, command-line, Web Screen Painter) are “supported”, meaning CA Support can assist with the basic suggestions and troubleshooting. CA Support do NOT perform any changes for the customer. The customer is responsible for the changes made. For example, adding a field to a table and putting the field on a form through Web Screen Painter is a fully supported “modification”. Similarly, installing or uninstalling a feature through the Options Manager administration is a fully supported “configuration”. Anything to do with SPEL code, Javascripting(or any language scripting), or a customer-specific changetothe underlying base code-line (done by CA Services or a Partner), is NOT supported by CA Support. The customer can perform these actions, but is responsible for the support, maintenance, and troubleshooting when an issue occurs. If such “customization” affect expected out-of-the-box behavior, CA Support will ask the customer to remove the customization and see if the behavior persists.

Retain Customization

When any form is modified, the customer changes are overwritten and has to be recreated. There is a process in the upgrade that attempts to detect and identify the differences in the forms, and reports it to the customer for their investigation. However, it is highly recommended to document your customization BEFORE you perform any upgrade. In some cases, a new feature may be similar to the user customization, so the user changes must be removed.

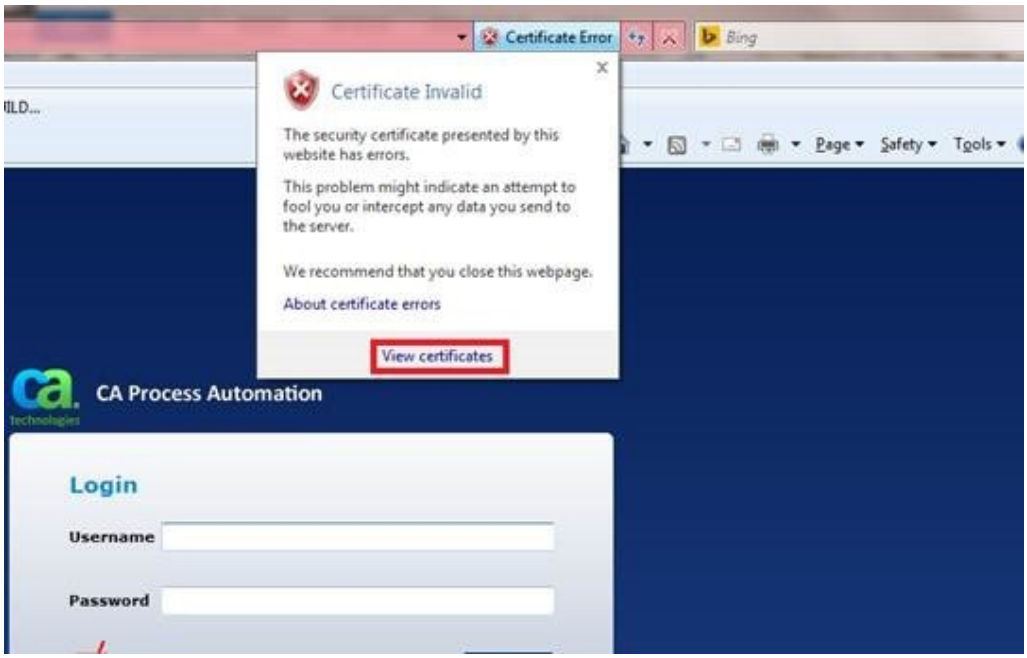
CA Process Automation Installation in an HTTPS Environment

Before the installation or upgrade, if your CA Process Automation instance is SSL enabled (configured withhttps), ensure that you add a CA Process Automation SSL certificate to the Java Runtime Environment (JRE)keystore. Without this certificate, JRE, under which the installer is running, does not connect to the CA Process Automation SSL URL and the following SSL validation errors may appear during the installation:

```
2014/11/11 19.04.39.728 DEBUG [AWT-EventQueue-0] [PAMWebserviceManager] Get ITPAM
version
2014/11/11 19.04.39.752 ERROR [AWT-EventQueue-0] [PAMValidator] CA PAM validation
failed
com.ca.smsi.installcore.webservices.WebserviceException: ; nested exception is:
javax.net.ssl.SSLHandshakeException: sun.security.validator.ValidatorException: PKIX
path building failed: sun.security.provider.certpath.SunCertPathBuilderException:
unable to find valid certification path to requested target
at com.ca.smsi.installcore.webservices.PAMWebserviceManager.getITPAMVersion
(PAMWebserviceManager.java:265)
```

Complete the following steps to add a CA Process Automation SSL certificate to the JREkeystore:

1. Download the SSL Certificate by accessing the CA Process Automation URL.



2. Copy this certificate file to some location. For example, c:\ItpamCert.cer

3. Extract the CA SDM DVD to a local drive. For example, C:\CASMDVD14\< >

4. Import the CA Process Automation SSL Certificate to a keystore file using the following command:

```
c:\CASMDVD14\java\jre\bin\keytool -importcert -file c:\ItpamCert.cer -alias
somealias -keystore c:/keystore_file -storepass somepass\
```

5. To enter the keystore and password values to the JRE, open the C:\CASMDVD14\setup.lax file in Wordpad or a similar text editor.

   Note: To avoid any formatting issues, it is recommended NOT to use Notepad.

6. Identify the "lax.nl.java.option.additional" property.

7. Append the reference to the JAVA keystore and keystorepass entries as follows:

   ```
   -Djavax.net.ssl.trustStore=c:/keystore_file -Djavax.net.ssl.
   trustStorePassword=somepass
   ```

   After the modification, the line would look like:

   ```
   lax.nl.java.option.additional=-Djava.library.path=".\\java\\bin; -
   DGET_SD_PRESETS=true -Djavax.net.ssl.trustStore=c:/keystore_file -Djavax.net.
   ssl.trustStorePassword=somepass
   ```

8. Save the file and restart the setup by executing C:\CASMDVD14\setup.exe command

CA Asset Portfoli o Management I nstallat ion Planning

Review and consider the prerequisites and installation planning consideration before proceeding with CA Asset Portfolio Management (CA APM) installation. For more information, see Plan your CA APM Installation (see page 304).

CA Service Catalog Installation Planning

Review and consider the prerequisites and installation planning consideration before proceeding with CA Service Catalog installation. For more information, see plan your CA Service Catalog installation (see page 564).

CA Service Desk Manager Installation Planning

Review and consider the prerequisites and installation planning consideration before proceeding with CA Service Desk Manager installation. For more information, see Step 1- Plan your CA SDM Installation (see page 450).

Important! To install CA Service Management from the non-root user on Unix or Linux, you must have the permissions to execute the sudo command.

Follow these steps:

1. Export the appropriate oracle variables and library paths.

2. Go to the CA Service Management instalelr DVD, then execute the below command:
   sudo -E PATH=$PATH ./setup.sh

Step 3 - Install the Common Components

Common components such as CA Embedded Entitlements Manager (CA EEM), CA Business Intelligence, and CA Process Automation provide the ability to integrate the CA Service Management products. If you have an existing installation of the common components in your environment, you can use these for CA Service Management as well. Ensure that the common components that you have installed is supported for CA Service Management, as listed in the Supportability Matrix (see page 119).

The common components provide the following capabilities:

- CA EEM provides the authentication and authorization capability. CA EEM eliminates plain text user names and passwords from being passed for authentication purposes.

  Note: CA EEM is mandatory for CA Service Catalog and CA Asset Portfolio Management.

- CA Business Intelligence provides the reporting capability.
- CA Process Automation provides the business process automation capability.

Install the following components, depending upon your requirement:

- Install CA Embedded Entitlements Manager (see page 283)
- Install CA Business Intelligence (see page 285)
- Install CA Process Automation (see page 292)

Install CA Embedded Entitlements Manager

This topic contains the following information:

The CA Service Management installer launches the CA EEM installer based on the system architecture. Hence, on a 32-bit Windows computer, the CA Service Management installer launches the 32-bit CA EEM installer and on a 64-bit computer, the CA Service Management installer launches the 64-bit CA EEM installer.

If CA iTechnology iGateway for CA APM installation is running as a 32-bit application on a 64-bit Windows computer, then CA EEM also runs as a 32-bit application.

If you have a 32-bit CA EEM installed on a 64-bit operating system, you see an error when you select **CA Embedded Entitlements Manager (CA EEM)** in **Select the required Installer** screen of the CA Service Management installer because the installer invokes the 64-bit CA EEM installer.

If you want to upgrade your existing 32-bit CA EEM on a 64-bit operating system, launch the CA EEM installer from the following location and not from the CA Service Management installer:

```
DVD\products\EEM\win32
```

Cluster-related CA EEM Requirements for CA Service Catalog

An installation of CA Service Catalog can include several clustered computers. Each installation of CA Service Catalog must map to an application name in CA EEM. You can set up a single instance of CA EEM and the CA Service Catalog database for multiple installations of CA Service Catalog (for example, Test and Production).

In this type of setup, the setup-related parameters (for example, the database, user, and application names) have the same values on every computer. Therefore, when you run the setup utility, you can use the remote configuration feature to copy the parameter settings from one computer to another.

If CA EEM is clustered with a load balancer, follow these steps before you run the setup utility:

1. Edit the Apache load balancer configuration file, proxy.conf file. This file is in the conf folder of the Apache installation directory.
2. Record the current setting of the MaxKeepAliveRequests property.
3. Set the MaxKeepAliveRequests property value to 0.
4. Restart the Apache load balancer services to make the configuration changes take effect.

For best performance, we recommend that you install CA EEM on a different server than the DBMS server.

Important! Make a note of your CA EEM administration password that you provide during CA EEM installation. You use this password while integrating CA Service Management products with CA EEM.

If you have a clustered environment, ensure that all the nodes in the CA EEM cluster are up and running before you install any of the CA Service Management products.

Install CA Embedded Entitlements Manager

Follow these steps:

1. Launch the CA Service Management Installer.

Note: If the Installation wizard does not open automatically, start the installation by double-clicking the setup.exe file, located at the root of the installation media.

2. Click **Select Language** to select a language from the list in the **Language Selection** screen.

3. Select **CA Embedded Entitlements Manager (CA EEM)** in **Select the required Installer** screen to launch the CA EEM installation.
   The wizard guides you through the process of installing or upgrading CA EEM.

   Note: CA EEM and CA Service Catalog each installs and uses its own JRE. Therefore, the JRE version of each product can be different.

   CA EEM has been installed.

4. Go to Start, All Programs, CA, Embedded Entitlements Manager, Admin UI on the CA EEM machine. Log into the application to ensure that the CA EEM installation was successful.

   Note: If CA EEM is configured to use an external LDAP data store, the privileged user must be created in the LDAP Directory.

You can optionally install one or more additional instances of CA EEM. To obtain high availability and fail over protection for CA EEM, cluster all CA EEM computers. For more information, see Failover configuration (https://wiki.ca.com/display/eem1251/How+to+Set+Up+a+Failover+Environment). For more information about CA EEM installation, see Installing CA EEM (https://docops.ca.com/display/eem1251/Windows+Installation).

Install CA Business Intelligence

CA Business Intelligence provides a consistent installation of SAP Business Objects Enterprise edition. Multiple CA Technologies products can share a license of CA Business Intelligence.

Important! You can integrate any CA Service Management product with CA Business Intelligence that is running on English Windows only.

Follow these steps:

- Review Hardware and Software Requirements (see page 286)
- Review Installation Considerations (see page 286)
- Install CA Business Intelligence Server and Client Tool Components (see page 287)
  - Special Instructions for Derived Universe (see page 288)
- Migrate Content from Release 3.3 to Release 4.1 SP3 (see page 288)
  - Back up Custom Universe (see page 288)
  - Import CA Business Intelligence Content (see page 289)
- Review the Best Practices to Use CA Business Intelligence (see page 292)

Review Hardware and Software Requirements

Understand the requirements and installation considerations for CA Business Intelligence from the CA Business Intelligence documentation (https://wiki.ca.com/display/CABI41SP3/Hardware+and+Software+Requirements+for+Installation). The minimum server hardware requirements for CA Business Intelligence 4.1 are:

- CPU performance of at least 8000 SAPS

  Note: SAPS, or the **SAP Application Performance Standard**, is a unit of measurement that describes the performance (throughput (http://en.wikipedia.org/wiki/Throughput) result) of a SAP system configuration. This hardware-independent unit is based on the SAP Sales and Distribution (SD) Benchmark.

- For CABI 4.x, SAP recommends 16GB RAM for a Development class machine.

Review Installation Considerations

Important! If you want to retain any one of the CA Service Management products at an older release level, you must have two instances of CA Business Intelligence. One CA Business Intelligence instance for the older release and one CA Business Intelligence 4.1 instance for 14.1. You can then access the reports for respective releases of CA Service Management products.

- Temporarily disable any antivirus software on the computer where you are installing CA Business Intelligence.
- CA Service Management integration with CA Business Intelligence is supported only when Apache Tomcat is the CA Business Intelligence application server.
- The database server details and the authentication details are available.
- You have the permission to install a new SQL Anywhere database or to use an existing SQL Anywhere database.
- You have the name for Server Intelligence Agent (SIA).
- The web application server has been installed and configured.
- For CA Asset Portfolio Management integration with CA Business Intelligence:
  - If you use MS SQL as the MDB, ensure that you install Microsoft SQL Server Native Client (64-bit) on the server where CA Business Intelligence is installed.
  - If you use Oracle as the MDB, define an Oracle Net Service Name (64-bit) on the server where CA Business Intelligence is installed. Make a note of the NSN, which you are asked to enter during the CA Asset Portfolio Management installation.

- The credentials for the CA Business Intelligence Administrator Account must be defined before running the installer for both new and custom installation.
- SAP Business Objects users with an existing installation of Business Objects can install and configure CA Business Intelligence (recommended) or they can use their existing Business Objects installation.

> **Note:** To modify the JRE version that is provided with CA Business Intelligence, see upgrade JRE in CA Business Intelligence (https://wiki.ca.com/display/CABI41SP3/Upgrade+JDK+and+JRE+in+CABI+4.1+SP3).

- Server and client installations are separate and can be installed on the same or different servers. For more information about platform installation, see CA Business Intelligence Platform Installation (https://wiki.ca.com/display/CABI41SP3/CA+Business+Intelligence+Platform+Installation).

> **Important!** For the successful CA Business Intelligence Configuration for CA Service Desk Manager, enter the Central Management Server (CMS) port number as 6400 while installing the CA Business Intelligence Server.

Install CA Business Intelligence Server and Client Tool Components

Install CA Business Intelligence on a separate server. Server and client tool components are installed separately for CA Business Intelligence Release 4.1 SP3. Both can be installed from the CA Service Management installer on the same or different servers.

Server components include Central Configuration Manager, Upgrade Management Tool, Central Management Console, BI Launchpad, Tomcat Configuration, and Tomcat Administration.

> **Note:** Before proceeding with the CA Business Intelligence Server installation, see the CA Business Intelligence Installation (https://wiki.ca.com/display/CABI41SP3/CABI+Installation+on+Windows) documentation.

Client tool components include Universe Design Tool (earlier known as Designer), Webi Rich Client, Business View Manager, Information Designer Tool, Translation Management tool, and so on. Universe Design tool is used for creating or modifying the Universes(.unv); IDT(Information Design Tool) is used for creating multi Source Universe(.unx); Webi rich Client is used for creating Webi Reports.

Follow these steps:

1. Launch the CA Service Management installer.
2. Click **Select Language** to select a language from the list in the **Language Selection** screen.

3. Select **CA Business Intelligence Server Installation** from the **Select the required installer** screen.

   Important! Refer to CA Support Online (https://support.ca.com/irj/portal/ProdCDNResults) for the correct DVD number.

4. Proceed with the installation. For more information, see the Full Installation (https://wiki.ca.com/display/CABI41SP3/Full+Installation) documentation.

5. Select **CA Business Intelligence Client Tools Installation** from the **Select the required installer** screen and complete the installation.
   You have successfully installed CA Business Intelligence.

Special Instructions for Derived Universe

Follow these steps:

1. Import the *CA Service Desk* universe from *Universe Design Tool* on the CABI Client Tools installed system.
2. Save and export the *CA Service Desk* universe.
3. From the *Universe Design Tool*, open the saved derived universe.
4. From the **File** menu, click **Parameters**.
5. Click the **Links** tab, add a link to enable the **Change Source** button.
6. Select the *CA Service Desk.unv*. Click **OK**.
7. Save and export the universe.

Migrate Content from Release 3.3 to Release 4.1 SP3

Before you migrate, ensure that you created the previous version of CA Business Intelligence content by creating the BIAR for each of the CA Service Management products. Create the BIAR using the Import wizard from the CA Business Intelligence Release 3.3 server. The BIAR includes all the previous version of out of the box Universe, Reports, Users and Groups. Also include Scheduled Instances and Custom Reports, if any.

Back up Custom Universe

If you have custom universe, take a backup.

Follow these steps:

1. Start Universe Designer.
2. Import your custom universe.

3. Save a copy of the universe on your local drive.
   The custom universe is backed up. Use this back up to update the custom universe link after you install and configure the CA Service Management products.

Import CA Business Intelligence Content

To import CA Business Intelligence 3.3 content to 4.1 server, use the Post Installation utility. Run this utility on the server where CA Business Intelligence Release 4.1 SP3 is installed.

Note: If you have installed CA Business Intelligence Release 4.1 SP3 using custom distributed, ensure that you run the utility in the web tier and Intelligence tier environment. Run the utility in the web tier environment only if you have Custom Action Framework enabled. For more information, see the post installation utility (https://wiki.ca.com/display/CABI41SP3/CA+Business+Intelligence+Platform+Post+Installation+Utility).

Follow these steps:

1. Log in to the Central Management Console installed windows machine as a CA Business Intelligence installed user.
2. Go to <CABIDVD>\utilities\PostInstall direcory from the command prompt.
3. Place the biar files that are created during the backup of the custom universe in the 3.x folder along with their corresponding properties files. Place the properties file at <CABIDVD>\utilities\PostInstall\3.x location.
4. Consider the following points:
   - Properties files are optional. Properties file must have the BIAR name. An example of the properties file for CA Service Desk Manager biar file that uses ODBC is as follows:
     - RDBMS=Generic ODBC datasource
     - DatabaseServer=casd_sdm_host
     - NetworkLayer=ODBC
     - UserName=ServiceDeskUser
     - Password=ServiceDeskPassword
     - Database= sdm_host
     - ArrayBindSize=10
     - ArrayFetchSize=10
     - PoolMode=Pooling

- PoolTime=10
- LogTimeOut=60

- Some of the properties for CA Service Catalog must be changed, as follows:
  - RDBMS= <Specify the MS SQL Server version> or For Oracle, RDBMS=<Generic ODBC datasource>
  - DatabaseServer=<DB server Name>
  - NetworkLayer=ODBC
  - UserName=sa or For Oracle, UserName=mdbadmin
  - Password=<Database password>
  - Database =caslcm_cabi_dsn
  - Some of the properties for CA Asset Portfolio Management must be changed as follows:
  - RDBMS=<Specify the name of your RDBMS>
  - DatabaseServer=<DB server Name>
  - NetworkLayer=OLE DB
  - UserName=uapadmin
  - Password=<Database password>
  - Database=<Name Of the NSN created in the datasource parameters>

5. Execute **PostInstall.bat** to run the utility from the <CABIDVD>\utilities\PostInstall path.
6. Enter **n** for Do you want to migrate data from CABI 3.x.
7. Enter **n** for Do you want to install CA Sample Templates.
8. Enter the CA Business Intelligence 4.1 SP3 Administrator password and press Enter.
   This step takes some time and after completion of the process a success message is displayed.
9. Verify the installation logs in the <INSTALLDIR>\SAP BusinessObjects Enterprise XI 4.0 \logging\postinstall.log directory.
10. Import the *CA Service Desk* universe from the Universe Design tool where the CABI Client tools is installed, and then, click **File**, **Close**, to close the universe.
11. From the Universe Design tool, import any Custom (Derived) universes, and then, click **File**, **Close**, to close the universe.
12. From the Central Configuration Manager, restart the Server Intelligence Agent.

13. (Only for CA Service Desk Manager) From the CA Business Intelligence Release 4.1 SP3 Server machine, run the CA Service Management installer to configure CA Business Intelligence (see page 549).

> **Note:** After you install the CA Service Management products and integrate any of those with CA Business Intelligence 4.1, the Universe and Reports for CA Service Management 14.1 are overwritten on the previous version of out of the box Universe and Reports. Scheduled Instances are retained from the previous releases, if they exist.

You have successfully migrated CA Business Intelligence to Release 4.1 SP3.

After migrating reports from CA Business Intelligence (CABI) 3.x to CABI 4.x, if you are using CA Service Desk Manager out of the box reports using the Reports tab, the following error may appear:

```
An Error occurred : could not find the document
```

This error message appears because in CABI 3.x, CA SDM out of the box reports are located at All Folders, CA Reports, CA Service Desk folder of CA Business Intelligence. In CABI 4.x, CA SDM out of the box reports are located at All Folders, CA Reports, CA Service Management, CA Service Desk folder of CA Business Intelligence. A CABI report is exposed in the CA SDM Reports tab using a CA SDM Web Form (Security and Role Management, Role Management, Web Forms, type=Report). Such Web Form detail screen has a Resource with a value similar to the following:

```
$BOServerURL?sPath=[CA+Reports],[CA+Service+Management],[CA+Service+Desk],
[Asset]&sDocName=Asset+List&sViewer=html
```

[CA+Service+Management] folder may not exist if the CA Business Intelligence 3.x content is migrated to 4.x. To resolve this issue, perform one of the following actions:

- Edit each such Resource values of the web forms and remove the ", [CA+Service+Management]" string. Save and retest.
- Complete the following steps to create a new folder in CABI 4.x:
  a. Using a web browser, access the Central Management Console, Folders, All Folder, CA Reports.
  b. Create the "CA Service Management" folder.
  c. Move the CA Service Desk folder from All Folders, CA Reports to All Folders, CA Reports, CA Service Management. This can be performed by right clicking on CA Service Desk, Organize, Move To option.
  d. Retest

If the problem persists, contact CA Technologies Technical Support.

14. Import the *CA Service Desk* universe from the Universe Design tool where the CABI Client tools is installed, and then, click **File**, **Close**, to close the universe.

15. From the Universe Design tool, select **File**, **Open**, and navigate to the previously saved Custom (Derived) Universe (created in Step 11 above), to open the Universe.

16. Click **File**, **Parameters**.

17. Click the **Change Source** tab.

18. Select the *CA Service Desk.unv* on the file system (created in step 14 above), and then, click **OK** .

19. Save and export the universe.

20. Exit the Universe Design tool.

Review the Best Practices to Use CA Business Intelligence

Follow these best practices when maintaining and using CA Business Intelligence:

- Install and maintain one universe per CA Technologies product.
- Do *not* modify the default universe. Instead, copy it and modify the copy. Otherwise, your changes can be erased when you apply service packs, patches, and other updates. Back up all your changes and then apply the patches to your customized universe.
- Reports:
  - Verify that the services in Central Configuration Manager (CCM) are running, when the reports stop running.
  - Do not overwrite predefined reports.
  - Always use a predefined report as a base to build a custom report and maintain consistent formatting in all reports.
  - Administrators *can modify all the reports and can create* new reports that are based on the existing universe. However, administrators must not add any reports to the existing folders.
  - Both administrators and end users *must not* change pre-defined reports. Any changes to those reports are applied to all other users using the same CA Business Intelligence instance. Instead, both administrators and end users must create their own custom folders, copy the reports there, rename them, and customize them.
  - Both administrators and end users must add new reports that they create to their custom folders.

Install CA Process Automation

CA Process Automation integrates with the CA Service Management products to automate the workflow business processes.

Important! If you use CA Process Automation, we recommend that you do *not* install the CA Process Automation domain orchestrator and CA Process Automation components on the same computer.

You can also configure CA Process Automation to use CA EEM as an authentication server.

Note: If you have installed CA EEM and CA Process Automation and integrate one or more CA Service Management products with these common components, ensure that you provide the same CA EEM information that you provided while installing CA Process Automation for auto-integration to be successful.

Follow these steps:

1. From the product download page (https://support.ca.com/irj/portal/DownloadCenter) use the following DVDs for installation:
    a. CA Process Automation 4.2 SP02 (4.2.2) Third Party Prerequisites - DVD 1 - DVD07090259E.iso
    b. CA Process Automation 4.2 SP02 (4.2.2)Product Installation - DVD 2 - DVD07090455E. iso
2. Follow the Installation wizard to complete the installation process.

Note: For information about implementing multi-tenancy with CA Process Automation, see the CA Process Automation installation and configuration documentation.

Step 4 - Install or Upgrade

Complete the following for installing CA Service Management or upgrading from an earlier release version to CA Service Management 14.1:

- If you are an existing customer and want to upgrade to CA Service Management 14.1, follow the procedures described in Upgrade to CA Service Management (see page 293).
- If you are new customer, follow the procedures described in Install CA Service Management (see page 296).

Upgrade to CA Service Management

The CA Service Management installer automatically detects the existing version of the products and upgrades them with minimal or no user intervention. You can upgrade the following products:

- Upgrades Supported for CA Asset Portfolio Management (see page 294)
- Upgrades Supported for CA Service Catalog (see page 295)
- Upgrades Supported for CA Service Desk Manager (see page 295)
- Upgrades Supported for Unified Self-Service (see page 295)

Important! You must install CA Business Intelligence Release 4.1SP3 (see page 285) before you upgrade CA Service Management.

Note: If you are planning to upgrade a product that was integrated and configured with Active Directory in an earlier release, before upgrading to CA Service Management 14.1, ensure to create the CasmAdmin user and OpenSpaceAdminGroup. Associate the CasmAdmin to the OpenSpaceAdminGroup in the Active Directory.

To upgrade the products, follow these steps:

1. Review the upgrade considerations and verify the upgrade prerequisites for the products. For more information, see the Upgrade CA Service Catalog (see page 579), How to Upgrade CA SDM (see page 399), Migrate CA APM Using the Migration Tool Kit (see page 325), and Upgrade Unified Self-Service (see page 295).

2. Launch the CA Service Management installer on the servers that you want to upgrade. The installer automatically detects the installed product release version and upgrades it to 14.1.

After you have upgraded, perform additional steps to finalize the integration with the common components (see page 546) and finalize the integration with the products (see page 559) depending upon the products you have upgraded.

Important! At the end of deployment, the services must be restarted for the integration changes to come to effect.

Upgrades Supported for CA Asset Portfolio Management

Upgrades from CA Asset Portfolio Management (CA APM) releases 11.3.4, 12.6, 12.8, and 12.9 are supported. Ensure to follow the onscreen instructions on the installation wizard while upgrading as upgrade instructions for CA ITAM release 11.3.4, 12.6, 12.8 may vary from CA ITAM 12.9.

Note:

- If you are upgrading CA Asset Portfolio Management from an earlier release to CA Service Management 14.1, ensure to set the database compatibility level to MS SQL Server 2008.
- If you are upgrading CA ITAM from an earlier release to 14.1, the changes you made to configuration files from an earlier release is not automatically merged with 14.1. Refer to the backup files located in *%Temp%\ITAM* directory and manually merge these changes with the current installed version.

Upgrades Supported for CA Service Catalog

Upgrades from CA Service Catalog releases 12.6, 12.7, 12.8, and 12.9 are supported.

Upgrades Supported for CA Service Desk Manager

Upgrades from CA Service Desk Manager releases 11.2, 12.1, 12.5, 12.6, 12.7, and 12.9 are supported.

Upgrades Supported for Unified Self-Service

Upgrades from CA Open Space releases 2.0, 2.0 SP1, and 3.0 are supported.

Pre-upgrade tasks

Complete the following tasks before you upgrade to Unified Self-Service:

- Back up the existing LAR file to retain any customization you made. Upgrading to Unified Self-Service updates the existing LAR file which overwrites any existing customization.
- Stop the existing CA Open Space server. On the computer where you installed CA Open Space, select Start, All Programs, CA, Open Space, Stop.

Post-upgrade tasks

After you run the installer and upgrade to Unified Self-Service, complete the following steps:

- If you have backed up the previous LAR file, apply the customizations in the new LAR file that has been created after the installation.
- Open the existing onboarded tenant page, if any, to verify the successful upgrade.

  Note: If you upgraded from Open Space 2.0 or Open Space 2.0 SP1, the Start menu does not contain the Default Tenant - Web Client option.

- If you want the Unified Self-Service users to view the assets requested from CA Service Catalog, you must enter the My Resources offering ID from CA Service Catalog. You can obtain this ID from CA Service Catalog.
  For example, log in to CA Service Catalog , navigate to Catalog, Offerings, IT Support Services,

Service Management, My Resources, and obtain the ID from the Details page. Ensure that the CA Service Catalog server is imported with the Service Management content pack. For more information about the content pack, see the CA Service Catalog documentation.

Install CA Service Management

You can use the CA Service Management Installer to install, upgrade, configure, and integrate the CA Service Management products in the solution. The installer performs the prerequisite checks and mandatory validations before installing the products.

Important! If you plan to use CA EEM that is configured with Active Directory, before installing CA Service Management 14.1, ensure to create the CasmAdmin user and OpenSpaceAdminGroup. Associate the CasmAdmin to the OpenSpaceAdminGroup in the Active Directory.

Ensure that you have also identified your installation scenario (see page 274) and planned for your installation (see page 280) accordingly, before you proceed with this section.

Note: For Windows SQL Server database, mdbadmin is the default user across all CA Service Management products.

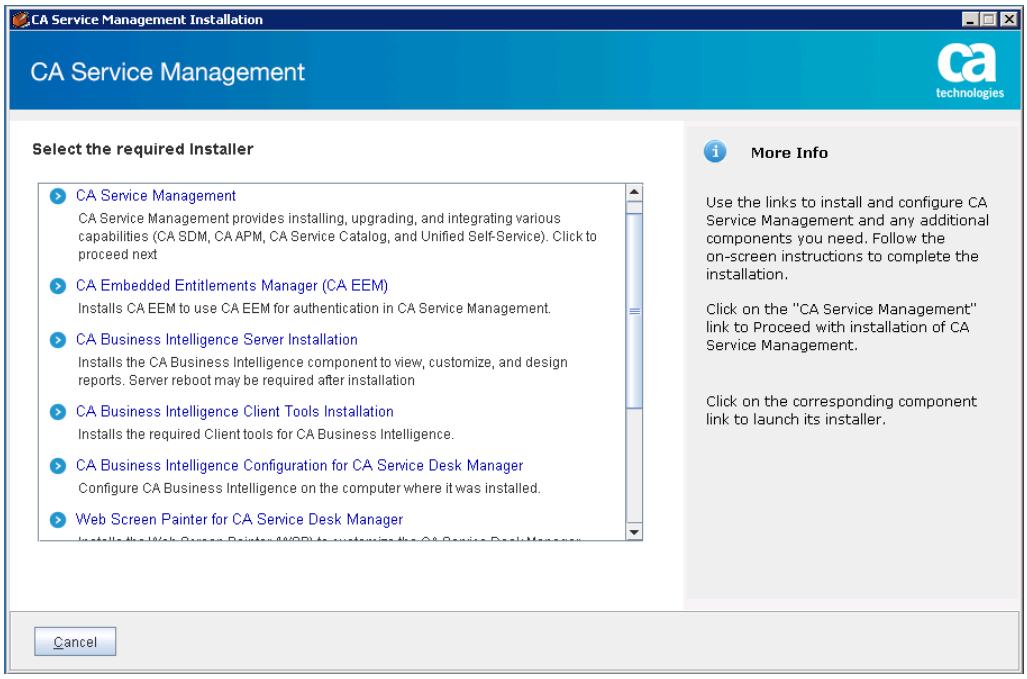
Follow these steps:

1. Launch the CA Service Management Installer.

   Note: If the Installation wizard does not open automatically, start the installation by double-clicking the setup.exe file, located at the root of the installation folder.

2. Click **Select Language** to select a language from the list.

3. Select **CA Service Management** in the **Select the required installer** screen. This option lets you install the products such as CA Service Desk Manager, CA Service Catalog, CA Asset Portfolio Management, and Unified Self-Service that are part of the the solution.



Select the required installer

4. Review and Accept the License Agreement Information.

5. Select SQL Server or Oracle as the database type in the Database Configuration screen. Enter the following information as per the selected database:
   If you have selected SQL Server, the following fields require explanation:

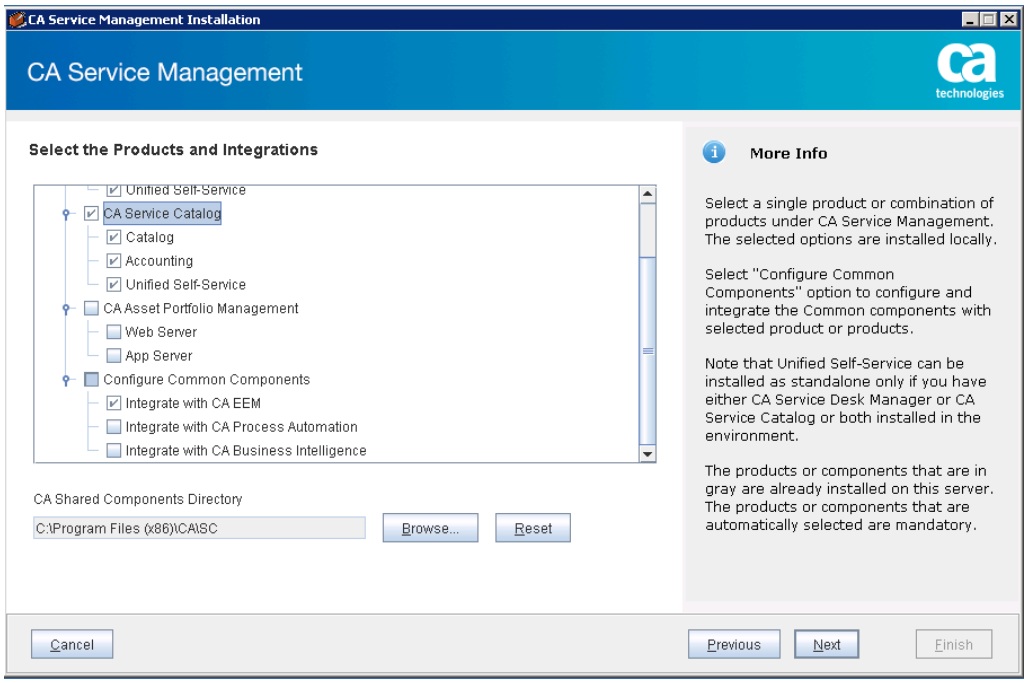
   - **Database Server**: The host name of the database server. If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
   - **Database Name**: Specifies the Database name (mdb), the name of the target DBMS. The default value is mdb.
   - **Database Port**: Specifies the port identifier for the target DBMS.
   - **Database Server Instance**: The database instance name. Leave this field blank if you are using the default instance.
   - **Database Admin User**: For SQL Server, “sa” is the default value. This is the admin user with permission to create user and schema.
   - **Database Admin Password**: Specifies the database password of user specified by database admin user. There is no default value for this parameter.
   - **mdbadmin Password**: Specify the password for the user specified for the mdbadmin user.
   - **Confirm mdbadmin Password**: Confirm the mdbadmin user password.

   If you have selected Oracle , the following fields require explanation:

- **Database Server**: The host name of the Oracle database server. If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
- **Oracle Service Name**: Specifies the Oracle Service name.
- **Listener Port**: Specifies the listener port for the database.
- **Net Service Name**: Identifies the Net Service Name of the Oracle database where the database resides. If the database is remote, use the Net Service Name defined within the Oracle client on the local computer. CA SDM and CA APM access the database using a local installation of the Oracle client, which may specify a Net Service Name that is different than the service name on the Oracle server.
- **DBA User Name**: Identifies the name of an Oracle user with DBA access. The default value for DBA user is SYS.
- **DBA User Password**: Identifies the password for the DBA user.
- **mdbadmin Password**: Specify the password for the user specified for the mdbadmin user.
- **Confirm mdbadmin Password**: Confirm the mdbadmin user password.
- **Tablespace Path (on DB Server)**: Specifies the tablespace path on the database server.
- **Oracle Home Path**: Specifies the Oracle client 32-bit path.
- **Data Tablespace Name**: Specifies the name of the data tablespace. The default value is MDB_DATA.
- **Index Tablespace Name**: Specifies the index Tablespace Name: Default value is MDB_INDEX.

6. Select any or combination of products in the **Select the Product and Integrations** screen**.**

Note: Ensure that you have verified the prerequisites and reviewed the planning considerations before proceeding with installing any or combination of these products.



Select the Products and Integrations

For example, if you have selected CA Service Catalog, you install CA Service Catalog (see page 590). Similarly, you can install CA Service Desk Manager (see page 479) and install CA Asset Portfolio Management (see page 301).

Note: CA Asset Portfolio Management App Server uses the reserved port 9080 and CA Service Catalog uses the reserved port 7777. Reserved ports are set internally and are not configurable during CA Service Management products installation. You must not configure any other services on these reserved ports.

Note: If you are installing CA Asset Portfolio Management capabilities on the same server, ensure to select your required options (either both App Server and Web Server options or any one of these options). The CA Service Management installer does not allow you to add these options later, on the same server.

7. Click **Browse** to locate the installed Common Components (see page 283)as per your installation requirement.
   Configures and integrates CA EEM, CA Process Automation, and/or CA Business Intelligence with the selected CA Service Management product or products.

8. Review the Installation Prerequisites report and take corrective measures to proceed with the installation.

9. Enter the required server details in the selected Common Component Details page. For example, if you have selected CA Process Automation as the common component, enter the server details in the **CA Process Automation Details** screen. Use the **Reintegrate CA Process Automation on local server** option to reintegrate common components (CA EEM, CA Process Automation, and CA Business Intelligence) on a system even after completing the CA Service Management installation. It allows you to reconfigure the common components again.
   For example, if while upgrading to CA Service Management, you have already integrated CA Service Desk Manager and CA EEM and then you decide to change the CA EEM server details and want to reintegrate these common components, you should select this option to reintegrate these products. Note this option only reintegrates the common components for CA Service Management.

10. Review the **PreInstallation Configuration Summary**.

11. Review the **Installation progress** information and click **Install** to install the selected product /products.

12. Review the log files stdout.txt and stderr.txt in the C:\ directory, If the installation failed. Fix the errors and click **Retry Install**.

13. Review the Installation Guidance Report summary to ensure that the installation succeeded.

You have successfully installed CA Service Management. Perform additional steps to finalize the integration with the common components (see page 546) and finalize the integration with the products (see page 559) depending upon the products you have installed.

Important! At the end of deployment, the services must be restarted for the integration changes to come to effect.

Note: As part of your CA Service Management product installation, if you have first selected and installed CA Service Catalog followed by other products (CA ITAM and/or CA SDM) and you try to integrate these products with CA process Automation, after installation it is observed that CA Process Automation configuration is not updated with CA ITAM and CA SDM host names under the CA Service Catalog and CA SDM dataset respectively.

After the installation of all CA Service Management products, launch the CA Service Management installer from the CA Service Catalog server from where you first installed or upgraded the application. On the **Select the Required Installer** page, scroll to the last option **Integrate pre-installed solution components** and follow the installation wizard instructions to complete the Redo Integration successfully.

Implementing CA IT Asset Manager

This topic contains the following information:

Important! Review the CA Service Management Release Notes (see page 69). Do not start your installation until you have read and understood the information.

Understand the CA Asset Portfolio Management Architecture

This article describes the CA Asset Portfolio Management components, and architecture.

CA Asset Portfolio Management Components

CA Asset Portfolio Management consists of the following components:

Web Server

The Web server is the main server that hosts the web application and builds the CA APM user interface. This server communicates with the user and the application server.

The following fields require explanation:

Web Server or Load Balancer IP/Host

The CA APM installation, by default, sets this field to the web server host name.

- In a single web server environment, you can enter the web server host name, or the web server IP address.
- In a multiple web server environment, you can enter either the web server host name, or the IP address of the Load Balancer.

Note: The web server can be registered with a different name in the Domain Name System (DNS) than what is registered as the web server host name. In this situation, specify the different name in this field.

You can configure additional web server components after you install the product.

Application Server

The application server is the server that connects the database server and the web server for CA APM. The business and data access logic reside on the application server. To allow for scalability, the application server and web server are on two distinct servers.

You can have more than one application server. The Export Service component and the Storage Management Service component must be installed on one of the application servers, but not necessarily on the same server.

The following fields require explanation:

Application Server or Load Balancer IP/Host

The CA APM installation, by default, sets this field to the application server host name.

- In a single application server environment, you can enter the application server host name, or the application server IP address.
- In a multiple application server environment, you can enter either the application server host name, or the IP address of the Load Balancer.

The application server can be registered with a different name in the Domain Name System (DNS) than what is registered as the application server host name. In this situation, specify the different name in this field.

You can configure more application server components after you install the product.

CA EEM

CA APM uses CA EEM for authentication. Other products that need CA EEM for authentication can use the same CA EEM server that CA APM uses.

- To manage security centrally for multiple CA Technologies products, specify the name, location, and login credentials for the existing CA EEM server.
- To manage CA APM security independently from other CA Technologies products, install CA EEM on any single application or web server other than the one where the existing CA EEM is installed.

CA Business Intelligence

CA Business Intelligence administers, monitors, and configures the reporting environment. CA APM uses CA Business Intelligence to integrate, analyze, and present information required for effective enterprise IT management.

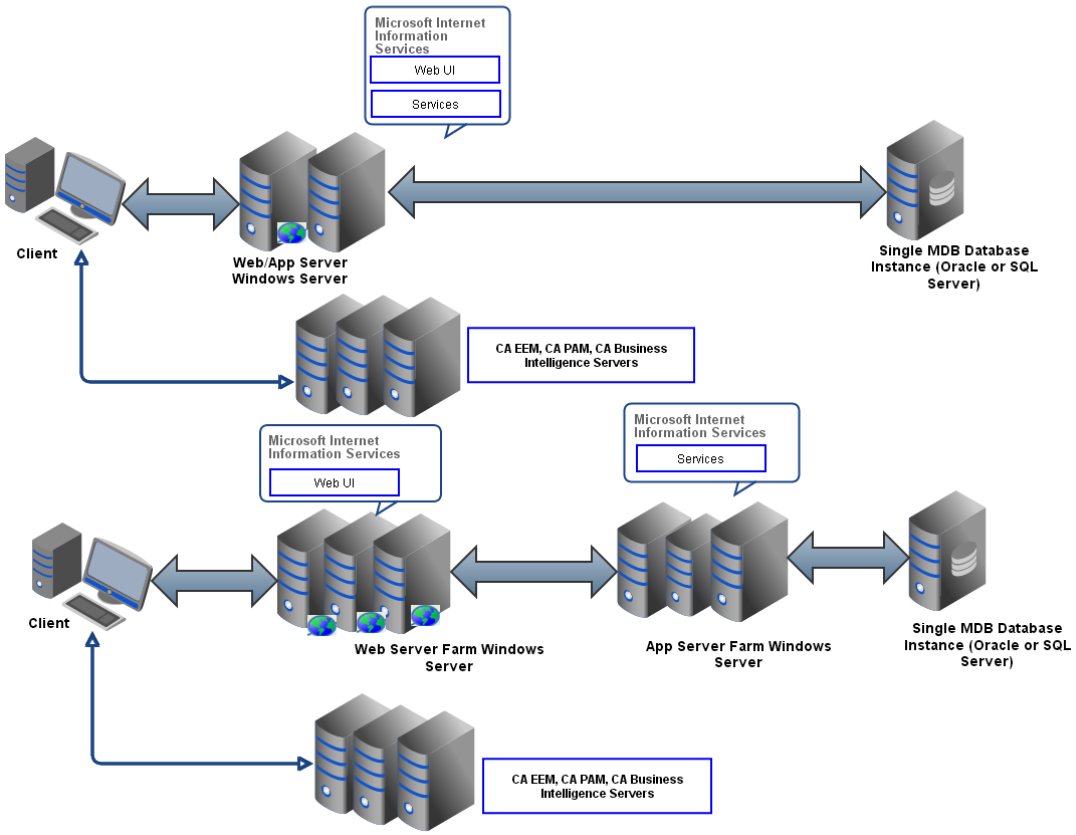
For information about the login credentials and connection information that you enter for the CA Business Intelligence component, see How to Integrate CA APM and CA Business Intelligence.

CA Process Automation Manager

CA APM and CA Process Automation integrate to let you set up and configure a notification process that delivers notifications to specific recipients after a defined event occurs. CA APM provides email notification processes with the product. These processes are delivered in files that are included on the product installation media. You import the files into CA Process Automation and specify process parameters in CA Process Automation and CA APM.

CA Asset Portfolio Management Architecture

The following figure shows the architecture for CA Asset Portfolio Management:



How to Install CA APM

This article describes the process of installing the CA APM

- Step 1: Verify the Installation Prerequisites and Checklist (see page 304)
- Step 2: Install CA APM (see page 309)
- Step 3: Upgrade to JRE 1.8.0_45 (see page 312)
- Step 4 (Optional): Update the Apache Tomcat Configuration File (see page 314)
- Step 5: Start the Services (see page 314)
- Step 6: Start the Web Interface (see page 315)
- Step 7: Verify the Installation (see page 317)

- Step 8 (Optional): Secure Network Communication Configuration (see page 318)
- Step 9: Configure Product Components (see page 319)

Tip! Before you install, ensure that you have performed the prerequisite tasks that are described in Step 1: Verify the Installation Prerequisites and Checklist (see page 304)

Step 1: Verify the Installation Prerequisites and Checklist

We recommend that you complete the prerequisites and checklist before you proceed with the installation and setup of CA APM.

- Verifying System Requirements (see page 304)
  - Hardware Requirements (see page 304)
  - Software Requirements (see page 305)
- Perform the Pre-Installation Tasks (see page 306)
  - Verify the Internet Information Services Installation (see page 306)
  - Remove CA iTechnology iGateway (see page 306)
  - Install Pentaho Data Integration (Kettle) (see page 307)

Verifying System Requirements

Ensure that your computer meets the requirements that are described in this topic.

Hardware Requirements

The following hardware requirements assume that you have between 80 and 100 concurrent users. For assistance with deployment architectures exceeding 100 concurrent users, contact CA Support (http://www.ca.com/us/support.aspx).

Component	Web Server and Application Server	Your Entry
Processor	3 GHz (dual core processor)	
RAM	8 GB	
Free Disk Space	5 GB	
Hard Drive Space	--	

Component	Database Server	Your Entry
Processor	3 GHz (dual core processor)	
RAM	8 GB	
Free Disk Space	--	
Hard Drive Space	4 GB	

Important! CA APM has time-sensitive processes. Verify that all servers are set to their correct date and time with their respective time zones.

Software Requirements

Component	Version	Comments	Your Entry
Java Runtime Environment (JRE)	1.7 (32-bit)		
CA EEM		Install CA EEM (see page 283) 12.51 CR02 using the CA Service Management Installation Media or upgraded an earlier installed version of CA EEM to CA EEM 12.51 CR02.	
JDBC Drivers			
Microsoft SQL or Oracle database server			
Internet Information Server (IIS)	7.5	Install IIS (see page 304)for CA SAM implementation.	
Microsoft .NET Framework	4.0		
Microsoft .NET Feature 3.5 for Windows Server 2012			
Windows Installer	5.0		
Microsoft Web Services Enhancements (WSE)	3.0		
CA Software Asset Manager		Download CA SAM from CA Support (http://www.ca.com/us/support/ca-support-online/product-content/recommended-reading/technical-document-index/ca-software-asset-manager-solutions-patches-catalogs-index.aspx). Required to manage software assets.	
CA SCM		CA SCM (and any cumulative releases) before installing CA APM to integrate CA SCM Release 12.6 with CA Asset Portfolio Management.	
Pentaho Data Integration (Kettle)	4.4	**(Optional)** Required if you are migrating from UAPM 11.3.4 to CA Asset Portfolio Management 14.1	
CA Business Intelligence		**(Optional)** Install CA Business Intelligence (see page 285) to configure reports.	

Component	Version	Comments	Your Entry
CA Process Automation		**(Optional)** Install CA Process Automation (see page 292) for event notification processing.	

Review the Supportability Matrix (see page 119) to understand the supported versions.

Perform the Pre-Installation Tasks

Perform the following pre-installation tasks to prepare the server for CA APM installation.

Verify the Internet Information Services Installation

Before you install CA APM, verify that Internet Information Services (IIS) is installed on all application and web servers. If the service is not on a server, add the service before you begin the installation.

Follow these steps:

1. For each application and web server, log in to the server.
2. Open the Control Panel (Administrative Tools, Services).
3. Verify that the IIS Admin service is on the server.

Install IIS version 7.5

1. From Server Manager, select Roles.
2. In the Roles Summary area, click Add Roles and click Next.
   The Select Server Roles dialog appears.
3. Select Application Server from the Roles list and click Next twice.
   The Select Role Services dialog for the Application Server role appears.
4. Select Web Server (IIS) Support and, under Windows Process Activation Service Support, select HTTP Activation.
5. If you are prompted to install more role services and features, click Add Required Role Services and click Next twice.
6. Verify that the summary of selections is correct and click Install.
7. Click Close after the installation completes.

Remove CA iTechnology iGateway

CA iTechnology iGateway, which is installed with CA EEM, is a shared component that various CA Technologies products use. CAiTechnologyiGatewayis a web server that sends requests and receives replies using the http protocol. CAiTechnologyiGatewaycan be installed with other products also.

If CA iTechnology iGateway exists on the computer where you are installing CA EEM, determine if it is 32-bit or 64-bit. If CAiTechnologyiGatewayand your CA EEM 12.51 server are both 32-bit or both 64-bit, no action is necessary. However, if the two products do not match (for example, one is 32-bit and the other is 64-bit), remove CA iTechnologyiGatewayand start the CA EEM installation. The correct version ofCA iTechnology iGatewayis installed when you complete the CA EEM installation.

Note: Various CA Technologies products or components install the 64-bit version of CA iTechnology iGateway, including the 64-bit CA Technologies eTrustITM agent.

Follow these steps:

1. On the computer where you are installing CA EEM, remove CA iTechnology iGateway.

   Note: To uninstall CA iTechnology iGateway successfully, first uninstall all products that are dependent on CA iTechnology iGateway.

   a. Open the Control Panel. Double-click Add or Remove Programs.
   Select CAiTechnologyiGateway and click Remove.

2. Remove theiGatewayandiTechnologyregistry key folders from the following location:

   `HKEY_localmachine\SOFTWARE\ComputerAssociates\`

3. Delete the IGW_LOC environment variable.

   a. From the Start menu, right-click My Computer and select Properties. Click the Advanced tab.
   Click Environment Variables. Select IGW_LOC in the System variables list, click Delete, and click OK.

4. Restart the computer.

5. Install CA Asset Portfolio Management.

6. When the CA Asset Portfolio Management installation is complete, reinstall the uninstalled componentsonthe computer where CA EEM is installed.

   Note: We do not recommend the installation of the CA Asset Portfolio Management components, except the Management Database, on a 64-bit computer that hosts a 64-bit Oracle database server.

Install Pentaho Data Integration (Kettle)

Install Pentaho Data Integration (Kettle) on the local computer where you install CA APM. Kettle is required only if you are upgrading from Release 11.3.4 to Release 14.1 or if you previously upgraded from Release 11.3.4 to Release 12.9.

Note: You can install Kettle before or after installing CA APM. However, we recommend that you install Kettle before you install CA APM.

Follow these steps:

1. Log in as the administrator to the computer where you are installing CA APM.
2. Download Kettle from the CA Support website and install Kettle on the server where you install CA APM Release 12.9.
    a. Click the following link (ftp://ftp.ca.com/pub/ca_itam/ca_apm/apm12_8/pentaho-kettle-4.4.0.zip)
    b. Savepentaho-kettle-4.4.0.zip in the desired directory.

       Example: C:\Program Files (x86)\CA\ITAM\
    c. Extract the contents ofpentaho-kettle-4.4.0.zip.

       A new folder that is named Kettle is created. Note the path of the folder.
3. Create an environment variable for Kettle by completing these steps.
    a. Click Start, Run, and type sysdm.cpl to access System Properties.
    b. Click the Advanced tab.
    c. Click Environment Variables.
    d. Click New in the System variables section and enter the following details:
       Variable Name
       KETTLE_HOME
       Variable value
       Path of the Kettle folder.

       Note: Ensure that the path is set to the parent folder that contains the “data-integration” folder, for example, C:\Program Files (x86)\CA\ITAM\Kettle.
    e. Click OK and exit System Properties.

Step 2: Install CA APM

Launch the CA Service Management Installer (see page 296) and complete the following steps to install CA APM:

Follow these steps:

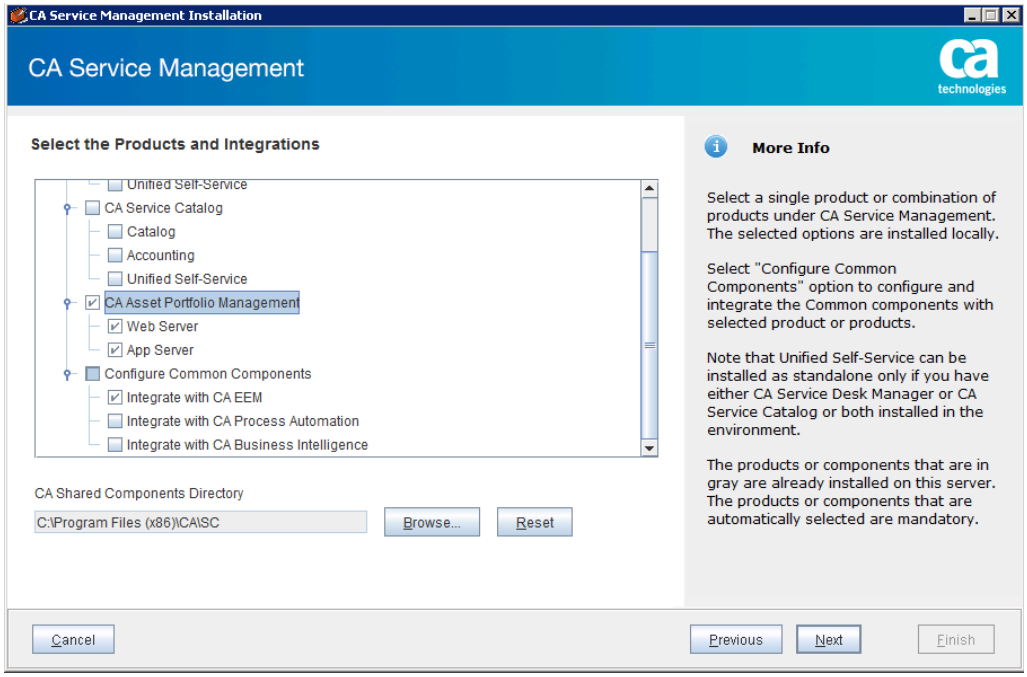
1. Select a language from the **Language Selection** screen.
   The installer provides additional information about the selected options on the right pane.

2. Accept the license agreement.

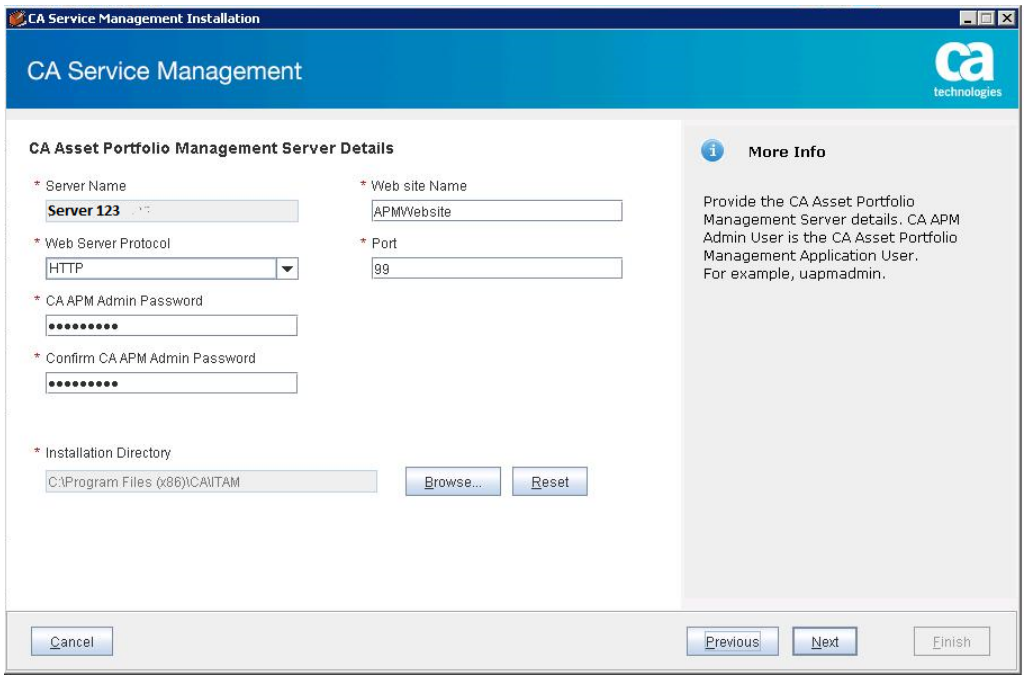
3. Enter the database information correctly.

> **Note:** Verify that you are providing a valid tablespace path if you have an Oracle database. The database installation fails if this path is invalid. The following path is an example of a valid Oracle tablespace path: C:\app\Administrator\oradata\Oracle_Service_Name.

4. Select **CA Asset Portfolio Management** from **Select the Products and Integrations** screen.



5. Provide the CA Asset Portfolio Management Server Details:



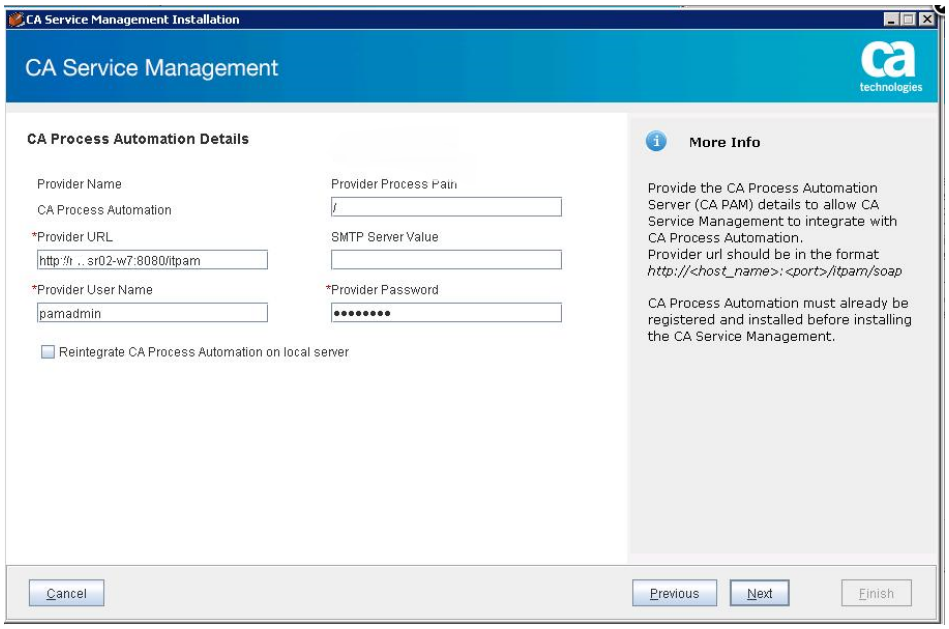
6. Select the Configure Common Components to integrate CA Asset Portfolio Management with CA EEM, CA Process Automation, or CA Business Intelligence.

    a. Providee the CA EEM server details for authentication and authorization. For more information, see Install CA EEM (see page 283)

    
    CA Embedded Entitlements Manager (CA EEM) Details

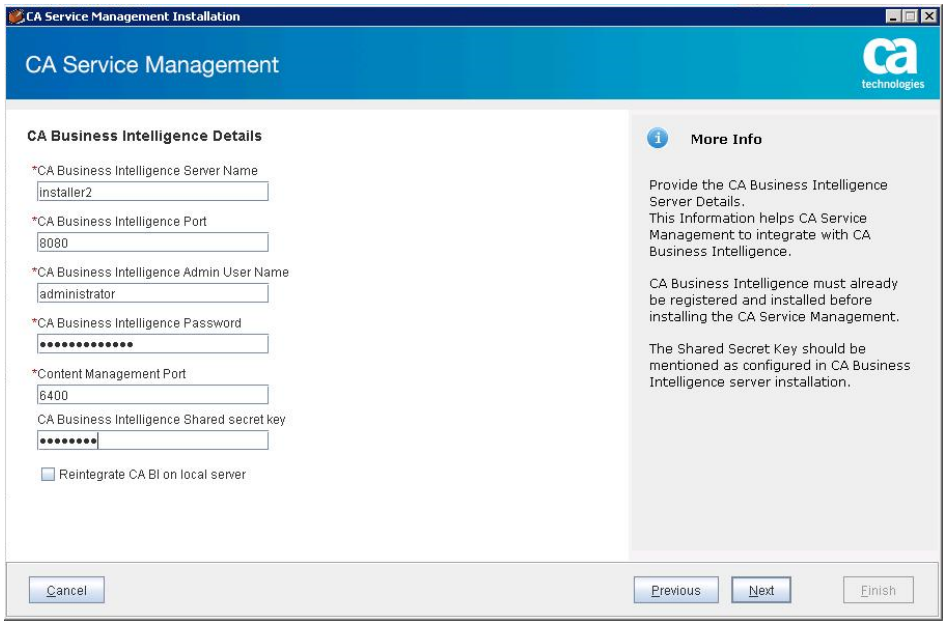
    Click **Next**.

    b. Integrate with CA Process Automation for event notification processing. For more information, see Install the CA Process Automation. (see page 292)



Click **Next**.

c. (Optional step). Install CA Business Intelligence for generating and viewing reports.



CA Business Intelligence Details

Note: In a web farm setup, the CA Business Intelligence and CA EEM panels do not appear if these common components are already installed on one of the servers in the web farm.

Click **Next**.

7. Review the Installation Progress Screen. Click **Install** to begin installation.

8. After the installation is complete, click **Finish**.

Step 3: Upgrade to JRE 1.8.0_45

This article describes the process of upgrading to JRE 1.8.0_45 to successfully implement CA IT Asset Manager.

- Upgrade CA CASM JRE to JRE 8 (see page 312)
- Upgrade AMS JRE7 to JRE8 (see page 313)

Upgrade CA CASM JRE to JRE 8

Follow these steps:

1. Stop the CA CASM service.

2. Navigate to http://tomcat.apache.org (http://tomcat.apache.org/) to download Tomcat 8.0.21. Extract the contents and rename the folder to Tomcat.

3. Navigate to http://www.oracle.com/technetwork/java/javase/downloads to download JRE 8u45.

4. Install JRE8u45 in a temporary location.

5. Copy the Tomcat and JRE 8 folders from the temporary location.

6. Navigate to CASM installation folder and backup the existing Tomcat and JRE folders.

7. Paste the folders that you copied in step 5.

8. Rename the “JRE 8” folder to “JRE”.

9. From the Tomcat backup, copy the following folders to the new Tomcat folder:

   - common
   - server
   - shared
   - webapps/balancer
   - webapps/casm

10. Navigate to SharedComponents\AMS, copy “AMSService.bat” to CASM folder and rename it to “CASMService.bat”

11. Edit “CASMService.bat” file to set JRE_HOME variable to point to JRE.

12. Open the command prompt, navigate to SharedComponents, CASM and execute the following command:

    ```
    CASMService install <service name>
    ```

    For Example:

    ```
    CASMService install CASM
    ```

13. Navigate to new Tomcat, conf.

14. Open server.xml and change the default port 8080 to existing port.

15. Start the service.

16. Delete the old service “CA CASM”.

Upgrade AMS JRE7 to JRE8

Follow these steps:

1. Stop the AMS service “Apache Tomcat 7.0 AMS”

2. Navigate to http://tomcat.apache.org (http://tomcat.apache.org/) to download Tomcat 8.0.21. Extract the contents and rename the folder to Tomcat.

3. Navigate to http://www.oracle.com/technetwork/java/javase/downloads to download JRE 8u45.

4. Install JRE8u45 in a temporary location.

5. Copy the Tomcat and JRE 8 folders from the temporary location.

6. Navigate to SharedComponents\AMS (AMS Installation folder) and backup the existing Tomcat and JRE 7 folders.

7. Paste the Tomcat and JRE8 folders that you copied in step 5.

8. From the Tomcat backup, navigate to webapps, copy the AMS folder, and paste it in the new Tomcat – webapps folder.

9. Navigate to SharedComponents\AMS, and edit the "AMSService.bat" to set JRE_HOME variable to point to JRE 8.

10. Open the command prompt, navigate to SharedComponents\AMS and execute the following command:

    ```
    AMSService install <service name>
    ```

    For Example:

    ```
    AMSService install AMS
    ```

11. To configure the port number in the server.xml, navigate to new Tomcat, conf.
12. Open server.xml and change the default port 8080 to existing port.
13. Start the service.
14. Delete the old service “Apache Tomcat 7.0 AMS”.

Step 4 (Optional): Update the Apache Tomcat Configuration File

This step is required only when you want to change the AMS port. The Common Asset Viewer lets you view discovered and owned data for an asset that has been linked through reconciliation. This data includes system configuration, operating system, system devices, and file systems. The Common Asset Viewer requires the Apache Tomcat server, which is included with the CA APM installation. You first update the port in the Apache Tomcat configuration file. Then, you change the port in the product (Administration tab, System Configuration, Common Asset Viewer).

Note: The Tomcat port number for CA APM defaults to 9080. If another product that is integrated with CA APM uses this port number, change the port number in CA APM so that you do not have a conflict.

Follow these steps:

1. On the application server where the Common Asset Viewer is installed, navigate to one of the following folders, depending on your server:
   C:\Program Files\CA\SC\AMS\Tomcat\conf (for 32-bit operating systems)
   C:\Program Files (x86)\CA\SC\AMS\Tomcat\conf (for 64-bit operating systems)
2. Select and open the server.xml file.
3. Navigate to the following section of the server.xml file:
   <Connector port="9080" protocol="HTTP/1.1"connectionTimeout="20000" redirectPort="
   8443" />
4. Update the Tomcat port number with the same number that CA APM uses (Administration tab, System Configuration, Common Asset Viewer).
5. Save the server.xml file.

Step 5: Start the Services

After the installation is complete, start all services.

Note: In certain circumstances, after the product installation, you can receive a message that CA Business Intelligence was installed but requires you to restart the web server. Restart the web server before verifying that the CA Business Intelligence services are started.

Follow these steps:

1. Open the Control Panel (for example, click Start, Settings, Control Panel).
2. Double-click Administrative Tools.
3. Double-click Services.
4. Locate and start each of the following services:

- Apache Tomcat 7.0 Application Management Suite (AMS) Service
- CA Asset Portfolio Management - Data Importer Engine
- CA Asset Portfolio Management - Event Service
- CA Asset Portfolio Management - Export Service
- CA Asset Portfolio Management - Registration Service
- CA Asset Portfolio Management - HW Reconciliation Engine
- CA Asset Portfolio Management - LDAP Import Service
- CA CASM

  Note: For performance reasons, we recommend that you do not start the CA CASM service when you do not use multi-tenancy.

- CA iTechnology iGateway 4.6

5. To verify CA Business Intelligence services with the Central Configuration Manager, select Start, Programs, BusinessObjects XI Release, BusinessObjects Enterprise, Central Configuration Manager. The Central Configuration Manager opens.
If any service is not started, right-click the service and select Start.

Step 6: Start the Web Interface

After the installation is complete, you can start the web interface to verify that CA APM is ready to use. After you verify that the web interface starts, provide all administrators with the URL and login credentials to log in and prepare the product for users. Administrators can then set up security, configure the user interface, set up hardware reconciliation, and, if necessary, configure the product components. After the administrators prepare the product, they can provide users with the URL and login credentials.

After you install IIS and ASP.NET on the computer where you plan to install CA APM, ensure that you register ASP.NET with IIS, before you start the web interface.

Follow these steps:

1. Depending on your Windows server, complete one of the following steps:

   - (On Windows Server 2008) Complete the following steps:

     a. In the command prompt, navigate to the appropriate Microsoft.NET framework folder. For example, C:\Windows\Microsoft.Net\Framework64\v4.0.30319 or C:\Windows\Microsoft.Net\Framework\v4.0.30319.

     b. Run the executable file, aspnet_regiis.exe/i
     ASP.NET is now registered with IIS.

   - (On Windows Server 2012) Complete the following steps:

     a. i. Open the Server Manager.

     ii. Under the Manage menu, select **Add Roles and Features**.
     The Add Roles and Features Wizard opens.

     iii. Follow the on-screen instructions and select the installation type and the destination server.

     iv. In the Select server roles pane, under **Roles**, expand **Application Server**, and select the appropriate ASP.NET version and click **Next**.

     v. Follow the on-screen instructions and complete the installation.

     ASP.NET is now registered with IIS.

2. Start the web interface using one of the following methods:

- Open a supported web browser and enter the appropriate URL in the following format:

  `http://servername:port/itam`

  - Replace servername and port with the name of the server and the port that are hosting the CA APM web servers.

Note: If the Internet Explorer browser security is set to high, a content warning message appears when you start the web interface. To avoid this message, add the web site to your trusted sites or lower your security settings.

- A Start menu shortcut is created on your web server that references the URL location. Click Start, Programs, CA, Asset Portfolio Management, Asset Portfolio Management.

  To log in to CA APM, enter the following default credentials:

- **User Name**
  uapmadmin
- **Password**
  uapmadmin

> **Note:** : If you changed the password during the installation, use the password that you created.

In some situations, a browser error or a user name error appears. You can resolve these errors by following the troubleshooting instructions in the message.

Step 7: Verify the Installation

After you have completed all installation procedures, you can verify that CA APM was installed successfully.

Follow these steps:

1. Log in to the servers where you installed CA APM.
2. (Windows Server 2008 or Windows Server 2012) From the Start menu, select Control Panel, Programs and Features.
3. Verify that the following component is available on all applicable servers:
   CA Asset Portfolio Management

   You have completed the installation verification.

> **Note:** If you backed up the Storage folder contents before installing, restore the contents now. Use the Storage folder contents that you copied and paste them into the following location:
>
> [ITAM Root Path]/Storage/

If you receive a prompt about folders that already exist, merge the folders.

Additional Products Installed

The following products are installed when you install CA APM:

- Common Asset Viewer
- CORA 12.5.0.34
- Common Administration for Service Management (CASM)

- Migration Toolkit

Step 8 (Optional): Secure Network Communication Configuration

After the installation is complete, configure CA APM for non-secure or secure network communication. For secure network communication (https), first configure IIS on the product servers to support the Secure Socket Layer (SSL) protocol. Then, set the CA APM configuration parameters for secure network communication.

Complete the following actions:

1. Configure IIS for secure network communication (see page 318).
2. Configure CA APM for secure network communication (see page 318).

Configure IIS for Secure Network Communication

Configure IIS on the product servers to support the Secure Socket Layer (SSL) protocol.

Follow these steps:

1. Launch the Internet Information Services (IIS) Manager on the CA APM web server.
2. Select Server Certificates.
3. Click Create Self-Signed Certificate and specify a certificate name.
4. Select the web site (on the left) where CA APM is installed (for example, Default Web Site).
5. Click Bindings under Actions on the right.
   The Site Bindings dialog opens.
6. Click Add.
7. Select https for the Type.
8. Specify the port and the SSL certificate name.
9. Perform these same steps on the CA APM application server.

Configure CA APM for Secure Network Communication

Configure CA APM on the product servers to support the Secure Socket Layer (SSL) protocol.

Follow these steps:

1. Log in to the product and navigate to Administration, System Configuration.
2. Click Web Server on the left.
3. Change the server protocol to https and click Save.
4. Click WCF Service on the left.

5. Change the server protocol to https and click Save.

6. Click Application Server on the left and select the Show Advanced Options check box to see all configuration parameters.

7. Change the server protocol to https.

8. Change the server port and the component server port to the port of the https protocol (by default, 443) and click Save.

9. Reset IIS on the web server and the application server.

You can now start the product web interface using secure network communication. Open a supported web browser and enter the following URL:

```
https://servername/ITAM/Pages/UserLogin.aspx
```

Replace *servername* with the name of the server that is hosting the CA APM web server.

Step 9: Configure Product Components

After installing CA APM, you can change the component configurations and configure additional product components. You can configure the following components:

- Recycle Settings in the Application Pool (see page 320)
- Database Server (see page 320)
- Web Server (see page 321)
- Application Server (see page 321)
- Hardware Reconciliation Engine (see page 322)
- CA EEM (see page 322)
- CA Business Intelligence (see page 322)
- CA Process Automation Manager (see page 322)
- Export Service (see page 322)
- Data Importer Engine Service (see page 322)
- Import Driver (see page 323)
- LDAP Data Import and Sync Service (see page 323)
- Storage Manager Service (see page 323)
- CA APM Registration Service (see page 323)
- Common Administration for Service Management (CASM) (see page 323)
- Event Service (see page 323)
- Common Asset Viewer (see page 324)
- WCF Service (see page 324)
- Software Asset Management (see page 324)
- CA Service Desk Manager (see page 325)

Follow these steps:

1. Log in to CA APM as the administrator.

2. Click Administration, System Configuration.

3. On the left, click the product component that you want to configure.

4. Configure the settings and click Save.

5. Recycle the settings in the application pool.
   For more information, see Recycle Settings in the Application Pool (see page 320).

6. Restart the services.
   For more information, see Start the Services (see page 314).

Note: You cannot configure the database server from the System Configuration page. Update the corresponding configuration files for any database server configuration settings.

For more information about changing the component configurations and adding servers, see Manage Product Components (see page 1585).

Recycle Settings in the Application Pool

After you configure a product component through System Configuration, recycle the settings in the Application Pool.

Follow these steps:

1. From the Start menu, open the Control Panel.

2. Double-click Administrative Tools and then double-click Internet Information Services (IIS) Manager.

3. In the Connections pane, expand the server name and click Application Pools.

4. In the Application Pools pane, select ITAM.

5. In the Actions Pane, click Stop and then click Start.

Database Server

The database server is a product component that hosts the Oracle or SQL Server database management system for CA APM. The CA MDB is installed on the database server. The application server, Hardware Reconciliation Engine, and other product components retrieve data from and store data in the CA MDB.

The following fields require explanation:

- **MS SQL Server Instance**
  Defines the name of the MS SQL Server instance that is being configured. Enter the instance name only when multiple SQL Server named instances exist. Leave the field blank if there is only one (default) instance.

Note: You can change the component configurations and configure additional components for your enterprise after you install the product. For more information about changing the component configurations and adding servers, see Managing Product Components (see page 1585).

Web Server

The web server is the main server that hosts the web application and builds the CA APM user interface. This server communicates with the user, the application server, and the database server.

The following fields require explanation:

Web Server or Load Balancer IP/Host

The CA APM installation, by default, sets this field to the web server host name.

- In a single web server environment, you can enter the web server host name, or the web server IP address.
- In a multiple web server environment, you can enter either the web server host name, or the IP address of the Load Balancer.

Note: The web server can be registered with a different name in the Domain Name System (DNS) than what is registered as the web server host name. In this situation, specify the different name in this field.

You can configure additional web server components after you install the product.

Application Server

The application server is the server that connects the database server and the web server for CA APM. The business and data access logic reside on the application server. To allow for scalability, the application server and web server are on two distinct servers.

You can have more than one application server. The Export Service component and the Storage Management Service component must be installed on one of the application servers, but not necessarily on the same server.

The following fields require explanation:

Application Server or Load Balancer IP/Host

The CA APM installation, by default, sets this field to the application server host name.

- In a single application server environment, you can enter the application server host name, or the application server IP address.

- In a multiple application server environment, you can enter either the application server host name, or the IP address of the Load Balancer.

The application server can be registered with a different name in the Domain Name System (DNS) than what is registered as the application server host name. In this situation, specify the different name in this field.

You can configure more application server components after you install the product.

Hardware Reconciliation Engine

The Hardware Reconciliation Engine is the service that matches discovered assets to their corresponding owned assets from different logical repositories. You can manage the assets based on your business practices. The Hardware Reconciliation Engine retrieves data from and stores the results in the CA MDB. You can install the Hardware Reconciliation Engine on one or more servers.

You can configure more Hardware Reconciliation Engine components after you install the product.

CA EEM

CA APM uses CA EEM for authentication. Other products that need CA EEM for authentication can use the same CA EEM server that CA APM uses.

- To manage security centrally for multiple CA Technologies products, specify the name, location, and login credentials for the existing CA EEM server.
- To manage CA APM security independently from other CA Technologies products, install CA EEM on any single application or web server other than the one where the existing CA EEM is installed.

CA Business Intelligence

CA Business Intelligence administers, monitors, and configures the reporting environment. CA APM uses CA Business Intelligence to integrate, analyze, and present information required for effective enterprise IT management.

For information about the access credentials and connection information that you enter for the CA Business Intelligence component, see How to Integrate CA APM and CA Business Intelligence.

CA Process Automation Manager

CA PAM can be integrated with CA Asset Portfolio Management to automate workflow business processes. For more information see Installing Common Components (see page 283).

Export Service

The Export Service exports data from CA APM and saves the results in formats such as a comma-separated value (CSV) file. To accomplish this task, the Export Service interacts with the Storage Manager Service so that you can specify where the exported files are stored.

Data Importer Engine Service

The Data Importer Engine Service imports bulk product information into the CA MDB through column and field mapping.

Import Driver

The Import Driver processes discovered hardware data exports from CA SAM. CA APM uses the discovered hardware data to link ownership and discovery data. CA APM exports ownership data back to CA SAM.

LDAP Data Import and Sync Service

The LDAP Data Import and Sync Service imports data into CA APM from CA EEM or external data sources (LDAP or CA SiteMinder). Install the LDAP Data Import and Sync Service on one of the Data Importer servers.

Storage Manager Service

The Storage Manager Service stores exported files, attachment files, data import data and map files, and log files for data import and mass change. If your current product release is any version of Release 12.6, 12.7, or 12.8, you must back up the contents of the Storage folder before you uninstall your current release. After you have completed the Release 12.9 installation, restore the contents of the folder.

CA APM Registration Service

The CA APM Registration Service consolidates individual CA APM CORA services into one main service. You can have installations of other CA Technologies products that also use the CORA API. The changes that you make to the CORA API in your CA APM environment do not affect the use of the CORA API by other CA Technologies products.

Common Administration for Service Management (CASM)

The Common Administration for Service Management (CASM) provides administrative functionality, such as multi-tenancy administration, to CA APM. Multi-tenancy is the ability for multiple independent tenants (and their users) to share a single implementation of CA APM.

Note: For more information about implementing multi-tenancy, see How to Implement Multi-Tenancy (see page 990).

Event Service

The Event Service manages the events and notifications process in CA APM. Events are important activities or data changes that you want to track and that you define in CA APM. After a defined event has occurred, notifications are sent to alert appropriate users and administrators about the event.

To perform the notification function, the Event Service interacts with a workflow provider (for example, CA Process Automation) using the Web Service. A workflow provider manages automated processes. If your workflow provider is CA Process Automation, you can specify the existing instance of CA Process Automation during the installation. You can also share CA Process Automation with CA Service Desk Manager and CA Service Catalog.

Common Asset Viewer

The Common Asset Viewer lets you view discovered and owned data for an asset that has been linked through reconciliation, including system configuration, operating system, system devices, and file systems. You can view this data on the Asset Details page by clicking the Owned Information or Discovered Information link.

The Common Asset Viewer requires the following components to install and execute successfully:

- Apache Tomcat server, which is included with the CA APM installation. The default value for the Apache Tomcat server port is 9080. You can change this value after the installation. You first update the port in the Apache Tomcat configuration file (see page 314). Then, you change the port in the product (Administration tab, System Configuration, Common Asset Viewer).

- Java Development Kit (JDK). Before you begin the CA APM installation, install the JDK on the application server on which you are installing the Common Asset Viewer.

After you install the Common Asset Viewer, the component is configured for non-secure network communication (http). You can configure the component for secure network communication (https) by first configuring the Apache Tomcat server (where the Common Asset Viewer is installed) to support the Secure Socket Layer (SSL) protocol. Then you need to change a setting for the Common Asset Viewer component in the web configuration file.

The Tomcat port number for CA APM defaults to 9080. If another product that is integrated with CA APM uses this port number, change the port number in CA APM so that you do not have a conflict.

WCF Service

The Windows Communications Foundation (WCF) service implements the web services in CA APM. The web services let you use a standards-based interface to build client applications that integrate with CA APM.

The web services let you create, search, update, copy, and delete CA APM objects from your external client application. Your assigned user role determines whether you have permission to access the web services in CA APM. Your role also restricts the objects and data (classes and attributes) that you can view or modify.

Specify the server name for the WCF Service component. You can modify the WCF Service protocol setting. You can change the configuration of the WCF Service component after you install the product.

Software Asset Management

The Software Asset Management component allows you to enable software asset management capabilities through CA SAM. If you implement both CA APM and CA SAM, you can coordinate the management of both hardware and software assets in your organization. CA APM maintains hardware asset data and CA SAM maintains software asset and license data. Common data that both products require is shared.

The product installation does not configure the Software Asset Management component. Configure this component through System Configuration after you install the product.

Note: You can change the component configurations and configure additional components for your enterprise after you install the product. For more information about changing the component configurations and adding servers, see Managing Product Components (see page 1585).

CA Service Desk Manager

CA Service Desk Manager component is used for integrating CA APM and CA SDM. Refer to Integrating CA ITAM and CA Service Desk Manager (see page 3251).

Migrate CA APM Release 11.3.4 to the Current Release

To migrate CA APM data, perform these steps:

1. Review the Prerequisites (see page 328)
2. Start the CA APM Migration Toolkit (see page 332)
3. Run the Pre-Migration Reports (see page 332)
4. Use the pre-migration report data for reference and corrective action (see page 339)
5. Specify the Duplicate Asset Rename Configuration (see page 344)
6. Run the Migration Utility (see page 345)
7. Start the CA APM Web Interface (see page 351)
8. Run the Post-Migration Reports for Manual Migration (see page 368)
9. Perform Manual Migrations (see page 351)
10. Perform Post-Migration Verification (see page 367)

As a system administrator, you perform the data migration when you want to move CA APM data from Release 11.3.4 to the current release . After you install the current release of CA APM, the CA Management Database (CA MDB) structures are upgraded and you are prompted to migrate your data.

Note: Use the current release of CA APM to migrate objects that were not migrated with Release 14.1. These objects are costs and payments extensions and audits, custom relationships and audits, and relationship extensions and audits. With this release, all relationships are migrated, including custom relationships and relationships that were not product-provided. If you previously migrated your data from Release 11.3.4, you can migrate the data for just these objects. You do not need to perform the complete data migration again.

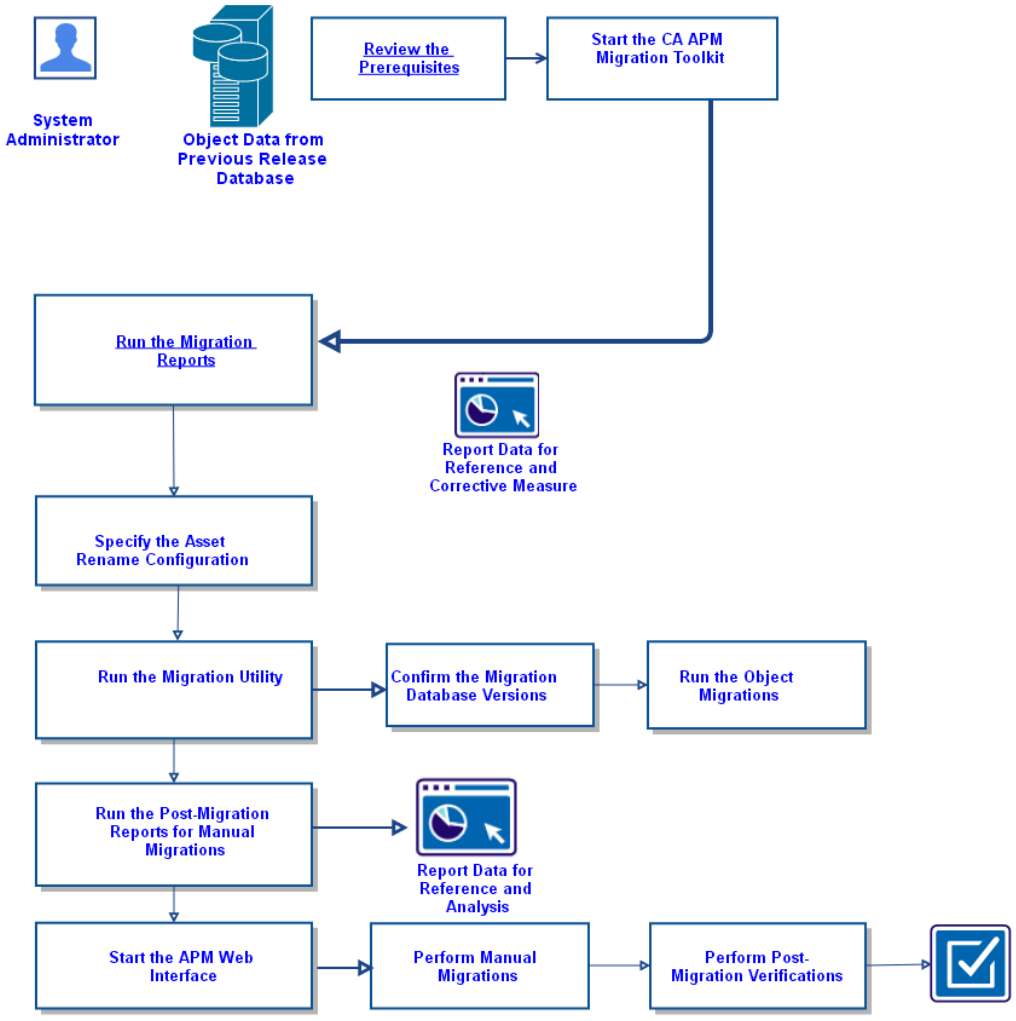
Installing the upgrade and migrating your data are separate processes:

- **Upgrade**: Updates the application and database structures to a newer version.
- **Migrate**. Transforms or moves the data from previous database structures to new database structures, which were created during the upgrade.

The CA APM Migration Toolkit contains the following tools to assist you with migrating your data from Release 11.3.4 database structures to the current release database structures:

- **Migration Documentation**: Provides the instructions for generating the migration reports, running the Migration Utility, and manually migrating objects.
- **Migration Reporting**: Generates reports that help you during the migration process. Generate the pre-migration reports (see page 332) *before* you run the Migration Utility (see page 345) to avoid potential problems during the migration. You can generate the post-migration reports (see page 368) *after* you run the Migration Utility. The post-migration reports help you manually migrate legacy database structures that cannot be migrated using the Migration Utility.
- **Duplicate Asset Name Configurator**: Specifies the renaming configuration to apply to duplicate Asset Names.
- **Migration Utility**: Provides automated steps to move the selected objects in your legacy database structures to new database structures.

The following diagram illustrates how a system administrator migrates data.



Example: Migrate CA APM Data from Release 11.3.4 to Current Release

Miriam is the CA APM system administrator at Document Management Company. She wants to upgrade CA APM Release 11.3.4 to the current release and migrate the data from legacy data structures to the upgraded data structures. Miriam reviews the prerequisites to start the migration and upgrades to the new release.

Miriam starts the CA APM Migration Toolkit. First, she generates and reviews the pre-migration reports. The reports help identify objects that she has to correct in the legacy data structures before successfully running the Migration Utility. She sets some of the reports aside to use later to configure new names for assets that have the same name and to perform manual migrations.

After Miriam makes the corrections to the legacy data structures, she reviews the Duplicate Asset Name Report to identify non-unique Asset Names. Miriam opens the Duplicate Asset Name Configurator and selects a renaming configuration for duplicate Asset Names. These assets are renamed when Miriam runs the Migration Utility.

Miriam opens the Migration Utility. She tests the database connection, which confirms that the correct CA APM legacy database version is being migrated to the correct new release database version.

Miriam selects the objects to migrate and runs the Migration Utility. She monitors the migration process by reading the progress and status messages. When all of the objects are migrated, the Audit History object becomes available for migration. She selects the Audit History object and reruns the Migration Utility.

When the Migration Utility process finishes, Miriam generates the post-migration reports. The reports specify the data that was successfully migrated and the data that was not migrated. Miriam has to migrate manually the data that was not migrated.

Manual migrations are performed using the upgraded CA APM current release web interface. Miriam starts the web interface. She performs the manual migrations using the post-migration report information. She verifies the migrated data to complete the migration process.

Review the Migration Prerequisites

This article contains the following topics:

Verify that you have completed these prerequisites in the following order to ensure that you can successfully migrate the data:

Note: Many of the migration prerequisites are completed while installing CA APM.

1. Review the following information:
   - Known Issues available on the Release Information (see page 69).
   - Relationship Differences Between Release 11.3.4 and the Current Release (see page 328).
2. Ensure that the current Release 11.3.4 patch level is cumulative patch 14 or higher. If the current patch level is unknown, or not cumulative patch 14 or higher, download and apply the latest CA APM Release 11.3.4 cumulative patch from the CA Support website.
3. Stop the following services and the scheduled tasks for CA APM and other integrated Service Management products:
   - CA Unicenter Asset Portfolio Management (CA APM)
     - CA APM Cache Service
     - CA APM Notification Service

- Automated reconciliation tasks
- CA Service Catalog Release 12.8 and 12.9
  - CA Service Catalog
  - CA Service Accounting
- CA Service Catalog Release 12.7
  - CA Service Accounting
  - CA Service Fulfillment
  - CA Service Repository Agent
  - CA Service View
- CA Service Desk Manager
  - CA Service Desk Manager Server
- CA Client Automation
  - For CA Client Automation Enterprise Managers and Domain Managers that directly share the CA MDB being migrated, stop the CA Client Automation Service using *caf* stop.
  - For other servers running supplemental Engine processes against the CA MDB being migrated, stop the CA Client Automation Service using *caf* stop.
  - For any Engine processes executing the Database Synchronization tasks to the CA MDB being migrated, stop the Database Synchronization jobs using the DSM Explorer.
  - Stop the Engine replication tasks to the Enterprise using the DSM Explorer for each CA Client Automation Domain Manager that reports to the Enterprise.

4. Back up the CA APM Release 11.3.4 database.
5. Locate the CA Migration Health Check Utility in the Health Check Utility folder on the CA APM installation media. Execute the utility on the CA APM Release 11.3.4 database.

   Important! For information about running the utility, see the *CA Migration Health Check Utility User Guide*, which is available on the installation media.

6. Review the Microsoft SQL Server Transaction Log Sequence settings for the CA MDB, and ensure that the settings are positioned for bulk loading. Complete the following steps to locate the information:

a. In a web browser, open the Microsoft website (http://www.microsoft.com) and search for "Transaction Log Management".

b. Follow the instructions in the article.

7. Install CA Service Management 14.1 against the Release 11.3.4 database.

> **Note:** If you previously migrated Release 11.3.4 data to Release current release, you need to perform some steps to retain the migration status of the migrated objects. For more information about how to retain the migration status, see Installation Planning.

8. Verify that no current release services are running. These services can still be running if you exited the CA APM Migration Toolkit before you ran the Data Migration Utility or generated the reports for manual migrations.

Relationship Differences Between CA APM Release 11.3.4 and the Current Release

CA APM Release 11.3.4 includes product-provided relationships and allows you to add new custom relationships. The support for relationships has changed in the current release.

Relationships that Are not Product Provided in CA APM

The following relationships and associated links that are provided in Release 11.3.4 are not product provided in the current release. However, these relationships are migrated to custom relationships in the current release:

- Activity Summary
- Contacts (Budget manager, Supported by, User)
- Dependencies (Depends on)
- Product Evolution (Evolved into)
- Product Upgrade (Upgraded to)
- User Allocation (Allocated to)
- SW Allocation (Allocated on)

Product-Provided Relationships in CA APM

The following Release 11.3.4 relationships are product provided in CA APM:

- Asset Entitlement (Licensed to)
- Company Acquisition (Acquired By)

- Company Entitlement (Licensed to)
- Contact Entitlement (Licensed to)
- Governing Document (Governed by)
- Image Partitions (Partitioned CPU)
- Legal Amendment (Amends)
- Location Entitlement (Licensed to)
- HW Asset Configuration (Generic component, Specific component)
- HW Model Configuration (Generic component)

The data structures to store the relationship information have changed. To move the relationship information from Release 11.3.4 to the current release, the Migration Utility must identify the relationships by Relationship Template name and Relationship Template Link name.

What You Must Do: Before you run the Migration Utility, change the modified names in Relationship Template or Relationship Template Link to the values in the original Release 11.3.4.

User Interface Changes

In CA APM Release 11.3.4, relationships and links are displayed and modified in separate sections in the user interface. In the current release, relationships and links are combined into a single entity that is displayed and modified in the same section in the user interface.

Some of the menu items for relationship names in the current release are different from Release 11.3.4. The following chart lists each Release 11.3.4 relationship and its associated current release relationship menu item. Some relationship menu items have a different label when viewing the relationship from the reverse direction. For example, the Company Entitlement relationship is displayed as Company Allocation when viewed from the software asset and Software Allocation when viewed from the company.

CA APM Release 11.3.4 Relationship	CA APM Release 14.1 Entity	CA APMRelease 14.1 Relationship
Asset Entitlement	Asset (software)	Asset Allocation
Asset Entitlement	Asset (hardware)	Software Allocation
Company Acquisition	Company	Company Acquisition
Company Entitlement	Asset (software)	Company Allocation
Company Entitlement	Company	Software Allocation
Contact Entitlement	Asset (software)	Contact Allocation
Contact Entitlement	Contact	Software Allocation

CA APM Release 11.3.4 Relationship	CA APM Release 14.1 Entity	CA APMRelease 14.1 Relationship
Governing Document	Legal Document	Governing Legal Document
Image Partitions	Asset	Image Partitions
Legal Amendment	Legal Document	Legal Amendment
Location Entitlement	Asset (software)	Location Allocation
Location Entitlement	Location	Software Allocation
HW Asset Configuration (Generic component)	Asset	Model Configuration
HW Asset Configuration (Specific component)	Asset	Asset Configuration
HW Model Configuration	Model	Model Configuration

Start the Migration Toolkit

During the upgrade of Release 11.3.4 to Release 14.1, the CA APM Migration Toolkit is installed on the same computer that is performing the upgrade. We recommend that you migrate your CA MDB data to the new release data structures immediately after the upgrade is complete.

Note: If multiple servers are deployed in your environment, the Migration Utility will be installed only on the first Server.

Start the CA APM Migration Toolkit on the same computer where you performed the upgrade.

Follow these steps:

- Click Start, All Programs, CA, Asset Portfolio Management, CA APM Migration Toolkit.

Run the Pre-Migration Reports before Migrating the Data

This article contains the following topics:

- Task Add Asset Report (see page 339)
- Customized Search Report (see page 339)
- Translation List Obsolete Report (see page 339)
- Translation List Unconverted Report (see page 339)

Before you migrate the CA MDB, you run the pre-migration reports. The pre-migration reports identify the following types of data:

- Data that can cause problems during data migration. You correct the data in the CA MDB *before* you run the Migration Utility. For example, if you renamed a relationship template that was provided with Release 11.3.4, this change could cause a problem during the migration of relationships. The Relationship Report identifies the renamed templates, which you change back to the original product-provided template names, before migration.

- Data that requires analysis for migration configuration decisions.

- Data that is not migrated with the Migration Utility, but can be migrated manually with updated product features. You reference this data during manual migration, *after* you run the Migration Utility. You must capture the data in these reports before you migrate your legacy data, because this data is not migrated to the current release. database structures. You save these reports and reference their information later, during manual migration for the current release.

- Data that is supported in Release 11.3.4 but is not supported in the current release. You cannot migrate this data with the Migration Utility or add it using the current release version. These reports identify unsupported data and provide legacy reference information.

Follow these steps:

1. On the CA APM Migration Toolkit main window, click Migration Reporting.
   The following Pre-Migration Reports area check boxes are selected:

   - Custom Index
   - Duplicate Asset Name
   - Reconciliation
   - Relationships

   Note: If you do not want to generate all reports, select only those report types that you want.

2. In the Report Output Folder area, click Browse and select the output folder where you want to save the reports.

3. Click Generate Reports.
   The status messages appear in the Messages area to help you monitor the report generation process.
   You are prompted to open the report output folder to view the reports.

4. Click Yes.
   Windows Explorer opens. The Reporting tool creates a folder for each report check box that you selected previously.

5. Navigate to, and open, a report folder.
   The reports appear in comma-separated value (CSV) format.

6. Right-click a report and select Open with, Excel, to open and view the report in a table format.
   The report data (see page 334) is presented in a table format. The table headings are in the first row.

   Note: You can click open the report to view in a text editor in CSV format.

Pre-Migration Report Data for Reference and Corrective Action

The Reporting tool generates reports in CSV format that you can open with a text editor. The report field names and field values are separated with commas. You can also open a report with Excel, which presents the data in a table format. When you open a report with Excel, the field names are the column headings, and the field values appear in the rows below the headings.

The following pre-migration reports give you information about data that you must change in the CA MDB *before* migration. The related objects can then be migrated successfully to the current release CA MDB data structures.

- Custom Index Report
- Relationship Report

The following reports identify data that you analyze for migration configuration decisions:

- Duplicate Asset Name Report
- Reconciliation Report:
  - Main Translation List Query Report

The following pre-migration reports identify data that you use *after* you run the Migration Utility, when you perform manual migrations. Save these reports and reference them during manual migration.

- Reconciliation Reports:
  - Main Task Query Report
  - Task Add Asset Report
  - Customized Search Report

The following reports identify data that is not supported in the current release and that provide legacy reference information:

- Reconciliation Reports:
  - Translation List Obsolete Report
  - Translation List Unconverted Report

Custom Index Report

The Custom Index Report identifies indexes that were added to fields in Release 11.3.4 (or previous releases) for customization. These indexes can create performance issues in the current release version. We recommend that you remove custom indexes from your database. The report provides SQL statements that you run to remove the custom indexes.

Remove Custom Indexes from Database

We recommend that you remove custom indexes from your database to avoid performance issues. Remove the indexes *before* you run the Migration Utility. The Custom Index Report provides the information that you use to remove the custom indexes.

Follow these steps:

1. Locate the Custom Index Report.
2. Copy the SQL statements from the Drop SQL column on the report.

   Note: Delete the quotation marks at the beginning and end of the statements.

3. Paste the SQL statements to your preferred tool, for example, Microsoft SQL Server Management Studio and Oracle SQL Developer, and run the statements.
   The following items are removed:
   - Custom indexes
   - Index definitions from the arg_index_member table
   - Index information from the arg_index_def table

Relationship Report

The Relationship Report identifies the relationship templates that were renamed from the original product-provided Release 11.3.4 names. Change this data in the CA MDB *before* migration.

The tool generates the Relationship Report in different languages. Use the appropriate report for the language that the Release 11.3.4 was configured to.

The report shows the following status for the relationship template or the relationship template link:

- **Customized**
  Indicates that the relationship templates or relationship template links are added or renamed by the user in Release 11.3.4.

  - If the relationship was added in Release 11.3.4, it is not a product-provided relationship in the current release. However, it is migrated to a custom relationship.

  - If the relationship is product provided in Release 11.3.4 and in the current release, you can migrate the relationship to the product-provided relationship in the current release. First, rename the relationship templates or relationship template links to their original values.

- **Migrated by Migration Utility**
  Indicates that the relationship templates or the relationship template links are supported in the current release and will be migrated by the utility.

- **No Longer Supported**
  Indicates the relationship templates or relationship template links that are not product provided in the current release. The Migration Utility migrates these relationships to custom relationships.

- **Not Found**
  Indicates the product-provided relationship templates or relationship template links in Release 11.3.4 that are not found in the database of the user. If the relationship templates or relationship template links were renamed and are product-provided in the current release, rename the relationship templates or relationship template links to their original values to migrate the relationship to the current release.

- **Rename to migrate**
  Indicates the renamed relationship templates or relationship template links in Release 11.3.4 that you have to change to the original name before migrating.

Complete the following actions if you want to include the renamed product-provided Relationship Templates in the migration:

- Change the renamed Relationship Template to the original product-provided name.

- Change the renamed Relationship Template Link to the original product-provided name.

Change the Renamed Relationship Template to the Original Product-Provided Name

Before you run the Migration Utility, you change the renamed Relationship Template names to the original product-provided Relationship Template names from Release 11.3.4.

You execute a SQL statement to change the Relationship Template Name. Perform these steps for each entry in the report with status ‘Rename to migrate’ and a value that is specified under ‘Relationship Template Rename’.

Follow these steps:

1. Execute the following SQL statement from your preferred tool (for example, Microsoft SQL Server Management Studio or Oracle SQL Developer):

> **Note:** The brackets and the text within the brackets are placeholders. The placeholder names represent the column names on the Relationship Report.

```
UPDATE arg_actiondf
SET adtext = '{Relationship Template Rename}'
WHERE adtext = '{Relationship Template Name}'
    AND ad1obty IN (SELECT slentry
        FROM arg_strlst
        WHERE slid = 9
        AND slvalue1 = '{Relationship Object Type}')
```

2. Replace the placeholders with the values in the same-named columns on the Relationship Report. For example, the report Relationship Template Rename column identifies the product-provided name Activity Summary. You replace {Relationship Template Rename} with Activity Summary.

Change the Renamed Relationship Template Link to the Original Product-Provided Name

Before you run the Migration Utility, you change the renamed Relationship Template Link Names to the original product-provided Relationship Template Link Names from Release 11.3.4.

You execute a SQL statement to change the Relationship Template Link Name. Perform these steps for each entry in the report with status ‘Rename to migrate’ and a value that is specified under ‘Link Rename’.

Follow these steps:

1. Execute the following SQL statement from your preferred tool (for example, Microsoft SQL Server Management Studio or Oracle SQL Developer):

> **Note:** The brackets and the text within the brackets are placeholders. The placeholder names represent the column names on the Relationship Report.

```
UPDATE arg_linkdef
SET ndtext = '{Link Rename}'
WHERE ndtext = '{Link Name}'
    AND nd2obty IN (SELECT slentry
        FROM arg_strlst
        WHERE slid = 9
        AND slvalue1 = '{Link Object Type}')
```

2. Replace the placeholders with the values in the same-named columns on the Relationship Report. For example, in the report, the Link Rename column identifies the product-provided template link name as Approved by. You replace {Link Rename} with Approved by.

Duplicate Asset Rename Report

The Duplicate Asset Name Report identifies non-unique asset names.

Note: Only the assets that share the same asset name and have no values set for the following registration fields are affected:

- Serial Number
- Alt Asset ID
- Host Name
- DNS Name
- Mac Address
- Serial Number

During migration, the CA APM Migration Toolkit can automatically configure a unique Asset Name for each duplicate Asset Name in your CA MDB. Use the Duplicate Asset Name Report to help you decide how to specify the asset rename configuration (see page 344).

Reconciliation Reports

The Reporting tool generates the following reconciliation reports:

- Main Translation List Query Report
- Translation List Obsolete Report
- Translation List Unconverted Report
- Main Task Query Report
- Task Add Asset Report
- Customized Search Report

Main Translation List Query Report

The Main Translation List Query Report identifies legacy translation list data for companies, operating systems, and models. You analyze the data on this report to determine whether to run the Migration Utility (see page 345) to migrate legacy translation lists to the current release normalization rules or migrate the lists manually.

If you decide to migrate the translation lists manually, use the data on the Main Translation List Query Report.

Main Task Query Report

The pre-migration Main Task Query Report identifies data that you use *after* you run the Migration Utility. The report provides information about the legacy reconciliation tasks from Release 11.3.4. Save the report and reference it during manual migration of Hardware Reconciliation tasks to create reconciliation rules in the current release.

Task Add Asset Report

The Task Add Asset Report provides data that you use *after* you run the Migration Utility, when you perform manual migrations (see page 351). The report identifies the legacy reconciliation tasks that add owned assets from Release 11.3.4. Save the report and reference it during manual migration of Hardware Reconciliation tasks.

Customized Search Report

The Customized Search Report provides data that you use *after* you run the Migration Utility, when you perform manual migrations. The report identifies the legacy hardware reconciliation customized searches from Release 11.3.4. The current release version of CA APM provides predefined hardware reconciliation reports. You can customize these reports using the CA Business Intelligence, which is also provided in the current release. Save the report and reference it during manual migration of hardware reconciliation searches.

Translation List Obsolete Report

The Translation List Obsolete Report identifies the Hardware Reconciliation legacy translation lists from Release 11.3.4 that are obsolete and not supported in the current release. This report is for your reference. No action is required.

Translation List Unconverted Report

The Translation List Unconverted Report identifies the Hardware Reconciliation legacy translation lists from Release 11.3.4 that have missing or invalid entries that will not be migrated to the current release. The translation list will be migrated, but some of the entries in the list will not be migrated, because supporting data is not present in the legacy database.

Use the data on the Translation List Unconverted Report and on the Main Translation List Query Report to add the missing entries to the normalization lists after migration.

Use the Migration Report Data for Reference and Analysis

This article contains the following topics:

The Reporting tool generates reports in CSV format that you can open with a text editor. The report field names and field values are separated with commas. You can also open a report with Excel, which presents the data in a table format. When you open a report with Excel, the field names are the column headings, and the field values appear in the rows below the headings.

The post-migration reports give you information about data that you enter in Release 14.1 *after* migration. This data could not be migrated using the Migration Utility.

The following post-migration reports provide information that you use to perform manual migrations (see page 351):

- Advanced Search Report (see page 340)
- Attachments Report (see page 341)
- Basic Search Report (see page 341)
- Event Reports (see page 341)
- Filtering Reports (see page 343)
- Role Security (Field and Functional Permissions) Reports (see page 343)

Advanced Search Report

The Advanced Search Report provides a summary of each advanced search and location information for the detail reports for each advanced search (see page 341). The Detail column of the report provides the location and name of each Advanced Search Detail Report.

The following report fields require an explanation:

- **Export Type**
  Indicates the Export Format for search results.
- **Refresh Interval**
  Identifies the start time and frequency for an Export Schedule.
- **Object Type**
  Indicates Role Access when the Security Search setting has one or more roles.
- **Assignment**
  Identifies the role name or contact that has permission to access the search.
- **Creator**
  Identifies the name of the last user to update the search. Use this information to delegate the manual migration (re-creation) of the advanced search. You do not assign this field to a setting in the advanced search.
- **Creator ID**
  Identifies the name of the last user to update the search. Use this information to delegate the manual migration (re-creation) of the advanced search. You do not assign this field to a setting in the advanced search.

Use the Advanced Search Report to migrate the advanced searches to Release 14.1 manually.

Advanced Search Detail Reports

Each Advanced Search Detail Report identifies the data for one advanced search. Review the information about advanced searches that were created in Release 11.3.4.

Use the Advanced Search Detail Reports to migrate these advanced searches to Release 14.1 manually.

Attachments Report

The Attachments Report identifies information that you use to migrate file attachments manually. The Migration Utility migrates the complete Web URL link attachments and the metadata for remote server and local file attachments. After migration, you move the physical file attachments to the Storage Manager Service.

The Attachments Report provides the file location and description and the following information for each attachment:

- **UUID**
  Universally Unique Identifier identifies an object and distinguishes between two objects that have the same name.

- **Object Type**
  Identifies the type of object to which the file is attached.

- **Assignment**
  Identifies the name of the object to which the file is attached.

Basic Search Report

Use the Basic Search Report to view the following information about searches that were created in Release 11.3.4 and to migrate these basic searches to Release 14.1 manually:

- Object Type that the search returns.

- Role, if any, permitted to view the search return fields.

- Search Return Fields, which were named Display Fields in Release 11.3.4.

Event Reports

The Notification History Event Report (see page 341) provides history information from Release 11.3.4, for you to review. The following Event Reports identify data that you use *after* you run the Migration Utility, when you perform manual migrations. Reference these reports during manual migration of events (see page 351):

- Date Event Report (see page 342)

- Watch and Change Event Report (see page 342)

Notification History Event Report

The Notification History Event Report provides history information from Release 11.3.4 for you to review. No action is required.

This report identifies events that were processed in the last year. The following fields require explanation:

- **Event Enabled**
  Indicates that the event is enabled and not inactive when the value is TRUE. Indicates that the event is inactive when the value is FALSE.

- **Event Field Name**
  The event is based on the value of this object field.

- **Event Recipient**
  The email address of the current event notification.

- **Event Notification Definition Text**
  The email message text of the current event notification.

- **Notification Type**
  Indicates the type of notification that the recipient receives. "Initial Event" indicates the recipient of the first notification. "Escalation" indicates the recipient of unacknowledged notifications.

- **Notification Text**
  The email message text of the past event notification.

- **Notification Recipient**
  The email address of the past event notification.

See CA Process Automation Integration for information about workflow provider process parameters that are specified in CA Process Automation. For information about notification process parameters, see your workflow provider documentation.

Date Event Report

The Date Event Report identifies data that you use *after* you run the Migration Utility, when you perform manual migrations. This report identifies date events and notifications. Reference the report during manual migration of events.

The Integrate with CA Process Automation Integration for a Notification Process Manually (see page 3489) section provides information about workflow provider process parameters that are specified in CA Process Automation. For information about notification process parameters, see your workflow provider documentation.

Watch and Change Event Report

The Watch and Change Event Report identifies data that you use *after* you run the Migration Utility, when you perform manual migrations. This report provides information about watch events and notifications and about change events and notifications, from Release 11.3.4. Reference the report during manual migration.

Note: Manual events were available in Release 11.3.4, but are not supported in Release 14.1. Manual events are not included on the Watch and Change Event Report.

The Integrate with CA Process Automation Integration for a Notification Process Manually (see page 3489) section provides information about workflow provider process parameters that are specified in CA Process Automation. For information about notification process parameters, see your workflow provider documentation.

Filtering Reports

The Filtering Report provides a summary of each filter and location information for the detail reports for each filter. The Detail column of the report provides the location and name of each Filter Detail Report.

Contact Filtering Detail Report

Each Filtering Detail Report identifies the data for one filter. Use the Filtering Detail Reports to view the information about filters that were created in Release 11.3.4 and to migrate filters manually.

Role Security (Field and Functional Permissions) Reports

Each Role Security Report identifies the data for one field, functional, or viewable linked object security setting. The Migration Toolkit generates the following types of role security reports:

- **Field Security Reports.** Generates one Field Security Report for each object that has role security settings. The report identifies the role, the object, the object field, and the permission that is assigned to the role for the field. The Update Permission report column label and the Add New Permission report column label refer to Release 11.3.4 functionality. Release 14.1 does not differentiate permissions for updating and creating objects.

- **Functional Security Reports.** Generates one Functional Security Report for each object that has role security settings. The report identifies the role, the object, the function related to the object, and the permission that is assigned to the role for the function.

- **Field Security Linked Object Viewable Report.** Generates one Field Security Linked Object Viewable Report for each object that has role security settings. The report identifies the role, the objects, and the assigned fields for the object.

Use the Role Security Reports to view the information about role security settings that were created in CA APM Release 11.3.4 and to migrate role security settings manually.

The following objects, fields, and functions are not supported in Release 14.1. They appear on the Release 11.3.4 database reports for reference only:

- Asset Version

- Asset Version Status History

- Model Version

- Keywords

Specify the Duplicate Asset Rename Configuration

CA APM Release 14.1 registration includes asset name, serial number alt asset ID, host name, DNS name, and mac address. A *unique* asset name is required for each asset object. Release 11.3.4 did not have this requirement, so your CA MDB could have asset names that are not unique for asset registration. The CA APM Migration Toolkit can automatically configure a unique asset name for each duplicate asset name in your CA MDB during migration.

The CA APM Migration Toolkit uses a configuration to rename the duplicate asset names. You choose the configuration on the CA APM Migration Utility Duplicate Asset Name Configuration dialog. When you run the Migration Utility, the duplicate assets are renamed in the current release database.

Note: A unique asset name is a requirement for asset registration by the Common Registration API (CORA) for the current CA APM release. If you do not have CORA enabled, asset registration does not occur.

Follow these steps:

1. Review the Duplicate Asset Name Report.
2. On the CA Asset Portfolio Management Migration Toolkit main window, click Duplicate Asset Name Configurator.
3. Select one of the following rename configurations:

   - **Replacement**
     Replaces the duplicate asset names with the value in another field. You select this field in the drop-down list.

     Note: The fields in the drop-down list are the same fields that are the headings on the Duplicate Asset Name Report.

     The Incrementation configuration is automatically selected and locked. If the Replacement configuration results in a duplicate asset name, adding Incrementation to the configuration ensures that the rename is unique.

   - **Concatenation**
     Appends the values of one or more fields onto the end of the duplicate asset names. You select up to four fields in the drop-down lists.

     Note: The fields in the drop-down lists are the same fields that are the headings on the Duplicate Asset Name Report.

The Incrementation configuration is automatically selected and locked. If the Concatenation configuration results in a duplicate asset name, adding Incrementation to the configuration ensures that the rename is unique.

- **Incrementation**
  Appends a unique integer value to the end of the duplicate asset names and increments the integer by one for each subsequent duplicate asset name. You enter the starting integer in the Integer Base Line Value.

- **NONE**
  Duplicate asset names are not renamed. You can select this option if you do not have CORA enabled or if you want to correct the assets manually after migration.

4. (Optional) Enter a one-character Field Delimiter that appears between each field and between a field and an incrementation integer in the Incrementation and Concatenation configurations.

5. Click Save.

Note: Depending on the number of records, it takes some time for the configuration to save. The progress bar indicates the status of completion.

6. Click Exit.

Run the Migration Utility

This article contains the following topics:

The Migration Utility migrates audits, objects, and events from one CA APM release to the upgraded database structure of another.

The hierarchical structure of the objects in the selection area on the CA APM Migration Utility window allows you to select all objects within a hierarchy level or to select individual objects within a level. A status icon displays the migration status for each object or object level.

The icon key in the top area of the window indicates the statuses. When an object status is Complete, you cannot select the object.

The Messages and Summary tabs allow you to monitor the migration process and to review the migration run.

Important: In addition to the services and the scheduled tasks detailed in Prerequisites, ensure the current release services are not running before you run the Migration Utility.

The first time that you open the window, you are prompted to confirm the migration database versions. After you complete this task, you can run the object migrations.

Note: With CA APM 14.1, you can migrate objects that were not migrated with Release 12.9. These objects are costs and payments extensions and audits, custom relationships and audits, and relationship extensions and audits. With this release, all relationships are migrated, including custom relationships and relationships that were not product-provided. If you previously migrated your data from Release 11.3.4, you can migrate the data for just these objects. You do not need to perform the complete data migration again.

You can migrate the following objects and associated events with the Migration Utility:

- Assets
  - Unique Asset Names for CORA
  - Asset Current Status History
- Cost and Payments
  - Billing Codes
  - Pricing Types
  - Cost Types
  - Currency Types
- Cost and Payment Extensions (and the associated audits)
- Legal Documents
  - Legal Definitions
  - Document Locations
  - Legal Status
  - Legal Document Status Histories
- Notes
  - Note Types
- OOTB Relationships (Original Product-Provided Relationships)

- Custom Relationships (and the associated audits)
- Extensions
  - Simple Extensions
  - List Extensions
  - Location Hierarchies
- Relationship Extensions (and the associated audits)
- Attachments
- Roles
- Reconciliation Translation Lists (supported types only)
  - Operating System Translation List
  - System Model Translation List
  - Manufacturer Translation List
- Legacy audits to audit archive tables. The Audit History object is enabled after you migrate other objects and the Audit Generation for Events shows the status as Complete.

Note: To ensure that events work properly in the product, select Audit Generation for Events from the list of Migration Objects. Audit Generation for Events establishes baseline audit records.

Confirm the Migration Database Version

You confirm the migration database versions by testing the database connection. The first time that you run the Migration Utility, the CA APM Migration Utility Configuration dialog automatically opens. The dialog fields are populated with the database configuration settings that you specified during installation.

Note: After you confirm the migration database versions, click Configure on the Migration Utility window.

When you test the database connections, the Migration Utility detects the product release version *from* which you are migrating data and the release version *to* which you are migrating data. The utility populates the From Version and To Version fields on the dialog with the detected product release versions. You cannot change the release versions on the dialog.

The detected From Version must be Release 11.3.4 and the detected To Version must be CA Service Management 14.1. If the Migration Utility detects a different release version, you cannot proceed with the migration.

Follow these steps:

1. Enter the Database Password.

2. Click Test Connection.
   A confirmation message indicates that the connection test succeeded or failed.

3. Click Save on the CA APM Migration Utility Configuration dialog if the confirmation message indicated that connection testing succeeded.
   The dialog closes.

4. If the confirmation message indicated that the database connection test failed, determine why the Migration Utility could not connect to the database configuration. After you resolve the problem, repeat the connection test.

> **Note:** If the Product Release Versions on the CA APM Migration Utility Configuration dialog do not match the release versions that you are trying to connect to the Migration Utility, the database connection test fails. You cannot proceed with the migration.

If you want to change the database configuration settings later, see Configure the Migration Database.

Configure the Migration Database

You do not need to configure the migration database during the migration. The database is configured to the settings that were specified during installation.

Later, if you change the location of the CA MDB, configure the migration database to the new location before you run the Migration Utility.

Follow these steps:

1. Click Configure on the Migration Utility window.

2. Enter the configuration settings.

3. Click Test Connection.
   A confirmation message indicates that the connection test succeeded or failed.

4. Click Save on the CA APM Migration Utility Configuration dialog if the confirmation message indicated that the connection test succeeded.
   The CA APM Migration Utility Configuration dialog closes.

5. If the confirmation message indicated that the database connection test failed, determine why the Migration Utility could not connect to the database configuration. After you resolve the problem, repeat the connection test.

Run the Object Migrations

Note: In addition to the services and scheduled tasks , ensure the Release 14.1 services are not running before you run the Migration Utility.

The CA APM Migration Utility window lists the migration objects in a hierarchical structure in the CA APM Objects area. You select the objects that you want to migrate. You can migrate the data in stages. The hierarchical structure allows you to select all objects within a hierarchy level or to select individual objects within a level.

When you select an object to migrate, all objects within the hierarchy of that object are also selected. These objects are called secondary objects. The secondary objects within the hierarchy migrate first, and the top-level object that you selected migrates last. For example, if you select the Cost and Payments top-level object, the Billing Code, Pricing Type, and Cost Type secondary objects within the Cost and Payments object hierarchy are also selected. Expand the top-level object to see its secondary objects. During migration, Billing Code, Pricing Type, and Cost Type migrate first. The top-level object Cost and Payments migrates after its secondary objects.

You can clear the check boxes next to the objects that you do not want to migrate. You can select one object, a group of objects, or all objects to migrate.

Objects that have already been migrated have a status of Completed, and their check boxes are disabled. In this way, the Migration Utility prevents you from trying to migrate an object that has already been migrated.

Right-click an object to view options that you can select to perform. The options that are available depend on the status of the object. The following options are available for you to select when you right-click an object:

- Clear the check boxes for the secondary objects
- Move to Completed
- Move to Not Started

The Audit History object is disabled initially. You start with migrating the non-audit objects. The audit history object is enabled when the migration is successful and the Audit Generation of Events shows the status as Complete. You can migrate the Audit History objects anytime once the option is enabled, and all the applications and services are back online.

Important! Depending on the size of the data, Audit History objects can take a long time to migrate. If the audit history has approximately 1 million records, it is recommended to migrate it during off peak hours.

Follow these steps:

1. On the CA APM Migration Utility window, select the check boxes next to the objects that you want to migrate.

   Note: To ensure the events work properly in the product, select Audit Generation for Events from the list of Migration Objects. Audit Generation for Events establishes baseline audit records.

2. Click Start.
   Look at the information in the Messages tab to monitor the migration progress.
   When the migration is successful, the objects in the selection area of the window have a status of Completed.

   Note: If the migration fails, view the details in the object migration log files in the following location:

   ```
   [ITAM Root Path]\Migration Toolkit\migration-utility\logs
   ```

3. (Optional) If the migration is successful, select the Audit History object and repeat Step 2.

4. Click Exit.
   The CA APM Migration Utility window closes.

When the migration completes, restart the services for the following Service Management products:

- CA Service Catalog
- CA Service Desk Manager
- CA Client Automation
- CA APM Release 14.1

Monitor the Migration Process

The Messages tab on the CA APM Migration Utility window shows the progress of the current migration process. You monitor the migration process by viewing the messages. The messages indicate the changing status of each object that is being migrated.

When the migration is finished, you can view a summary of the successful, pending, and failed migrations on the Summary tab. The Summary tab shows the migration status for all migrations that ran during your session.

You can view the object migration log files from the following location:

```
[ITAM Root Path]\Migration Toolkit\migration-utility\logs
```

For any failure messages appearing in the log files, contact CA Support.

Start the CA APM Web Interface

You start the CA APM web interface to run CA Service Management 14.1 upgraded product and manually migrate data to this database. Complete the Migration Utility automated migrations and run the post-migration reports (see page 368) *before* you perform manual migrations (see page 351).

To start the web interface, open a web browser and enter the following URL:

```
http://servername/itam
```

Replace *servername* with the name of the server that is hosting the CA APM web servers.

Note: If the Internet Explorer browser security is set to high, a content warning message appears when you start the web interface. To avoid this message, add the web site to your trusted sites or lower your security settings.

A Start menu shortcut is created on your web server that references the URL location.

To log in to CA APM after you open the URL, enter the following default credentials:

- **User Name**
  uapmadmin
- **Password**
  uapmadmin

Note: In some situations, a browser error or a user name error appears. You can resolve these errors by following the troubleshooting instructions (see page 374).

Perform Manual Migration from CA APM 11.3.4 to the Current Release

You can perform the manual migration of data to the current release after you complete the following tasks:

- You migrated data using the Migration Utility.

- You generated the post-migration reports.

When you migrate data manually, you use the CA APM current release version to enter the data in the new-release data structures. The migration reports specify the fields and values that you enter.

Important: Exit the Migration Toolkit and start the web interface (see page 351) before you can perform the manual data migrations.

Perform the following manual migrations:

- Migrate Basic Searches (see page 352)
- Migrate Advanced Searches (see page 354)
- Migrate File Attachments (see page 358)
- Migrate Events (see page 360)
- Migrate Filters (see page 360)
- Migrate Role Security (Field and Functional Permissions) (see page 362)
- Migrate Hardware Reconciliation Tasks and Rules (see page 364)
- Migrate Hardware Reconciliation Translation Lists (see page 365)
- Migrate Hardware Reconciliation Searches (see page 366)

Migrate Basic Searches

In Release 11.3.4, the search return fields that a user can see are set in the Security feature by role. The current release version of CA APM enhances the Basic Search functionality so that it is more closely aligned to the Advanced Search. All fields are available in the Basic Search. In the current release version of CA APM, you set the search return fields that a user can view in the search feature. When you create a search and save the configured search, you can apply security to the search by selecting specific user roles and configurations.

By default, the security for the searches you create makes them available only to the creator. You assign roles and configurations to your searches to grant access to the users who are assigned to those roles and configurations.

Note: For information about searching, see Searching (see page 2431).

These changes cannot be migrated with the Migration Utility. Use the Basic Search Report data during the manual migration.

Follow these steps:

1. Identify the Object Type for the search on the Basic Search Report.
2. In CA APM, click the tab and optional subtab for the object that you want to find.
3. On the left, click New Search.
   The Add Fields dialog appears.

   Note: For some object types, you are prompted to select templates, families, or other attributes to narrow the search.

4. Using the report Search Return Fields, select the fields to add to the search. In Release 11.3.4, these fields were labeled Display Fields.
5. In the Add Fields(s) To area at the bottom of the dialog, select Search Criteria and Search Results.
6. Click OK.
   The fields are added to both the search criteria and search results. The Add Fields dialog closes.
7. At the top of the page, click CONFIGURE SEARCH: OFF.
   The configuration of the search is complete.
8. In the Search Information area, enter the search title and any other descriptive information, for example, Category and Description.
9. (Optional) Open the Search Security area.
10. (Optional) In the Search Security area, select the user roles for which the search is available.

    Note: We recommend that you select the user role that is identified on the Basic Search Report (see page 339).

11. (Optional) In the Search Security area, select the configuration for which the search is available.

    Note: If you do not select either a role or a configuration, the search is available only to the search creator.

12. Locate the Search Criteria area and the criteria fields that you entered.

13. For each Search Criteria field, enter the field value. You can click the search icon to search for a value.

14. (Optional) Open the Additional Settings area, and add other settings, for example, sorting settings.

15. Click Save.
    The search is saved.

16. If you selected user roles in the Search Security area, perform the following steps for each role:

    a. Click Administration, User/Role Management.

    b. On the left, expand the Role Management menu.

    c. Click Role Search.

    d. Search for and select the role.
       The role details appear.

    e. In the Default Searches area, click Select New.

    f. Search for the search that you just created.

    g. Assign the search as a default search for the role.

    h. Click Save.
       The updated role is saved.

Migrate Advanced Searches

In CA APM Release 11.3.4, the search return fields that a user can see are set in the Security feature by role. In this release, searches support an added level of security. You set the search return fields that a user can view in the search feature. When you save the configured search, you can apply security to the search by selecting specific user roles and configurations.

By default, the security for the searches you create makes them available only to the creator. You assign roles and configurations to your searches to grant access to the users who are assigned to those roles and configurations.

Note: For information about searching, see Searching (see page 2431).

These changes cannot be migrated with the Migration Utility.

When you migrate Advanced Searches, you complete the following steps:

- Create the Advanced Search (see page 355)

- Schedule a Search and Export Results (see page 357)

Create an Advanced Search

Use data from the Advanced Search Report (see page 339) and the Advanced Search Detail Report (see page 339) during the manual migration.

Follow these steps:

1. Identify the Object Type for the search on the Advanced Search Detail Report.
2. In CA APM, click the tab and optional subtab for the object that you want to find.
3. On the left, click New Search.
   The Add Fields dialog appears.

   Note: For some object types, you are prompted to select templates, families, or other attributes to narrow the search.

4. On the detail report, identify the fields that are in *both* the Return Fields and the Selected Criteria Fields.
5. On the Add Fields dialog, select the common fields that you identified on the report.
6. In the Add Fields(s) To area at the bottom of the dialog, select Search Criteria and Search Results.
7. Click OK.
   The fields that are both Search Criteria and Search Results fields are added to the search, and the Add Fields dialog closes.
8. Click Add Fields.
   The Add Fields dialog appears.
9. Select the Return Fields that are not common to the Return Fields and the Selected Criteria Fields on the detail report.
10. In the Add Fields(s) To area at the bottom of the dialog, select Search Results Only.
11. Click OK.
    The Search Results Only fields are added to the search, and the Add Fields dialog closes.
12. Click Add Fields.
    The Add Fields dialog appears.
13. Select the Selected Criteria Fields that are not common to the Return Fields and the Selected Criteria Fields on the detail report.
14. In the Add Fields(s) To area at the bottom of the dialog, select Search Criteria Only.

15. Click OK.
    The Search Criteria Only fields are added to the search, and the Add Fields dialog closes.

16. At the top of the page, click CONFIGURE SEARCH: OFF.
    The configuration of the search is complete.

17. In the Search Information area, enter the search title and any other descriptive information from the report. For example, Category and Description.

18. (Optional) Expand the Search Security area.

19. (Optional) In the Search Security area, perform the following steps to select the user roles for which the search is available:

    a. Click Select New in the Role Access area.
       The Role Search dialog opens.

    b. Enter the Role Name that is identified in the Assignment field on the Advanced Search Report. Role Name can be the name of a role or a contact name.

    c. Enter a Description, if you want.

    d. Select whether to include Inactive records in the search for the new role.

    e. Click Go.
       The search results appear.

    f. Select the roles or contacts for which the search is available.

    g. Click OK.
       The Role Search dialog closes.

20. (Optional) In the Search Security area, select the configuration for which the search is available.

    Note: If you do not select either a role or a configuration, the search is available to all users and configurations.

21. Locate the Search Criteria area and the criteria fields that you selected.

22. Click Advanced.
    The advanced Search Criteria area opens.

23. For each Search Criteria, perform the following steps:

    a. Click the Edit Record icon next to a Search Criteria.

    b. Locate the Criteria information about the report.

c. Enter the Operator, Value, Connector, and parenthesis, as indicated on the detail report.

d. Click the Complete Record Edit icon.

24. (Optional) Open the Additional Settings area, and add other search settings, for example, sorting.

> **Note:** In the Search Results Sorting area, select the Selected Field and Sort Direction values, as identified on the detail report Sort Order area.

25. Click Save.
The advanced search is saved.

Schedule a Search and Export Results

You can schedule a search to process periodically and export the search results to a CSV file or a database view.

Follow these steps:

1. In CA APM, click the tab and optional subtab for the object that you want to find.
2. On the left, click Manage Searches.
3. Search for and select the search that you saved.
4. On the left, click New Export.
5. Enter the basic export information that is based on the detail report export information.
6. The following fields require explanation:

- **Export name**
Specifies the export name.
- **Export Format**
Specifies the format for the exported search results.
- **View Name**
Specifies the database view name.

> **Note:** The view name is required if you select Database View for the Export Format. The name must be a valid database view name.

- **Description**
  Specifies a description for the exported search results.

- **Retention Days**
  Specifies the number of days that the exported search results are retained before the results are purged.

- **Folder Name**
  Specifies the folder for the exported CSV file search results.

- **Never Expires**
  Specifies that the CSV file or database view is never purged.

7. Schedule the search in the Export Schedule area. Use the detail report Refresh Interval value to schedule the search.
   The following fields require explanation:

   - **Run Time**
     Specifies the time of day to process the search, in the local time zone on the CA APM application server.

   - **Interval Type**
     Specifies the type of interval for the search, for example, Day, Month, Quarter, Week, or Year.

   - **Interval Day**
     Specifies the day during the interval to process the search. For example, if the Interval Type is Month and the Interval Day is 1, the search is processed on the first day of the month.

   - **First Run Date**
     Specifies the date when the first search starts to process.

   - **Interval**
     Specifies how often the search processes, which are based on the selected Interval Type. For example, if the Interval Type is Weekly and the Interval is 2, the search processes every two weeks.

   - **Last Day of Interval**
     Specifies that the search processes on the last day of the selected Interval Type.

8. Specify whether all roles and configurations that are assigned to the search receive the exported search results.

9. Click Save.
   The search is saved. The search processes at the scheduled time and the search results are exported.

Migrate Attachments

In the current release, the Storage Manager Service handles all attachment files. You can specify two types of attachments:

- **Web URL link.** Provides direct access to the page specified in the URL. When you add this type of attachment, include the prefix *http://* for the link to work correctly.
- **File path.** Provides direct access to a file. The file opens using the default program for the file type. At the time that you create this attachment type, the file is copied from your file system to the file system on a CA APM server.

  Note: If you add multiple attachments (to one object or to different objects), the name and file path or URL for each attachment must be unique for all objects.

In Release 11.3.4, file attachments were stored in a common share folder.

The Migration Utility migrates the complete Web URL link attachments and the metadata for remote server and local file attachments. The metadata includes the attachment description information and file path location information. The Migration Utility changes the file path location to the Storage Manager Service. After migration, you move the physical file attachments to the Storage Manager Service.

After you run the Migration Utility, you copy the Release 11.3.4 file attachments from the share folder and your local server to the current release Storage Manager Service. Web URL link attachments are migrated by the Migration Utility.

Note: For more information about file attachments, see Manage an Attachment (see page 2349).

Use the Attachments Report (see page 339) data during the manual migration.

Follow these steps:

1. Navigate to the file attachment location that is identified on the report.
2. Copy and paste the file attachment to the following location on the Storage Manager Service on the application server:

   - *[ITAM Root Path]*\Storage\Common Store\Attachment*attachment.extn*

   Replace *attachment.extn* with the attachment filename and extension.
   Enter the complete path to the file attachment, for example:
   C:\Program Files (x86)\ITAM\Storage\Common Store\Attachment\legaldoc1.docx
3. Repeat these steps for each remote server or local file attachment on the report.

   Note: Files that are not moved to the Storage Manager Machine location are not available in the product.

4. If you deleted an attachment from the remote server or your local machine, but not from CA APM, the Migration Utility migrates the metadata for the attachment. If the report identifies attachments that no longer physically exist, use the current release version of CA APM to delete the attachment metadata.

Migrate Events

You can use the user interface to define date, change, and watch events. You can set up notifications using hard-coded text and the CA APM object values. For example, you can specify that the subject of a notification include the words "Acknowledgment required for" followed by the value of the CA APM legal document identifier object. When an event occurs, email notifications can be sent to specific recipients. Notifications that are not acknowledged can be escalated.

Use the Date Event Report (see page 339) data and the Watch and Change Event Report (see page 339) data during the manual migration of events and notifications.

Follow these steps:

1. Follow the instructions for creating events and notifications i*n Administration (see page 1568)*.

2. Use the information in the Date Event Report and the Watch and Change Event Report to create the events and notifications.

Note: See CA Process Automation Integration (see page 3489) for information about workflow provider process parameters that you specify in CA Process Automation. For information about notification process parameters, see your workflow provider documentation.

Migrate Filters

In CA APM Release 11.3.4, the filters that a user can see are set in the Security feature, by role. In this release, filters support an added level of security. You set the filters that a user can view in the filters feature. When you configure a filter, you can apply security to the filter by selecting specific user roles and users who have permission to see the filter.

By default, the security for the filters you create makes them available to all roles and users. By applying unique security to your filters, you ensure that certain users cannot view sensitive information in a filter.

These changes cannot be migrated with the Migration Utility. Use the Filter Detail Reports (see page 339) data during the manual migration.

Follow these steps:

1. Identify the object for the filter on the Filtering Detail Report.

2. In CA APM, click the Administration tab and the Filter Management sub tab.

3. Click New Filter.
   The Filter Details page opens.

4. In the Filter Information area, perform the following steps, using the information in the Filtering Detail Report:

   a. Enter the Filter Name and the Object that you want to filter.

   b. (Optional) Enter a Description.

   c. (Optional) Select Assign Filter to All Users, if you want all users to be able to view the filter data. If you want to apply security to the filter, complete the Filter Security area, as described in the following steps.

5. In the Filter Security area, perform one or more of the following actions:

   - To enter roles that can see the filter:
     - Click Select New in the Roles area.
       The Role Search dialog opens.
     - Search for and select the roles that are permitted to see the filter.
     - Click OK.
   - To enter users who can see the filter:
     - Click Select New in the Users area.
       A search dialog opens.
     - Search for and select the users who are permitted to see the filter.
     - Click OK.

6. Click Add Fields.
   The Add Field(s) dialog opens.

7. Select the fields that appear on the report in the Selected Criteria Fields section.

8. Click OK.
   The Add Field(s) dialog closes and the fields that you selected appear in the Filter Criteria area.

9. Using the information in the Criteria area of the detail report, perform the following steps for each Filter Criteria:

   a. Click the Edit Record icon next to a Filter Criteria.

   b. Enter the Operator, Value, Connector, and parenthesis, as indicated on the report.

   c. Click the Complete Record Edit icon.

10. Click Save.
    The filter is saved.

Migrate Role Security

The Migration Utility migrates user roles, but not the role security settings. You migrate the role security (field, functional, and viewable linked object permissions) manually.

A user role is the primary record that controls security and user interface navigation. Each role defines a focused view of the product by exposing only the functionality necessary for users to perform the tasks that are typically assigned to their roles in their business organization. The default role for a user, together with the user interface configuration, determines what the user sees when logging in. A user can belong to only a single role.

You configure user roles to apply functional and field-level repository access rights. You determine and assign the level of access that is required for each role. Role assignment prevents the users from performing unauthorized tasks, such as adding or deleting data.

Field security defines the role permissions for an object field, for example, full control. Functional security defines the role permissions for functions on an object, for example, copy an asset. Viewable Linked Object Security defines the fields for the object.

You create the security permission settings for an object in the object local configurations. Then, you assign one of the object configurations to a role. The field and functional security permissions for a role are determined by the object configurations that are assigned to that role. The object configuration for each role is identified on the Role Security Reports for the object.

You perform the following manual migrations to migrate the role security:

- Migrate Role Field Security (see page 362)
- Migrate Role Functional Security (see page 363)
- Migrate Role Viewable Linked Object Security (see page 364)

Use the information in the Role Security Reports to migrate the role field security, role functional security, and role viewable linked field security manually.

Migrate Role Field Security

Use the information in the Role Security Reports (see page 339) to migrate role field security manually.

Follow these steps:

1. For role field security permissions, on the Field Security Report for the object, locate a field and the role permission for the field.
2. Create and name a local configuration for the object field. The following field security configurations are available:
   - **Full Control.** The field is editable by the role.

- **Hidden.** Hidden and removed from the user interface for the role.
- **Read Only.** The field is read only for the role.

> **Note:** For information about configuring the user interface, see How to Configure the User Interface (see page 1520).

Migrate Role Functional Security

Use the information in the Role Security Reports to migrate role functional security manually.

Follow these steps:

1. For role functional security permissions, on the Functional Security Report for the object, locate a function and the role permission for the function.
2. Create and name a local configuration for the object function. Functional security configurations can be one of many functions, for example, allow users to change the asset model. Functional security configurations have a permission of Granted Permission or Denied Permission.

> **Note:** For information about configuring the user interface, see the How to Configure the User Interface (see page 1520).

3. Save the object configuration.
4. Click Administration, User/Role Management.
5. On the left, expand the Role Management area.
6. Click Role Search.
7. Search for the role indicated on the Security Report.
8. Click the role name link in the Search Return area.
   The Basic Information area opens.
9. On the left, click Role Configuration.
   The Role Configuration area appears.
10. Click Select New.
    The list of saved configurations appears.
11. Select the object configuration that you want to assign to the role.

12. Click OK.
    The object configuration is assigned to the role.

Migrate Role Viewable Linked Object Security

Use the information in the Role Security Reports to migrate role viewable linked object security manually.

Follow these steps:

1. For role viewable linked object security permissions, on the Field Security Linked Object Viewable Report, locate a linked object and the role for the object.
2. Create and name a local configuration for the object. Link the fields that are defined as Assigned Fields for the Object in the report.
3. Save the object configuration.
4. Click Administration, User/Role Management.
5. On the left, expand the Role Management area.
6. Click Role Search.
7. Search for the role indicated on the Security Report.
8. Click the role name link in the Search Return area.
   The Basic Information area opens.
9. On the left, click Role Configuration.
10. Click Select New.
11. Select the object configuration that you want to assign to the role and click OK.

The object configuration is assigned to the role. Repeat the steps for each role in the report.

Migrate Hardware Reconciliation Tasks and Rules

The hardware reconciliation process involves the following steps:

1. Establish data normalization rules to map data values between discovery repositories and the product.
2. Define a reconciliation rule to specify how to limit the data being processed and how to process the records that were found.

> **Note:** The reconciliation rules in this step replace the Release 11.3.4 reconciliation tasks. You create reconciliation rules that are based on the Release 11.3.4 tasks from the Main Task Query Report (see page 332) and the Task Add Asset Report (see page 332), during the manual migration.

3. (Optional) Define reconciliation update options to specify the owned-asset fields that you want the Hardware Reconciliation Engine to update automatically with changes found in the corresponding discovered assets.

4. Define asset matching criteria to match owned and discovered assets for a reconciliation rule.

5. View the reconciliation results in the message queue.

Use the Main Task Query Report and Task Add Asset Report data during the manual migration of tasks to reconciliation rules.

Follow these steps:

1. Follow the instructions for defining reconciliation rules in *Define a Reconciliation Rule (see page 2417)* section.

2. Use the information in the Main Task Query Report and Task Add Asset Report to create the reconciliation rules.

Migrate Hardware Reconciliation Translation Lists

If you choose *not* to migrate the Hardware Reconciliation translation lists using the Migration Utility, you migrate the lists manually. You analyze the Main Translation List Query Report to make this decision.

The current release of CA APM replaces multiple translation lists of the same type with normalization rules for Model, Manufacturer, and Operating System.

Use the Main Translation List Query Report (see page 332) data during the manual migration of translation lists to normalization rules.

Follow these steps:

1. Follow the instructions for creating normalization rules in the Data Normalization (see page 351) section.

2. Use the information in the Main Translation List Query Report to create the normalization rules.

> **Note:** Merge all of the lists of the same type, eliminate duplicate entries, and migrate the combined list to the corresponding normalization rules.

Migrate Missing Entries from Hardware Reconciliation Translation Lists

The Translation List Unconverted Report identifies the Hardware Reconciliation legacy translation lists from CA APM Release 11.3.4 that have missing or invalid entries that are not migrated to the current release. The translation list is migrated, but some of the entries in the list are not migrated, because supporting data is not present in the legacy database.

The product replaces multiple translation lists of the same type with normalization rules for Model, Manufacturer, and Operating System.

Use data from the Translation List Unconverted Report (see page 332) and the Main Translation List Query Report (see page 332) to add missing entries on the legacy translation lists to the current release normalization rules.

Follow these steps:

1. Follow the instructions for updating normalization rules in the Data Normalization (see page 2407) section.

2. Use the information in the Translation List Unconverted Report to update the normalization rules in with the missing entries identified in the report.

> **Note:** Merge all of the lists of the same type, eliminate duplicate entries, and migrate the combined list to the corresponding normalization rules.

Migrate Hardware Reconciliation Searches

You migrate the hardware reconciliation custom searches from CA APM Release 11.3.4 to the current release hardware reconciliation reports. The product provides predefined hardware reconciliation reports that are generated by CA Business Intelligence software. You can customize these reports using CA Business Intelligence, which is also provided.

Hardware reconciliation reports provide the following information:

- Owned assets that have been reconciled to a discovered asset, including both discovered inventory and network discovery records.
- Billed assets (an active or received asset having a valid bill code) not matched to a discovery record.
- Discovered assets not reconciled to an owned asset.
- Discovered assets not processed due to missing or invalid data.
- Counts of the current discovery data volume.
- Owned assets matched to discovery records.
- Owned assets not matched to discovery records.

- Matches between network discovery data and agent discovery data.
- Potential lost revenue, including assets not being billed, but discovered. This report exposes revenue opportunities that are based on the number of assets being billed. Use the information in this report to provide proof that an asset is active and discovered.
- Network discovery records that have not been matched to a corresponding discovered inventory. Network discovery provides limited data to identify an asset on the network. Discovery provides detailed hardware and software information about an asset.

Use the Release 11.3.4 search information in the Customized Search Report (see page 332) to determine which hardware reconciliation reports to generate and possibly customize.

Follow these steps:

1. Follow the instructions for generating hardware reconciliation reports in the Reconciliation Reports (see page 2428) section.
2. Use the information in the Customized Search Report to locate the related hardware reconciliation report and enter the search criteria.

Note: To add unreconciled assets by generating and exporting the results of a report and then importing the report results through Data Importer, see Add Assets from Unreconciled Discovered Records (see page 2425).

Perform Post-Migration Verification for CA SDM and CA Service Catalog Integration

If you integrated CA Service Desk Manager and CA Service Catalog before performing the data migration, perform the post-migration verification of these integrations. You perform this verification after you have completed migrating all data to CA APM 14.1.

Follow these steps:

1. Click Run and execute services.msc.
2. Select and start the service, if the CA Service Desk Manager service is not running.
3. Go to the CA Service Desk Manager directory.
   If the CA Service Desk Manager PDM Tomcat service is not running, select and start the service.
4. Log in to CA Service Catalog. Go to Administration and click Configuration.
5. Click the CA APM Web Services hyperlink and enter the CA APM web server name.Enter the port number and click Save.
6. Log out and start the CA Service View service in services.msc.
   Verify that the CA APM integrations with CA Service Desk Manager and CA Service Catalog work.

Run the Post-Migration Reports for Manual Migration

After you run the Migration Utility, run the post-migration reports, which you use during manual migrations. The post-migration reports identify object data that you have to enter into the current release. The utility could not migrate some data because the feature associated with the data changed.

Follow these steps:

1. On the CA APM Migration Toolkit main window, click Migration Reporting.
2. Clear all of the check boxes in the Pre-Migration Reports area and select the following reports in the Post-Migration Reports area:
   - Advanced Searches
   - Attachments
   - Basic Search Return Fields
   - Events
   - Filters
   - Role Security (Field and Functional Permissions)

   Note: If you do not want to generate all post-migration report types, select only those report types that you want.
3. In the Report Output Folder area, click Browse, and select the output folder where you want to save the reports.
4. Click Generate Reports.
   The status messages appear in the Messages area to help you monitor the report generation process.
   You are prompted to open the report output folder to view the reports.
5. Click Yes.
   Windows Explorer opens. The Reporting tool creates a folder for each Post-Migration Reports check box that you selected previously.
6. Navigate to, and open, a report folder.
   The reports appear in comma-separated value (CSV) format.
7. Right-click a report and select Open with, Excel, to open and view the report in a table format.
   The report data (see page 339) is presented in a table format. The table headings are in the first row.

Note: You can open a report and view in a text editor, in CSV format.

CA APM Migration Utility Patch

Complete the following steps to apply the CA APM Migration Utility Patch:

Verify the Prerequisites

This CA APM Migration Utility Patch can be applied on CA APM Release 12.9 or CA APM Release 14.1.

Install the Patch

Follow these instructions to install the patch.

Download and Extract the Patch.

Follow these steps:

1. Download the CA APM Migration Utility patch from CA Support Online to the CA APM web server in a temporary folder.
2. Unzip the CA APM Migration Utility patch.
3. After unzipping, verify the availability of the following files:
   - Database.exe
   - healthcheck-version-1_0_0_737.exe
   - version-1_0_0_737.exe
4. Run the ‘Database.exe’ file, and verify availability of the following folders:
   - 12.9MDB
   - 14.1MDB
5. Run the 'healthcheck-version-1_0_0_737.exe' file, and verify availability of the following folders:

- com
- lib

6. Run the 'version-1_0_0_737.exe' file, and verify availability of the following folder:
   - Migration-CoraConfigurator
   - migration-documentation
   - Migration-launchUI
   - migration-reporting
   - migration-utility

Run the Health Check Utility.

From the extracted 'healthcheck-version-1_0_0_737' folder, run the Health Check Utility.

To run the Health Check utility, see the 'CA Migration Health Check Utility User Guide.docx' available within the 'healthcheck-version-1_0_0_737' folder.

Upgrade the Database.

Follow these steps:

1. Perform the following steps on the web server:
   a. For APM 12.9, from the command prompt, go to the [Extracted Database Folder] \Database\12.9MDB\mdb folder
   b. For APM 14.1, from the command prompt, go to the [Extracted Database Folder] \Database\14.1MDB\mdb folder
2. For **SQL Server**, execute the following command:

```
setupmdb.bat -DBVENDOR=mssql -DBNAME=<mdb_name> -DBHOST=<database_hostname> -
DBUSER=<database_username> -DBPASSWORD=<database_password> -
MANIFEST=Unicenter_Asset_Portfolio_Management -WORKSPACE=UAPM
```

DBVENDOR
Specifies the database vendor name. Enter mssql for SQL Server.

DBNAME
Specifies the existing CA APM Release 12.9 or CA APM Release 14.1 MDB database name.

DBHOST
Specifies the database server system host name.

DBUSER
Specifies the existing CA APM Release 12.9 or CA APM Release 14.1 MDB database user name.

DBPASSWORD
Specifies the existing CA APM Release 12.9 or CA APM Release 14.1 MDB database password.

Important! The -DBUSER and -DBPASSWORD parameter values must match your existing CA APM Release 12.9 or CA APM Release 14.1 database user name and password.

MANIFEST
Specifies the name of the manifest file. Do not change the default value for this parameter.

WORKSPACE
Specifies the name of the workspace. Do not change the default value for this parameter.

3. For **Oracle Server**, execute the following command:

```
setupmdb.bat -DBVENDOR=oracle -DBNAME=<oracle_service_name> -
DBHOST=<database_hostname> -DBUSER=<database_username> -
ORA_TBLSPACE_PATH=<tablespace_path> -DBPASSWORD=<database_password> -
MDB_ADMIN_PSWD=<mdb_administrator_password> -
MANIFEST=Unicenter_Asset_Portfolio_Management -WORKSPACE=UAPM
```

DBVENDOR
Specifies the database vendor name. Enter oracle for Oracle.

DBNAME
Specifies the existing Oracle Service name.

DBHOST
Specifies the database server system host name.

DBUSER
Specifies the existing Oracle database user name.

ORA_TBLSPACE_PATH
Specifies the path to the Oracle tablespace.

DBPASSWORD
Specifies the existing Oracle database password

Important! The -DBUSER and -DBPASSWORD parameter values must match your existing CA APM Release 12.9 or CA APM Release 14.1 database user name and password.

MDB_ADMIN_PSWD
Specifies the existing MDB administrator password.

MANIFEST
Specifies the name of the manifest file. Do not change the default value for this parameter.

WORKSPACE
Specifies the name of the workspace. Do not change the default value for this parameter.

Verify MDB Installation

Open the install_<databasename>.log file with a text editor.

Note: In the log file name, database name is replaced with the name of the database. For example, if the database name is test, the log file name is install_test.log.

Verify that a message similar to the following message appears at the end of the log file:

'*MDB setup completed successfully*'

Upgrade to CA APM Release 12.9 or CA APM Release 14.1

Upgrade to CA APM Release 12.9 or CA APM Release 14.1.

For more information, see Migrate CA APM Release 11.3.4 to the Current Release (see page 325).

Run the Migration Utility.

Follow these steps:

1. Generate Pre-Migration Reports:
    a. Log in as an administrator
    b. Navigate to the folder 'version-1_0_0_737'\migration-reporting'.
    c. Run the 'migration_reporting.bat' file.
    d. Select the option for Pre-Migration reports.

    Note: When the CA APM Migration Utility for Reporting is launched, configure the database manually.

2. If the Health Check Utility reports a duplicate asset name, perform the following steps:
    a. Log in as an administrator
    b. Navigate to the folder 'version-1_0_0_737\Migration-CoraConfigurator'.
    c. Run the 'Migration-CoraConfigurator.bat' file.

> **Note:** When the CA APM Migration Utility for Duplicate Asset Name Configuration is launched, configure the database manually.

3. Run the Migration Utility:
    a. Log in as an administrator
    b. Navigate to the folder 'version-1_0_0_737'\Migration Utility'.
    c. Run the 'Migration-Utility.bat'

> **Note:**When the CA APM Migration Utility is launched, configure the database manually.

4. Generate Post-Migration Reports:
    a. Log in as an administrator
    b. Navigate to the folder 'version-1_0_0_737'\migration-reporting'.
    c. Run the 'migration_reporting.bat' file.
    d. Select the option for Post-Migration reports.

> **Note:** When the CA APM Migration Utility for Reporting is launched, configure the database manually.

Fixes

The following defects have been fixed in the CA APM Migration Utility patch:

Title	Description
Cost and Payment Issue	Cost and Payments Node failed due to duplicate records. Cost and Payments Node failed due to an invalid reference fields cost center.
App filter and extensions Issue	Asset saves failed due to missing iscikey attribute in metadata. Asset extensions were not migrating due to an error in the upgrade scripts.
Heap fixes Issue.	Relationship audit history that is failed with a heap error. Asset audit history that is failed with a heap error.

Title	Description
Health Check Utility Issue	Health Check Utility processing MDB 1.5 definitions for Table Reference Diagnosis. This is invalid as it runs against MDB 1.4 database.

Enhancements

The CA APM Migration Utility patch includes the following enhancements:

1. If the upgrade script fails, the database installation stops.
2. Roll back schema objects is available in upgrade scripts when the MDB script fails.
3. A security warning dialogue box appears when you try to run the Health Check Utility again. You can click **Yes** to continue or **No** to discard.

Troubleshoot the CA APM Migration Utility

This article contains the following topics:

Web Servers Named with Underscore Characters

Symptom:

Using underscore characters in web server host names cause problems when you log in to the product or when you use CA EEM for user configuration.

Solution:

If you are using a virtual or ghosted system, configure a new host name by creating another image without the underscore character. For a production system, add a host name to your internal Domain Name System (DNS) so that the product can be accessed with a different URL.

Audit History Migration Fails

Symptom:

After you execute the Migration Utility, the status icon for Audit History shows “Error” indicating the migration has failed and the migration utility logs shows the following message:

```
Audit History migration has aborted due to a history data conflict with the Group Separator. Contact CA Support to determine a unique Group Separator.
```

Solution:

Contact CA Support.

Migration Utility Class Error

Symptom:

When you try to launch the Migration Utility from the toolkit or command prompt, you get the following error message:

```
Could not find the main class: com.ca.core.gui.Appplication
```

Solution:

The error occurs if you have configured an incorrect path for the KETTLE_HOME. Ensure that the KETTLE_HOME environment variable is set to the path of Kettle which contains the folder “data-integration”. For example: C:\Program Files\Pentaho\Kettle\.

Duplicate Asset Name Configurator link fails to launch

Valid on Windows 2008 Operating System

Symptom:

You cannot execute the Duplicate Asset Name Configurator with User Access Control (UAC) turned ON.

Solution:

To execute the Duplicate Asset Name Configurator with UAC turned ON, launch the UI as an administrator.

- Right-click LaunchUI.bat and click Run as Administrator.

Implementing CA SAM with CA APM

This section contains the following articles:

CA SAM and CA APM Overview

CA APM coordinates with CA SAM to allow you to perform software asset management functions. CA SAM is the next evolution of software asset and compliance management, superseding CA Software Compliance Manager (CA SCM). See the product support site on CA Support Online for more information about the plans for CA Software Compliance Manager.

Note: We do not recommend that you manage software assets in CA APM. To take advantage of the enhancements that CA APM provides, we recommend that you use CA SAM to manage your software assets and licenses.

Important! If CA APM is integrated with CA SAM in your solution deployment, consider the following:

- To install/upgrade to CA SAM 3.6.5 or later, you must install/upgrade to CA APM 14.1.01 or later to be fully compatible with CA SAM.
- For older versions of CA APM (14.1 or older), you must not upgrade CA SAM to version 3.6.5 or later.

CA SAM provides the following advantages:

- Supports the process of determining your software license compliance position by comparing the number of available licenses with the number of used licenses.
- Integrates a software license import function into the CA SAM user interface.
- Facilitates the creation and maintenance of a software license catalog with detailed commercial information about the licenses.
- Assigns installation and usage data to defined products in the software license catalog.
- Performs software product recognition.
- Permits financial analysis of product prices, license costs, and contract payments (this function is available through an additional module).

If you implement both CA APM and CA SAM, you can coordinate the management of both hardware and software assets in your organization. CA APM maintains hardware asset data and CA SAM maintains software asset and license data. Common data that both CA APM and CA SAM require is shared.

CA APM and CA SAM Data Synchronization

The article contains the following topics:

When you implement CA APM with CA SAM, CA APM and CA SAM share data that is required for hardware and software asset management. To maintain the integrity of the data and of the asset management process, data must be synchronized between CA APM and CA SAM. Data synchronization ensures that objects that are the same in both CA APM and CA SAM contain the same data values. This data synchronization occurs in the following ways:

- Automatic - When you create, update, or delete the following objects in CA APM (through the user interface, web services, or Data Importer), the objects are automatically synchronized in CA SAM. Create, update, or delete the following objects in CA APM only.
  - Company
  - Location
  - Cost center
  - Division
  - Contact

Important! The CA SAM Administrator must designate these objects as read-only in CA SAM to prevent any unauthorized change and to ensure that data is synchronized correctly. For more information about this requirement, see Data Management Recommendations. For more information about designating objects as read-only in CA SAM, see the CA SAM documentation.

Note: These objects use the same labels in CA APM and CA SAM, except Contact. In CA SAM, the Contact object is labeled "User".

For Contact, Company, and Location, the automatic synchronization occurs for specific data types only as shown in the following table:

Object	Automatically Synchronize when Type Is
Contact	User
Company	Internal
Location	NULL

- Manual - When you create or update the following objects in CA APM or CA SAM, synchronize the objects manually. Create or update the following objects in CA APM or CA SAM.
  - Country
  - Region

For example, if you create a Country object in CA SAM, manually create the same object in CA APM. If you update a Region object in CA APM, manually update that object in CA SAM.

Note: For more information about manual data synchronization, see the Data Management Recommendations.

- Data Loading - When you upgrade to CA APM Release 12.9 from a previous CA APM Release 12.6 installation, you can load your existing CA APM data for Company, Location, Cost center, Division, and Contact into CA SAM. For more information about data loading, see Load CA APM Data into CA SAM (see page 389).

Note: If you are implementing CA APM with an existing instance of CA SAM, there is existing CA SAM data that has not yet been synchronized. Before you start the automatic synchronization process, synchronize the existing CA SAM data with the CA APM data. For more information, see the following article on the CA SAM product page (https://support.ca.com/irj/portal/prddtlshome?prdhmpgform=p&productID=8572) on CA Support, Recommended Reading section: "How to Synchronize CA APM Data with an existing CA SAM Instance".

How to Configure Data Synchronization

You can configure the automatic data synchronization of CA APM and CA SAM data to suit your particular business needs. You can configure the type and attributes of the objects that are synchronized. You can also configure the criteria that are used to select the data rows for synchronization. To configure the data synchronization, edit the configuration file SAMDataSynchConfig.xml.

Important! The product installation saves the data synchronization configuration file SAMDataSynchConfig.xml with default settings for the data attributes and criteria. You modify this file *only* if you want to customize the default settings.

You can find the data synchronization configuration file in the following Event Service and Application Server folders:

```
<InstallFolder>\CA\ITAM\EventService\SAMDataSynchConfig.xml
<InstallFolder>\CA\ITAM\Application Server\SAMDataSynchConfig.xml
```

Note: If you change the configuration file in one of the folders, make the same changes to the configuration file in the other folder.

Example SAMDataSynchConfig.xml Configuration File Structure

The following example shows a section of the configuration file with the following changes to the default attributes and criteria:

- APMCriteria statements (highlighted) - Analyst was added as a criterion for the CA APM contact attribute (contacttype.value). User is the default criterion.

- SamField statements (highlighted) - CA APM contact (contactid) was mapped to the CA SAM user (import_user_id). The default statement (commented out in the example) mapped the CA APM asset owner (resourceownerid) to the CA SAM user (import_user_id).

```
<SamTable apmsyncclass="contact" samsynctable="users" >
   <SamField apmattribute="individualid" samattribute="import_id" />
   <SamField apmattribute="emailid" samattribute="login" />
   <SamField apmattribute="costcenterkey" samattribute="import_level_2_id" />
   <SamField apmattribute="lastname" samattribute="last_name" />
   <SamField apmattribute="firstname" samattribute="first_name" />
   <SamField apmattribute="emailid" samattribute="email" />
   <APMCriteria>
    <Criteria apmattribute="contacttype.value" value="User" />
    <Criteria apmattribute="contacttype.value" value="Analyst" />
   </APMCriteria>
</SamTable>
<SamTable apmsyncclass="asset" samsynctable="devices" >
   <SamField apmattribute="costcenterkey" samattribute="import_org_level_2_id" />
   <SamField apmattribute="locationid" samattribute="import_location_id" />
   <!--<SamField apmattribute="resourceownerid" samattribute="import_user_id" />-->
   <SamField apmattribute="contactid" samattribute="import_user_id" />
</SamTable>
```

The following terms in the example require explanation:

- **SamTable**
  Specifies the XML node that represents the mapping of the CA APM and CA SAM data objects or table.

- **Apmsyncclass**
  Specifies the name of the data synchronization object in CA APM.

- **Samsynctable**
  Specifies the name of the database table that the CA APM objects map to in CA SAM.

- **SamField**
  Specifies the XML node that represents the mapping of CA APM and CA SAM attributes.

- **Apmattribute**
  Specifies the CA APM attribute of the data synchronization object. To generate the name of the attribute, log in to the CA APM database using a database client tool and execute the following query:

  ```
  select attribute_name, class_name, table_name, field_name from arg_attribute_def where class_name='object_name';
  ```

  Use the value of the attribute_name column as the value for the Apmattribute XML attribute in the configuration XML.

- **Samattribute**
  Specifies the field name in the database table that the CA APM attributes map to in CA SAM. For the list of CA SAM objects and attributes, see the *CA Software Asset Manager Administration Manual.*

- **APMCriteria**
  Specifies the XML node that holds one or more child criteria nodes.

- **Criteria**
  Specifies the XML node that represents the criteria that is applied with the OR connector in the CA APM database table.

Data Synchronization Configuration Limitations

The following limitations apply to the changes that you can make to the data synchronization configuration file:

- You can change the mapping of attributes within a data object. You cannot change the mapping at the object level. For example, you cannot map the CA APM Location with the CA SAM User. You can map the CA APM Location with the CA SAM Location only.

- You can add columns under criteria. For example, the Contact object has User as the default Contact Type. As a result, all the data rows in the Contact object with Contact Type of User are selected for data synchronization. You can add other criteria. The following statements show a sample of how to add criteria:

```
<APMCriteria>
    <Criteria apmattribute="contacttype.value" value="User" />
    <Criteria apmattribute="contacttype.value" value="Analyst" />
    <Criteria apmattribute="costcenter.value" value="NewCostCenter" />
</APMCriteria>
```

  These statements specify the following selection criteria for data synchronization:

  - All Contacts with a Contact Type equal to User or Analyst
  - All Contacts with a Cost Center equal to New Cost Center

- Each criteria XML node can have only one value. For example, the default criteria value for Contact Type is User. More values (for example, “Analyst” or “Employee”) can be added (or removed). However, you cannot have “Analyst, Employee” as the criteria value. Create a criteria XML node for each unique value.

Add an Attribute

You can add an attribute to the data synchronization configuration file. You can also change an existing attribute in the file by editing an existing statement.

Follow these steps:

1. Create a SamField node by adding the following statement under the existing SamField nodes:

   ```
   <SamField apmattribute="attribute_name" samattribute="attribute_name" />
   ```

Note: Perform the following steps to identify the values that are needed for this statement.

2. Execute the following query on the CA APM database using a database client tool:

```
select class_name, attribute_name, table_name, field_name
from arg_attribute_def where class_name='object_name';
```

3. In the query results, copy the attribute_name value that was generated in the previous step. Paste this value in your new SamField node statement as the apmattribute value.

4. Access the *CA Software Asset Manager Administration Manual,* Data Imports chapter, and locate the field tables in the Formats section.

5. Copy the appropriate field name and paste it in your new SamField node statement as the samattribute value.

Note: For help with selecting the appropriate CA SAM fields, contact CA Services.

Add Criteria

You can add criteria to the data synchronization configuration file to expand the data values that are selected for data synchronization.

Follow these steps:

1. Create a criteria node by adding the following statement under the existing criteria nodes:

```
<Criteria apmattribute="value" value="value" />
```

Note: Perform the following steps to identify the values that are needed for this statement.

2. Execute the following query on the CA APM database using a database client tool:

```
select class_name, attribute_name, table_name, field_name
from arg_attribute_def where class_name='object_name';
```

3. In the query results, copy the attribute_name value that was generated in the previous step. Paste this value in the new criteria node statement as the apmattribute value.

4. Provide the criteria values by completing the following steps:

    a. Execute the following query:

```
Select field_name, table_name from arg_attribute_def where class_name =
'<apmsyncclass value>' and attribute_name = <apmattribute value>.
```

b. In the query results, select the field_name from the table_name.

c. Copy the field value and paste it in the *value="value"* parameter from Step 1.

Note: Create a separate criteria node for each unique value that you want to synchronize.

How to Implement CA SAM with CA APM

Perform the following steps to implement CA SAM with CA APM:

1. Review the prerequisites (see page 382).
2. Configure the CA APM Event Service for CA SAM (see page 383).
3. Configure the SAM Import Driver (see page 384).
4. Schedule the Windows task for the Hardware Import (see page 385).
5. Start the CA APM Event Service (see page 386).
6. Enable the software asset management capabilities (see page 386).
7. Load CA APM data into CA SAM (see page 389).

Note: To implement CA SAM, you also need to download the latest version of the CA SAM Catalog from CA Support Online and apply the Catalog in CA SAM. You can perform the Catalog download before or after you implement CA SAM with CA APM. For information about the CA SAM Catalog, see the CA SAM documentation (https://support.ca.com/irj/portal/anonymous/phpsupcontent?contentID=fd1d7034-8f4f-4f28-9de8-3a9f503e9b2a&productID=8572).

Review the Prerequisites

Review the following prerequisites to ensure that you can successfully implement CA SAM with CA APM.

- You installed CA APM.

Important! Verify that the CA APM workflow provider URL is accessible and the corresponding login credentials are valid.

> **Note:** If your CA APM environment integrates with CA Service Desk Manager (CA SDM), verify that you have enabled the CA SDM audit history.

- You installed CA SAM from the CA SAM installation media. For information about installing CA SAM, see the CA SAM documentation (https://support.ca.com/irj/portal/anonymous/phpsupcontent?contentID=fd1d7034-8f4f-4f28-9de8-3a9f503e9b2a&productID=8572).

  > **Important!** Microsoft .NET Framework 4.0 must be installed also on the CA SAM server.

  If you are using CA SAM to manage software assets for more than 250,000 hardware assets, we recommend the following installation configuration for improved system performance:

  - Install a CA SAM staging server for processing discovery data only. Implement the staging server on a MySQL database for improved performance and scalability.
  - Install the CA SAM production server on either a SQL Server or an Oracle database.
  - Transfer the discovery data to the CA SAM production server when processing is complete on the staging server.

- You installed CA SAM version 3.5.1 or later.
- (Optional) You verified and uninstalled CA SAM Import and Export Service.
  CA SAM Import and Export Service is no longer required to implement CA SAM with CA APM. If you are upgrading from CA APM 12.7, 12.8, or 12.9, we recommend that you uninstall the CA SAM Import Export Service.

Configure the CA APM Event Service for CA SAM

Configure the CA APM Event Service by validating or editing the parameters on the CA APM Administration tab.

Follow these steps:

1. Log in to CA APM on the web server as the administrator.
2. Navigate to Administration, System Configuration, Event Service page.
3. Click Show Advanced Options.
   The parameters that apply to CA SAM appear.
4. Validate or edit the values in the following parameters:

- **Interval between Event Occurrence check (in milliseconds)**
  The amount of time, in milliseconds, that CA APM waits between database checks for field changes related to defined events.
  If SAM capabilities are enabled, verify that this parameter is set to 30000. If SAM capabilities are not enabled, verify that this value matches the setting in the Event Service configuration

file.
Default (without CA SAM implementation): 3600000 (1 hour)
Default (with CA SAM implementation): 30000 (30 seconds)

- **Interval between triggering events check (in milliseconds)**
  Amount of time, in milliseconds, that CA APM waits between database checks for triggered events that need to be sent to the workflow provider.
  If SAM capabilities are enabled, verify that this parameter is set to 60000. If SAM capabilities are not enabled, verify that this value matches the setting in the Event Service configuration file.
  Default (without CA SAM implementation): 3600000 (1 hour)
  Default (with CA SAM implementation): 60000 (60 seconds)

- **Interval between triggered events status update (in milliseconds)**
  The amount of time, in milliseconds, that CA APM waits between updates to the status of triggered events that were sent to the workflow provider.
  If SAM capabilities are enabled, verify that this parameter is set to 60000. If SAM capabilities are not enabled, verify that this value matches the setting in the Event Service configuration file.
  Default (without CA SAM implementation): 3600000 (1 hour)
  Default (with CA SAM implementation): 60000 (60 seconds)

- **Interval between asset contact update (in milliseconds)**
  The amount of time, in milliseconds, that CA APM waits between updates to asset contacts in the CA CMDB.
  Default: 43200000 (12 hours)

- **CA SAM Status Update Frequency**
  The frequency for updating the status of CA SAM import jobs in the MDB (in milliseconds).
  Default: 120000 (120 seconds)

- **On Demand Max Threads**
  The maximum number of threads for processing the data synchronization between CA APM and CA SAM. The default (zero) indicates that the system creates the required number of threads, depending on the system hardware configuration. Any value other than the default value uses the same number of threads, regardless of the system configuration.
  Default: 0

- **CA SAM Events Notification Email**
  The CA APM administrator email address for receiving notifications about the CA SAM data synchronization.

- **Query Top**
  The number of triggered events that are processed at one time.
  Example: This value is set to 1000 and 1500 events are triggered. The first processing pass processes the first 1000 records, and the next processing pass processes the remaining 500.
  Default: 1000

Configure the SAM Import Driver

Configure the SAM Import Driver by validating or editing the parameters on the CA APM Administration tab.

Follow these steps:

1. Log in to CA APM on the web server as the administrator.
2. Navigate to Administration, System Configuration, SAM Import Driver page.
3. Validate or edit the values in the following parameters:
   - **ITAM Root Path**

     The path to the root location where the product is installed.
   - **File Path**

     The path to the root location where CA SAM export files are imported.

     Example: [ITAM Root Path]\ITAM\Import Driver\Input
   - Import Processor Executable Path

     The path to the Data Importer Processor executable file (ImportProcessor.exe)

     Example: [ITAM Root Path]\ITAM\Import Processor\ImportProcessor.exe

Schedule the Windows Task for the Hardware Import

Use the Windows Task Scheduler to schedule a task to import into CA APM the discovered hardware data from CA SAM. The following procedure schedules the import to run once every day.

Note: While this procedure describes the use of the Windows Task Scheduler, you can also use another task scheduler or process orchestration tool.

Follow these steps for Windows Server 2008:

1. From the Start menu on the CA APM application server, open the Windows Task Scheduler. For example, on Windows Server 2008, go to Control Panel, System and Security, Administrative Tools, Schedule Tasks.
2. Click Create Task.
3. On the General tab, enter a name for the task.
4. Select the check box for “Run whether user is logged in or not”.
5. Navigate to the Actions tab and click New.
6. In the Action field, select Start a program.
7. In the Program/script field, browse to locate the Import Driver Program folder, select the ImportDriver.exe file, and click OK.

8. Navigate to the Triggers tab and click New.
9. In the Settings field, select Daily.
10. In the Start field, select 12:00:00 AM.
11. Select Recur every 1 day and click OK.
12. On the Create Task dialog, click OK.
    You have completed scheduling the Windows task to import discovered hardware data.

Start the CA APM Event Service

If you are upgrading from a previous CA APM release, you start the CA APM Event Service to complete the implementation of CA SAM with CA APM:

Follow these steps:

1. From the Start menu on the CA APM application server, open the Control Panel, Administrative Tools, Services.
2. Locate the entry for the CA Asset Portfolio Management - Event Service.
3. Right-click the service and select Start.
   The service is started.

Enable Software Asset Management Capabilities

After you install and configure all CA APM components, you then enable the software asset management capabilities.

If you currently have an integration between CA APM and CA Software Compliance Manager (CA SCM), uninstall CA SCM before you enable software asset management capabilities. For information about uninstalling CA SCM, see How to Uninstall CA Software Compliance Manager (see page 395). For more information about how and when to uninstall CA SCM, contact your CA Services representative.

Note: If you enabled software asset management capabilities in a previous release and you are now upgrading, skip the following steps. However, update the web.config configuration file on the CA APM web server to refer to the CA SAM section of the common home page. Update the following statement:

```
<add key="CASAMWebClientUrl" value="http://CA_SAM_server_name/prod" />
```

Example:

```
<add key="CASAMWebClientUrl" value="http://itamsam/prod" />
```

Follow these steps:

1. Log in to CA APM on the web server as the Administrator.

2. Navigate to Administration, System Configuration, Software Asset Management.

3. Complete the requested information. The following fields require explanation:

   CA SAM Web Client URL
   Specifies the URL for the CA SAM home page.
   Note: You can copy the web client URL from the CA SAM home page after you log in.

   Enable SAM Capabilities
   Specifies that software asset management capabilities are enabled. If you previously had CA SCM fields on the CA APM user interface, they are removed after you select this check box.

   CA SAM Web Service WSDL URL
   The URL for the CA SAM Web Service Definition Language (WSDL). This URL is used to access the CA SAM web service. Use the following format:

   ```
   http://[CA SAM System Name]:[Port Number]/prod/soap/dyn_server.php
   ```

   Replace [CA SAM System Name] with the name of the CA SAM server.
   Replace [Port Number] with the port number where the CA SAM Web Service is hosted.

   CA SAM Web Service Login
   Login name for the CA SAM web service.
   Note: Verify that this login name and the CA SAM Web Service Password match the login name and password in the config_soap.inc file. This file is found in the following CA SAM installation folder path:

   ```
   app\includes\prod\st\config_soap.inc
   ```

   Important! The default content of the config_soap.inc file is commented. Remove the comment delimiters (/* */) and configure the login name and password.

   CA SAM Web Service Password
   Login password for the CA SAM web service.

   CA SAM Database Type
   Specifies the Database type of SAM server.
   Default: SQL Server

   CA SAM Data exchange directory
   Specifies the name of the Data Exchange directory on SAM server used for Data synchronization.
   Example: external
   Default: superuser

   CA SAM SSO Encryption Algorithm
   Specifies the encryption algorithm to be used for single sign-on access to CA SAM from the CA Asset Portfolio Management common home page.
   This entry must match the entry in CA SAM System Configuration for the

security_auth_token_cipher field.
For more information about CA SAM single sign-on, see the description of single sign-on in the *CA Software Asset Manager Administration Manual*.

CA SAM SSO Encryption Algorithm
Specifies the encryption algorithm to be used for single sign-on access to CA SAM from the CA Asset Portfolio Management common home page.
This entry must match the entry in CA SAM System Configuration for the security_auth_token_cipher field.
Note: For more information about CA SAM single sign-on, see the description of single sign-on in the *CA Software Asset Manager Administration Manual*.

CA SAM SSO Authentication Mechanism
Specifies the mechanism to be used for logging in to CA SAM.
This entry must match the entry in CA SAM System Configuration for the security_auth_method field.
Note: We recommend that you select auth_token_password for this mechanism. The auth_token mechanism disables the login for other CA SAM users.

CA SAM SSO Field to Authenticate User
Specifies the type of unique identifier (import ID or email address) that is used to authenticate the user.
This entry must match the entry in CA SAM System Configuration for the security_auth_token_user_identifier field.

CA SAM SSO Secret Key
Specifies the key that CA APM and CA SAM share and that is used to encrypt and decrypt the user authentication. This key ensures that CA APM users who do not have the proper authentication cannot access CA SAM.
This entry must match the entry in CA SAM System Configuration for the security_auth_token_key field.

4. Click Save.

5. Restart the Apache Tomcat Common Asset Viewer service.

Note: Also restart the Apache Tomcat Common Asset Viewer service if you change the entries in any of the following fields at a later time:

6. Restart Internet Information Services (IIS) on the CA APM web servers and application servers by executing the iisreset command.

7. Software asset management capabilities are enabled, and CA SCM fields are removed from the CA APM user interface.

The Load Data button is enabled if CA APM data exists (for example, if you had an existing CA APM 12.6 installation and you are upgrading). You can then load existing CA APM data for selected objects into CA SAM. For information about loading data, see Load CA APM Data into CA SAM (see page 389). This button is not enabled if you are performing a new installation of CA APM. You do not have existing data with a new installation.

Common Home Page Single Sign-On

When the CA SAM implementation is complete, the CA IT Asset Manager common home page displays Hardware and Software Asset Management dashboards. These dashboards contain links that open pages in CA APM and CA SAM. After you log in to CA APM and open the common home page, you can access CA SAM pages without logging in to CA SAM.

To implement the single sign-on, verify that the following steps are completed:

1. The user ID in CA APM exists as a user ID in CA SAM, also.
2. The user email address and Import ID in CA SAM match the user email address and Contact ID in CA APM.
3. The CA SAM user is authorized to perform CA SAM functions.
    a. Access the CA SAM user details page by selecting Organization, User, and then editing an existing user record or creating a user record.
    b. Select the check box for CA Software Asset Manager authorization.

Load CA APM Data into CA SAM

After you enable software asset management capabilities in CA APM, you can load existing CA APM data for selected objects into CA SAM. This data load allows you to synchronize the data so that objects that match in CA APM and CA SAM have the same data values. The CA APM data that you can load includes the following objects:

1. Location
2. Division
3. Company
4. Cost Center
5. Contact

If you had a previous installation of CA APM, you have existing CA APM data for these objects. If you are performing a new installation of CA APM, you do not have any existing data.

Note: Before you load CA APM data into CA SAM, verify that your CA APM data meets CA SAM requirements. These requirements are defined in Field Requirements for Automatic Data Synchronization.

Follow these steps:

1. On the Administration, System Configuration, Software Asset Management page, verify that the Load Data button is enabled.

> **Note:** The Load Data button is enabled if CA APM data exists (for example, if you had an existing CA APM 12.6 installation and you are upgrading).

2. Click Load Data.
   The data load copies the Location, Division, Company, Cost Center, and Contact object values to CA SAM. A status table displays the progress of the data load.
   If some of the objects fail to synchronize with CA SAM, the error records are written to a log file. You can view this log file by clicking the Get Error Records button. The Get Error Records button is available only after you enable SAM capabilities.

3. Click Get Error Records to verify if any data synchronization errors occurred.
   You are prompted to open or save a CSV file. If errors exist in the CSV file, the errors are grouped by object in the following order:

   a. Location

   b. Division

   c. Company

   d. Cost Center

   e. Contact

4. Review the errors and explanations in the CSV file and correct the CA APM object data.
   The corrected objects are synchronized with CA SAM during the next data synchronization.

How to Implement Multi-tenancy with CA SAM

If you implemented multi-tenancy and your tenants require to perform software asset management functions, you can integrate each tenant with CA SAM. For example, you manage 20 tenants and only 12 of them require software asset management functions. You can integrate each of these tenants with CA SAM separately.

To implement multi-tenancy, create a CA SAM instance for each tenant on CA APM. For example, if you manage ten tenants using CA APM, you must install CA SAM on ten different computers. Each installation of CA SAM corresponds to a single tenant.

If you configured multiple tenants in CA APM to a single instance of CA SAM, discovered asset information is updated based on the matching asset details. However, if the discovered asset is a new asset, CA APM creates a new asset but is not assigned to any tenant.

Important! You cannot integrate a tenant group with CA SAM.

When you integrate a tenant with CA SAM, CA APM creates a data synchronization configuration file with the name SAMDataSynchConfig-*<Tenant Name>*.xml. For example, if the name of the tenant is Tenant1, data synchronization configuration file is named SAMDataSynchConfig-Tenant1.xml.

For more information on data synchronization, see CA APM and CA SAM Data Synchronization (see page 376).

Note: When you implement multi-tenancy with CA SAM, public data is not synchronized.

To implement multi-tenancy with CA SAM, perform the following steps :

- Identify the tenants that require integration with CA SAM.
- For each tenant you identify, determine the computer on which you plan to install CA SAM. For information on CA SAM system requirements, see CA SAM documentation (https://support.ca.com/irj/portal/anonymous/phpsupcontent?contentID=fd1d7034-8f4f-4f28-9de8-3a9f503e9b2a&productID=8572).
- Map the tenant in CA APM to the instance of CA SAM. See Configure CA SAM Settings for a Tenant (see page 391).

Configure CA SAM Settings for a Tenant

After you install CA SAM on the computers that you identified, map each tenant in CA APM to the respective instance of CA SAM. You can perform the mapping by specifying the CA SAM settings for each tenant in the System Configuration page.

Follow these steps:

1. Log in to CA APM on the web server as the administrator.
2. Navigate to Administration, System Configuration, Software Asset Management.
3. In the APM Tenant drop-down list, select the tenant for which you want to specify the CA SAM settings.
4. Specify the requested information and click Save.

For information on the CA SAM configuration settings, see Enable Software Asset Management Capabilities (see page 386).

Data Management Recommendations

Contents

The recommendations in this section help you manage your data when CA APM is implemented with CA SAM.

Manual Data Synchronization

Data must be synchronized between CA APM and CA SAM to maintain the integrity of the data and of the asset management process. Data synchronization ensures that objects that are the same in both CA APM and CA SAM contain the same data values.

When you create or update the Country and Region objects in CA APM or CA SAM, synchronize the objects manually. For example, if you create a Country object in CA SAM, manually create the same object in CA APM. If you update a Region object in CA APM, manually update that object in CA SAM.

Manual Data Synchronization Rules

To ensure that data is synchronized correctly, use the following rules when you create or update the Country and Region objects:

- Country - The CA APM abbreviation for a country must match the CA SAM record import ID for the same country.
- Region - The CA APM name for a region must match the CA SAM record import ID for the same region.

Cost Center Data Management

The data synchronization between CA APM and CA SAM ensures the integrity of the data and of the asset management process. This synchronization occurs automatically for the following objects:

- Company
- Location
- Cost Center
- Division
- Contact

Note: These objects use the same labels in CA APM and CA SAM, except Contact. In CA SAM, the Contact object is labeled "User".

When you create, update, or delete the Contact, Company, Location, and Division objects in CA APM, the objects are automatically synchronized in CA SAM. The CA SAM Administrator must designate Contact, Company, Location, and Division as read-only in CA SAM. This action prevents CA SAM users from changing these objects, which will be overwritten when the next data synchronization occurs. However, the Administrator cannot designate the Cost Center object as read-only in CA SAM because the Cost Center reporting hierarchy must be administered in CA SAM.

Recommended Guidelines for Cost Center Data Management

To facilitate Cost Center data management, we recommend that you use the following guidelines:

- Add permissions to manage the Cost Center object to an Administrator role in CA SAM. Other user roles are not able to access the Cost Center object.
- Use CA APM when you perform the following actions:
  - Insert or delete Cost Centers.
  - Update Cost Center name or description.

  Important! If you change the Cost Center name or description in CA SAM, the changes are overwritten after the next data synchronization.
- Use CA SAM when you perform the following actions:
  - Administer Cost Center reporting hierarchy.
  - Assign a Cost Center to a country.

Inventory Units of Measurement

CA SAM sends hardware discovery data to CA APM to help with hardware asset management. CA APM requires specific units of measurement for the following hardware inventory items that are sent from CA SAM:

- Total Disk Space: Gigabytes (GB)
- Total Memory: Megabytes (MB)
- Processor (CPU) Speed: Megahertz (MHz)

When you load and manage hardware inventory data for these items in CA SAM, verify that the CA SAM data uses these units of measurement.

Field Requirements for Automatic Data Synchronization

Automatic data synchronization copies the CA APM data for the Company, Location, Cost Center, Division, and Contact objects to the corresponding objects in CA SAM. To ensure a successful synchronization, follow the field requirement guidelines for the objects in the following subsections.

Contact

Some of the fields for the Contact object are optional in CA APM but required in CA SAM. These fields are summarized in the following table. Verify that all fields that are required in CA SAM contain data in CA APM.

CA APM Field	Required in CA APM?	Required in CA SAM?
User ID/User Name	No	Yes
Cost Center	No	Yes
Last Name	Yes	Yes

First Name	No	Yes

Company

CA SAM allows you to report compliance for hierarchical groupings (Division, Company, and Cost Center). To report on Divisions, CA SAM requires Division details for the Company object. Verify that the CA APM Company object has Division details to ensure a successful data synchronization.

Note: To enter Division details for a company in CA APM, you first create divisions in Directory, List Management, Company Lists, Division. Then when you create or update a company on the Company Details page, select a Company Type of Internal. The Division text box appears and you can select a division for the company.

Cost Center

CA SAM allows you to report compliance for hierarchical groups (Division, Company, and Cost Center). To report on Companies, CA SAM requires Company information for the Cost Center object. Verify that the CA APM Cost Center object has Company details to ensure a successful data synchronization.

Assets with Undefined Operating Systems

Discovery data that CA APM receives can contain operating system names that are not defined in CA APM. When this situation occurs, CA APM assigns an operating system value of Undefined to the corresponding asset. CA APM displays the Undefined value in the Operating System field on the Asset Details page.

You can view the original discovered names of the Undefined operating systems, and you can add those names to the CA APM operating system names. You can also update the assets that have Undefined operating systems to include the new names.

Note: CA APM can receive data with undefined operating systems from any discovery source (including CA SAM).

Follow these steps to view the original names of Undefined operating systems:

1. Log in to CA APM as the administrator.
2. Navigate to Administration, Reconciliation Management, Reconciliation Message Search. A list of Reconciliation messages displays.
3. Locate the messages that identify the missing operating systems.

Note: You can search on this page for "Missing Operating System" in the message text.

The messages include the original discovered names.

Follow these steps to update assets with Undefined operating systems:

1. Navigate to Directory, List Management, Operating System and add the missing operating system names to the CA APM names.
2. Update an individual asset with an Undefined operating system by using the following steps:
    a. Navigate to the Asset Details page for an asset with an Undefined operating system.
    b. Click the Select New icon in the Operating System field and select the new name.
3. Update multiple assets with Undefined operating systems by using the following steps:
    a. Navigate to Administration, Reconciliation Management.
    b. Click the reconciliation rule name.
    The Reconciliation Rule Details page appears for the selected rule.
    c. Verify that Monitor Asset Updates is selected.
    d. In the Update Options area, select Operating System and Last Run Date.
    e. Click Save.
    When CA APM receives new discovery data for assets with Undefined operating systems, CA APM updates the operating systems with the new names that you entered.

How to Uninstall CA Software Compliance Manager

To enable SAM capabilities when CA APM is integrated with CA Software Compliance Manager (CA SCM), uninstall CA SCM.

Note: Verify that all users have logged out from CA SCM. Any user who does not log out from the product before the uninstallation begins receives an error when attempting to complete a task.

Follow these steps to uninstall CA SCM 12.0:

1. Log in to the computer on which you installed CA SCM 12.0.
2. Uninstall the CA SCM Release 12.0 cumulative patches, if any, through the Control Panel, Add /Remove Programs.

3. Log in to the CA APM application server where you installed CA APM Release 14.1.
4. Navigate to the folder where you installed CA APM Release 14.1.
5. Copy the SWCM12.0Uninstall folder and all of its contents to a temporary location on each computer (except the database server) where you installed CA SCM 12.0.
   Example of temporary location:

   ```
   C:\Windows\Temp
   ```
6. Navigate to the Uninstall folder in the temporary location on the CA SCM 12.0 computer.
7. Start the uninstallation by double-clicking the SWCM_Uninstall.bat file.
8. Follow the on-screen instructions in the uninstallation process.
   The uninstallation runs and successfully removes all installed CA SCM 12.0 components, except CA Business Intelligence, CA EEM, CA MDB, and the Content Import Client.

Follow these steps to uninstall CA SCM 12.6:

Note: Complete these steps on each computer (except the database server) on which you installed CA SCM 12.6.

1. Log in to the computer on which you installed CA SCM 12.6.
2. Uninstall the CA SCM Release 12.6 cumulative patches, if any, through the Control Panel, Add /Remove Programs.
3. Navigate to the Uninstall folder where CA SCM 12.6 is installed.
   Example:

   ```
   C:\Program Files\CA\SWCM\Uninstall
   ```
4. Start the uninstallation by double-clicking the SWCM_Uninstall.bat file.
5. Follow the on-screen instructions in the uninstallation process.
   The uninstallation runs and successfully removes all installed CA SCM 12.6 components, except CA Business Intelligence [assign the value for boe in your book], CA EEM, CA MDB, and the Content Import Client.

Step 1 - Plan Your CA Asset Portfolio Management Installation

This article contains the following topics:

Before you begin with the installation, ensure that you have completed the following:

- Reviewed the CA Service Management Release Notes (see page 69).

- Reviewed the supportability matrix (see page 119) for a list of third-party software products that are certified for use with CA Asset Portfolio Management.
- Considered and planned for the network availability, usage bandwidth, and responsiveness.
- Reviewed the CA APM product components (see page 319).

Step 1c - Complete the Planning Checklist

Ensure to review and complete the following CA IT Asset Manager Installation Planning Checklist:

Select	Task	Comments
	Ensured that the servers meet the hardware and software requirements (see page 397).	
	Installed Internet Information Services (IIS) 7.0 or above on all the application and web servers..For more information, see Verify that Internet Information Services (IIS) 7.0 or above. (see page 397)	
	Installed Microsoft .NET Framework 4.0 or above.	
	Installed Microsoft Web Services Enhancements (WSE) 3.0 Runtime.	
	Common Components: Installed CA EEM, CA Business Intelligence, and CA Process Automation. ▪ **CA EEM**: Installed CA EEM 12.51 CR02 using the CA Service Management Installation Media or upgraded an earlier installed version of CA EEM to CA EEM 12.51 CR02. For more information, see Install CA EEM (see page 283). Installed CA iTechnology iGateway with CA EEM. It is a shared component that various CA Technologies products use. CA iTechnology iGateway web server sends and receives requests using the http protocol. CA iTechnology iGateway can be installed with other CA products also. ⚠ **Note:** If CA iTechnology iGateway exists on the computer where you are installing CA EEM, determine if it is 32-bit or 64-bit. If CA iTechnology iGateway and your CA EEM 12.51 CR02 server are both 32-bit or both 64-bit, no action is necessary. However, if the two products do not match (for example, one is 32-bit and the other is 64-bit), remove CA iTechnology iGateway (see page 397) and start the CA EEM installation. The correct version of CA iTechnology iGateway is installed when you complete the CA EEM installation ▪ **CA Process Automation:** Installed CA Process Automation for event notification processing. For more information, see Install the CA Process Automation. (see page 292)	

Select	Task	Comments
	▪ **CA Business Intelligence**: Reviewed the CA Business Intelligence Integration (see page 547) content. Installed CA Business Intelligence and recorded the login credentials and connection information. For more information, see Install CA Business Intelligence (see page 285). **Note:** CA EEM is mandatory for CA Asset Portfolio Management while CA Process Automation and CA Business Intelligence are optional.	
	Installed CA SCM (and any cumulative releases) before installing CA Asset Portfolio Management to integrate CA SCM Release 12.6 with CA Asset Portfolio Management.	

Implementing CA Service Desk Manager

As an administrator, install or upgrade CA SDM to avail the service desk capabilities which is an integral part of the CA Service Management solution. This topic describes the planning process, the procedure to install or upgrade, and to configure the product after the installation.

For a successful CA SDM implementation in your enterprise, plan and perform the following steps:

- Plan and prepare for a new installation or an upgrade.
- Install or upgrade all of the necessary product components.
- Configure the product components.
- Integrate with the required CA Technologies products.

Note: This section does not detail integration with all CA Technologies products. For more information about CA SDM Integrations, see the CA Service Desk Manager Integration Best Practices Green Book at http://ca.com/support.

Audience

- System administrators, administrators, and implementation consultants: Install and configure CA SDM for the first time or to upgrade from an earlier version to the latest version.
- Integrators: Integrate CA SDM with the other CA Service Management products.

To implement CA SDM, the following prerequisites apply:

- A working knowledge of the Windows and/or UNIX operating systems, depending on your current production environment.

- The ability to perform basic administrative tasks for your operating system.
- Depending on your working environment, knowledge of mainframe, mobile devices, and server installations.

More Information:

- How to Upgrade CA SDM (see page 399)
- How to Install CA SDM (see page 446)
- How to Install CA SDM Connector (see page 525)
- Uninstall the CA SDM Connector (see page 542)

How to Upgrade CA SDM

You can upgrade CA SDM to the latest version using the migration console. Ensure that you read the planning process before you start the upgrade.

More Information:

- Step1: Plan the CA SDM Upgrades (see page 399)
- Step 2: Use the CA SDM Migration Console (see page 409)
- Step 3: Perform Post Upgrade Configuration (see page 419)
- Support Automation Data Migration (see page 442)

Step1: Plan the CA SDM Upgrades

This article contains the following topics:

General Considerations

- CA SDM supports upgrade from r11.2, r12.0, r12.1, r12.5, r12.6, r12.7, and r12.9 for all supported platforms. For Windows, you can upgrade directly from r11.2, r12.0, r12.1, r12.5, r12.6, r12.7, and r12.9.
- If you installed CA SDM on Linux or UNIX, the upgrade from versions prior to r12.5 requires multiple steps. If your installation is running on an older version of the product, such as r11.2, r12.0 and r12.1 on Linux/UNIX, you must run the automated upgrade script for CA SDM r12.5 and move CA SDM to a supported platform and database before running the automated upgrade script for the new release. If you have modifications, you only have to apply them once - after running the final automated upgrade script to the new release.
- If you have an earlier version of the product, such as CA Service Desk Manager r6.0 or r11.1, you *must* upgrade to CA SDM r11.2 before upgrading.

- You manually added a variable in the NX.env file or updated a variable value and want to retain these variables after the migration. Ensure that you add these variables to the NX.env template file before the configuration and migration.

- CA SDM only supports ITIL. If you are upgrading from a non-ITIL system, the installation updates you to an ITIL environment.

- If you have a combined CA SDM r11.2 and CA CMDB r11.1 installation, you cannot upgrade directly. You *must* first upgrade CA CMDB to r11.2, and then run the upgrade. This process upgrades CA SDM r11.2 to r12.5, and also upgrades CA CMDB r11.2 to r12.5. CA CMDB r12.0 and r12.1 can also be upgraded directly.

  Note: For more information about upgrading from an earlier version, see the *CA SDM Implementation Guide r11.2.* For upgrade patches and assistance, contact Technical Support at http://ca.com/support (http://www.ca.com/support).

- If you are planning to migrate from an earlier version of CA SDM to the current version, before migrating validate that the servlet path URL(in each Repository Server) is in the correct format. To validate, complete the following steps:

  1. Login to CA SDM.
  2. Navigate to **Administration**, **Attachment Library**, **Repository**.
  3. Edit each repository servlet path URL. Remove the Fully Qualified Domain Name (FQDN) from the servlet path and replace it with the hostname in the servlet URL.
     For example, change (http://myhostname.ca.com:8080/CAisd/UploadServlet) to (http://myhostname:8080/CAisd/UploadServlet)
     Ensure that the repository server functionality is intact and working.

- UTF-8 locale must be installed on Linux/UNIX platforms.

- On Linux/UNIX, CA SDM no longer uses the smtp_mail script to process outgoing mail notifications. If you are an existing customer using smtp_mail, and you upgrade to the current release, your administrator must configure the appropriate mail options using the Default Mailbox Detail page to enable the mail notification feature of CA SDM.

  Important! Migration from an advanced availability environment is not possible using rolling maintenance. You must shutdown the CA SDM services in all the application and standby servers before starting the migration activity. You need to first migrate the background server and then verify whether the background server processes are running. Migrate the other servers only after ensuring that the background server processes are running.

- Fresh CA SDM Release 14.1 installation does not install the copy_inactive web option in Options Manager. So the links to inactive objects are not copied. If you are upgrading from CA SDM r12.5 or r12.6, links to inactive objects are copied because migration installs the option.

- If a previous version uses *domsrvr:01*, rename the server ID before starting the upgrade. Execute the *pdm_edit.pl* command and update the domsrvr ID from 01 to another ID value.

  Note: The CA Service Desk Manager 14.1 enhances the *pdm_edit* command to provide an easier interface to configure the servers. As part of this enhancement, the *domsrvr:01* name for object manager is reserved and cannot be used by the custom configuration.

Database Considerations

- Before you migrate from CA SDM Release 12.7 SP2, ensure that you run the following command:

```
update mdb_schema_information set FileTimestamp='2012-04-23T09:19:09+0000'
  where FileName like 'doc_rep.xml'
```

- Back up your existing database using your typical database backup procedures.
- (Applicable for all non-windows machines) If the previous releases of CA SDM is configured with oracle 10gr2 database, install Oracle 11gr2 client before you upgrade.

  Important! Before upgrading, change the Oracle home path to oracle11g r2 client path in the $NXROOT/NX.env file.

- Archive the installation directory ($NX_ROOT) using your typical archive procedures. This action lowers the amount of data movement and saves disk space.
- Run the appropriate script from a command prompt to identify any duplicate records on your database:

  Note: Run this script on the secondary servers. If you want to run this script using SQL Query Analyzer, edit the **SQLCheckr12UniqueIndexes.sql** script and remove the EXIT argument before you run the command.

  - (Oracle) Run OracleCheckr12UniqueIndexes.sql, located in the \Migrate directory on the installation media.
- - (SQL Server)

    Note: The database is named as "use mdb" by default. Before you run the script, update the database name manually to **use <other_database_name>** using the **SQLCheckr12UniqueIndexes.sql** file.

    1. Open a Command Prompt window and run **SQLCheckr12UniqueIndexes.sql** as follows:

```
cd $NX_ROOT\samples\views\SQLServer
```

2. Enter the command:

```
Sqlcmd  - E  - e < SQLCheckr12UniqueIndexes.sql
```

Note: After you upgrade, you can find these files at *$NX_ROOT/samples/views/SQLServer* or *$NX_ROOT/samples/views/Oracle* on the server.

Important! These scripts identify your duplicate records. Delete identified duplicate records before you proceed with the migration.

- For Windows, you can upgrade directly from r11.2, r12.0, r12.1, r12.5, r12.6, r12.7, and r12.9.
- If you installed CA SDM on UNIX or Linux, you can upgrade from r12.5, r12.6, r12.7, and r12,9.
- If your installation contains an earlier version of the product, such as CA SDM r11.2, r12.0, or r12.1 on a non-supported UNIX/Linux operating system and database, you must upgrade to CA SDM r12.5. Then, move CA SDM to a supported operating environment and database before you upgrade.
- Upgrade your CA SDM r11.2 system to a supported database (SQL Server and Oracle).

  Note: For more information about supported database, see the Supportability Matrix (see page 119).

- Upgrade from CA Service Desk Manager r11.0 to CA SDM r11.2 before migrating your data to a supported database.
- Special Windows characters, such as a long hyphen, in CA SDM or Knowledge Management on a non-Windows system, are not properly stored in the database.
- **Ingres** -- If you are using an Ingres database, convert your data to Oracle or SQL Server before upgrading.

  Note: For information about the conversion process, see your database documentation.

- **Oracle** -- Oracle does not support case insensitive indexes for Configuration Item registration. Before you start the migration on Oracle, verify SQLPlus and Oracle DB are able to communicate using hostname. If communication fails, verify that Oracle is configured with loopback adaptor.

> **Note:** When you migrate in a double-byte character environment with an Oracle database, increase the maximum open cursor limit to at least 500. For more information, view Oracle documents about ORA-01000 (maximum open cursor exceeded).

- **SQL Server** -- For an SQL Server upgrade to the current release of CA SDM, the default database for the configured Database Userid must be CA MDB. If the default database is not CA MDB, the migration console fails and displays the following message:
  "The acctyp_v2 table does not exist on the MDB"

- **Tomcat** -- (for CA Service Desk Manager r11.0, r11.1 or CA SDM r11.2) If you configured Tomcat for external authentication, manually reconfigure Tomcat for external authentication after upgrading to the current product release.

- **Table Updates** -- Consider the following table updates that occur during migration:

  - **Status Tables** -- These tables are also updated with the appropriate status records when the same code values do not exist in your database. For example, *Cr_Status* is updated with the code *AEUR* (Awaiting End User Response).

  - **Functional Areas** -- For each role, migration automatically adds a row for each *usp_functional_access* record. Migration sets the access level to the same level for each CA SDM r12.0 and r12.1 functional area that the *usp_role* table includes. New functional areas are mapped using a reference field.

- **Foreign Keys** -- Consider the following information:

  - Foreign keys (SRELs) that reference tables, in which the primary key is a UUID, change from integer type to UUID type (or BYTE 16).

  - If you dropped foreign key constraints in your previous CA SDM system to mass load data, recreate the foreign key constraints before you run the upgrade. The scripts that drop the constraints are found in the following locations:

    - Oracle
      $NX_ROOT/samples/views/Oracle/OracleDropConstraints.sql

    - SQL Server
      $NX_ROOT/samples/views/SQLServer/SQLDropConstraints.sql

    > **Note:** Reapply the dropped constraints by running the appropriate script *OracleAddConstraints.sql* or *SQLServer/SQLAddConstraints.sql*. These scripts are found in the same directory as the drop constraints and contain instructions within the files mentioned.

- **MDB** -- The MDB provides a consistent database schema for various IT management data. During the development of the MDB, data elements from your previous CA SDM environment were incorporated into this schema. The size of the data elements can increase and, consequently, increase the overall database size.

Note: When standard data elements extend beyond the column width defined for the MDB, the update process can truncate data in these elements. Messages alert you to any truncation that occurs during the upgrade.

- **Distributed Setup** -- We recommend you upgrade your servers in the following order, depending on your CA SDM configuration:

  1. **Conventional**
     - Primary server
     - (Optional) One or more secondary servers
  2. **Advanced Availability**
     - Background server
     - One or more standby servers
     - One or more application servers

- **Remote Database** -- If you are using a SQL Server MDB database, sqlcmd must be on the client computer before connecting to the remote MDB.

Knowledge Management Considerations

For customers upgrading from a previous release of CA SDM that used the FAST ESP search engine, you *must* change to the EBR search engine. The FAST ESP license expires in May 2013. To change to the EBR search engine, click Options Manager, Search Engine and edit ebr_version to specify KT Search Engine.

LREL Migration Considerations

A *List Relationship* (LREL) represents an association between two objects. An LREL has a left-hand side (lhs) and right-hand side (rhs) relationship. Each side of the relationship is an attribute of the majic object that contains the data relationship.

In previous releases of the product, .maj LREL statements and objects described many-to-many DBMS data relationships. Many-to-many relationships no longer use the LREL majic statement. Instead, individual tables store both sides of the relationship. Objects access the relationship with a standard BREL statement. For example, you can see the relationship between change orders and CIs by reviewing the new usp_lrel_asset_chgnr table and in the corresponding lrel_asset_chgnr object.

The LREL changes eliminate the need to store attribute names in the database. The two sides of the relationship are foreign key single relationships (SREL) that are easy to join and index. If necessary, the relationship can contain additional relational attributes.

During the upgrade, the following activities occur as LREL table data migrates to current release of CA SDM:

- The system automatically migrates tables and objects with LREL relationships.
- The system names new tables using the *usp_lrel_lhsName_rhsName* format.
  For example, the *usp_lrel_asset_chgnr* table has a left-hand relationship to assets and a right-hand relationship to change orders.
- The system names the corresponding objects using the *lrel_lhsName_rhsName*.
  For example, the *lrel_asset_chgnr* object corresponds to the *usp_lrel_asset_chgnr* table.
- Because of a database limitation, some names are abbreviated.
- Your data is migrated from the old tables and all CA SDM code is modified to use the tables of the updated release.
- The system no longer uses the old LREL database tables, such as *bmlrel*. However, for reference purposes, the old tables retain the data.
- A backward relation (BREL) attribute to the new object replaces the original LREL attribute in each related majic object definition.
- If you are using a supported API, such as the *CreateLrelRelationship()* web service method, the code works as expected.
- If you added any custom LREL style relationships, CA SDM migrates them to the tables of the updated release.
- Any site-defined code or reports that directly access the old LREL tables operate on old data because the system no longer uses those tables. We recommend that you update the code to use the tables of the updated release for the code and reports to run properly.

Important! If your code directly accesses legacy LREL objects or tables, the code fails after migration. We recommend that you upgrade the code before migration. For example, if your code uses majic statements to establish LREL relationships, use the *createLrelRelationships()* method instead of directly populating a table.

Note: We recommend that you verify site-defined code or reports that directly access the database or address the legacy LREL majic objects such as the lrel1 object to verify that they operate properly. You can update your code to use a supported interface, such as Web Services. You also update the necessary table names. For reports, you can also update the queries with the new DBMS table references.

Status Transition Considerations

Consider the following information if you plan to use Status Transitions after upgrading from CA SDM r11.2, r12.1, and r12.1:

- Status transitions are inactive when you upgrade.

  Note: All modified status code descriptions that appear on ticket forms are retained during the upgrade process.

- The *Status_Policy_Violations* option is installed and set to Warn by default after you upgrade. This setting allows undefined transitions to occur, but logs a warning.

- If you set the option to Allow, undefined transactions are not logged.

How to Upgrade CA EEM

The current version of CA SDM uses EEM 12.51 SDK which is not compatible with the EEM 8.4 server. To support the existing customers who are using EEM 8.4 server, EEM 8.4 SDK patch has to be applied on the CA SDM server. Find the patch details from the CA Support Online.

You install CA EEM separately.

When migrating, upgrade to at least CA EEM r8.4 SP4.

Note: You can upgrade from CA EEM r8.1 directly to r8.4 SP4.

To upgrade CA EEM, perform the following tasks:

1. Verify that you upgraded to the current version of CA SDM
2. Insert the installation media into your drive.
3. Install CA EEM.

After you install CA EEM, manually set the appropriate options in the Options Manager. Review the upgraded options carefully. The default Process Manager URL is no longer pmService.

Note: The *cawf_pm_url* option has changed to a default of: *http://<wf_hostname>:<wf_tomcat_port>/pm/service/pmService2*, so you *must* manually change "pmService" to "pmService2" for CAWF communication to remain functional.

Important! After you upgrade CA EEM, set the *eiam_hostname*, *use_eiam_artifact*, and *use_eiam_authentication* options in Options Manager, Security if you previously used eIAM CA SDM user authentication.

CA Process Automation Integration

To ensure that CA SDM and CA Process Automation integration works properly, add the ServiceDesk user in CA EEM (if not already added) during the upgrade.

Retain Your Modifications

Before you upgrade, consider the following information to retain the modifications that you have made:

- Any “modifications” or “adaptions” or “configurations” that are done administratively through the interface (web browser, command-line, Web Screen Painter) are “supported”, meaning CA Support can assist with the basic suggestions and troubleshooting. CA Support do NOT perform any changes for the customer. The customer is responsible for the changes made. For example, adding a field to a table and putting the field on a form through Web Screen Painter is a fully supported “modification”. Similarly, installing or uninstalling a feature through the Options Manager administration is a fully supported “configuration”. Anything to do with SPEL code, Java scripting (or any language scripting), or a customer-specific change to the underlying base code-line (done by CA Services or a Partner), is NOT supported by CA Support. The customer can perform these actions, but is responsible for the support, maintenance, and troubleshooting when an issue occurs. If such “customization” affect expected out-of-the-box behavior, CA Support will ask the customer to remove the customization and see if the behavior persists.

- **Modified Reports** -- When you modify the reports that access database tables from previous versions and that have been moved to renamed tables, the column names have been changed in Release 14.1.

- **Modified Forms** -- Upgrade retains the modification of the forms from the previous release of CA SDM. However, you cannot view the CA SDM Release 14.1 functionality on the modified forms after you upgrade.

- **Modified Admin Tree** -- When you modify the Admin tree in CA Service Desk Manager r11.0, these changes are not upgraded due to modifications in the architecture to support the role-based user interface. These Admin tree modifications include the addition of new nodes, renaming of existing nodes, modifying access types, or other data alterations. To use the modifications, perform the following actions:

  1. Before you upgrade, review your CA Service Desk Manager r11.0 Admin tree and note any modifications that you want to use after the upgrade.

  2. After the upgrade completes, identify which roles have Admin tree modifications.

  3. Apply the modifications to the appropriate CA SDM Release 14.1 role-based Admin trees.

  4. Review and test to verify that the desired functionality has been retained.

- **Modified Form Buttons** -- After the upgrade completes, buttons on modified forms in */site/mods /htmpl* that did not have quotes around the msgtxt(n) part of the code result in an error message, instead of the button name.
  For example, in the detail_cr.htmpl form, modify msgtxt(441) with quotes as follows to display the correct button name:

```
ImgBtnCreate("btnchg", "msgtext(441)", "detailSave('NEW_CHANGE')",
```

```
true, 0, msgtext(440)); // Save and Create Change Order
```

- **Retaining Modifications**-- When you need the CA SDM Release 14.1 functionality and would like to preserve your modifications from a previous release then redo the modification on a base CA SDM Release 14.1 form, which has the Release 14.1 functions. When any form is modified, the customer changes are overwritten and has to be recreated. There is a process in the upgrade that attempts to detect and identify the differences in the forms, and reports it to the customer for their investigation. However, it is highly recommended to document your customization BEFORE you perform any upgrade. In some cases, a new feature may be similar to the user customization, so the user changes must be removed. The custom JavaScript file must be customized again according to the base release 14.1 JavaScript file. For more information, see JavaScript Modification (see page 1805).

  Note: When you modify the *acctypedtl.rpt* and *acctypesum.rpt* reports, then the return data in CA SDM Release 14.1 is obsolete.

- **Notification Rules** -- When you remove the default activity notifications Contact, Object Contacts, and Contact Types from the previous installation of CA SDM and want to retain this functionality, then note the default contacts removed before migration. After you upgrade to the new version, remove the default Notification contacts again.

- **Role-based Functionality** -- Upgrading can cause issues with the role-based functionality. If you modified any of the following forms, they are considered as read-only by the Web Screen Painter in CA SDM Release 14.1 and they include an xxx_site.htmpl version where you can use custom code:

  - ahdtop.htmpl
  - menu_frames.htmpl
  - reports.htmpl
  - std_body.htmpl
  - std_footer.htmpl
  - std_head.htmpl
  - styles.htmpl
  - msg_cat.js
  - menu_frames_role.htmpl

- **Modified HTMPL Files** -- Consider the following information:

  - All modified HTMPL files retain their default menu bar settings after you upgrade. A pop-up window inherits its menu bar from the main page tab, as a result of the role-based user interface. Modified HTMPL files are not available on the modified forms from the previous release after the upgrade.

- CA SDM Release 14.1 does not use some modified HTMPL files from previous releases. The migration script executes the perl script $NX_ROOT/bin/*migrate_to_r12_9_web_check.pl* that appends the files with the *incompatible_for_r2_9* extension. After migration completes, open $NX_ROOT/site/web_check_files.txt with a text editor to see the list of incompatible forms for Release 14.1.

- If you modifiedthe list_dblocks.htmpl file in a previous release of CA SDM, this form does not work in CA SDM Release 14.1. If you modifiedthe Admin Tree to display the list_dblocks.htmpl in other parts of the tree, the modification does not work after you migrate. Modify the form manually to use the new URL and form. To complete this modification, click Security and Role Management, Menu Tree Resources and open Current Locks. Update the resources with the following CA SDM Release 14.1 string:

```
OP=SEARCH+FACTORY=record_lock+QBE.NN.lock_time=NULL
```

- **Foreign Keys** -- When the upgrade process detects referential integrity issues while attempting to reset foreign keys then the errors appear in the migration.log file. The associated foreign key sets to a predefined valid reference.

- **Servers and Web Director Configuration** -- When your previous installation was configured to use additional servers or web directors, then you must first create the configuration for the specific servers and run the CA SDM server configuration utility (pdm_configure). **CA Support Automation Divisions** -- When you migrate the divisions to tenants, then convert this data before enabling and configuring Support Automation in CA SDM Release 12.9.

- **Rename Modified HTMPL Forms** – If you modified HTMPL forms in a previous release of CA SDM, you run a script to rename them before you upgrade. You run this script on all CA SDM servers. The migrate_to_r12_9_web_check.pl script renames all modified web forms, style sheets, Java scripts, images, and macros in the site/mods directory. Renaming these files helps you identify your modified forms.
  Follow these steps:

  1. From a command prompt, executepdm_perl $NX_ROOT/bin/migrate_to_r12_9_web_check.pl.
     The script appends the modified forms with an *incompatible_for_r12_9* extension.

  2. Open $NX_ROOT/bin/migrate_to_r12_9_web_check.pl with a text editor.
     A list of incompatible forms for Release 14.1 appears.

  Note: The script does not restore files from backup folders to the legacy or site/mods directories as in previous releases of CA SDM.

Step 2: Use the CA SDM Migration Console

The migration console guides you through the migration and upgrade processes for CA SDM. The console automatically detects an existing installation, such as CA SDM r11.2. The console performs the following tasks:

1. Verifies that your product is CA SDM r11.2, r12.0, r12.1, r12.5, r12.6, r12.7 or r12.9.

2. Converts passwords to a FIPS 140-2 compliant format.

3. Applies MDB updates.

> **Important!** The remote MDB version must be at least CA MDB r1.5, or the migration fails.

4. Migrates LREL data.
5. Converts modified files to UTF-8.
6. Converts access type records to the CA SDM Release 14.1 role and access type records.
7. Migrates and upgrades user scoreboard queries for role-based operations.
8. Migrates and upgrades existing notifications to use notification rules and notification message templates.

> **Note:** After you select Perform Upgrade and click Install, you cannot roll back the migration and upgrade. If you close the Migration Console before the process finishes, it continues to run in the background.

Follow these steps:

1. Consider the following points before you start using the migration console:
   - If your configured web forms are not compatible with CA SDM Release 14.1, the migration console displays a message indicating that these forms moved to the site/mods/wwww /htmpl directory. For more information about these forms, view the Web_Forms_Changed.txt file in the site/mods/ directory.
   - The CA SDM Migration Console does not convert divisions to tenants. If you want to configure Support Automation in a multi-tenancy environment, you *must* separately migrate (see page) CA Support Automation r6.0 SR1 eFix5 divisions to CA SDM Release 14.1 tenants before enabling Support Automation in CA SDM.
   - Uninstall Visualizer before you start using the migration console.
   - Reviewed the following migration scenarios:
     - Upgrade CA SDM Using the SWING Box Method (see page 413)
     - Upgrade CA SDM on Similar Hardware Setup (see page 417)
     - Migrate Data to CA Service Desk Manager 14.1 (see page 418)
2. Start the upgrade from the installation media or start it manually using the following command:
   - **Windows:** $NX_ROOT\bin\migrate_to_r14_1.vbs

- **Linux/UNIX:** $NX_ROOT\bin\migrate_to_r14_1.sh

> **Note:** If migration fails with a "Schema Validation" error, use the previously mentioned command to run the upgrade again.

The installer detects your version of CMDB, such as CMDB 11.2. You can upgrade CMDB from a previous release of CA SDM, such as 11.2, 12.0, and 12.1. If you cancel migration, you *must* execute the script to relaunch the migration console. The script is located in the */bin* directory of the product, such as *C:/CMDB/bin*. For example, if you cancel migration on Linux or Unix, execute the *migration_to_r14.1.sh* script.

> **Note:** If you are upgrading from a standalone CMDB release, you can continue to use standalone CMDB functionality in the updated CA SDM release. If you are upgrading from an environment with CMDB and CA SDM, or if you are upgrading from a CA SDM environment without CMDB, the full CA SDM Release installs during the upgrade. If you are upgrading from a combined CA SDM and CMDB installation, the installer displays the detected environment as a CMDB release, not CA SDM.

3. Click Next.
   The installation warns you not to use CA SDM and Knowledge Management until migration completes.

4. Click Next.
   If the installation detects Visualizer, you are prompted to uninstall it manually.

> **Important!** After you uninstall Visualizer, you *must* reboot and relaunch the CA SDM installer.

5. Accept the terms of the License Agreement and click Install.
   The installation backs up your data and shuts down services.

> **Note:** The CMDB upgrade does *not* back up your database.

After the installation completes, the migration console appears with a warning to review your migration documentation.

6. Click Migrate.
   The migration console loads system data, updates your MDB, and recycles services.

Note: If you encounter problems during the migration and upgrade, the migration log provides a record of the entire process. You can access this log at $NX_ROOT/log /pdm_migrationr14_1.log.

7. The console verifies tables, processes data, backs up, and upgrades CA SDM.
   The CA SDM configuration appears.

8. (Optional) Configure CMDB Only.
   If you are upgrading from a standalone CMDB environment, a *Configure CMDB Only* check box displays on the General Settings form.

   Important! During configuration, when you migrate from CA CMDB stand alone version to CA SDM, a Configure CMDB Only check box displays. When you clear the Configure CMDB Only check box and you click Next, you cannot configure CA CMDB again. Even if you click Back, the Configure CMDB Only check box is no longer available. A message warns you of this behavior in the configuration dialog. If you cancel the configuration before it completes and rerun it, the Configure CMDB Only check box is available.
   The Configure CMDB Only check box controls the value of the CA SDM environment variable NX_CMDB. The environment variable controls whether the Support Automation feature is configured. If the check box is cleared, Support Automation is configureable, otherwise it is not. The environment variable affects the behavior of some Web forms.

   If you are upgrading from a standalone CMDB environment, and want to use standalone CMDB functionality in updated CA SDM Release, you cannot configure Support Automation.

9. Complete the configuration, as appropriate to your environment.

10. (Optional) Reviewed the Migrate from a Nonsupported Windows Environment (see page 412) and Migrate from a Nonsupported Non Windows Environment (see page 413) examples.

Example Migrate from a Nonsupported Windows Environment

In this example, you have CA SDM r11.2 installed on Windows 2003 (32-bit) with SQL Server 2005. You want to migrate your data and upgrade to CA SDM Release 14.1 on a Windows 2008 64-bit system with SQL Server 2008 successfully.

Follow these steps:

1. Migrate to CA SDM Release 14.1 on the same computer.

2. Upgrade SQL Server 2005 to 2008.

3. Back up the MDB database.

4. Install CA SDM Release 14.1 on Windows 2008 (64-bit).

5. Load the MDB backup that you completed in Step 3.
6. Move the $NX_ROOT\site\mod folder from the older computer to the new computer.
7. Update the NX.env file with the modified variables.
8. Copy the Attachment folder from the older computer to the new computer.
9. Run configuration again on the new computer.
10. Update the computer details in the required places in Options Manager.

Example Migrate from a Nonsupported Non Windows Environment

In this example, you have CA SDM r11.2 installed on Redhat Enterprise Linux 4 with Oracle 10g. You want to migrate your data and upgrade to CA SDM Release 14.1 on a Redhat Enterprise Linux 6 system with Oracle 11g R2 successfully.

Follow these steps:

1. Migrate to CA SDM r12.5 on the same computer.
2. Back up the MDB database.
3. Install CA SDM r12.5 on Redhat Enterprise Linux 6 with Oracle 11g R2.
4. Load the MDB backup that you completed in Step 2.
5. Move the $NX_ROOT\site\mod folder from the older computer to the new computer.
6. Update the NX.env file with the modified variables.
7. Copy the Attachment folder from the older computer to the new computer.
8. Run configuration again on the new computer.
9. Update the computer details in the required places in Options Manager.
10. Migrate from CA SDM r12.5 to Release 14.1.

Upgrade CA SDM Using the SWING Box Method

The SWING Box method is performed by using a separate server, typically, referred to as a SWING system.

In this method, the following are the main steps:

- Replicate your current production system on the SWING system.
- Migrate to CA Service Desk Manager (SDM) 14.1.
- Move the migrated CA SDM 14.1 data and customizations to a clean (never migrated) server.

- Install on new hardware.

This method has the following advantages:

- The current production system retains its integrity even during a DR issue or failed migration.
- At the end of the process, you install CA SDM 14.1 on a never migrated, system, with an updated version of the operating system and database.
- If you are using a VMware environment as the SWING system, you can use the snapshot functionality to test the migration process multiple times, gather data on timings and steps, ensure an easy migration.

Ensure that you consider the following prerequisites before performing this method:

- After initiating migration testing, *do not* perform any changes to the form, or schema (tables and columns) customizations on any system. For example, *do not* make any modification on 12.7/12.x production or 14.1 development, test, SWING, and so on. If you plan to add or modify additional tables or columns, it should be done either on 12.7/12.x and should put into production before testing migration. You can also modify during another outage that is planned after your production migration is complete and you are running CA SDM 14.1 on the new production system.
- You have completed the following tasks:
  - A test migration of the replicated production system
  - Customized again the custom forms from 12.7/12.x that are incompatible with CA SDM 14.1.
  - Ensured that the you have the latest customized and complete *site**mods* directory from a 14.1 environment where all testing was completed.
- Replicate the most recent migrated CA SDM 14.1 test environment installation to the latest production hardware, including your customized forms built for CA SDM 14.1.

Follow these steps:

- Step 1: Gather Files or Data from Current Production System (see page 414)
- Step 2: Prepare the SWING Environment and Replicate Production to SWING (see page 415)
- Step 3: Upgrade and Migrate to CA SDM 14.1 on the SWING System (see page 416)
- Step 4: Move Migrated SWING Box Install to New Production Hardware (see page 417)

Step 1: Gather Files or Data from Current Production System

Follow these steps:

1. Create an SQL backup of the MDB as a .bak file (usually a normal SQL backup).
2. Copy the *C:**Program Files**CA**Service Desk**site**mods* directory and create a zip file, if possible.
3. Copy the *C:**Program Files**CA**Service Desk**site**attachments* (or the directory where your repositories are configured to store your attachments in) and create a zip file, if required.

4. Copy the files in steps 1 - 3 to a stand-by directory on that system. Do not paste them yet on the SWING environment.

Step 2: Prepare the SWING Environment and Replicate Production to SWING

Note: If your SWING environment has both Database and Application running on the same system, then you might start at step 3. In this section, the database server is referred to as SWING-DB and the application server as SWING-APP.

Follow these steps:

1. On SWING DB (assuming SQL is already installed), run the MDB installer wizard from the CA SDM 12.7/12.x install media.

2. On SWING-APP, install the SQL client and native client (workstation tools also).

3. Install CA SDM 12.7/12.x on SWING-APP and run configuration so that you have a vanilla 12.7 /12.x Service Desk Manager installation running.

4. As the database administrator, execute the SQL Restore and restore the MDB from your current production that you backed up, to the SWING-DB server. Set option to *OVERWRITE entire database* when restoring.

5. Execute the stored procedure in SQL to fix the orphaned users which are created when restoring a database from one SQL instance to another. Example: sp_change_users_login 'AUTO_FIX','ServiceDesk'.

6. Copy the *site**mods* directory that you backed up from current production and put in place on SWING-APP system.

7. Copy the *site**attachments* directory (or whichever attachments directory) you backed up from current production and place it on SWING-APP system.

8. Execute *pdm_configure*:

    a. Skip selecting **TO LOAD DEFAULT DATA**.

    b. In the configuration wizard, click **next** at the database section. A message displays, stating that database was previously configured.
    This message indicates that you restored the MDB from a different environment.

    c. Click **Yes**.

9. After the configuration is complete, perform the following tasks:

    a. Start CA SDM services (if not started).

    b. Test the system functionality to ensure 12.7/12.x is running with your data, and customizations, as a full replica of your production environment.

Step 3: Upgrade and Migrate to CA SDM 14.1 on the SWING System

Test the migration and become familiar with the process and issues you might run into while migrating your production system. If your SWING system is on a VMware environment, then take a snapshot. You can roll back to that snapshot, then take your production system down, do another SQL backup on production, restore it to the SWING environment and then complete the steps mentioned in this section. In case migration fails, you can bring your 12.7/12.x production system back up and start the services. You can then retest migration on the SWING environment again, and schedule it for another time.

Follow these steps:

1. Mount CA SDM 14.1 install media from a local folder, or run the setup.exe from the local folder where the install media is being stored.

   Important! If you are extracting an ISO of the install media, it should be stored in a path and folder that has no spaces in the name, for example, SD127Setup. Also, run locally from the same drive volume where you plan to install CA SDM 14.1. Do not run the installer from a network drive or mounted share as this has been known to cause install and even post install problems to occur.

2. Launch the CA Service Management 14.1 installer.

3. Select a language and click **Next**.
   For example, select English and then click **Next**.

4. Select CA Service Management.

5. Follow the prompts to perform this upgrade.

6. Copy the CA Service Management 14.1 *site**mods* folder from previous test or development environment to this SWING system and run a *pdm_configure* to ensure that all customizations are properly implemented.

7. Test the migrated, and customized 14.1 SWING system for integrity and functionality.

   Note: If this is your test run on the SWING environment, the re-build your form customizations using the 14.1 forms that are delivered with the product as your previously customized 12.7/12.x versions are incompatible in 14.1. Once you have completed the rebuilding of your customizations, take a backup of your *site**mods* directory on the SWING box and store it somewhere outside of this environment for use later (as described in step 6).

8. If all tests are successfully completed, you might now start the process of moving your migrated data, and customizations to the new production hardware.

Step 4: Move Migrated SWING Box Install to New Production Hardware

Follow these steps:

1. Create an SQL backup on the SWING system, and let your database administrator perform an SQL Restore onto the SQL instance that your new production system is using.
   For more information, see Step 2 procedure and execute the steps 4-7.

2. If you are using the Advance Availability configuration, complete the following steps or skip to step 4:

   a. Ensure that you have installed the following components:

      - (Oracle) client is installed and net service name is configured to connect with the new database server.

      - (MS SQL) MS SQL client is installed.

   b. From the DBCleanupUtility folder of the installer DVD, run the following script:

   - (Windows) ResetSDMuspServers.bat

   - (UNIX) ResetSDMuspServers.sh

   a. Follow the steps that are provided in the script (it might need database credentials). This utility deactivates all the servers present in usp_servers table.

3. If you are using the conventional configuration, add NX_SWING_BOX_MIGRATE=Yes variable to NX.env file and run pdm_configure:

   a. Skip selecting **TO LOAD DEFAULT DATA**.

   b. In the configuration wizard, click **next** at the database section. A message displays, stating that database was previously configured.
      This message indicates that you restored the MDB from a different environment.

   c. Click **Yes**.

4. After the configuration is complete, perform the following tasks:

   a. Start CA SDM services (if not started).

   b. Test the system functionality to ensure 12.7/12.x is running with your data, and customizations, as a full replica of your production environment.

Upgrade CA SDM on Similar Hardware Setup

Follow these steps to upgrade CA SDM advanced availability configuration with the similar hardware setup:

1. Shutdown all the services on the application and standby servers.

2. Upgrade CA SDM on the background server. Ensure that the background server is up and running.

3. Upgrade CA SDM on the standby and application servers.

Migrate Data to CA Service Desk Manager 14.1

This topic contains the following information:

How to Migrate Data to CA SDM Release 14.1 on a 64-Bit Linux/UNIX

Follow these steps:

1. Install the Oracle 32-Bit client.

2. Establish the connection with Oracle_Server_SID.

3. Create a Local Net Service Name and test the connection.

4. Export TWO_TASK variable.

5. Edit the ORACLE_HOME and PATH variables to have oracle_client home and remove server home, as shown in the following example:

   ```
   ORACLE_HOME= /opt/app/product/11.2.0/client_1
   PATH= /opt/app/product/11.2.0/client_1/bin
   ```

   Note: Update the ORACLE_HOME variable in the NX.env as shown in the previous example.

6. Set LD_LIBRARY_PATH and LIBPATH to the client-lib which are 32 -bit binaries, as shown in the following example:

   ```
   LD_LIBRARY_PATH=/opt/app/product/11.2.0/client_1/lib
   ```

7. Execute pdm_configure with ORACLE_HOME set to client_home, as shown in the following example:
   C:\app\Administrator\product\11.2.0\client_1\

8. Install CA SDM Release 14.1.

How to Migrate Data to CA SDM Release 14.1 on a 64-Bit Windows

Follow these steps:

1. Install the Oracle 32-bit client.

2. Establish the connection with Oracle_Server_SID.
3. Create a Local Net Service Name and test the connection.
4. Edit the PATH variable to have oracle_client home and remove server home from PATH, as shown in the following example:
   C:\app\Administrator\product\11.2.0\client_1\bin
5. Execute pdm_configure with ORACLE_HOME set to client_home, as shown in the following example:
   C:\app\Administrator\product\11.2.0\client_1\
6. Install CA SDM Release 14.1.

Step 3: Perform Post Upgrade Configuration

Configure the product after the upgrade. Use the configuration wizard to verify your existing modifications.

Note: If the Configuration dialog closes without completing post-upgrade configuration, run *pdm_configure -s* from the command line.

Consider the following post-upgrade configuration:

- User Interface Migration (see page 419)
- KPI Data (see page 420)
- Configure Support Automation Role Access (see page 420)
- Configure the Servers After Upgrade (see page 420)
- Configure Ticket Management After Upgrade (see page 423)
- Modify HTMPL Forms (see page 426)
- Set Ticket Values for Self-Service Users (see page 427)
- Upgrade Knowledge Management from Older Releases (see page 429)
- LREL Post-Migration (see page 434)
- Modify Functional Access Areas (see page 437)
- Email Upgrading (see page 440)

User Interface Migration

- Migration backs up forms automatically. If you used modified HTMPL forms in CA SDM r11.2, r12.0, r12.1, or r12.5, you *must* modify them again after upgrading.
- After you upgrade, modify all the changed HTMPL forms that contained notebook controls to include the new web macros and provide the appropriate tab group names. You modify <PDM_NOTEBOOK> statements to <PDM_MACRO name=startNotebook> and <PDM_TAB> statements to <PDM_MACRO name=TAB> in WSP.

KPI Data

After you upgrade, all versions (active and inactive) of webLicenseCt KPIs are no longer available and all the related KPI data becomes invalid. These data still remain in the usp_kpi_data table, but this data is not fetched while reporting. Customers can choose to execute the OOTB KPI Rule, KPI Data (System) (inactive by default), to remove this data.

Important! We recommend you to check the data available in the usp_kpi_data table, as executing this KPI rule will also archive and/or purge other system KPI collected data.

Note: A new KPI, webConcurrentTotalLicenseCt is used in current release of CA SDM to calculate the number of unique users logged in to CA SDM during that interval. For more information, see User Authentication (see page 1007).

Configure Support Automation Role Access

If you configure Support Automation before migration, the role access configures properly. If you configure Support Automation after migration, set the Support Automation access field for each role to the appropriate value. If the role access is not properly set up, you cannot access the Support Automation Analyst Interface or the End User interface.

The following process outlines how you configure the Support Automation role access after migration:

1. Install the *supportautomation_url* option.
2. Set the Support Automation access field for each role you want to access Support Automation.

Configure the Servers After Upgrade

This article contains the following topics:

Inactive Servers Other Than Primary or Secondary

After you upgrade, all the servers that are not entered as primary server in the usp_servers table are converted to secondary server. Before upgrading, if you have added any server in the usp_servers table, which are not secondary or primary server, inactive them after you upgrade. You can inactive servers from the primary server Web UI.The local host name is stored in the usp_servers table in local_host column.

Clear the Webengine and Browser Cache

After you upgrade CA SDM, run the pdm_webcache utility to clear the cache for the webengine and browser.

```
pdm_webcache -b -H
```

- **-b**
  Warns the user to clear their browser cache.

- **-H**
  Clears the webengine cache.

Configure the Web Director and Servers

After you upgrade, we recommend that you configure the servers and Web Director.

To configure the Web Director and servers

If the previous version was configured to use additional servers, or web directors, you can configure the servers and web director and apply the configuration after upgrade.

For more information, see Managing Servers.

Adjust Data Partition Settings

You can adjust partition constraints after you configure the roles in your system. You adjust the partition constraints to verify that the appropriate permissions function properly after you upgrade to the current release of the product.

To adjust data partition constraints

1. On the Administration tab, browse to Security and Role Management, Data Partitions, Data Partition Constraints.

2. Verify the Majic code constraint settings for the following tables:

   - **SKELETONS**
     Specifies the table used for Knowledge Documents.

   - **O_INDEXES**
     Specifies the table used for Knowledge Categories.

   The table constraint settings are verified.

3. Click Show Filter and enter the Data Partitions you previously used.

Note: You can also use the Table Name field in the Search area to limit your list. For example, enter *SKELETONS* or *O_INDEXES* in the Table Name field and click Search.

Default Constraint Settings

The typical default settings for Constraints are listed as follows:

- **Constraint Settings for the Customer (like) and Employee (like) Data Partitions**

Constraint Settings for Customer (like) and Employee (like) Data Partitions should be the following:

SKELETONS Table

View constraint as:

'SKELETONS READ_PGROUP in @root.pgroups or READ_PGROUP.[pgroup] contained_roles.role in @root.role) and ACTIVE_STATE = 0'Pre-update and Delete constraint:

'id = 0' (id=0 indicates no access)

- **O_INDEXES Table**
  View constraint as:
  READ_PGROUP in @root.pgroups or READ_PGROUP.[pgroup] contained_roles.role in @root.role
  Pre-update and delete constraint:WRITE_PGROUP in @root.pgroups OR WRITE_PGROUP.
  [pgroup] contained_roles.role IN @root.role

Constraint Settings for CA SDM Analyst (like), Knowledge Managers (like) and Knowledge Engineers (like)

Constraint Settings for CA SDM Analyst (like), Knowledge Managers (like) and Knowledge Engineers (like) should be the following:

SKELETONS Table

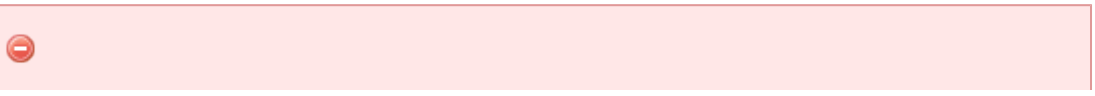
View constraint as:(ACTIVE_STATE >=0)and (READ_PGROUP in @root.pgroups or READ_PGROUP.
[pgroup] contained_roles.role in @root.role) OR (ACTIVE_STATE > 0 AND ASSIGNEE_ID = @root.id)
OR (ACTIVE_STATE = 0 AND OWNER_ID = @root.id)) Active

Pre-update and delete constraint:(ACTIVE_STATE >= 0) AND (WRITE_PGROUP in @root.pgroups OR
WRITE_PGROUP.[pgroup] contained_roles.role IN @root.role) OR (ACTIVE_STATE > 0 AND
ASSIGNEE_ID = @root.id) OR (ACTIVE_STATE = 0 AND OWNER_ID= @root.id)) Active

- **O_INDEXES Table**
  View constraint as:READ_PGROUP in @root.pgroups or READ_PGROUP.[pgroup] contained_roles.
  role in @root.role
  Pre-update and delete constraint:WRITE_PGROUP in @root.pgroups OR WRITE_PGROUP.
  [pgroup] contained_roles.role IN @root.role

Start the IIS Web Interface (CAisd)

After you upgrade a CA SDM r11.2 Windows installation that had an IIS integration, the CA SDM IIS web interface (CAisd) stops. If you want to continue using the IIS integration, manually start CAisd after you upgrade.



Important! If you want to use IIS 7.0, you *must* install the CGI and Metabase Compatability components.

Configure Ticket Management After Upgrade

This article contains the following topics:

How to Add the Incident Priority Field to Incidents

The *incident priority* is the sum of the Urgency and Impact values. The incident priority is only for the incident ticket type. The Incident Priority value appears on the incidents after you install the use_incident_priority option and add it to the incident Detail page form with Web Screen Painter.

To add the Incident Priority field to incident, do the following:

1. Install the use_incident_priority option from the Options Manager, Request Mgr.
2. Use Web Screen Painter to add the Incident Priority field to the Incident Detail pages. The Incident Priority value appears on saved Incident Detail page when the use_incident_priority option is installed. When the use_incident_priority option is not installed, the Incident Priority value is zero.

Note: The use_incident_priority option only manages the Incident Priority value. This option is not related to priority calculation.

Add the Urgency Field to Employee Tickets

By default the Urgency field does not appear on Employee incidents or requests. However, you can add the Urgency field by using the urgency_on_employee option.

Note: When you uninstall the urgency_on_employee option and disable priority calculation, the Priority field appears on the Request and Incident Detail pages for self-service Users.

To add the Urgency field to Employee tickets, install the urgency_on_employee option from the Options Manager, Request Mgr. The Urgency field appears on Employee incidents or requests. Self-service users can override the value on the incident.

Activate Status Transitions

After the upgrade, all predefined status transitions are inactive, so status transitions are not in effect. You can activate and modify these status transitions to accommodate the ticket status transition flow you want.

Note: All modified status code descriptions that appear on ticket forms are retained during the upgrade process.

To activate a status transition

1. On the Administration tab, expand the Service Desk node, and select one of the following ticket types:
   - Change Orders
     - Change Order Transitions
   - Issues
     - Issue Transitions
   - Requests/Incidents/Problems:
     - Incident Transitions
     - Problem Transitions
     - Request Transitions

   The Transitions List appears.
2. Select Show Filter on the Transitions List page.
   The top portion of the page reveals additional search fields.
3. Select Inactive in the Record Status field and click Search.
   The Transitions List at the bottom of the page displays all inactive transitions.
4. Open the transition for editing.
5. Select Active in the Record Status drop-down list.
6. Click Save, Close Window.
7. Click Search.
   The Transition List displays the active transition.

Enable Priority Calculation

Priority calculation is a set of values that automatically set Priority, Urgency, and Impact values on problems and incidents. For new CA SDM installations, the default priority calculation is enabled for problem and incident ticket types by default. However, if you are upgrading from a previous release, the default priority calculation is inactive.

If you create and activate a different priority calculation, the ticket values reflect the settings in the active priority calculation that is associated with an incident or a problem. When no priority calculation is active, users can manually set the Priority and other values on tickets.

Note: The modified forms on the Employee and Customer interface operate in the same manner as the previous versions. The Self-Service users can directly change the Priority regardless of the settings in Priority calculation.

To enable priority calculation after the migration, do the following:

1. On the Administration tab, navigate to Service Desk, Request/Incidents/Problems, Priority Calculation.

2. Right-click the default priority calculation or another priority calculation and select Edit from the short-cut menu.
   The Update Priority Calculation page appears.

3. Set the Status to Active.

4. Select one or more of the following ticket types:

   - **Incidents**
     Enables this priority calculation to manage incident tickets. Only one active priority calculation can manage incidents.

   - **Problems**
     Enables this priority calculation to manage problem tickets. Only one active priority calculation can manage problems.

5. Click Save.
   The values on the default priority calculation apply to new tickets unless you activated another priority calculation. On new tickets that use a priority calculation, the Priority field is read-only.

Activate Transition Types

By default, all predefined transition types delivered with the product are inactive, so status transition buttons are not in effect. You can activate and modify these transition types to accommodate the status transition flow you want.

To activate a transition type

1. Select Show Filter on the Transition Type List page.
   The top portion of the page reveals additional search fields.

2. Select Inactive in the Record Status field and click Search.
   The Transition Type List displays all inactive transition types.

3. Right-click the title of the transition type and select Edit from the menu.

4. Select Active in the Record Status drop-down list.

5. Click Save, Close Window.

6. Click Search.
   The Transition Type List displays the active transition type.

Modify HTMPL Forms

This article contains the following topics:

After you upgrade CA SDM, you modify all the HTMPL forms that contained notebook controls to include web macros and provide the appropriate tab group names.

For each modified form, use WSP to modify <PDM_NOTEBOOK> statements to <PDM_MACRO name=startNotebook> and <PDM_TAB> statements to <PDM_MACRO name=TAB>.

SITEMODS.JS File

Lines of code added to the sitemods.js file of the previous version, called from an HTMPL page, must be merged into the current sitemods.js file before the code works.

Modify Help Sets after Migrating Roles

After you upgrade, CA SDM provides all migrated roles with the complete *Online Help*. You can modify help sets for any role, as appropriate to the needs of your online help system.

To modify help sets for a role

1. On the Administration tab, browse to Security and Role Management, Role List.

2. Open the Role for modification, such as *customer*.

3. Click Edit.

4. Select the Web Interface Tab.
   Click Help View.
   The list of available Help Sets appears for the selected role.

5. Select a Help Set, such as customer.

6. Save the Role.
   The help View for the role changes to the selected online help set.

You can also view the topics available under an online help set by selecting the help set detail and clicking the View Help button.

DocType Validation

Previous releases of CA SDM used the following DocType for HTML generated from HTMPL forms in the HtmplDoctype property of web.cfg:

```
HtmplDoctype <!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN">
```

The HtmplDoctype property of web.cfg appears as follows:

```
HtmplDoctype <!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Frameset//EN" "http://www.
w3.org/TR/html4/frameset.dtd">
```

This line begins on the first list of a page, typically. After you upgrade, verify that the HtmplDoctype property value changed in your modified forms. You can open an HTML file from the $NX_ROOT /bopcfg/www/wwwroot/html directory with text editor and can verify the DocType value.

Set Ticket Values for Self-Service Users

This article contains the following topics:

You can control the Urgency and Priority values that appear to Self-Service users. The properties you set properties in the *web.cfg* file manage choices that appear to users while they create or edit tickets.

To set ticket values for Self-Service users, consider the following:

1. For each override value in the *web.cfg* parameter, specify one or more values.
2. For Urgency values (see page 428), specify one or more numbers from 0 through 4.
3. For Priority values (see page 429), specify one or more numbers from 1 through 5 or the word None.
4. Separate each value with a space.
5. Specify the first value that appears in the list as the default value that appears on tickets. If necessary, you can repeat the default value in the list to improve legibility.

Set the Urgency Range for Self-Service Users

For self-service incidents and requests, you can set default Urgency values in the *web.cfg* file. When you set a range of Urgency values, self-service users such as employees, VIP employees, or guests can set Urgency values on tickets. The choices that appear to self-service users are based on the range of values that you set in the *web.cfg*.

To set the default Urgency range for self-service users

1. Open the w*eb.cfg* file from the appropriate directory:
   - (Windows) %NX_ROOT%\bopcfg\www\

- (UNIX) $NX_ROOT/bopcfg/www/

2. For each parameter, specify one or more urgency property values (see page 428). Separate each value with a space:

   - **ESCEmpUrg**
     Specifies how VIP employees can override Urgency on tickets.

   - **EmpUrg**
     Specifies how employees can override Urgency on tickets.

   - **AnonymousUrg**
     Specifies valid priorities for tickets created by guest users.

3. Save the *web.cfg*.
   On new tickets, employees, VIP employees, or guests can set Urgency values based on the range of values in the *web.cfg*.

Example: Show Guests Only Two Urgency Values on a Request

1. Open the *web.cfg.*

2. Set the *AnonymousUrg* parameter as 0 4. For example, AnonymousUrg 0 4.

3. Save the *web.cfg*.
   The Urgency values that appear to the self-service user are 1-When Possible and 5-Immediate. The default Urgency is 1-When Possible.

Urgency Property Values

The *web.cfg* contains settings to control how self-service users override Urgency on tickets. The following Urgency property values are available:

- **0** -- Lets the user set the Urgency to 1-When Possible
- **1** -- Lets the user set the Urgency to 2-Soon
- **2** -- Lets the user set the Urgency to 3-Quickly
- **3** -- Lets the user set the Urgency to 4-Very Quickly
- **4** -- Lets the user set the Urgency to 5-Immediate

Set the Priority Range for Self-Service Users

You can set a range of valid priorities to allow self-service users to override Priority values on tickets. When you set the priority range, customers, employees, or guests can set Priority values based on the range of values in the *web.cfg*.

To set the priority range for self-service users

1. On the w*eb.cfg* file from the appropriate directory:

- (Windows) %NX_ROOT%\bopcfg\wwww\
- (UNIX) $NX_ROOT/bopcfg/wwww/

2. For each of the parameters, specify one or more Priority property values (see page 429).
   - **CstPrio**
     Specifies how customers can override Priority on tickets.
   - **EmpPrio**
     Specifies how employees can override Priority on tickets.
   - **AnonymousPrio**
     Specifies how employees can override Priority on tickets.
3. Save the *web.cfg*.
   On new tickets, customers, employees, or guests can set Priority values based on the range of values in the *web.cfg*.

Example: Show Guests Only Two Priority Values

1. Open the *web.cfg*.
2. Set the *AnonymousPrio* parameter to None 4. For example: AnonymousPrio None 4.
3. Save the *web.cfg*.
   When a guest works with tickets, the values for Urgency are None or 4. The default value is None.

Priority Property Values

The *web.cfg* contains settings to control how self-service users override ticket Priority. The following Priority property values are available:

- **None** -- Lets the user set the Priority to None
- **1** -- Lets the user set the Priority to 1 (highest priority)
- **2** -- Lets the user set the Priority to 2
- **3** -- Lets the user set the Priority to 3
- **4** -- Lets the user set the Priority to 4
- **5** -- Lets the user set the Priority to 5 (lowest priority)

Upgrade Knowledge Management from Older Releases

This article contains the following topics:

Upgrade Knowledge Management From CA SDM r12.x

Upgrading from CA SDM r12 or r12.1 automatically upgrades your Knowledge Management environment. When the upgrade finishes, complete the following steps:

1. Map links created in a resolution of a document to the database to locate broken links.

   Note: You use the default *Flag broken links* policy to locate broken links.

2. On the Administration tab, browse to Knowledge, Automated Policies, Policies, Scheduling. The Scheduling page appears.

3. Select the Run Calculation check box in the Last Updated field.

4. Enter a date in the Schedule text box or click the Calendar icon to select a date.

5. Select the time interval to perform the calculation and run the policies.

6. Click Save.
   The policies are processed at the specified date and time.

7. On the **Administration** tab, browse to **Knowledge**, **Systems**, **General Settings**.
   The General Settings page opens.

8. Complete the following information:

   Path for EBR Index Files

   Defines the location for storing EBR index files. CA SDM creates EBR index files when you save and publish any knowledge document. Depending on your configuration type, consider the following points while defining the EBR index file path:

   - Conventional: If you are upgrading from the CA SDM Release 12.9 from r11.2 or r12.X, you may choose not to use UNC shared path. If you have not created a UNC path, CA SDM uses the default path to store EBR index files. If you are using a UNC shared drive, manually copy the ebr/ebr_ADM folders from the default location ($NX_ROOT/site/) to the UNC shared path.

   - Advanced availability: If you are upgrading to the advanced availability configuration from CA SDM r11.2 or r12.X, you must create the UNC shared path and use it to store EBR index files. The UNC credentials are not required for the default path. After you create the UNC path, manually copy the ebr/ebr_ADM folders from the default location ($NX_ROOT/site/) to the UNC shared path.

     Important!EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

   Default: $NX_ROOT/site/ebr

- **Path For Knowledge Import/Export Files**

Defines the location for storing KEIT import/export packages during an import/export operation. Depending on your configuration type, consider the following points while defining KEIT file path:

- Conventional: If you are upgrading to CA SDM Release 12.9 from r11.2 or r12.X, you may chose not to use UNC shared path. If you have not created a UNC path, CA SDM uses the default path to store the KEIT files. If you are using a UNC shared drive, manually copy the Import/Export package folders from the default location ($NX_ROOT/site/keit) to the UNC shared path.

- Advanced availability: If you are upgrading to the advanced availability configuration from CA SDM r11.2 or r12.X, you must create the UNC shared path and use it to store the KEIT files. The UNC credentials are not required for the default path. After you create the UNC path, manually copy the Import/Export package folders from the default location ($NX_ROOT/site/keit) to the UNC shared path.

  Important!EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

Default: $NX_ROOT/site/keit

- **UNC Credentials**

You can use this option to create UNC credentials to access the network shared drive to access EBR indexing files and import/export packages. Use the **UNC Credentials** link to create the UNC credentials.

Note: UNC paths and UNC credentials are required in case of the advanced availability configuration. Restart the CA SDM service when you change any of the UNC details (UNC paths or UNC credentials).

9. (For Keyword Search implementations) Enter the following command at the command prompt:

```
pdm_k_reindex factory:all
```

Important! The *all* variable is case sensitive. If you use factory:ALL, errors appear in the log files.

The Knowledge Management environment is upgraded.

Note: After the upgrade, printing Knowledge Documents can result in a large space inserted after the Resolution section of the document. This space is inserted due to an issue with upgrading document templates from a previous release. For more information about resolving this printing issue, see the CA Service Desk Manager Known Knowledge Management Issues (see page 152).

Important! After you upgrade, Knowledge Management notification data from previous releases of CA SDM uses the Release 14.1 notification engine. For example, there are default activity notifications and notification rules for object types, such as the Knowledge Report Card.

Upgrade Knowledge Management From r11.2

Upgrading CA SDM r11.2 automatically upgrades your Knowledge Management environment. When the upgrade finishes, complete the following steps:

1. Map links created in a resolution of a document to the database to locate broken links.

   Note: You use the default *Flag broken links* policy to locate broken links.

2. Select **Knowledge**, **Automated Policies**, **Scheduling** on the **Administration** tab.
   The Automated Policies page opens.

3. Select the **Run the Automated Policies calculation** check box.

4. Select the time interval to perform the calculation and click **Save**.
   The policies will start processing at the specified date and time.

5. Select **Knowledge**, **Systems**, **General Settings** on the **Administration** tab.
   The **System** page opens.

6. Complete the following information:

   Path for EBR Index Files

   Defines the location for storing EBR index files. CA SDM creates EBR index files when you save and publish any knowledge document. Depending on your configuration type, consider the following points while defining the EBR index file path:

   - Conventional: If you are upgrading from the CA SDM Release 12.9 from r11.2 or r12.X, you may choose not to use UNC shared path. If you have not created a UNC path, CA SDM uses the default path to store EBR index files. If you are using a UNC shared drive, manually copy the ebr/ebr_ADM folders from the default location ($NX_ROOT/site/) to the UNC shared path.

- Advanced availability: If you are upgrading to the advanced availability configuration from CA SDM r11.2 or r12.X, you must create the UNC shared path and use it to store EBR index files. The UNC credentials are not required for the default path. After you create the UNC path, manually copy the ebr/ebr_ADM folders from the default location ($NX_ROOT/site/) to the UNC shared path.

  Important!EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

Default: $NX_ROOT/site/ebr

- **Path For Knowledge Import/Export Files**

Defines the location for storing KEIT import/export packages during an import/export operation. Depending on your configuration type, consider the following points while defining KEIT file path:

- Conventional: If you are upgrading to CA SDM Release 12.9 from r11.2 or r12.X, you may chose not to use UNC shared path. If you have not created a UNC path, CA SDM uses the default path to store the KEIT files. If you are using a UNC shared drive, manually copy the Import/Export package folders from the default location ($NX_ROOT/site/keit) to the UNC shared path.

- Advanced availability: If you are upgrading to the advanced availability configuration from CA SDM r11.2 or r12.X, you must create the UNC shared path and use it to store the KEIT files. The UNC credentials are not required for the default path. After you create the UNC path, manually copy the Import/Export package folders from the default location ($NX_ROOT/site/keit) to the UNC shared path.

  Important!EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

Default: $NX_ROOT/site/keit

- **UNC Credentials**

You can use this option to create UNC credentials to access the network shared drive to access EBR indexing files and import/export packages. Use the **UNC Credentials** link to create the UNC credentials.

Note: UNC paths and UNC credentials are required in case of the advanced availability configuration. Restart the CA SDM service when you change any of the UNC details (UNC paths or UNC credentials).

7. Run pdm_k_reindex as follows:

- **pdm_k_reindex -pm**
  Fixes the document links and embedded images inside the resolution field.

  Important! After you upgrade, you can get a critical error when running *pdm_k_reindex -pm*. If you get this error, browse to Knowledge, Approval Process Manager, Approval Process Settings, and change the *Permissions for Document Edit after Publish* option to *User with full permissions may edit documents,* and then run pdm_k_reindex -pm.

- **pdm_k_reindex -ml**
  Fixes the document links inside the resolution field and maps them to the database.

- **pdm_k_reindex**
  Indexes the documents so they are searchable in your knowledge environment.

The Knowledge Management environment is upgraded.

Note: After the upgrade, printing Knowledge Documents can result in a large space inserted after the Resolution section of the document. This space is inserted due to an issue with upgrading document templates from a previous release. For more information about resolving this printing issue, see the CA Service Desk Manager Known Knowledge Management Issues (see page 152).

Important! After you upgrade, Knowledge Management notification data from previous releases of CA SDM uses the Release 14.1 notification engine. For example, there are default activity notifications and notification rules for object types, such as the Knowledge Report Card.

LREL Post-Migration

This article contains the following topics:

After migration, complete the following verification steps:

1. Query the contents of the new tables to verify that the tables contain the correct data.

2. Update each site-defined report to verify that report data originates from the new LREL tables.

3. Test site-defined reports.

Deprecated Object and Tables

The following objects and tables are deprecated for this release of CA SDM. During migration, the system copies the data to Release 12.9 LREL tables. The system uses the LREL tables and objects, but for reference purposes, the old tables retain the data that was present at the time of the upgrade.

DBMS Name	Object Name
Attachment_Lrel	attmnt_lrel
Business_Management_Repository_ Lrel	bmlrel
Chgcat_Group	chgcat_grp
Chgcat_Loc	chgcat_loc
Chgcat_Workshift	chgcat_workshift
Group_Loc	grp_loc
Isscat_Group	isscat_grp
Isscat_Loc	isscat_loc
Isscat_Workshift	isscat _workshift
Knowledge_Lrel_Table	kmlrel
Lrel_Table	lrel1
Pcat_Group	pcat_grp
Pcat_Loc	pcat_loc
Pcat_Workshift	pcat_workshift
Wftpl_Group	wftpl_grp

LREL Tables and Objects

These tables and objects information help users to understand how CA SDM/CMDB schema work and troubleshoot problems. The migration process automatically creates the following tables and objects to manage many-to-many data relationships:

DBMS Name	Object Name
usp_lrel_asset_chgnr	lrel_asset_chgnr
usp_lrel_asset_issnr	lrel_asset_issnr
usp_lrel_att_cntlist_macro_ntf	lrel_att_cntlist_macro_ntf
usp_lrel_att_ctplist_macro_ntf	lrel_att_ctplist_macro_ntf
usp_lrel_att_ntflist_macro_ntf	lrel_att_ntflist_macro_ntf
usp_lrel_attachments_changes	lrel_attachments_changes

usp_lrel_attachments_issues	lrel_attachments_issues
usp_lrel_attachments_requests	lrel_attachments_requests
usp_lrel_aty_events	lrel_aty_events
usp_lrel_bm_reps_assets	lrel_bm_reps_assets
usp_lrel_bm_reps_bmhiers	lrel_bm_reps_bmhiers
usp_lrel_cenv_cntref	lrel_cenv_cntref
usp_lrel_dist_cntlist_mgs_ntf	lrel_dist_cntlist_mgs_ntf
usp_lrel_dist_ctplist_mgs_ntf	lrel_dist_ctplist_mgs_ntf
usp_lrel_dist_ntflist_mgs_ntf	lrel_dist_ntflist_mgs_ntf
usp_lrel_false_action_act_f	lrel_false_action_act_f
usp_lrel_false_bhv_false	lrel_false_bhv_false
usp_lrel_kwrds_crsolref	lrel_kwrds_crsolref
usp_lrel_notify_list_cntchgntf	lrel_notify_list_cntchgntf
usp_lrel_notify_list_cntissntf	lrel_notify_list_cntissntf
usp_lrel_notify_list_cntntf	lrel_notify_list_cntntf
usp_lrel_ntfr_cntlist_att_ntfrlist	lrel_ntfr_cntlist_att_ntfrlist
usp_lrel_ntfr_ctplist_att_ntfrlist	lrel_ntfr_ctplist_att_ntfrlist
usp_lrel_ntfr_macrolist_att_ntfrlist	lrel_ntfr_macrolist_att_ntfrlist
usp_lrel_ntfr_ntflist_att_ntfrlist	lrel_ntfr_ntflist_att_ntfrlist
usp_lrel_oenv_orgref	lrel_oenv_orgref
usp_lrel_status_codes_tsktypes	lrel_status_codes_tsktypes
usp_lrel_svc_grps_svc_chgcat	lrel_svc_grps_svc_chgcat
usp_lrel_svc_grps_svc_isscat	lrel_svc_grps_svc_isscat
usp_lrel_svc_grps_svc_pcat	lrel_svc_grps_svc_pcat
usp_lrel_svc_grps_svc_wftpl	lrel_svc_grps_svc_wftpl
usp_lrel_svc_locs_svc_chgcat	lrel_svc_locs_svc_chgcat
usp_lrel_svc_locs_svc_groups	lrel_svc_locs_svc_groups
usp_lrel_svc_locs_svc_isscat	lrel_svc_locs_svc_isscat
usp_lrel_svc_locs_svc_pcat	lrel_svc_locs_svc_pcat
usp_lrel_svc_schedules_chgcat_svc	lrel_svc_schedules_chgcat_svc
usp_lrel_svc_schedules_isscat_svc	lrel_svc_schedules_isscat_svc
usp_lrel_svc_schedules_pcat_svc	lrel_svc_schedules_pcat_svc
usp_lrel_true_action_act_t	lrel_true_action_act_t
usp_lrel_true_bhv_true	lrel_true_bhv_true

Verify Data in New LREL Tables

During data migration, the system adds to manage many-to-many relationships. You can verify the contents of the new tables and updated site-defined code and reports.

Follow these steps:

1. Query the contents of the tables to verify that they contain the correct data.
2. Update each site-defined report to verify that report data originates from the new LREL tables.
3. Update the queries with the new DBMS table references.
4. Test site-defined reports and code. Update your code to use the new LREL tables and a supported interface, such as Web Services. If necessary, update the table names in your code.

Verify Database Modifications

You can verify that your database modifications are migrated correctly to the current release of the product.

Follow these steps:

1. Review each modified table using either your database management product or WSP.
2. Verify that your modified files appear in the following directory:

   ```
   $NX_ROOT/site/mods/
   ```

Verify Web Form Modifications

You can verify that your web form modifications work correctly in the current release of the product.

Follow these steps:

1. Verify that your modified forms appear in the *$NX_ROOT/site/mods/www/htmpl* directory.
2. Verify that your web form opens correctly within a browser.
3. Verify that your web form opens correctly in Web Screen Painter.

Modify Functional Access Areas

This article contains the following topics:

A *functional access area* is a group of objects that let you restrict user access. Previous versions of CA SDM included eight fixed functional access groups to restrict access to code components.

During migration, the functional access groups migrate to new functional access areas for each role. Migration automatically handles the Majic changes, the default reference data, and role mapping to the new functional access areas.

After migration, consider the following actions:

- Review how the objects map to existing and new functional access areas and role permissions to each area. Use Web Screen Painter to verify the functional access areas.
- Use CA SDM to remap or change permissions. Verify that users have the proper access to features and objects.

Note: For details about default permissions and how objects map to the new functional access areas, see the Product Support website. For information about how to change or add functional access areas, see How Functional Access Areas Works.

The following table maps Functional access areas to code components:

Functional access area	Code Component	New
Administration	admin	No
Incident/Problem/Request	call_mgr	No
Change Order	change_mgr	No
Inventory	inventory	No
Issue	issue_mgr	No
Knowledge Document	kd	No
Notification	notify	No
Reference	reference	No
Security	security	No
Announcement	announcement	Yes
Incident/Problem/Request Reference	call_mgr_reference	Yes
Incident/Problem/Request Template	call_mgr_template	Yes
Change Order Template	change_mgr_template	Yes
Change Order Reference	change_reference	Yes
Configuration Item	ci	Yes
Configuration Item Common	ci_common_ro	Yes
Configuration Item Reference	ci_reference	Yes
Contact	contact	Yes
Group	group	Yes
Issue Template	issue_mgr_template	Yes
Issue Reference	issue_reference	Yes
Location	location	Yes
Notification Reference	notification_reference	Yes

Organization	organization	Yes
Prioritization	prioritization	Yes
Service Level	service_level	Yes
Site	site	Yes
Stored Query	stored_queries	Yes
Survey	survey	Yes
Tenant Admin	tenant_admin	Yes
Timezone	timezone	Yes
Workflow Reference	workflow_reference	Yes
Workshift	workshifts	Yes

Post-Migration Access Level Changes

After migration, you can verify functional access levels for every role. Because the objects moved to another functional access areas, the user could have access to some screens in some situations that they were denied previously. They can also be denied access to forms to which they had access previously. Both situations can occur when a new functional access area manages permissions for two of the original functional access areas.

Note: For details about default permissions and how objects map to the new functional access areas, see the Product Support web site.

Edit Access Types

When you upgrade from CA SDM r11.2, the upgrade process automatically creates roles for all access types and correctly assigns access and permissions to the roles. If you want to take advantage of the new roles in Release 12.9, you can create roles for access types.

To create roles for access types

1. Log in to the web interface as a user with the ability to access the Administration tab.
2. Click the Administration tab.
3. In the tree on the left, select Security and Role Management, Access Types.
   All available access types display.
4. Click an available access type.
5. Click the Roles tab.
6. Select a new role for the access type and click Update Roles.
   The new role is associated with the access type.

Note: You can also create a custom role and assign it to the access type.

Adjust Access Types

If you modified access types and data partitions in the previous release of CA SDM, you may have a problem with the Knowledge Management data partitions settings after upgrading. These customizations can cause a problem with the permission groups settings on categories and documents. For example, a user has access to restricted information.

Note: Even if you recreated a data partition or an access type after deleting it, verify your access type and data partition settings after the upgrade.

To adjust access types

1. Click the Administration tab.
2. Click Security and Role Management, Role Management, Role List.
3. Complete the following steps for each role:
    a. Right-click the role and select Edit.
    b. Review the Data Partition Name field under the Authorization tab.
    If this field is empty, there is no data partition associated with the selected access type, so the user has no restrictions and can access any document or category in the product, even if you set up permission groups.
    This action can be appropriate for administrators, but not for all roles. If there is no data partition associated with the role, you can create or modify one.

Email Upgrading

This article contains the following topic:

- Maileater.cfg Considerations (see page 441)

CA SDM replaces the Options Manager, Email inbound email options with a Mailbox (*usp_mailbox* table) that supplies corresponding options. The Email outbound email options are still present under the Options Manager. When you upgrade, CA SDM uses your existing email settings to configure a mailbox, instead of the default Mailbox settings that are supplied with the release. Each email option, except EMAIL_ATTACHMENT_DIR (which is no longer needed), is mapped to an option in the *usp_mailbox* table. Any option that is not set, is set as null in the table.

The following table lists options that are removed from the Email options, provided in the *usp_mailbox* table, and indicates their labels in the Mailbox Detail page:

Email Option	usp_mailbox Option	Default Mailbox Detail Label
EMAIL_ALLOW_ANONYMOUS	allow_anonymous	Allow Anonymous
EMAIL_ATTACHMENT_DIR	N/A	

Email Option	usp_mailbox Option	Default Mailbox Detail Label
		N/A **Note:** Because EMAIL_ATTACHMENT_DIR is deprecated, you must manually select an Attachment Repository if this option was set and EMAIL_ATTACHMENT_REPOSITORY was not.
EMAIL_ATTACHMENT_REPOSITORY	attmnt_repository	Attachment Repository
EMAIL_FORCE_ATTACHMENT_SPLITOUT	split_out_attachment	Force Attachment Splitout
EMAIL_IS_ATTACHMENT	attach_email	Attach Entire Email
EMAIL_SAVE_UNKNOWN_EMAILS	save_unknown_emails	Save Unknown Emails
MAIL_EATER_IMAP_HOST_PORT	host_port	Port Override
MAILEATER_CHECK_MAIL_INTERVAL	check_interval	Check Interval
MAILEATER_HOST	host_name	Hostname
MAILEATER_LOGIN_PASSWORD	password	Password
MAILEATER_LOGIN_USERID	userid	Userid
MAILEATER_POP3_HOST_PORT	host_port	Port Override
MAILEATER_SECURITY_LEVEL	security_lvl	Security Level
MAILEATER_SERVER_TYPE	email_type	Email Type

Important! The Attachment Directory setting is deprecated after you upgrade, so you *must* specify an Attachment Repository before you continue polling the mailboxes.

Maileater.cfg Considerations

Information that was previously included in the *maileater.cfg* file maps to the *usp_mailbox_rule* table after you upgrade. Consider the following information about the mapping from *maileater.cfg* to *usp_mailbox_rule*:

- The '-i' at the beginning of the line denotes case insensitivity and maps to the filter_ignore_case field.
- The search filter "Subject: *..." previously denoted a regular expression on which to filter. The "Subject:" is removed, is replaced with a "^" symbol, and the remaining value maps to the *filter_string* field. The Filter_type is set to "Subject Contains" type.
- The "TEXT_API xxx" denotes the object that is processed for the rule. The string "TEXT_API " is removed, and the remainder maps to the *action_object* field. The *action_operation* field is set to Create/Update Object.
- The reply to the user typically contains "PDM_MAIL ...". If you have "PDM_MAIL" set, set reply_method to 1800 or else leave it set to null.
- If the - s parameter is set, remove the subject field from the text and set the *reply_subject* with this value.
- The functionality maintains the order of entries. A sequence number starting at 100 and incremented by 100 is set for each valid row.

The other fields in the *usp_mailbox_rule* are set as follows:

Field	Value
mailbox	Default
action_write_to_log	0
action_log_prefix	null
delete_flag	0
description	Migrated from pdm_maileater.cfg file
reply_failure_html	<leave blank to inherit default action>
reply_failure_text	<leave blank to inherit default action>
reply_success_html	<leave blank to inherit default action>
reply_success_text	<leave blank to inherit default action>
text_api_defaults	null
text_api_ignore_incoming	null
action_subject_handling	null
last_mod_dt	null
last_mod_by	null
inclusion_list	"*"
email_address_per_hour	-1
exclusion_list	null
log_policy_violation	1

Support Automation Data Migration

This topic contains the following information:

You can migrate CA Support Automation r6.0 SR1 eFix5 data to CA SDM Release 14.1 from the following environments:

- CA Service Desk Manager r11.2
- CA SDM r12.0
- CA SDM r12.1
- CA Support Automation r6.0 SR1 eFix5 without CA SDM.

Note: You can only migration data from CA Support Automation r6.0 SR1 eFix5. We recommend that you run a full backup of the CA Support Automation r6.0 SR1 eFix5 database before migrating.

Important! Branding modifications from CA Support Automation r6.0 SR1 eFix5 do not migrate automatically. We recommend that you review the modified branding to verify that it corresponds to the CA SDM branding. If necessary, copy and paste the Header, Footer, and CSS URL data of each division to the corresponding tenant (or public) in CA SDM to migrate the branding data.

Migrate a Support Automation Database

You can configure the migration tool to migrate data from the Support Automation database to the CA SDM database, including Support Automation names transformation into the CA SDM database conventions. Migrate the data from the Support Automation database to the CA SDM database before the first usage of Support Automation.

If you do not want to migrate all the historical data from the CA Support Automation r6.0 SR1 eFix5 database, you can purge some of the historical data. You can configure the number of days to leave in the database in the purge script setup. You can download the purge script from ftp://ftp.ca.com/pub/supportbridge/6.0/patch-01/purge_history_6.0_sp1.zip.

Follow these steps:

1. Export (see page) the CA Support Automation data using the script on the installation media.
   The export tool converts the data into *.DAT* format. The tool performs the following major steps when you migrate the data:

- Import the Support Automation database schema into the CA SDM database.
  This schema creates the necessary tables that Support Automation uses.

- Migrate the data from the Support Automation database migration XML into the CA SDM database.
  The CA SDM migration tool generates necessary UUIDs and creates necessary records which represent relationships between Support Automation ID and CA SDM UUID.

2. Copy the CA Support Automation data export folder to the NX_ROOT/site/sbmigration/SA60 directory.
   The data export completes.

3. Import (see page) the data into CA SDM using the CA Support Automation Migration tool.
   The data loads into the database and migration completes.

Convert Divisions to Tenants

You can only migrate divisions from CA Support Automation r6.0 SR1 eFix5. You convert these divisions to tenants to use multi-tenancy in a Support Automation environment. You can migrate each division separately as its own tenant. During the initial data import, all rows in tenant-optional tables are made tenanted.

Important! You migrate this data before enabling Support Automation in CA SDM.

Follow these steps:

1. Export (see page) the division data using the script on the installation media.
   You can export a single division or all divisions.

2. The export tool converts the data into *.DAT* format.
   The tool displays the status of the division export.

3. Copy the CA Support Automation data export folder to the NX_ROOT/site/sbmigration/SA60 directory.
   The data export completes.

4. Import (see page) the data into CA SDM using the CA Support Automation Migration tool.
   The data loads into the database and migration completes.

Export CA Support Automation Data

You export CA Support Automation r6.0 SR1 eFix5 data by converting it to the *.DAT* format that CA SDM uses. You can export divisions into separate tenants, and import the data to a public environment. The export tool logs the process and displays the output directory of the log file after the export completes. The export process records the successful output of each table and indicates any unexpected conditions or errors it encounters.

Important! You can only migrate divisions from CA Support Automation r6.0 SR1 eFix5.

Follow these steps:

1. Execute the *SA60Export* script from the installation media in the /casd.nt/SAMigration directory:

   Note: The file extension depends on your operating system. For example, Windows uses “bat,” UNIX uses “sh” for the bourne shell script, “csh” for the C shell, or “ksh” for the korn shell, and so on.

   The CA Support Automation Migration tool appears.

2. Perform the following actions:

   a. Enter the CA Support Automation r6.0 SR1 eFix5 "WEB-INF" installation parent directory.

   b. Enter a directory to export your CA Support Automation data.
   Note: After the export completes, move this folder to the *NX_ROOT/site/sbmigration /SA60* directory on the CA SDM server.

   c. (Optional) Specify whether passwords can be exported. If you select this option, passwords are exported for users, default credentials, and automated task credentials.

   d. (Optional) Export a single division or all the divisions. If you select this option, a drop-down list displays all active divisions.

3. Click Run.
   The Process Status displays information about the export, such as the database table being migrated, and a count of the records in the table.
   A message appears if the tool detects unrecoverable errors.

   Note: You can stop the export by selecting Stop from the toolbar or file menu.

   The data export completes.

4. Configure and implement Support Automation, as appropriate to your environment.

Import Support Automation Data

You import Support Automation data after converting it to *.DAT* format. You can import the data into CA SDM using the Support Automation migration script. You invoke the utility after installing and configuring CA SDM. You can also execute *sa_migrate.pl* using the *pdm_perl* command.

You can access the script in the *NX_ROOT**bin*\ directory. The migration script performs tasks such as processing tables to maintain database constraints, creates corresponding CA SDM objects, maps tenant column values, and so on.

The default location for migration-related files in the CA SDM installation is in the *NX_ROOT/site /sbmigration* directory. For example, you can find the import configuration file in the *NX_ROOT/site /sbmigration/config* folder. The *sa_migration_config.dat* file stores the id, prop_name, value, and prop_description columns in the CA SDM data format.

The directory stores CA Support Automation r6.0 SR1 eFix5 export data, migration utility code, and Perl scripts, and so on.

Follow these steps:

1. Start the CA SDM Service.
   The service starts and you can verify that it is running.

2. Enter the following on the command line:

   ```
   pdm_perl <NX_ROOT>\bin\sa_migrate.pl
   ```

   The Support Automation data loads into the database from the export package.

How to Install CA SDM

This topic contains the following information:

For a successful CA SDM implementation, you need to understand the CA SDM deployment model and the different configurations that are available.

Deployment Model

You can deploy CA SDM using one of the following deployment models that best suits your requirement:

- **Centralized** – Installs and configures all product components on one server. This is the default installation. You can implement multiple Object Managers and web engines for load balancing and failover, however your business may outgrow this implementation.

- **Distributed** – Installs and configures product components on servers that are closer to the clients receiving the service. For example, a business with many subnets can have analysts that are using the Web Client. In this type of deployment you place an additional server at the branch location. This server performs caching and reduces the network traffic and response time between the branch location and the main server location. This type of implementation supports the implementation of multiple Object Managers and web engines for load balancing and failover.

- **Global** – Having two or more centralized or distributed implementations that are known as regions. The main server of a region replicates minimal information to and from a master region. Hence, a single region can have all necessary information about all other regions. An analyst is aware of tickets from all regions and can connect to a region when required. This type of implementation is useful when network bandwidth is too limited for a distributed implementation. For example, business locations in different countries with a slow link between them.

CA SDM Configuration

Conventional (see page 447) or the advanced availability (see page 448) are two types of configurations that are deployed using the centralized and distributed models. You can install CA SDM using one of the configurations.

CA SDM Architecture for Conventional Configuration

The conventional configuration includes a primary server, a database, and one or more secondary servers. The secondary servers are optional; configure them to support a large number of concurrent users. Only the primary server can access the database directly. The secondary servers access the database through a central process that is available on the primary server. A secondary server can be removed from the configuration without disrupting other servers. Only the users connected to the specific secondary server are affected.

When to Opt for Conventional Configuration

Conventional is the default configuration and is suitable for smaller deployments. Choose the conventional configuration if you do not require any high availability. Be aware that with conventional configuration, the application is not available during maintenance or when a server crashes.

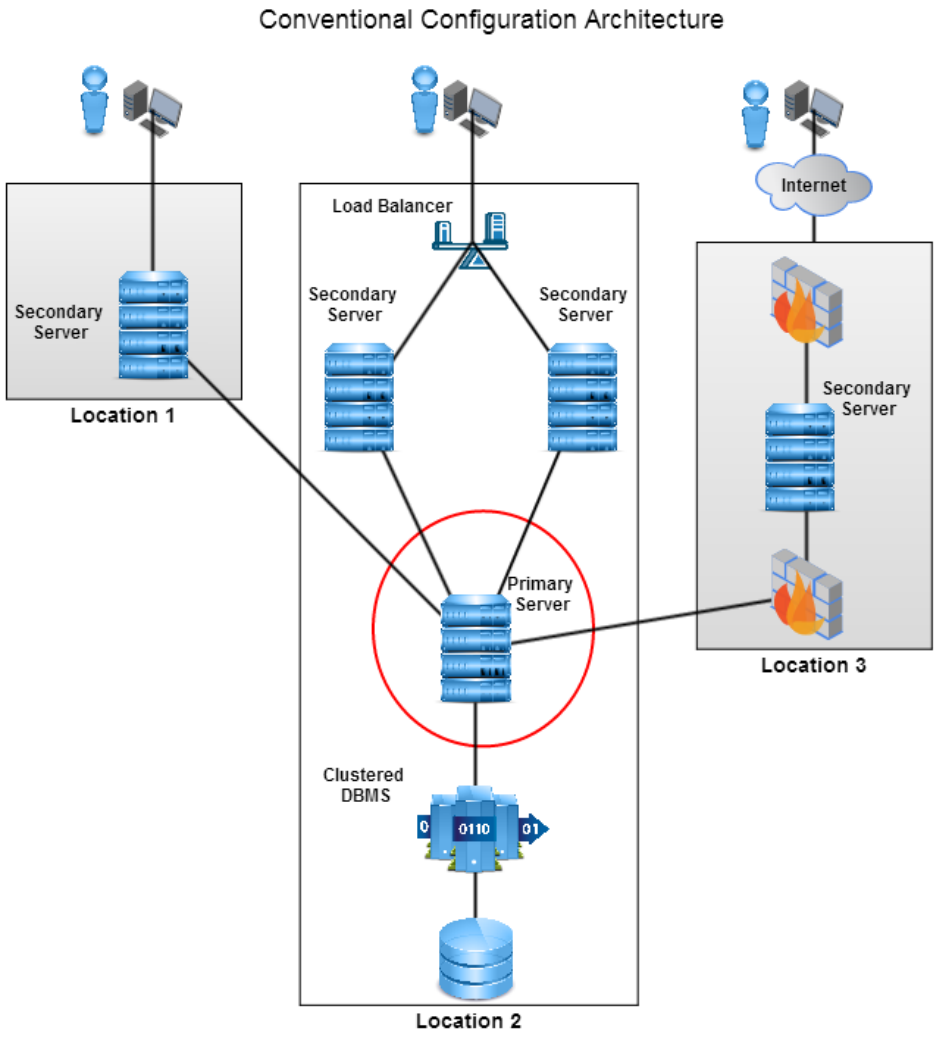
Primary Server

The Primary Server is the main server in a conventional configuration. In a single server CA SDM configuration, the server is the Primary Server. When CA SDM is distributed across two or more servers, one server is designated as the Primary Server. This server performs roles in the configuration such as accessing the database. There is always only one Primary Server.

Secondary Server

A Secondary Server is configured when there are more than one CA SDM server in a configuration. In this scenario, all servers other than the Primary Server are configured as Secondary Servers. Secondary servers perform only a subset of the roles of the Primary Server. Secondary Servers are added to a configuration to scale CA SDM to handle more users.

The following diagram provides an example of the conventional configuration architecture:



CA SDM Architecture for Advanced Availability

The advanced availability configuration includes a background server, one or more standby servers, and one or more application servers. To reduce the single point of failure, each of these servers has a direct connection with the database. All the components of the architecture communicate using an internal CA protocol.

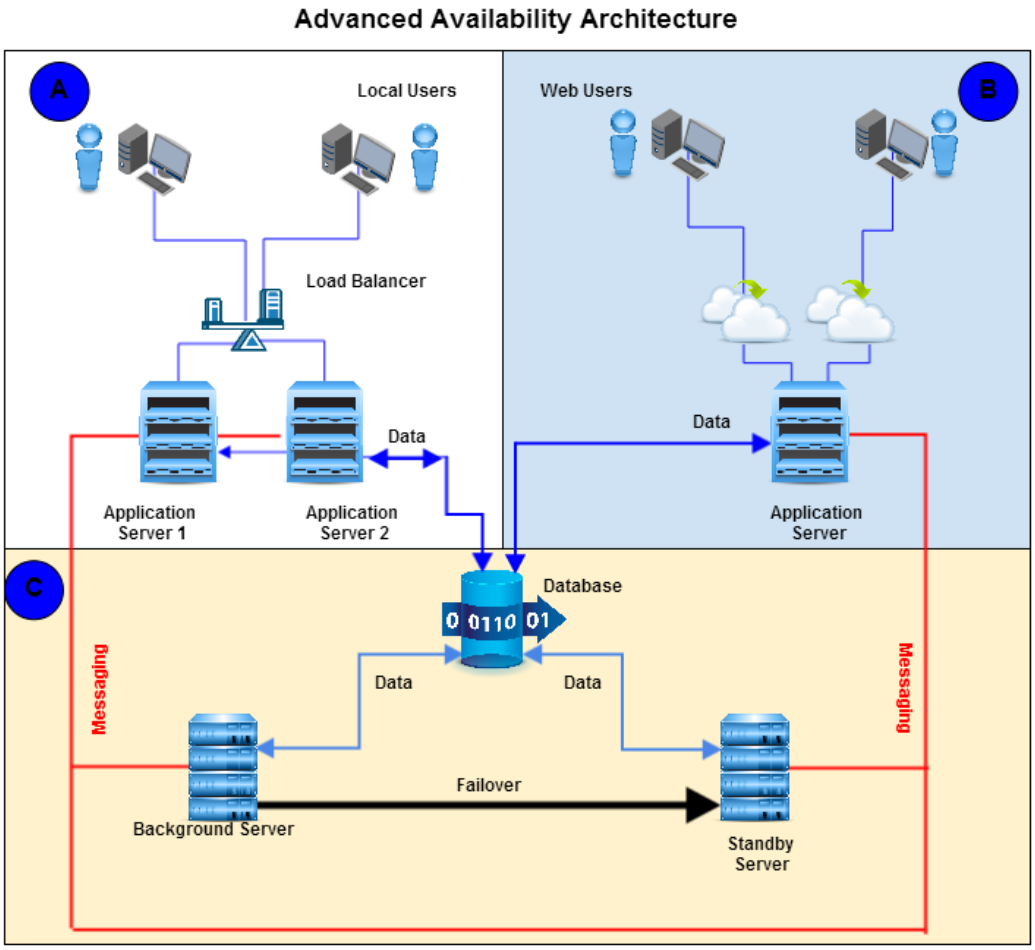
When to Opt for Advanced Availability Configuration

The advanced availability configuration provides higher availability, reduces down times, and supports rolling maintenance. Consider the advanced availability configuration when any of the following factors is true:

- You require a high degree of CA SDM availability.
- You require the CA SDM servers to be more independent and more resilient to failures.

- You require an ability to remove and return the CA SDM servers to service, without bringing down the entire CA SDM installation.
- You require near zero downtime during rolling maintenance.

The following diagram provides an example of advanced availability architecture:



The architecture is spread across three different locations A, B, and C. Location A has two application servers, serving users through a load balancer. The location B has an application server directly serving the users and the location C has the background server, the standby server, and the database. Each of the servers has direct connection to the database. The blue lines mark the flow to and from the database. The red lines identify the internal communication between the components.

Background Server

The background server is the core of the advanced availability architecture. This server provides ancillary services to other servers and runs all singleton processes of CA SDM. A process can be is designated as singleton when only single copy of it can be active in any SDM installation. Only the users with the Administrator Access Type have access to the background server. To increase the availability, the standby server shadows the background server. You can switch the standby server as the background server in case of any failure or when performing rolling maintenance.

Standby Server

The primary function of the standby server is to act as a warm standby for the background server. The standby server has the same hardware and OS platform as the background server. The standby server can run all processes that run on the background server. The standby server stays idle during normal working of the system. However, it listens to the internal CA SDM system messages for database changes and updates the critical caches continuously. If the background server fails or requires rolling maintenance, you can promote the standby server to background server. When you promote the server, the application servers as well as the end users have minimal disruption. You can invoke a utility to perform this switchover.

The standby server is only running a small subset of the processes that normally run on the background server. You cannot log on to the web interface on the standby server.

Application Server

The application server has all the CA SDM components necessary to serve the end users through various interfaces like web, SOAP, and RESTful web services. The application servers are independent of each other and resilient to the background server outages for short periods of time. Users access the application servers. You can individually remove the application servers and return to service by using the new Quiesce facility. The quiesce facility allows current users to complete their work and then sign in to an alternate application server.

More information:

- Step 1- Plan your CA SDM Installation (see page 450)
- Step 2- Install CA SDM (see page 479)
- Step 3- Install Other Components (see page 498)
- Step 4- Post-Installation Requirements (see page 504)
- Step 5- Configure the Servers (see page 505)
- Step 6- Verify the Installation (see page 519)
- Troubleshooting the Installation (see page 523)
- Secure CA SDM from Cross-Site Scripting Vulnerabilities (see page 524)
- Install and Configure JRE 1.8.0_45 (see page 525)

Step 1- Plan your CA SDM Installation

Before you start installing CA SDM, ensure that you have reviewed the following considerations:

- Hardware and Software Requirements for the Install (see page 452)
- Installation Considerations (see page 467)

(Recommended) After you review the considerations, keep the following checklist in place while you are installing CA SDM, to ensure that you do not miss any critical step.

Select	Task	Comments
	Installed the database of your choice (SQL Server or Oracle).	
	Decided the type of configuration (advanced availability or conventional) that you would want to implement.	
	Decided the number of servers required for the CA SDM installation.	
	Ensured that the hardware and software requirements are met.	
	To help ensure that you can configure the product and components on the **Micros oft SQL Server**, you completed the following steps: 1. a. Enabled TCP/IP on the computer on which you want to perform the installation and configuration. b. Obtained the following information: ▪ ▪ ▪ ▪ The named instance of the server that is running Microsoft SQL Server. ▪ The Microsoft SQL Server database user name and password. ▪ The Microsoft SQL Server database port number.	
	To help ensure that you can configure the product and components on **Oracle**, you obtained the following information: 1. a. Whether the Oracle database is local or remote. b. Whether you need to create tablespaces. c. The Net service name. d. The DBA user name and password. e. The data and index tablespace name. f. The complete path for the tablespace. g. JDBC connection information, including the system identifier (SID) and listener port.	
	(For configuring to a 64-bit Oracle database on a 64-bit computer) Pointed the system library path to the 32-bit Oracle libraries. The 32-bit Oracle libraries are found in $ORACLE_HOME/lib32.	
	(For configuring a 64-bit Oracle 11g database on a 64-bit computer) Installed the Oracle 32-Bit Client on the server and while configuring the database pointed the system library path to the 32-bit Oracle libraries. This step is required for both configuration and runtime. Also, created a net service name on the Oracle client to point to the Oracle database server instance.	
	(If you are using an Oracle database and you want to use existing tablespaces) Created a Data tablespace that is at least 400 MB, and an Index tablespace that is at least 100 MB before configuring CA SDM.	
	Increased the hardware configuration of the DBMS server. Each of the servers is directly connected to the database, leading to an increased resource contention at the DBMS level.	

Select	Task	Comments
	If you are installing CA SDM in the pure IPV6 environment, the installation may fail. Ensure that the NX_PROTOCOL_ONLY variable is set to IPV6 and click on Retry Install.	
	(If you plan to install Unified Self-Service with CA SDM) Before you install Unified Self-Service, download Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases). **Note:** Do not Install Liferay Manually as the installer unzips the downloaded file and installs Liferay.	
	(If you would like to identify performance problems in CA SDM) For a Windows installation, install the pslist.exe tool and add its directory path variable to the system path variable. For more information, see the How to Identify Performance Problems in CA SDM (see page 3329) topic.	
	(If you have CA Business Intelligence 3.3 and if you want reporting capability) Install CA Business Intelligence Release 4.1 SP3 (see page 285) and then install CA SDM	
	For CA Business Intelligence ODBC services to start properly, export the library path, as follows: ▪ (For AIX) Export LIBPATH=$LIBPATH:<CA_SharedComponent>/lib:<NX_ROOT>/lib **Example:** Export LIBPATH=$LIBPATH:/opt/CA/SC/lib:/opt/CAisd/lib ▪ (For Solaris/Linux) Export LD_LIBRARARY_PATH=$ LD_LIBRARARY_PATH:/opt/CA/SC/lib:<NX_ROOT>/lib **Example:** Export LD_LIBRARARY_PATH=$ LD_LIBRARARY_PATH:/opt/CA/SC/lib:/opt/CAisd/lib	

Hardware and Software Requirements for the Install

Review the following requirements before you proceed with the installation:

- Operating Systems (see page 452)
- Database Management Systems (see page 454)
- Hardware Requirements (see page 455)
- Server Components (see page 458)

Operating Systems

Find more information about version numbers of each operating system in the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix). Depending on the operating system that you use, ensure that you read the following considerations.

IBM AIX Operating Systems

- Before installing CA SDM (or migrating from a previous release), the IBM XL C/C++ Runtime Environment version 9.0.0.9 (or later) must be installed and running on IBM AIX servers.

- You can integrate CA SDM with CA Business Intelligence, which uses Business Objects Enterprise XI, although we do not support installing CA Business Intelligence on IBM AIX.
- On IBM AIX, install CA EEM by following the instructions provided when CA EEM is selected during installation.

Important! CA SDM does *not* provide tools.jar and javac for AIX. Configuring REST Web Services and Support Automation requires the tools.jar file. To use the REST sample files, you must install javac on AIX. You can download the Java SDK for AIX from the IBM website in the IBM Developer kits section for Linux. Download the 32-bit binaries of Java SE and install JDK 1.7 SR4 on the AIX computer at any location. Copy tools.jar from the installed JDK location to <Shared Component>\JRE\1.7.0_04\lib and copy javac to \JRE\1.7.0 _04\bin. You can also find the JRE location in the NX_JRE_INSTALL_DIR variable. You *must* copy the tools.jar file across all AIX installation, before you run the product configuration.

Redhat Enterprise Linux Operating Systems

- You can integrate CA SDM with CA Business Intelligence, which uses Business Objects Enterprise XI, although we do not support installing CA Business Intelligence on Redhat Linux.
- Verify that you have the following Java libraries on Redhat Linux to launch the product installer:
  - java-1.4.2-gcj-compat-1.4.2.0-40jpp.115
  - java-1.4.2-gcj-compat-devel-1.4.2.0-40jpp.115
  - java-1.4.2-gcj-compat-devel-1.4.2.0-40jpp.115
  - java-1.4.2-gcj-compat-src-1.4.2.0-40jpp.115
- To install CA SDM on RedHat Enterprise Linux 6.0 successfully, verify that you have the following RPM packages and their dependencies:

Required RPM	Dependencies
libXp-1.0.0-15.1.el6.i686.rpm	▪ libXau-1.0.5-1.el6.i686.rpm ▪ libxcb-1.5.1-1.el6.i686.rpm ▪ libXext-1.1.3-1.el6.i686.rpm ▪ libX11-1.3.2-1.el6.i686.rpm
libXtst-1.0.99.2-3.el6.i686.rpm	libXi-1.3.3-3.el6.i686.rpm
openssl-1.0.0-4.el6.i686.rpm	▪ zlib-1.2.3-25.el6.i686.rpm ▪ libselinux-20.94-2.el6.i686.rpm ▪ keyutils-libs-1.4-1.el6.i686.rpm ▪ krb5-libs-1.8.2-3.el6.i686.rpm
openldap-2.4.19-15.el6.i686.rpm	▪ db4-4.7.25-16.el6.i686.rpm

Required RPM	Dependencies
	▪ cyrus-sasl-lib-2.1.23-8.el6.i686.rpm
pam-1.1.1-4.el6.i686.rpm	▪ ▪ cracklib-2.8.16-2.el6.i686.rpm ▪ audit-libs-2.0.4-1.el6.i686.rpm ⚠ **Note**: These 32-bit packages (pam-1, cracklib-2, and audit-libs-2) are required on both 32-bit and 64-bit systems.

- ▪ Verify that you have the following pcre and libuuid packages:
  - pcre-7.8-3.1.el6.i686.rpm
  - libuuid-2.17.2-6.el6.i686.rpm

⚠ **Note**: These 32-bit packages (pcre-7 and libuuid-2) are required on both 32-bit and 64-bit systems.

Oracle Solaris Operating Systems

- You can integrate CA SDM with CA Business Intelligence, which uses Business Objects Enterprise XI, although we do not support installing CA Business Intelligence on Oracle Solaris.
- You can install CA EEM on Oracle Solaris, however CA SDM on Oracle Solaris cannot use external authentication for CA EEM on any platform. The CA EEM authentication feature requires the site to move the boplgin daemon to a Windows, Linux, or AIX operating system. The boplgin daemon on Oracle Solaris cannot integrate with the CA EEM Server on any platform.

Novell SUSE Linux (SLES) Operating Systems - You can integrate CA SDM with CA Business Intelligence, which uses Business Objects Enterprise XI, although we do not support installing CA Business Intelligence on SUSE Linux.

VMware Operating Systems - If you want to configure CA SDM on Windows in a network address translation (NAT) environment, modify the local HOSTS file with the hostname and IP address of your server. You can find the hosts file in the *system32**drivers**etc**hosts*\ directory.

Database Management Systems

Consider the following information:

- For UNIX/Linux Oracle implementations, set the Oracle environment variables before you install or migrate CA SDM.
- To resolve some known issues with Oracle 11g, you *must* force case sensitivity by setting the NX.env variable as NX_ORACLE_CASE_INSENSITIVE=0. We recommend that you also set NX_DSSORT to BINARY to make the domsrvr sort case sensitive. After upgrading to the latest release of Oracle 11gR2 (which *must* include Oracle patch 10248523), you can reset NX_ORACLE_CASE_INSENSITIVE=1 for case insensitivity support.

- If you want to use a remote MDB, the database client (Oracle or SQL Server) *must* be installed on the same computer where you install CA SDM.
- (For Oracle database only) 32-bit ORACLE client must be installed on all CA SDM servers.
- We support remote MDB on HP UNIX with Oracle 11g R2.

Hardware Requirements

We recommend that at least 512 MB of temporary disk space is available for the CA SDM installation and 256 MB of temporary disk space is available for CA MDB installation. If the temporary disk space on your system is less than the recommended minimum value, use the IATEMPDIR variable to redirect this temporary space of the installer to another folder.

Note: If you plan to install Unified Self-Service with CA Service Desk Manager, 2 GB RAM is required in addition to the listed hardware requirements.

(Advanced availability configuration) The following requirements must be met or exceeded for a CA SDM server to install and run properly:

Server Type	CPU Requirements	RAM Requirements	Disk Space Requirements
Standby or Background server	Minimum Dual Processor 2 GHz Preferred Quad Core Processor 2 GHz	Minimum 4 GB Recommended 8 GB	4 GB (for product installation and for minimal application log growth.)
Application server (minimum recommended configuration for each of the application servers must be the same)	Minimum Dual Processor 2 GHz Preferred Quad Core Processor 2 GHz	Minimum 4 GB Recommended 8 GB (Can be increased based upon the number of *domsrvr or webengine pairs)	4 GB
Remote MDB	Minimum Dual Processor 2 GHz	Minimum 4 GB Recommended 8 GB	20 GB (recommended minimum disk space) You should also allow for

Server Type	CPU Requirements	RAM Requirements	Disk Space Requirements
	Preferred Quad Core Processor 2 GHz		incremental growth to accommodate both new MDB table entries and to provide enough space for additional Service Desk-related documents.
Attachments It is not recommended to have the attachment repository location as part of the standby or background or application server to avoid any link breakup during failover. It is recommended to keep it on an independent file server, preferably on a shared storage location, For advanced availability configuration, you may use SAN with RAID 5 configured. Best performance is achieved by using multiple repositories on multiple application servers.			Based on your organization requirements.

(Conventional configuration) The following requirements must be met or exceeded for a CA SDM server to install and run properly:

Server Type	CPU Requirements	RAM Requirements	Disk Space Requirements
Primary server	Minimum Dual Processor 2 GHz	Minimum 4 GB Recommended 6 GB (Can be increased based upon the number of domsrvr or webengine pairs)	4 GB
Secondary server	Minimum Dual Processor 2 GHz	Minimum 4 GB Recommended 6 GB (Can be increased based upon the number of *domsrvr or webengine pairs)	4 GB
Remote MDB		Minimum 4 GB Recommended 8 GB	20 GB (recommended minimum disk space)

Server Type	CPU Requirements	RAM Requirements	Disk Space Requirements
	Minimum Dual Processor 2 GHz Recommended: Quad Core Processor 2 GHz		You should also allow for incremental growth to accommodate both new MDB table entries and to provide enough space for additional Service Desk-related documents

Note: Use only one *DOM server or Web engine pair for each CPU and allocate 1GB RAM per pair.

The following requirements must be met or exceeded for a CA SDM Web Client computer to access CA SDM with better performance:

Hardware	Requirements
CPU	Dual Processor 2.0 GHz preferred
RAM	Minimum 2 GB available free memory
Disk Space	4 GB

Based on the size of your CA SDM environment, the following requirements must be met or exceeded for the product install and run properly:

Database Size	Hardware	Requirements
Small—Used for installing CA SDM in a test environment.	CPU	Minimum Dual Processor 2.0 GHz
	RAM	Minimum 2 GB
	Disk Space	4 GB minimum. This will increase over time to accommodate database growth.
Medium—The CA SDM default. The recommended setting for most CA SDM installations.	CPU	Dual Processor 2.0 GHz
	RAM	Minimum 4 GB Recommended 6 GB
	Disk Space	4 GB minimum. This will increase over time to accommodate database growth.
Large—Used for large CA SDM installations.	CPU	Quad Processor 2.0 GHz

Database Size	Hardware	Requirements
	RAM	Minimum 4 GB Recommended 8 GB
	Disk Space	4 GB minimum. This will increase over time to accommodate database growth.

* The domsrvr or DOM server is the internal daemon which manages the objects in the memory. The webengine is the internal daemon which generates the HTML pages and sends it to the client. A single webengine and domsrvr are deployed in pairs. Each pair requires one dedicated processor core and at least 1 GB of RAM. Each webengine or domsrvr pair can serve 200-250 users. If you need to add more than one pair for scaling up the system, ensure that you have the necessary processor and the RAM are available.

Note: The data files directory of the database server for the MDB requires at least 2 GB of space.

Important! When CA SDM is up and running, it is recommended to check the process memory. For optimal performance, we recommend the following method:

1. Set a notification when the process memory exceeds 1.25 GB and begin a check on the processes that are running.
2. Set a warning notification when the process memory exceeds 1.5 GB and take corrective actions to check the memory usage.

Server Components

CA SDM includes components that work together and run on different servers, depending on the CA SDM configuration. Before, you begin your implementation, ensure that you have a basic understanding of the following components:

Daemon Manager (pdm_d_mgr)

Starts process sets as defined in the startup file, pdm_startup. By default, the daemon manager tries to start a failed component up to 10 times. To check the status of all CA SDM components, use the pdm_status utility. The pdm_d_refresh utility instructs the daemon manager to start a new cycle of 10 attempts to start any process marked as previously failed.

The daemon manager runs on all CA SDM servers.

Message Dispatcher (sslump_nxd)

Acts as a common bus or message passing system. Components that need to communicate with each other first register with the Message Dispatcher. When a component sends a message, the Message Dispatcher delivers it to those components that have registered to receive that type of message. If two components communicate so much that it would be inefficient to pass the messages through the Message Dispatcher, they create a fast channel between them. You can view a list of registered components using the slstat utility.

The message dispatcher runs on the following servers, depending on your CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Database Agent (platform_agent)

Performs SQL queries on the database. Database agents adhere to the logical schema of CA SDM and translate the SQL at this level to the physical database platform SQL.

Note: The database agent detects momentary disconnection and failed queries, and attempts to reconnect and communicate with the database. This is only meant for short outages, such as for a brief network outage and momentary disconnection. It is not meant for long outages such as shutting down a database service for maintenance, and so forth. The agent will only retry the connection for a defined number of times (the default is 3 times), and only for a short time period of a few minutes. If the outage is longer than a few minutes, the agent will stop trying to connect, and CA SDM must be recycled after the database has been made available again.

The database agent runs on the following servers, depending on your CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Agent Provider (platform_prov_nxd)

Starts or stops database agents. By default, a number of agents are running. If more are required to handle the number of database queries, the Agent Provider starts them. If the system no longer requires so many database agents, the Agent Provider terminates the unnecessary ones.

The agent provider runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Virtual Database (bpvirtdb_srvr)

Enables the operation of multiple Object Managers. All Object Managers running on primary or secondary servers connect to the Virtual Database, which arbitrates their access to database agents. For example, when retrieving a new range of ticket reference numbers, the Virtual Database helps ensure that only one Object Manager at a time accesses the table containing the reference numbers. The Virtual Database also performs caching of database information for Object Managers.

The Virtual Database runs on the following servers, depending on CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Continuous Archive and Purge (arcpur_srvr)

Runs your archive and purge rules as configured by the CA SDM administrator.

The Continuous Archive and Purge runs on the following servers depending on CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Database Monitor (dbmonitor_nxd)

Monitors changes to common tables in the CA MDB, for example, ca_contact.

The Database Monitor runs on the following servers depending on CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Mail Daemon (pdm_mail_nxd)

Sends outbound email notifications.

The Mail Daemon runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Mail Eater (pdm_maileater_nxd)

Accepts inbound email for ticket creation and updates.

The Mail Eater daemon runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Notification Manager (bpnotify_nxd)

Manages notifications in a Windows environment.

The Notification Manager runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Application, background, and standby servers

Spell Checker (lexagent_nxd)

Performs spell checking as requested by clients.

The Spell Checker runs on all CA SDM servers.

Text API Daemon (pdm_text_nxd)

Creates and updates tickets by external interfaces, such as the command line and email.

The Text API daemon runs on all CA SDM servers.

Timed Event (animator_nxd)

Runs the delay times of events. In an implementation that has many service types or contracts, there may be many active events that the Timed Event engine has to track. In this situation, you must dedicate the primary server Object Manager entirely to the Timed Event engine. You can configure other Object Managers on the primary or secondary servers for product access as appropriate.

The Timed Event daemon runs on the following servers, depending on CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Time-To-Violation (ttv_nxd)

Calculates projected violation times for service types.

The Time-To-Violation daemon runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Proctor Daemon (pdm_proctor_nxd)

(Windows only) Starts and restarts the CA SDM components, as instructed by the Daemon Manager, on primary and secondary servers. When you install a secondary server, the pdm_proctor_nxd process is installed as the CA SDM Remote Daemon Proctor service. When the primary server starts,

the Daemon Manager instructs the Remote Daemon Proctor to connect to the Message Dispatcher. The Daemon Manager then instructs the Remote Daemon Proctor to start components on the secondary server. The process for starting the components is defined by the Process Sets in the startup file pdm_startup.

The Proctor daemon runs on all the CA SDM servers in advanced availability configuration.

Object Manager (domsrvr)

Acts as the server process of CA SDM. When you install a primary server, by default, two Object Managers are installed: one for connections to the product, and one dedicated to the Web Screen Painter. Having multiple Object Managers helps you test your modifications without affecting the production environment. When you install a secondary server, you can configure more Object Managers.

There must always be a default Object Manager running on the primary server to which clients such as the Timed Event engine can connect.

The Object Manager also caches various records and tables for clients. If you use pdm_userload to manipulate these records, you can also use the pdm_cache_refresh utility to make the Object Manager retrieve the new data.

The Object Manager runs on all the CA SDM servers in advanced availability configuration.

Method Engine (spel_srvr)

Runs SPEL code, event, macros, and so forth, for an Object Manager. We recommend that you run every Object Manager with its own method engine.

The Method Engine runs on all CA SDM servers.

Login Server (boplgin)

Manages authenticated user sessions.

The Login Server runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

LDAP Virtual Database (ldap_virtdb)

Interfaces with an LDAP directory.

The Method Engine runs on the following servers depending on the CA SDM configuration:

- Conventional: Primary or secondary server
- Advanced Availability: Background or application server

Knowledge Management Search Daemon (bpebr_nxd)

Performs knowledge base searches. Upon CA SDM startup, the bpebr_nxd daemon caches Knowledge Document data in its memory from the database. With a large document base, you might have memory resource issues. The bpebr_nxd daemon has the following size requirements:

Knowledge Management Search

- 100,000 documents
- Memory size = 332,000 KB

The Knowledge Management daemon runs on the following servers depending on the CA SDM configuration:

- Conventional: Primary or secondary server
- Advanced Availability: Background server

Knowledge Management/Keyword Indexing Daemon (bpeid_nxd)

Indexes the knowledge base.

The Keyword Index daemon runs on the following servers depending on the CA SDM configuration:

- Conventional: Primary or secondary server
- Advanced Availability: Background server

Knowledge Management FAQ Ratings Daemon (bu_daemon)

The bu_daemon runs on the following servers depending on the CA SDM configuration:

- - Conventional: Primary or secondary server
  - Advanced Availability: Background server

Knowledge Report Card Daemon (krc_daemon)

Performs the calculations for the Knowledge Management Knowledge Report Card (KRC) feature. This feature enables analysts and managers to display different matrix views of their knowledge contributions and provide feedback about which documents are most effective. The information that is provided can be used to improve the processes of creating knowledge documents and providing the best support to customers.

The Knowledge Report Card daemon runs on the following servers depending on the CA SDM configuration:

- Conventional: Primary or secondary server
- Advanced Availability: Background server

Knowledge Management Daemon (kt_daemon)

Manages knowledge base administration and knowledge management logic. It also manages notifications and the document approval process.

The Knowledge Management daemon runs on all CA SDM servers.

Repository Daemon (rep_daemon)

Manages the attachment repositories for CA SDM and the Knowledge Management/Keyword Search Daemon.

The Repository Daemon runs on the following servers depending on the CA SDM configuration:

- Conventional: Primary or secondary servers
- Advanced Availability: All servers

Version Control Daemon (pdm_ver_nxd)

Synchronizes the schema files between a primary and secondary server to ensure that they are using the same schema.

The Version Control Daemon runs on the following servers depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Apache Tomcat Web Server (javaw)

Enables certain features to be implemented, regardless of whether Microsoft Internet Information Server (IIS) is used as the web server for access to CA SDM. These features include Graph Items, Attachments, and Web Services.

The Apache Tomcat web server can be administered with the apache Tomcat controller (*pdm_tomcat_nxd*).

The Apache Tomcat Web Server runs on all CA SDM servers.

Web Engine (webengine)

Connects to web browsers through a pdmweb cgi running on a Microsoft IIS or Apache Tomcat web server. There must be at least one web engine for WSP on the following servers, depending on your CA SDM configuration.

- Conventional: Primary server
- Advanced availability: Application, standby, and background servers

This process ensures that WSP Schema Designer can write schema files. Web engines are the true client of an Object Manager, which the web browser uses to access the product.

Web engines cache .htmpl web forms for connected users. You can manipulate the cache using the pdm_webcache utility and can see connection statistics using the pdm_webstat utility.

The Web Engine runs on all CA SDM servers.

RF Broker (pdm_rfbroker_nxd)

(Applicable for advanced availability configuration only). Manage the roles of the servers and controls them across the configuration. This daemon runs on all servers in advanced availability configuration and performs the following tasks:

- Acquire information about background and standby servers.
- Update information (such as slump ID, node name, server type) in the ServerStatusMonitor class.
- Receive broadcast messages of server status changes.
- Quiesce the requests. Register for SLUMP_NODE_GONE messages that are forwarded to ServerStatusMonitor objects when the failing node is the background server.

Login User Authentication (bopauth_nxd)

This daemon performs the operating system user account validation. To match a user with an access type, the contact record lookups using the System Login field.

If your business provides CA SDM for other client businesses, place the Login server on a secondary server at a single client location. The external authentication is then enabled in access types. Based on the CA SDM configuration, the daemon runs on the following servers:

- Conventional: Primary or secondary (if configured) server
- Advanced Availability: Background or application (if configured) server

Interval Logger (pdm_intrvlog_nxd)

The interval logger daemon gathers the debugging information for debugging the system. Runs on all CA SDM servers.

QRY KPI Daemon (kpi_qry_daemon)

Executes the SQL queries for updating the Key Performance Indicators (KPIs) in the database. The QRY KPI daemon runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

SYS KPI Daemon (kpi_sys_daemon)

Daemon to collect system type key performance indicators and write to the database. The SYS KPI daemon runs on the following servers, depending on your CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Confirm Database (confirm_db)

A utility to verify database access that runs on all CA SDM servers.

Data Dictionary (ddictbuild)

A utility to build the data dictionary and runs on all CA SDM servers.

Set LogFile (pdm_logfile)

A utility to display or set the log file size limits. The pdm_logfile daemon runs on all CA SDM servers.

Report Manager (pcrpt_nxd)

A utility for PC reporting that runs on all CA SDM servers.

RPC Server (rpc_srvr)

Used for making outbound SOAP web service calls and runs on all CA SDM servers.

CA SA Tomcat (sa_tomcat)

CA SA Tomcat to run support automation and can be configured on any CA SDM server.

Visualizer Tomcat (viz_tomcat)

The Tomcat instance to run visualizer and can be configured on the following servers:

- Conventional: All servers
- Advanced Availability: Application server

Event Manager (ehm_nxd)

The Event Manager manages events coming from CA NSM. The Event Manager runs on the following servers, depending on the CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: Background server

Knowledge Management Indexing Daemon (bpeid_nxd)

Responsible for indexing the knowledge documents and runs on the following servers:

- Conventional: Primary server
- Advanced Availability: Background server

Registration Server (mdb_registration_nxd)

An agent for handling MDB registration requests. The Registration Server runs on the following servers, depending on your CA SDM configuration:

- Conventional: Primary server
- Advanced Availability: All servers

Installation Considerations

This article includes the following topics:

This topic provides the general information that you must be aware of, before you install CA SDM. Read the considerations for the specific operating systems and components that are described in the respective sections.

General Considerations for CA SDM

Installation Home Directory

When installing CA SDM, do not install the CA Shared Components in the same directory as the CA SDM installation directory (NX_ROOT).

Note: References to NX_ROOT pertain to the environmental variable containing the installation path of CA SDM. The NX_ROOT variable is set in the NX.env configuration file that is used to set environmental variables for CA SDM.
Example: NX_ROOT Definition
@NX_ROOT=C:\Program Files\CA\Service Desk Manager

(Applicable for Windows only) Filesystem

Complete the following steps to ensure that the filesystem where you are installing CA SDM is 8.3 enabled:

1. Run the following command on the drive where you plan to install CA SDM:
   <installation drive>:\Users\Administrator>FSUTIL.EXE 8dot3name query *<installation drive>:*
   For example, if you are using the D drive to install CA SDM, then the following command must be used:

   ```
   D:\Users\Administrator>FSUTIL.EXE 8dot3name query d:
   ```

2. If 8dot3 name creation is **disabled** on D drive, the following result is displayed:

```
The volume state is: 1 (8dot3 name creation is disabled).

The registry state is: 2 (Per volume setting - the default).
```

3. To enable, run the following command:
   <installation drive>: \Users\Administrator> FSUTIL.EXE 8dot3name set *<installation drive>*: 0
   For example,

```
D:

\Users\Administrator>

FSUTIL.EXE 8dot3name set d: 0
```

Database

- If CA SDM has been configured with one database, and then the configuration is run a second time with a different database type, the configuration does not work. For example, you initially configure for SQL Server and you configure again for an Oracle database. The workaround is to restart the computer before the second configuration is run.
- Database connection information, if different, is not accepted in subsequent configurations. If an additional configuration is needed as a result of a change in the database connection information, delete the $NX_ROOT\NX.env file before proceeding.
- **Oracle**
- - When configuring to a 64-bit Oracle database on a 64-bit computer, the system library path must point to the 32-bit Oracle libraries. The 32-bit Oracle libraries are found in $ORACLE_HOME/lib32.
- - For configuring a 64-bit Oracle 11g database on a 64-bit computer, you must also install the Oracle 32-Bit Client on the server. When configuring the database, the system library path must point to the 32-bit Oracle libraries. This step is required for both configuration and runtime. Also, create a net service name on the Oracle client to point to the Oracle database server instance.
- - Suppose that you are using an Oracle database and you want to use existing tablespaces. Create a Data tablespace that is at least 400 MB, and an Index tablespace that is at least 100 MB before configuring CA SDM.
- - Set the Oracle environment variables before you install or migrate CA SDM, as follows:
- - Verify that the ORACLE_HOME variable is set correctly.

Important! Export TWO_TASK variable when Oracle 32-bit client variables are exported on non-Windows operating systems.

-

- Include the 32-bit Oracle libraries (typically $ORACLE_HOME/lib32 for 64-bit Oracle) in the library path variable LD_LIBRARY_PATH (LIBPATH on AIX).

Internationalization

- You cannot use multi-byte characters for either the user you are logged in as or for the CA SDM privileged username. This applies when you install on multi-byte operating systems such as Simplified Chinese and Japanese. Doing so causes the installation to fail.
- Do not specify multi-byte characters in the file path names during installation and configuration. Doing so causes one or both to fail.
- CA SDM must run on UTF-8 locale on Linux and UNIX platforms.
- The Timespan Symbol names that are provided with the default CA SDM installation (Administration tab, Service Desk, Application Data, Codes, Timespans) are in English. For example, TODAY, YESTERDAY, THIS MONTH. For localized versions of the product, administrators may want to define new localized Timespans as required. Do not delete or modify the default Timespans.
- Date formats in CA SDM do not support international specifiers such as, localized date-picture specifiers. For example, "jj/MM/AAAA" for French. The syntax is limited to generic specifiers such as "DD/MM/YYYY". However, many international short date-time patterns can be constructed from these generic specifiers (for example, "YYYY.MM.DD" would supply a common Japanese short date format).
- For outbound plain-text email notifications, the NX_SMTP_HEADER_CHARSET and NX_SMTP_BODY_CHARSET options may have to be adjusted in the NX.env file. Adjusting the options helps tag the email message with the character encoding used by the international operating environment correctly. The default values for these options are set to UTF-8 on all platforms.
- International users may want to adjust the DateFormat property in web.cfg to use the date and date-time formats.
- International users may want to change from the default spell check lexicon to a lexicon matching their regional language. Use the LEX_LANG option in the Options Manager.
- Short File Names -- If you have disabled short file names on your Windows operating system, enable them before attempting to install CA SDM. In addition to enabling short files names, you set both the TEMP and TMP environment variables to a short file name. For example, c:\temp, after enabling short file names before starting the installation process. For more information, see the Microsoft Knowledge Base Article 121007 on the Microsoft Help and Support web site.
- Web Interface and Internet Information Services (IIS)--To configure the web interface with IIS 7.0 on Windows 2008, install the CGI and Metabase Compatibility components of IIS 7.0. Add these components using the Roles section of the Server Manager, after installing the IIS Management Compatibility modules.
- Localized releases of CA SDM are supported only on the matching localized Windows server operating environment. In all cases, configure the "Language for non-Unicode programs" for your computer accurately to support the target certified language. This setting is available in the

Regional and Language Options window in the Control Panel. For more information about the localized releases of Windows Server operating systems, see the Microsoft Global Development and Computing Portal.

- Knowledge searches containing multi-byte Japanese characters works properly with SQL Server only when SQL Server is installed with Windows collation. Make sure to specify the Collation option for your data during the SQL Server installation.

Special Characters and Spaces (Directory, Media Path, and Folder Name)

- (UNIX, Linux, and Windows) Do not specify spaces in the installation media path and folder name. If you do, the installation does not work.

Tomcat

- Tomcat is set as the default CA SDM web server during the product installation. If you want to use IIS as the default web server, run the configuration and select IIS. Or, re-run the configuration and select IIS.
- If Tomcat is configured with the external authentication on the primary server, set up a secondary server with a webengine and repository daemon. This setup allows users that are not authenticated to use attachments. The Tomcat installation on the secondary server cannot use external authentication.
- The CA SDM installation sets the Tomcat port to 8080. Other CA products, such as CA Asset Portfolio Management or the Service Delivery Suite of products, also default the Tomcat port to 8080. If you are installing multiple CA products on the same server, select a port number other than 8080 for subsequent CA product installations. Selecting a different port number helps the products function properly together. To change the Tomcat port number to something other than 8080 for CA SDM, install the product. If the product is already installed, re-run the product configuration and specify an available port number for Tomcat when prompted.
- After a restart, the CA SDM Tomcat process may not start properly. To start Tomcat properly, stop and restart Tomcat using the following commands:
- - pdm_tomcat_nxd - c STOP
- - pdm_tomcat_nxd - c START

Users and Authentication

- User authentication does not work if the system is using shadow files and there is an x in the password field of the /etc/passwd file.
- On HP-UX, if you have configured security to store the system passwords in /etc/shadow (for example, anx is stored in /etc/passwd in place of passwords), CA SDM user authentication fails. Users cannot log in to CA SDM.
- The password that is specified for the privileged user must conform to the password policy imposed by the network domain. If the password does not meet the policy, CA SDM configuration does not work.

Web Screen Painter
When you install Web Screen Painter as part of the CA SDM installation, you must configure it to work properly.

copy_inactive Web Option

Fresh CA SDM Release 14.1 installation does not install the copy_inactive web option in Options Manager. So the links to inactive objects are not copied. If you are upgrading from CA SDM r12.5 or r12.6, links to inactive objects are copied because migration installs the option.

Consider the following information when you do not install the copy_inactive option:

- CA SDM does not copy SRELs that point to inactive objects, unless SREL is required.
  For example, the Organization org1 has an inactive Location. When you copy org1, the new organization does not have a location. However, if SREL is required, CA SDM ignores this rule and copies the location. For example, CA SDM ignores the rule and you can copy a CI with an inactive class.

- CA SDM does not copy LREL (many-to-many) relationships to inactive objects.
  For example, the CI named CITest1 has a relationship to the inactive Organization org2. When you copy CITest1, org2 does not link to the new CI.

Important! These rules also apply when you copy a ticket, even if you create a ticket from a template. Whether you installed copy_inactive, the exception to the rule is for Inactive Areas and Categories, which are not copied from existing tickets or populated from templates.

Support Automation Planning Considerations

You can use the following information to research and gather information to help you plan for a successful Support Automation configuration.

- **Server and Network** -- Consider the following supported Support Automation server modes:
  - **Main Server** -- Support Automation uses main application server. The server provides socket-based and HTTP-based communications.
  - **Socket Proxy Server** -- Support Automation uses a socket proxy on the same tier as the web server. The web server off-loads encryption/decryption processing from the main server for direct socket connections to support scalability.
  - **Message Routing Server (MRS)** -- Support Automation separates high bandwidth and unpredictable traffic from the main application server. The separation supports server scalability and provides a network routing shortcut for geographical scalability using remote control connections.
- **Server Sizing** -- Consider the following server variables:

- **Network characteristics of end-user and analyst connections** -- The server load is directly proportional to the data of the message routing component. Low bandwidth, high latency, and high packet loss contribute significantly to lowering the load on the server. When network conditions are optimal (high bandwidth, low latency, low packet loss), the speed on the server is much higher. The total number of concurrent analyst users and end-user logins per minute, including self-service user, can place a heavy load on the server.

- **Connection type** -- The number of socket connections as opposed to the number of HTTP connections affects the servers as follows:

  - When you connect predominantly through socket connections, the load on the servers is very light. If we assume powerful hardware, the application is network bound rather than CPU bound. The hardware does not limit the number of concurrent connections but rather the network can limit the connections.

  - When you connect through HTTP, the load on the web and application servers is higher and the application is CPU bound unless scaled significantly.

- **Remote Control usage** -- Remote Control uses significant network bandwidth in a sustained way whenever it is running. All traffic that is routed between end users and analysts flows through the server. The number of concurrent Remote Control connections has a significant role in any sizing assessments.

  Note: Remote Control is the only high-bandwidth tool in the Live Assistance toolset. Chat and Automation are low bandwidth. Screenshot and File Transfer can use high bandwidth for short periods while files are transferred.

Support Automation Network and Bandwidth Considerations

The amount of bandwidth you consume on the end-user computer depends on the tools you use as follows:

- For the Chat and Automation features, the amount of bandwidth that is required is small. A dial-up modem of 56 kbps or less is adequate to support these functions.

- For the Remote Control feature, the amount of bandwidth required increases. However, Live Assistance Remote Control automatically adapts to low-bandwidth environments by reducing the image quality and refresh rate of the remote control session.

The amount of bandwidth also depends on the connection model you employ. Two connection models are available:

- HTTP connectivity -- Use HTTP when the end user is behind a restrictive firewall and the firewall lets only HTTP connections to the server.

- SSL direct socket -- Use SSL direct socket when the end user connects to the server using a connection on the SSL port 443.

The following chart illustrates the necessary bandwidth depending on the tools you use.

Tools/Bandwidth	Chat/Automation	Remote Control
< 3 KBps (28.8 kbps dial-up)	Very fast and responsive	Slow
< 5 KBps (< 56 kbps dial-up)	Very fast and responsive	Adequate with image degradation
< 50 KBps (Cable/ADSL)	Very fast and responsive	Very fast and responsive
< 100 KBps (LAN)	Very fast and responsive	Very fast and responsive

Considerations for Advanced Availability Configuration

We recommend you to consider the following points before you decide to implement the advanced availability configuration:

General

All the planning considerations of the conventional configuration are valid for the advanced availability configuration. For more information, see How to Convert from Advanced Availability to Conventional Configuration (see page 514) and Step 1- Plan your CA SDM Installation (see page 450)

- Additional hardware costs are expected as you require one background, at least one standby, and one or more application servers. The configuration of standby and background server must be identical.
- You require a remote database server and a server to share knowledge Management index files and import/export files, archive purge output files, and attachment repositories. To allow the background and the standby server to access these files, a shared location is required. Linux and Unix installations can use NFS mounts. UNC support has been added for Windows installations.
- The CA SDM performance is expected to remain the same even with the additional servers for background and standby operations. If you deploy more application servers, the performance can possibly improve.
- Each of the servers is directly connected to the database, leading to an increased resource contention at the DBMS level. We recommend increasing the hardware configuration of the DBMS server. For more information, check the system information.
- Converting a conventional configuration to an advanced availability configuration is a manual effort. The larger implementations are usually more complex and you may have to engage CA Services for the assistance.
- To migrate to the advanced availability configuration, upgrade to CA SDM Release 12.9 in the conventional configuration and then convert to the advanced availability configuration.
- Install the background and the standby server on the same network subnet to make ping times and latencies from different application servers similar.
- Consider locating the background and the standby servers in a central location with a good network connectivity to all your users. The application servers can be located either centrally or they can be distributed across the globe.

- An advanced availability configuration must always have one background server and at least one standby server.
  (Recommended) Ensure that both background server and all other standby servers have similar configuration. This process ensures that during a failover when a standby server becomes the new background server, it can function exactly like the old background server.

Any number of standby servers can be configured. To increase the CA SDM availability, consider placing one standby server in your backup data center or the disaster recover site.

- The minimum advanced availability implementation requires one application server. We recommend you to have two application servers to increase the availability and a load balancer to direct web traffic.

- Except for CA SDM administrators, no other users are allowed to log in to the background server. Also, no users are allowed to log in to the standby servers.

We can send email notifications from all CA SDM servers. There is no way to limit or configure this option. Every server in the advanced availability configuration must have a connection to the mail server.

- An email notification resulting from an end-user interaction is sent from the application server to which the user is connected.

- An email notification resulting from a background process is sent by the pdm_mail_nxd utility running on the background server. Animator processing an Attached Event is an example of a background process.

- During a background server failure, the queued emails are sent when the background server comes up as a standby server.

Failover

During a failover of the background server to the standby server, consider the following points:

- The new users cannot log in.

- For the users that are already connected, some actions do not work during the failover. The users must try the actions after the failover. The following actions do not work:

  - Creating the tickets with attachments

  - Downloading the attachments

  - Searching Knowledge documents

  - Indexing the new knowledge documents

  - Inbound email

  - The SLA events that are not triggered until the failover has completed

Important! If you have configured your third-party tool to enable the auto-failover of the CA SDM servers, you must disable it before starting the rolling maintenance.

Database

- A direct connection exists from each of the servers to the other as well as to the database. If the CA SDM server is within DMZ, open the firewall ports or implement a tunneling proxy technology for this connectivity. Also consider licensing arrangements with your DBMS vendor.
- Ensure that you install the database client on all the CA SDM servers.
- In advanced availability configuration, all the servers still connect to a single database. As the database can be a single point of failure, consider taking the advantages of database clustering to increase the availability of DBMS.
- Microsoft SQL Server is only natively supported on the Windows platform. For example, suppose that your implementation consists of servers with heterogeneous operating systems such as Windows and Linux. Select Oracle as the DBMS as Microsoft SQL Server is not supported on Linux.
- The pdm_isql utility works only on the application server.

System Configuration, Administration, and Operation

- SOAP Web Services and RESTful Web Services are only supported on the application servers. Web directors can be configured on all CA SDM servers.
- As the application servers are independent of each other, web directors can only service web engines running on the same application server. Web directors cannot service web engines across application servers.
- Since the servers in the advanced availability configuration have a higher degree of independence, most command-line utilities function only on the local server. For example, pdm_status only shows you the CA SDM processes running on the server on which you are executing the command. The pdm_webcache utility only refreshes the form caches on the server on which it was issued.
- In advanced availability, processes on each server are controlled independently. This is unlike conventional configuration, where you run pdm_d_mgr on the primary server to start and stop CA SDM processes.
- We recommend you to use the new pdm_server_control instead of pdm_halt command to shutdown application servers. Before the shutdown, you can ask the active users to move to another application server. You can notify the users using the quiesce option.
- The pdm_edit utility has been replaced with a new graphical user interface, eliminating many manual configuration file changes required earlier.

- Unlike conventional, in the advanced availability configuration, you can use the bopauth_host option to specify the authentication server details. The option is available in the Options Manager of the background server Web interface. You no longer make this configuration change in pdm_edit for the advanced availability configuration. Users cannot log in when the authentication server is unavailable.

  Note: In the conventional configuration, you can use a secondary server to integrate CA SDM with an authentication system running on a different system or even on a different hardware platform.

- To prevent rogue servers from joining the advanced availability configuration, define all servers from the background server Web interface, before you configure them.

- The role and other information for a server in the advanced availability configuration can be changed from the **Administration** tab. Stop the CA SDM services before attempting to change a server definition. The server reconfiguration is required for the changes to take effect.

- You can change a server between the conventional configuration and the advanced availability configuration by running the configuration utility. Be sure to change all servers in the implementation. Your data remains unaffected, but the manual updates are required to change the settings.

- Use the latest pdm_startup files while migrating to CA SDM Release 12.9. Do not use the files from previous versions of CA SDM. For example, files that are generated by the pdm_edit utility.

- New environment variables have been added to NX.env to support the advanced availability and the system automatically maintains the variable values.

  Important! Do not change NX.env manually unless instructed to do so.

- A new facility generates ticket numbers and numeric record keys. To avoid possible database corruption, never try to load or manually alter the Key_Control table.

- You cannot move the Knowledge Management daemons to another server in the advanced availability configuration. The kt_daemon now runs on all servers. All other Knowledge Management daemons run as singletons on the background server.

- Knowledge Management now support UNC file paths on Windows for the EBR index files and input/output files locations. These files are used by the Knowledge Export Import facility. This feature is available for both the advanced availability and the conventional configurations.

  Important! EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

- Version control distributes the files (for example, htmpl, .maj, .mod, and .sch) that are configured in the server_secondary_custom.ver file from the background server. Upon startup, the standby or the application server runs the version control client to pull updated files from the background server.

- Archive/Purge runs on the background server and supports UNC file paths on Windows for output files. This feature is available in the advanced availability and the conventional configurations.

- Attachments on incoming emails are now stored by pdm_maileater when the repository is on a remote server.

- Ensure that you allow the daemon manager to modify the procsets and do not run the pdm_dmnmode command for this action.

General Web User Interface

- A web server is required on all the servers of the advanced availability configuration.

- When the background server is not available due to failover, a Delayed Server Response form is presented to the web users. Users are allowed to resume their work when the standby server is promoted to the background server.

- The value of the web_cgi_url option must point to:

  - The load balancer if you have more than one application servers.

  - The application server, if you have only one application server.

Attachment

- You can increase the availability of attachments by configuring multiple document repository processes to access a shared file repository.

Web Screen Painter

- You can use the Web Screen Painter (WSP) only on the background server.

- Follow the recommended procedure to publish WSP form changes so that the updated forms are distributed to all the servers in the installation. For more information, see the *How to Modify Schema Using Web Screen Painter* and *How to Modify Web Interface using Web Screen Painter* scenarios.

- The virtual database layer daemons run on all servers. Install the CA SDM database modifications and object definitions on all the servers.

Reporting

- CA Business Intelligence can automatically retrieve data from alternate application servers. You can configure this feature to increase the availability of CA SDM reporting.

- BOXI is not integrated with the background server. For this reason, you cannot view reports from the background server web UI. An error message is displayed if you select the Reports tab from the background server web UI.

- (If you have CA Business Intelligence Release 3.3) Install CA Business Intelligence Release 4.1 SP3 (see page 285) and then install CA SDM.

- For CA Business Intelligence ODBC services to start properly, export the library path, as follows:

  - (For AIX) Export LIBPATH=$LIBPATH:<CA_SharedComponent>/lib:<NX_ROOT>/lib
    Example: Export LIBPATH=$LIBPATH:/opt/CA/SC/lib:/opt/CAisd/lib

  - (For Solaris/Linux) Export LD_LIBRARARY_PATH=$ LD_LIBRARARY_PATH:/opt/CA/SC/lib:<NX_ROOT>/lib
    Example: Export LD_LIBRARARY_PATH=$ LD_LIBRARARY_PATH:/opt/CA/SC/lib:/opt/CAisd/lib

Options Manager

You can install or uninstall options through Options Manager only from the background server web UI. After you install or uninstall the options, restart the CA SDM servers.

Web Services

- You can configure web services only on the application servers.

- The webservices_domsrvr option no longer exists in the Options Manager. You can configure NX_WEBSERVICES_DOMSRVR variable independently on each application server by modifying NX.env.

Integration

- The URL to the CA SDM web user interface must point to a properly configured application server. The ca_application_registration contains a URL to your CA SDM installation that other CA products use. This URL points to the CA SDM server that is configured first, which is most commonly the background server. Only the CA SDM administrators can change the value through the administration facility. If you are using a load balancer, point this URL to the load balancer instead of a single application server. For more information, see the *Online Help*.

- Most end-users interaction and integrations with other software products are done at the application server level. There is no failover for the application servers. If the application server is unavailable, the web services for the application server are also unavailable. To increase the application server availability, you can deploy a load balancer to route requests among different application servers.

- You can integrate NSM only to a single application server as the IP addresses are involved. The NSM integration is unavailable when that server is down.

- CA SDM and Unified Self-Service Integration:

  - Ensure that you install both the products on different machines.

- Before you install Unified Self-Service, download Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases).

Note: Do not Install Liferay Manually as the installer unzips the downloaded file and installs Liferay.

Conversion

- You can convert the background server to a primary server only.
- You can convert the primary server to a background server only.
- You can convert the secondary server to a standby server or application server only.
- You can convert the standby or an application server to the secondary server only.

CA SDM Connector Considerations

For CA SDM connector to function for CA SDM installed in supported locales, you must apply RO72246 (Language Independent) and RO72249 (Language Combo) patches on CA SDM 12.9. Then apply the following patches.

Language	Patch
German	T52Y442
Simplified Chinese	T52Y443
Japanese	T52Y444
English	T52Y445
French	T52Y446
French Canadian	T52Y447
Spanish	T52Y448
Italian	T52Y449
Brazilian Portuguese	T52Y450

Step 2- Install CA SDM

You can use the CA Service Management Installer (see page 293) to install or upgrade CA SDM in conventional (see page 480)or in advanced availability (see page 487) configuration. When you install CA SDM on a server, the following files, components, and features are installed:

- Server functionality, which is based on how you configure the product after installation.
- The ODBC Interface

Important! The ODBC interface is installed solely for use to access the ODBC driver for Business Objects reporting in CA SDM with CA Business Intelligence. Use of the ODBC driver by other applications is not directly supported, certified, or warranted by CA Technologies. You use it at your own risk.

- CA MDB - If CA SDM is installed on the primary server, CA MDB is installed automatically during the installation.
- The Web Interface
- Visualizer
- Support Automation

Note: For optimal performance, consider setting up Unified Self-Service in a clustered environment (see page 619).

Install CA SDM Using Conventional Configuration

You can install CA SDM using the conventional configuration.

For UNIX/ Linuix, mount the installation media on your drive and navigate to the root directory of the installation media and start the installation by running the following command:

```
sh ./setup.sh
```

Also, consider the following points:

- When installing on Linux and UNIX, you may not be able to view some pop-up messages clearly, for color properties white on white.
- Suppose that Internet Protocol Version 4 (IPv4) and Internet Protocol Version 6 (IPv6) hosts coexist on the network. Verify that the appropriate transition strategies, tools, and mechanisms to support these technologies are in place before you start the product configuration.
- If you start, and then stop the installation on UNIX or Linux, you may see a directory at the root of the installation named install.dir.#####. This is a feature of InstallAnywhere. These files are not needed and you can safely delete them.
- Create the **CA Service Desk Manager Server Privileged** user before you begin the installation.

Follow these steps:

1. Ensure that you completed the following steps from the CA Service Management Installer (see page 293):
    a. Selected a language and **CA Service Management** from the **Select the required installer** screen

b. Accepted the license agreement.

c. Entered the database information correctly.

> **Note:** For Linux/ UNIX, only information related to Oracle database is required.

d. Select **CA Service Desk Manager** from the **Select the Products and Integrations** screen. If you want to integrate Unified Self-Service with CA SDM, keep the check box for Unified Self-Service selected.

> **Important!** While integrating these products, use the Unified Self-Service User ID and Email Address in CA SDM.

e. Review the Installation Prerequisites report and take corrective measures to proceed with the installation.

2. If you are installing for the first time, you need to enter the common Administrator credentials for CA Service Management in the **CA Service Management Administrator details** screen.

3. Navigate to **CA Service Desk Manager Product Configuration** screen.

   a. Select the **Conventional** radio button.

   b. Select **Primary Server** from the **Select Server Type** drop down.

   c. Select the other components that you want to install on this server. For example, Federated Search.

   d. If you have already created server process configuration, then select the configuration or else keep the **Default** option selected.

   e. Click **Browse** to select the installation directory and click **Next**. The following screenshot corresponds to the installation on Windows.

4. Enter the following information in the **CA Service Desk Manager Server Details** screen:

> **Note:** Enter the primary server host name in the **Primary Server Node** field (defaulted to the localhost name).

Image 9_1.JPG

5. On the **CA Service Desk Manager Server Privileged User Details** screen, select the **Load Default Data** check box to load on the predefined date and enter the privileged user details.

6. On the **CA Service Desk Manager Optional Component Details** screen, enter the port numbers to install the components that you have chosen.

Image 11.JPG

7. If you have selected to integrate CA SDM with Support Automation, enter the following information:

   - **Main Server:** Configures the Support Automation server in main server (standalone) mode. If you select the **Main Server Configuration Type**, the **Host Name** or **IP** field defaults to the local Host Name. All parameters must be provided for the **Main Server** except the **Internal Port** section and the **Bind to IP** in **Socket Server** section, which are optional. Configure the main server on the following CA SDM server according to the CA SDM configuration type:

   -
     - Conventional: Primary server or secondary server.
     - Advanced availability: Background server.

Important! When you set the **supportautomation_url** *option*, this URL must use the URL of the Support Automation main server. It should not reference the proxy server or load balancer server. This is applicable only for conventional model. In the advanced availability configuration the URL can point to load balancer, main server, or proxy server.

Note: If you select the **Main Server** option, and are also planning to configure one or more socket proxy servers, you *must* set the **Socket Server host name** and **external port** to the socket proxy host and external port. For multiple socket proxies, you set the **Socket Server to the host** and **external port** of the load balancer server.

   - **Tomcat Port:** Specifies the Support Automation Tomcat port.
   - **Tomcat Shutdown Port:** Specifies the Support Automation Tomcat Shutdown port.

Note: When you change the main server Tomcat port, also change the port references in the server.properties file with tomcat server.xml.

- **Host Name or IP**: Specifies the address of your server.
- **External Port** : Specifies the external port of your server.
- **Host Name or IP**—Specifies the address of your socket server.
- **External Port** —Specifies the external port of your socket server.
- **Internal Port**—Specifies the internal port of your socket server.
- **Bind to IP**—Specifies the IP where you want to bind the server.
- **Socket Proxy Server:** Configures the Support Automation server in socket proxy mode. Use a Socket Proxy Server to off-load some of the CPU-intensive operations of Support Automation, such as encryption/decryption from the main server.
-
  - Advanced Availability: Application server.
  - Conventional: Secondary server.
- **Main Server Host Name or IP**: Specifies the address of the main server.
- **Main Server Internal Port**: Specifies the internal port of the main server.
- **Main Server HTTP Port**: Specifies the HTTP port of the main server. This field is available only for conventional configuration.
- **External Port**: Specifies the external port of the server.
- **Bind to IP**: Specifies the IP where you want to bind the server.
- **Message Routing Server:** Configures the Support Automation server in message routing server mode. Use Message Routing Servers (MRS) to manage multiple Remote Control sessions that are based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions.
  - Advanced Availability:Application server.
  - Conventional: Secondary server.
- **External Port**—Specifies the external port of the socket.
- **Bind to IP**—Specifies the IP where you want to bind the server.

CA SDM installs and configures the following Support Automation components:

- End-User Client

- Support Automation Analyst Interface
- Server

You install and configure the following components separately:

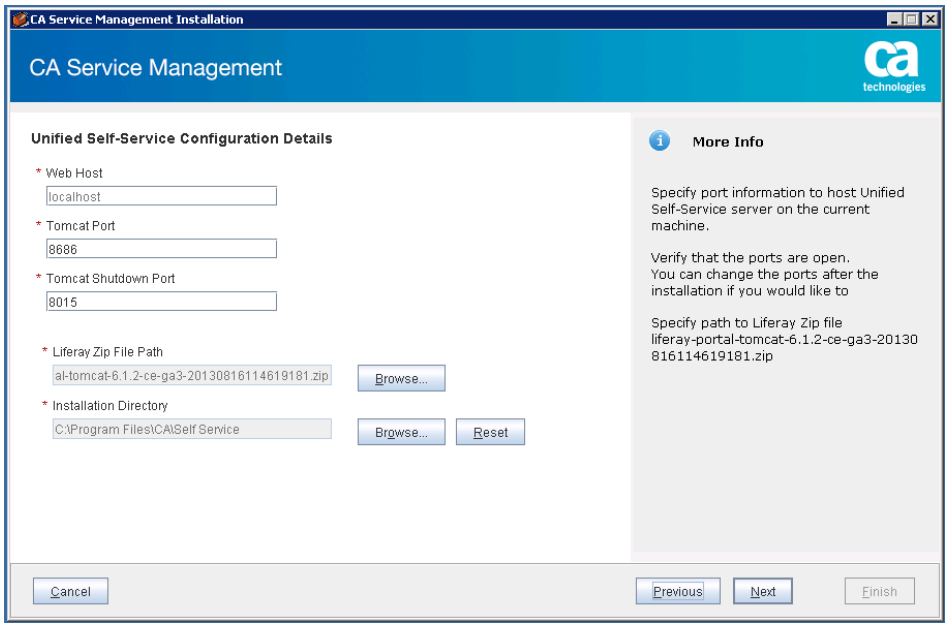
- End-User Agent
- Automated Tasks Editor IDE

8. If you have selected to integrate CA SDM with Unified Self-Service, complete the following steps:

> **Note:** For optimal performance, consider setting up Unified Self-Service in a clustered environment (see page 619).

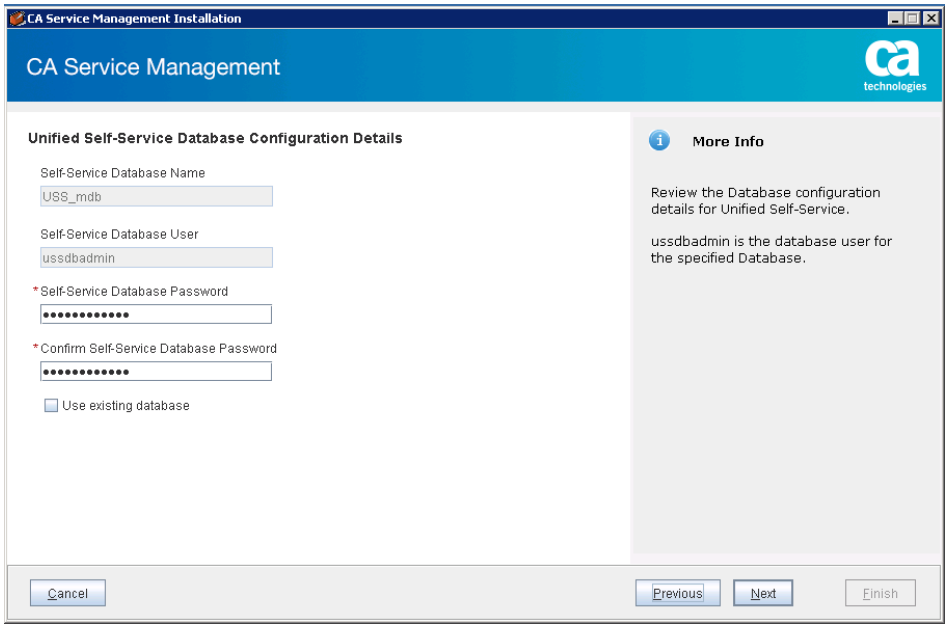
a. Enter the configuration details in the **Unified Self-Service Configuration Details** screen. Enter the Web Host as the host name of the machine where you are installing Unified Self Service.

> **Note:** Before you install Unified Self-Service, download Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases). Do not Install Liferay manually as the installer unzips the downloaded file and installs Liferay.



Unified Self-Service Configuration Details

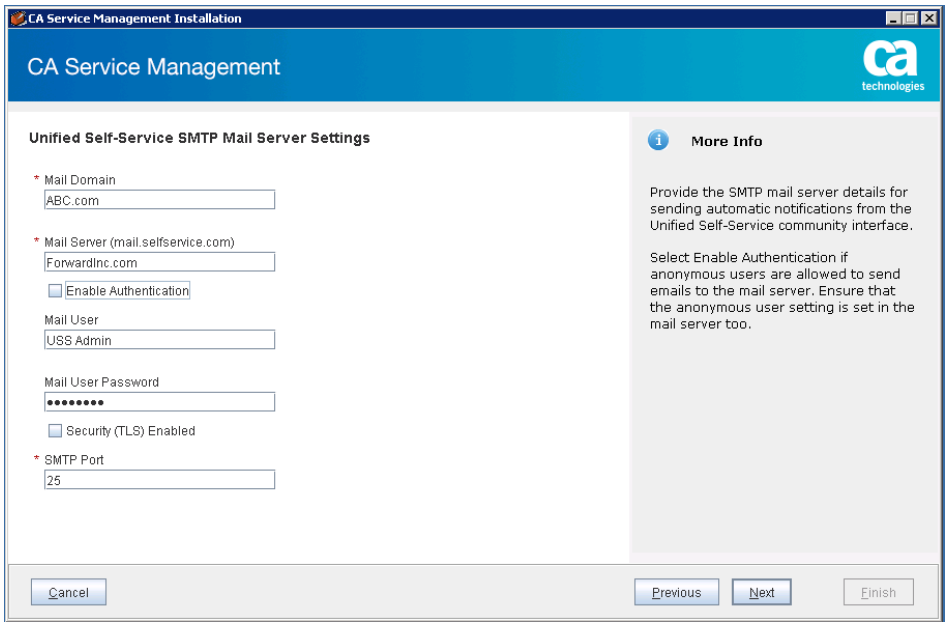
b. Enter the database information in the **Unified Self-Service Database Configuration Details** screen. If you have already set up a database, select the Use existing database check box and select the backup file. The database for Unified Self-Service is created during this installation.



Unified Self-Service Database Configuration Details

c. Enter the SMTP mail server details to send automatic notifications from the Unified Self-Service community interface in the **Unified Self-Service SMTP Mail Server Settings** screen:

- **Mail User**
  Defines the name of the mail user using which you want to send automatic notifications.
- **Mail User Password**
  Defines the password of the mail user.
- **Security (TLS) enabled**
  Specifies whether the TLS security is enabled or not for the mail server.



Unified Self-Service SMTP Mail Server Settings

You have entered all the Unified Self-Service information.

Important! For integration between Unified Self-Service and CA Service Desk Manager to work appropriately, ensure the Unified Self-Service users that are available in CA Service Desk Manager have the same User ID and email address.

9. Review the Pre-Installation Configuration Summary Report.
10. Review the Installation progress information and click **Install** to install the selected product /products.
11. Review the Installation Guidance Report summary to ensure that the installation succeeded.
12. After installing CA SDM on the primary server, create the server process configuration for the secondary server.
13. Log in to the secondary server and start the CA Service Management installation. You can either skip the database configuration to come to the **CA Service Desk Manager Product Configuration** screen directly or enter the database information (if different from the primary server) and proceed with the installation.

Image 7_1.JPG

14. After you install CA SDM (or migrate to CA SDM from a CMDB standalone system), run the *cmdb_update_ambiguity* utility. Use the -h command to view the mandatory options.

Note: If configuration fails during the Validate Extension Tables step, database connectivity can be an issue. Retry the installation and verify that you provided the correct database connectivity information.

Install CA SDM Using Advanced Availability Configuration

You can install CA SDM using the advanced availability configuration.

For UNIX/ Linuix, mount the installation media on your drive and navigate to the root directory of the installation media and start the installation by running the following command:

```
sh ./setup.sh
```

Also, consider the following points:

- When installing on Linux and UNIX, you may not be able to view some pop-up messages clearly, for color properties white on white.
- Suppose that Internet Protocol Version 4 (IPv4) and Internet Protocol Version 6 (IPv6) hosts coexist on the network. Verify that the appropriate transition strategies, tools, and mechanisms to support these technologies are in place before you start the product configuration.
- If you start, and then stop the installation on UNIX or Linux, you may see a directory at the root of the installation named install.dir.#####. This is a feature of InstallAnywhere. These files are not needed and you can safely delete them.
- Create the **CA Service Desk Manager Server Privileged** user before you begin the installation.

Follow these steps:

1. Ensure that you completed the following steps from the CA Service Management Installer (see page 296):
    a. Selected a language and **CA Service Management** from the **Select the required installer** screen
    b. Accepted the license agreement.
    c. Entered the database information correctly.

Note: For Linux/ UNIX, only information related to Oracle database is required.

    d. Selected **CA Service Desk Manager** from the **Select the Products and Integrations** screen. If you want to integrate Unified Self-Service with CA SDM, keep the check box for Unified Self-Service selected.

> **Important!** While integrating these products, use the Unified Self-Service User ID and Email Address in CA SDM.

e. Review the Installation Prerequisites report and take corrective measures to proceed with the installation.

2. If you are installing for the first time, you need to enter the common Administrator credentials for CA Service Management in the **CA Service Management Administrator details** screen.

3. Navigate to **CA Service Desk Manager Product Configuration** screen.

   a. Select the **Advanced Availability** radio button. The background server option is selected by default.

   b. Keep the **Default** option selected.

   c. Click **Browse** to select the installation directory and click **Next**. The following screenshot corresponds to the installation on Windows.

4. Enter the following information in the **CA Service Desk Manager Server Details** screen:

Image 9_1_AA.JPG

5. On the **CA Service Desk Manager Server Privileged User Details** screen, select the **Load Default Data** check box to load on the predefined data and enter the privileged user details.

6. On the **CA Service Desk Manager Additional Server Details** screen, enter the following information of the servers that you want to add:

Image 11_AA.JPG

7. If you have selected to integrate CA SDM with Support Automation, enter the following information:

   - **Main Server:** Configures the Support Automation server in main server (standalone) mode. If you select the **Main Server Configuration Type**, the **Host Name** or **IP** field defaults to the local Host Name. All parameters must be provided for the **Main Server** except the **Internal Port** section and the **Bind to IP** in **Socket Server** section, which are optional. Configure the main server on the following CA SDM server according to the CA SDM configuration type:

     - Conventional: Primary server or secondary server.

- Advanced availability: Background server.

Important! When you set the ***supportautomation_url*** *option*, this URL must use the URL of the Support Automation main server. It should not reference the proxy server or load balancer server. This is applicable only for conventional model. In the advanced availability configuration the URL can point to load balancer, main server, or proxy server.

Note: If you select the **Main Server** option, and are also planning to configure one or more socket proxy servers, you *must* set the **Socket Server host name** and **external port** to the socket proxy host and external port. For multiple socket proxies, you set the **Socket Server to the host** and **external port** of the load balancer server.

- **Tomcat Port:** Specifies the Support Automation Tomcat port.
- **Tomcat Shutdown Port:** Specifies the Support Automation Tomcat Shutdown port.

Note: When you change the main server Tomcat port, also change the port references in the server.properties file with tomcat server.xml.

- **Host Name or IP**: Specifies the address of your server.
- **External Port** : Specifies the external port of your server.
- **Host Name or IP**—Specifies the address of your socket server.
- **External Port** —Specifies the external port of your socket server.
- **Internal Port**—Specifies the internal port of your socket server.
- **Bind to IP**—Specifies the IP where you want to bind the server.
- **Socket Proxy Server:** Configures the Support Automation server in socket proxy mode. Use a Socket Proxy Server to off-load some of the CPU-intensive operations of Support Automation, such as encryption/decryption from the main server.
-
  - Advanced Availability: Application server.
  - Conventional: Secondary server.
- **Main Server Host Name or IP**: Specifies the address of the main server.

- **Main Server Internal Port**: Specifies the internal port of the main server.
- **Main Server HTTP Port**: Specifies the HTTP port of the main server. This field is available only for conventional configuration.
- **External Port**: Specifies the external port of the server.
- **Bind to IP**: Specifies the IP where you want to bind the server.
- **Message Routing Server:** Configures the Support Automation server in message routing server mode. Use Message Routing Servers (MRS) to manage multiple Remote Control sessions that are based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions.
  - Advanced Availability:Application server.
  - Conventional: Secondary server.
- **External Port**—Specifies the external port of the socket.
- **Bind to IP**—Specifies the IP where you want to bind the server.

CA SDM installs and configures the following Support Automation components:

- End-User Client
- Support Automation Analyst Interface
- Server

You install and configure the following components separately:

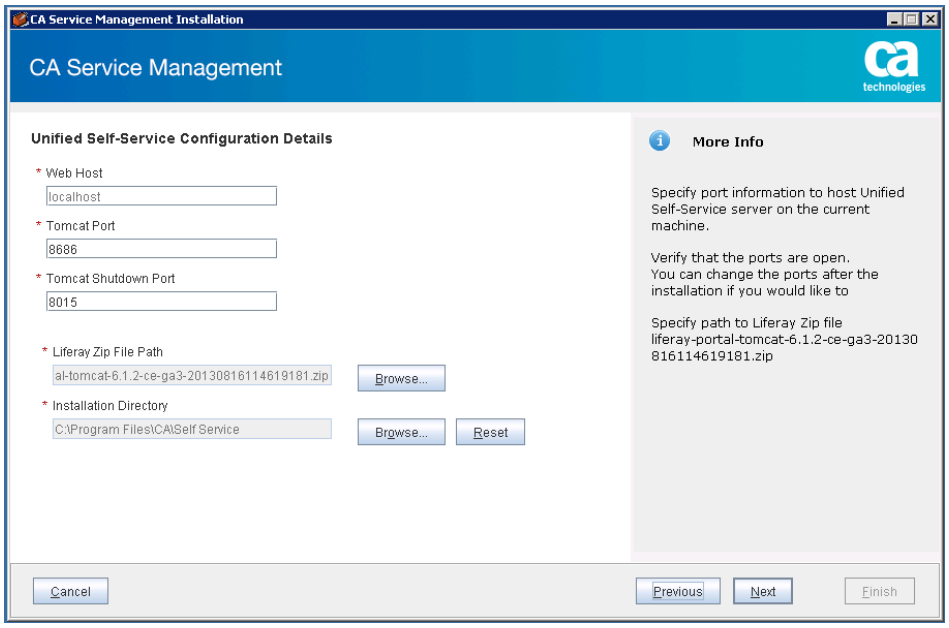
- End-User Agent
- Automated Tasks Editor IDE

8. If you have selected to integrate CA SDM with Unified Self-Service, complete the following steps:

   Note: For optimal performance, consider Setting up Unified Self-Service in a clustered environment (see page 619).

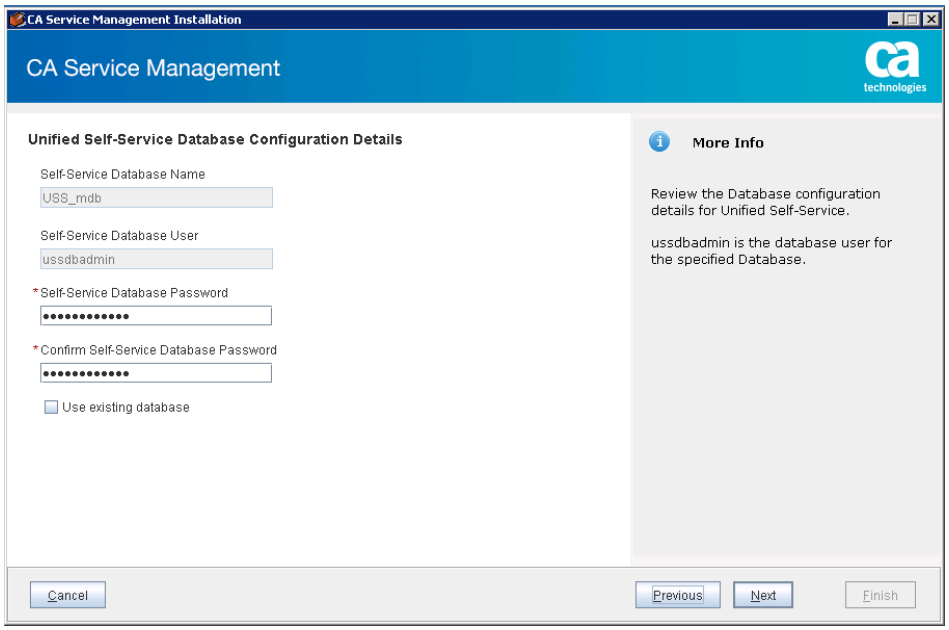
   a. Enter the configuration details in the **Unified Self-Service Configuration Details** screen. Enter the Web Host as the host name of the machine where you are installing Unified Self Service.

Note: Before you install Unified Self-Service, download Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases). Do not Install Liferay manually as the installer unzips the downloaded file and installs Liferay.



Unified Self-Service Configuration Details

b. Enter the database information in the **Unified Self-Service Database Configuration Details** screen. If you have already set up a database, select the Use existing database check box and select the backup file. The database for Unified Self-Service is created during this installation.



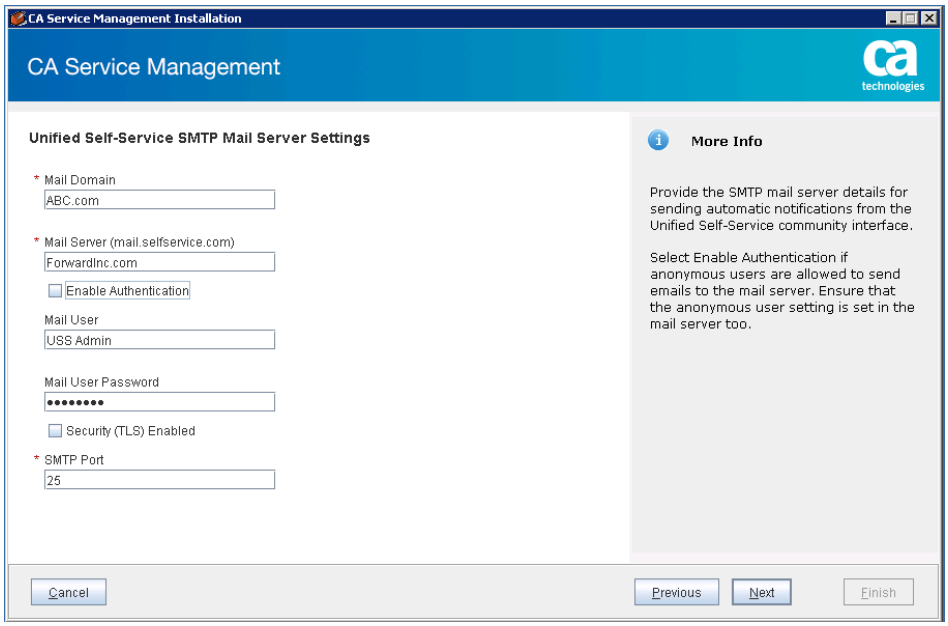
Unified Self-Service Database Configuration Details

c. Enter the SMTP mail server details to send automatic notifications from the Unified Self-Service community interface in the **Unified Self-Service SMTP Mail Server Settings** screen:

- **Mail User**
  Defines the name of the mail user using which you want to send automatic notifications.

- **Mail User Password**
  Defines the password of the mail user.

- **Security (TLS) enabled**
  Specifies whether the TLS security is enabled or not for the mail server.



Unified Self-Service SMTP Mail Server Settings

You have entered all the Unified Self-Service information.

Important! For integration between Unified Self-Service and CA Service Desk Manager to work appropriately, ensure the Unified Self-Service users that are available in CA Service Desk Manager have the same User ID and email address.

9. Review the PreInstallation Configuration Summary Report.
10. Review the Installation progress information and click **Install** to install the selected product /products.
11. Review the Installation Guidance Report summary to ensure that the installation succeeded.
12. After installing CA SDM on the background server, create the server process configuration for the other servers.
13. Install CA SDM on the other servers. For the application server, on the **CA Service Desk Manager Optional Component Details** screen, enter the port numbers to install the components.

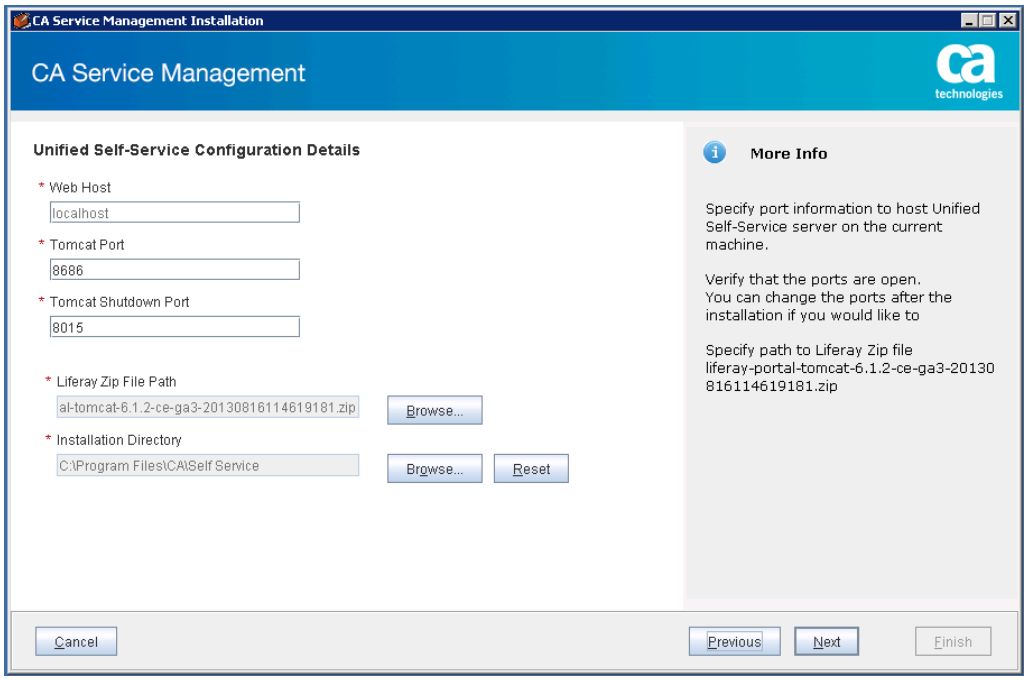
Image 11.JPG

Install Unified Self-Service with CA Service Desk Manager

Note: For optimal performance, consider setting up Unified Self-Service in a clustered environment (see page 619).

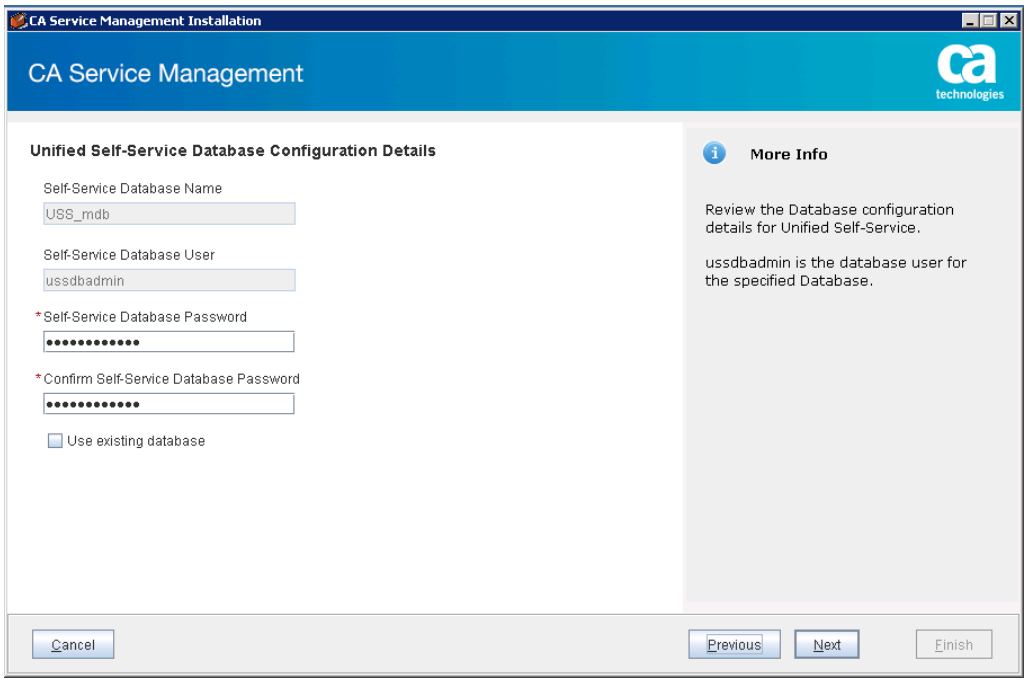
1. Enter the configuration details in the **Unified Self-Service Configuration Details** screen. Enter the Web Host as the host name of the machine where you are installing Unified Self Service.

   Note: Before you install Unified Self-Service, download Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases). Do not Install Liferay manually as the installer unzips the downloaded file and installs Liferay.



Unified Self-Service Configuration Details

2. Enter the database information in the **Unified Self-Service Database Configuration Details** screen. If you have already set up a database, select the Use existing database check box and select the backup file. The database for Unified Self-Service is created during this installation.



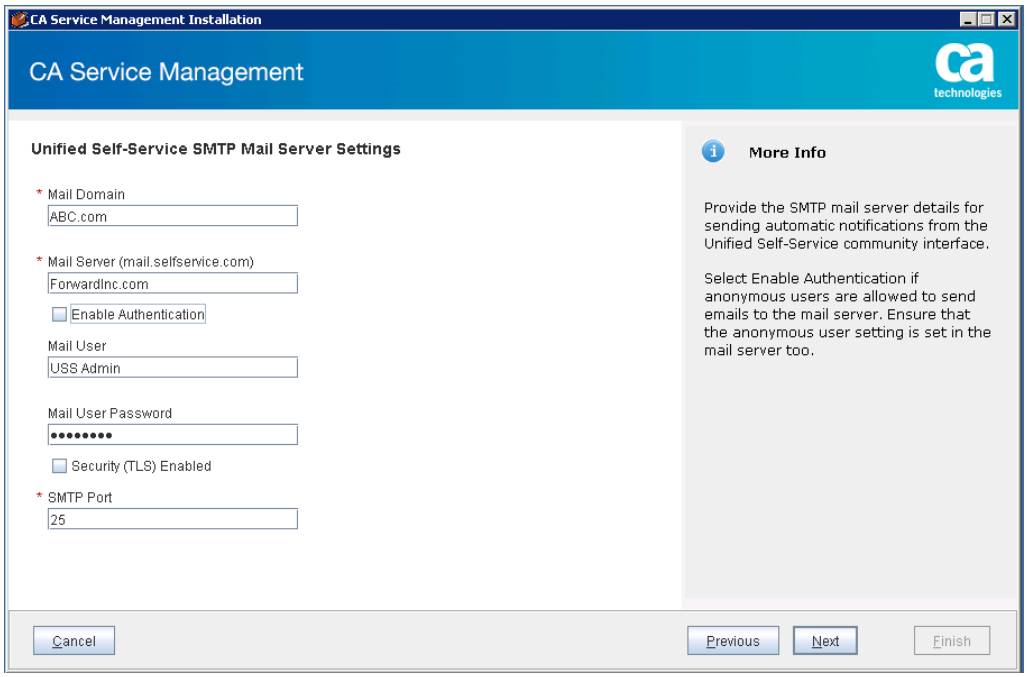
Unified Self-Service Database Configuration Details

3. Enter the SMTP mail server details to send automatic notifications from the Unified Self-Service community interface in the **Unified Self-Service SMTP Mail Server Settings** screen:

   - **Mail User**
     Defines the name of the mail user using which you want to send automatic notifications.

   - **Mail User Password**
     Defines the password of the mail user.

   - **Security (TLS) enabled**
     Specifies whether the TLS security is enabled or not for the mail server.



Unified Self-Service SMTP Mail Server Settings

You have entered all the Unified Self-Service information.

Important! For integration between Unified Self-Service and CA Service Desk Manager to work appropriately, ensure the Unified Self-Service users that are available in CA Service Desk Manager have the same User ID and email address.

Support Automation Configuration Details

Enter the following information:

Main Server: Configures the Support Automation server in main server (standalone) mode.

Tomcat Configuration

Tomcat Port

Specifies the Support Automation Tomcat port. **Default:** 8070

Tomcat Shutdown Port

Specifies the Support Automation Tomcat Shutdown port. **Default:** 8075

Note: When you change the main server Tomcat port, also change the port references in the server.properties file with tomcat server.xml.

HTTP

- **Host Name or IP**—Specifies the address of your server.
- **External Port** —Specifies the external port of your server. **Default:** 8070.

Socket Server

- **Host Name or IP**—Specifies the address of your socket server.
- **External Port** —Specifies the external port of your socket server. **Default:** 10443.
- **Internal Port**—Specifies the internal port of your socket server.
- **Bind to IP**—Specifies the IP where you want to bind the server. **Default:** 7005.

Socket Proxy Server

Configures the Support Automation server in socket proxy mode. Use a Socket Proxy Server to off-load some of the CPU-intensive operations of Support Automation, such as encryption/decryption from the main server.

- - Advanced Availability: This option is available only for the application server.
  - Conventional: This option is available only for the secondary server.

Socket Configuration

Main Server Host Name or IP—Specifies the address of the main server.

Main Server Internal Port—Specifies the internal port of the main server. **Default:** 7005

Main Server HTTP Port—Specifies the HTTP port of the main server. This field is available only for conventional configuration.

External Port—Specifies the external port of the server. **Default:** 10444

Bind to IP—Specifies the IP where you want to bind the server.

Message Routing Server

Configures the Support Automation server in message routing server mode. Use Message Routing Servers (MRS) to manage multiple Remote Control sessions that are based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions.

- - Advanced Availability: This option is available only for the application server.
  - Conventional: This option is available only for the secondary server.

Socket Configuration

External Port—Specifies the external port of the socket. **Default:** 10444

Bind to IP—Specifies the IP where you want to bind the server.

Step 3- Install Other Components

This article includes the following topics:

Install Web Screen Painter

Install Web Screen Painter to modify the schema and web interface.

Follow these steps:

1. Log in to the following server where you want to install Web Screen Painter, depending on your CA SDM configuration:
   - Conventional: Primary or secondary server or any remote computer
   - Advanced availability: Background server

   Important! Web Screen Painter can only run on the background server. The Web Screen Painter installer does not stop you from installing it on any other server. However, it prevents from running standalone, or on the standby server and application server. For example, you installed Web Screen Painter on a server other than background server. The Web Screen Painter shortcuts appear on the Start menu and on clicking the shortcut, an error message is displayed.
2. Launch the installer.
3. Click CA Web Screen Painter for Service Desk Manager in the Select the required installer page.
4. Continue following the on-screen instructions to complete the Web Screen Painter installation.

Web Screen Painter is installed. In a Web Screen Painter preview session in test mode, search filters are ignored on new tables that are not published.

Install and Configure JRE 1.8.0_45

Complete the following steps to install and configure JRE 1.8.0_45 (32-bit) to use with CA SDM release 14.1:

1. Shut down the CA SDM Daemon or CA SDM Proctor Service, or both on the relevant CA SDM server (primary or secondary, or both).
2. Download JRE 1.8.0_45 (jre-8u45-windows-i586 via the Download JRE link) from http://www.oracle.com/technetwork/java/javase/downloads/jre8-downloads-2133155.html

3. During the installation, select the Change destination folder option and enter the destination folder as <drive>:\<install_directory>\CA\SC\JRE\1.8.45

4. Take a backup of NX.env, located at <drive>:\<install_directory>\CA\Service Desk\

5. Modify NX.env as follows:

   ```
   @NX_JRE_INSTALL_DIR=C:/Program Files (x86)/Java/jre1.8.0_45
   ```

6. Start Service Desk.

7. Install and configure Apache Tomcat 7.0.59 (see page 498) for Support Automation to work properly.

Install and Configure Apache Tomcat 7.0.59

CA SDM 14.1 provides out-of-the-box Apache Tomcat 7.0.23. Complete the following steps to upgrade to Apache Tomcat 7.0.59:

1. Shut down CA SDM Daemon Service or CA SDM Proctor Service, or both on the relevant CA SDM server (primary or secondary, or both).

2. Download Tomcat 7.0.59 (apache-tomcat-7.0.59.zip) from http://archive.apache.org/dist/tomcat/tomcat-7/v7.0.59/bin/

   Note: CA SDM supports service packs and point releases of Operating Systems, Databases, Web Servers, Web Browsers, Java, Servlets, and so on. This may not be noted in the certification matrix as long as the reported problem is reproducible with versions that are listed in the matrix. CA reserves the right to refuse support of new point releases should the reported problem require a major rework or redesign to function properly. Both Technical Support and Sustaining Engineering does their best to resolve any issues that occur in a timely manner. If the resolution to the problem is determined to be outside the realm of their support responsibilities, they may ask you to escalate your request for certification to your local account team.

3. Unzip apache-tomcat-7.0.59.zip and copy the files at <drive>:\<install_directory>\CA\SC\tomcat\7.0.59

   Note: After unzipping, ensure that <drive>:\<install_directory>\CA\SC\tomcat\7.0.59 contains conf, bin, webapps, and other directories.

   <drive>:\<install_directory>\CA\SC\tomcat\7.0.59 must NOT contain <drive>:\<install_directory>\CA\SC\tomcat\7.0.59\apache-tomcat-7.0.59. Presence of this directory indicates that the unzipping was done incorrectly.

4. Take a backup of the NX.ENV directory, located at the CA SDM install directory (NX_ROOT).

5. Modify NX.ENV as follows:

   ```
   @NX_TOMCAT_INSTALL_DIR=C:\Program Files\CA\SC\tomcat\7.0.59
   ```

6. Backup NX_ROOT\bopcfg\www\CATALINA_BASE\conf and the following directories (whichever exist):

   - $NX_ROOT\bopcfg\www\CATALINA_BASE_SA\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_REST\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_VIZ\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_WF\conf

7. Copy all files from **<drive>:\<install_directory>\CA\SC\tomcat\7.0.59\conf** to **NX_ROOT\bopcfg\www\CATALINA_BASE\conf**

8. Verify that the server.xml file located in directory NX_ROOT\bopcfg\www\CATALINA_BASE\conf has the same startup (connector) and shutdown ports as defined in the original server.xml file. Complete the following steps to verify:

   a. <Server port="8085" shutdown="SHUTDOWN">

   b. <Connector port="8080" protocol="HTTP/1.1" connectionTimeout="20000" redirectPort="8443" />

   c. Ensure no other ports are used as follows. If it is used, you must comment them according to the original server.xml file.

      ```
      <Connector port="8009" protocol="AJP/1.3" redirectPort="8443" />
      ```

   Note: If any other changes were made to the original server.xml file, then make the same changes to the new server.xml file.

9. Edit NX_ROOT\bopcfg\www\CATALINA_BASE\conf\catalina.properties using the text editor and modify **shared.loader=** as **shared.loader=${catalina.base}/shared/lib/*.jar.** Save the file.

10. If CA Support Automation is installed, verify that the server.xml file located at NX_ROOT\bopcfg\www\CATALINA_BASE_SA\conf has the same startup (connector) and shutdown ports as defined in the original server.xml file.

    Note: If any other changes were made to the original server.xml file, then they would need to be made to the new server.xml file.

11. Modify config.properties located at NX_ROOT\site, as follows:

```
web.tomcat_home=<drive>\:\\<install_directory>\\CA\\SharedComponents\\tomcat\\7.
0.59
web.tomcat.version=7.0.59 web.cawf_tomcat_home==<drive>\:
\\<install_directory>\\CA\\SharedComponents\\tomcat\\7.0.59
```

12. For CA Visualizer, copy the CMDBVisualizer.xml file from the backup conf directory that you created in step 7 to NX_ROOT\bopcfg\www\CATALINA_BASE_VIZ\conf\Catalina\localhost

> **Important!** If this step is not performed then the applications will not deploy properly when Tomcat is started.

13. If CA Advanced Workflow is installed, copy the pm.xml and wl.xml files from the backup of the conf directory you created in step 6 to the following location:

```
<drive>:\<install_directory>\CA\Service Desk
Manager\bopcfg\www\CATALINA_BASE_WF\conf\Catalina\localhost
```

> **Important!** If this step is not performed then the applications will not deploy properly when Tomcat is started.

14. Start Service Desk.

> **Note:** Similar to Support Automation, if Visualizer, Federated Search or REST Tomcats are installed, then appropriate changes can be performed similar to the approaches as suggested from step 1 to step 9.

15. Apply the following Support Automation Digital Patches:

- For CA SDM 12.9:

OS	Patch
Windows	RO81494
Linux	RO81495
AIX	RO81496
Solaris	RO81497

- For CA SDM 14.1:

OS	Patch
Windows	RO81482
Linux	RO81483
AIX	RO81484
Solaris	RO81485

Install and Configure Apache Tomcat 7.0.59

CA SDM 14.1 provides out-of-the-box Apache Tomcat 7.0.23. This topic provides information to upgrade to Apache Tomcat 7.0.59.

Follow these steps:

1. Shut down CA SDM Daemon Service or CA SDM Proctor Service, or both on the relevant CA SDM server (primary or secondary, or both).

2. Download Tomcat 7.0.59 (apache-tomcat-7.0.59.zip) from http://archive.apache.org/dist/tomcat/tomcat-7/v7.0.59/bin/

   Note: CA SDM supports service packs and point releases of Operating Systems, Databases, Web Servers, Web Browsers, Java, Servlets, and so on. This may not be noted in the certification matrix as long as the reported problem is reproducible with versions that are listed in the matrix. CA reserves the right to refuse support of new point releases should the reported problem require a major rework or redesign to function properly. Both Technical Support and Sustaining Engineering does their best to resolve any issues that occur in a timely manner. If the resolution to the problem is determined to be outside the realm of their support responsibilities, they may ask you to escalate your request for certification to your local account team.

3. Unzip apache-tomcat-7.0.59.zip and copy the files at <drive>:\<install_directory>\CA\SC\tomcat\7.0.59

   Note: After unzipping, ensure that <drive>:\<install_directory>\CA\SC\tomcat\7.0.59 contains conf, bin, webapps, and other directories.

   <drive>:\<install_directory>\CA\SC\tomcat\7.0.59 must NOT contain <drive>:\<install_directory>\CA\SC\tomcat\7.0.59\apache-tomcat-7.0.59. Presence of this directory indicates that the unzipping was done incorrectly.

4. Take a backup of the NX.ENV directory, located at the CA SDM install directory (NX_ROOT).

5. Modify NX.ENV as follows:

```
@NX_TOMCAT_INSTALL_DIR=C:\Program Files\CA\SC\tomcat\7.0.59
```

6. Backup NX_ROOT\bopcfg\www\CATALINA_BASE\conf and the following directories (whichever exist):
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_SA\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_REST\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_VIZ\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\conf
   - $NX_ROOT\bopcfg\www\CATALINA_BASE_WF\conf
7. Copy all files from **<drive>:\<install_directory>\CA\SC\tomcat\7.0.59\conf** to **NX_ROOT\bopcfg\www\CATALINA_BASE\conf**
8. Verify that the server.xml file located in directory NX_ROOT\bopcfg\www\CATALINA_BASE\conf has the same startup (connector) and shutdown ports as defined in the original server.xml file. Complete the following steps to verify:
   a. <Server port="8085" shutdown="SHUTDOWN">
   b. <Connector port="8080" protocol="HTTP/1.1" connectionTimeout="20000" redirectPort="8443" />
   c. Ensure no other ports are used as follows. If it is used, you must comment them according to the original server.xml file.

      ```
      <Connector port="8009" protocol="AJP/1.3" redirectPort="8443" />
      ```

Note: If any other changes were made to the original server.xml file, then make the same changes to the new server.xml file.

9. Edit NX_ROOT\bopcfg\www\CATALINA_BASE\conf\catalina.properties using the text editor and modify **shared.loader=** as **shared.loader=${catalina.base}/shared/lib/*.jar.** Save the file.
10. If CA Support Automation is installed, verify that the server.xml file located at NX_ROOT\bopcfg\www\CATALINA_BASE_SA\conf has the same startup (connector) and shutdown ports as defined in the original server.xml file.

Note: If any other changes were made to the original server.xml file, then they would need to be made to the new server.xml file.

11. Modify config.properties located at NX_ROOT\site, as follows:

```
web.tomcat_home=<drive>\:\\<install_directory>\\CA\\SharedComponents\\tomcat\\7.
0.59
web.tomcat.version=7.0.59 web.cawf_tomcat_home==<drive>\:
\\<install_directory>\\CA\\SharedComponents\\tomcat\\7.0.59
```

12. If CA Advanced Workflow is installed, copy the pm.xml and wl.xml files from the backup of the conf directory you created in step 6 to the following location:

    ```
    <drive>:\<install_directory>\CA\Service Desk
    Manager\bopcfg\www\CATALINA_BASE_WF\conf\Catalina\localhost
    ```

    Important! If this step is not performed then the applications will not deploy properly when Tomcat is started.

13. Start Service Desk.

    Note: Similar to Support Automation, if Visualizer, Federated Search or REST Tomcats are installed, then appropriate changes can be performed similar to the approaches as suggested from step 1 to step 9.

14. Apply the following Support Automation Digital Patches:

    - For CA SDM 12.9:

OS	Patch
Windows	RO81494
Linux	RO81495
AIX	RO81496
Solaris	RO81497

    - For CA SDM 14.1:

OS	Patch
Windows	RO81482
Linux	RO81483
AIX	RO81484
Solaris	RO81485

Step 4- Post-Installation Requirements

Complete the following steps after you install CA SDM:

1. Run the *cmdb_update_ambiguity* utility. Use the -h command to view the mandatory options.

> **Note:** If configuration fails during the Validate Extension Tables step, database connectivity can be an issue. Retry the installation and verify that you provided the correct database connectivity information.

2. Restart the services for the integration changes to come to effect.
3. You may need to perform some manual steps to finalize the integration (see page 548).

Step 5- Configure the Servers

As a system administrator, you configure the CA SDM servers under the following circumstances:

- You completed a new installation of CA SDM or upgraded to the latest version of CA SDM and want to implement the advanced availability (see page 508) or conventional (see page 505) configuration.

> You must configure the servers before you start using CA SDM. If you do not configure the servers, you cannot access the application.

- You convert from conventional configuration to advanced availability (see page 516).
- You convert from advanced availability to conventional configuration (see page 514).

Configure Servers for Conventional Configuration

The conventional configuration contains one primary server and one or more secondary servers, all of which you need to configure.

Follow these steps:

1. Configure the Primary Server
2. Add a Server
3. Configure the Secondary Server
4. Verify the Server Details

Configure the Primary Server

Primary server must be configured before you configure any secondary servers.

Follow these steps:

1. Log in to the server that you want to configure as the primary server.

2. Use the pdm_configure command to start the configuration.
   The **Select Server Configuration** screen opens.

3. Select **Conventional** as the configuration type and follow the prompts to complete the configuration. For more information about the configuration, see *Server Configuration Utility (see page 869)*.
   The primary server is now configured.

Add a Server

If you want to install a new server in your CA SDM deployment, you must first add the corresponding server record before you configure it.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server
2. Select System, Servers from the Administration tab.
3. Click Create New to add a server record for the following server, depending on CA SDM configuration:
   - Conventional: Secondary server
   - Advanced availability: Application or standby server
4. Complete the fields as appropriate for the server.
5. Click Save to add the server detail.

Create Server Fields

The following fields appear when you create or update a server:

- **Host Name**
  Specifies the local host name of the server. The local host name is stored in the usp_servers table in local_host column.

  Important! Ensure that host name is entered as case-sensitive in the usp_servers table.

- **Attachment Servlet Path**
  You must specify the fully qualified domain name of a server using this field:
  http://<host>:<port>/CAisd/Upload/Servlet
  Where <host> is the fully qualified domain name of a server.
  We recommend that you configure this field.

- **Time Zone**
  Specifies the time zone where the server is located. This time zone value is used to trigger events in the application. This value is used only if the Use End User Time Zone option is not selected, or if no time zone is specified for the service type.

- **Record Status**
  Indicates the state of the server. Active status indicates that the server is a part of the CA SDM deployment.

  Important! If you have inactivated any server, it is recommended not to start CA SDM services on that server. This action may result in unexpected behaviour.

- **Server Type**
  Specifies the type of server that you want to configure. Following server types can be selected, depending on your CA SDM configuration:

  - Advanced Availability: Application or standby server
  - Conventional: Secondary server

- **Configured**
  Available only for advanced availability configuration. This field indicates the state of the configured server. The default value of this field is No. The value is updated to Yes after you successfully run pdm_configure on that server. If you edit any of the automatically entered field values of a server record, the Configured field turns to No.

Configure the Secondary Servers

You configure each secondary server after configuring the primary server. This configuration is required to establish communication with the primary server.

Follow these steps:

1. (If you are adding a new secondary server) Ensure that you added the server record of the secondary server that you are configuring. For more information, see the Add a Server section.
2. Log in to the server that you want to configure as the secondary server
3. Use the pdm_configure command to start the configuration.
4. The **Select Server Configuration** screen opens.
5. Select **Conventional** as the configuration type and follow the prompts to complete the configuration. For more information, see *Server Configuration Utility (see page 869)*.
   The secondary server is now configured.
6. Repeat steps 1-3 on each of servers that you want to configure as the secondary server.

Verify Server Details

After you have configured all the servers, ensure that each one is properly configured and available.

Follow these steps:

1. Make sure that primary and all secondary servers are running.
2. Log in to the primary server Web UI.
3. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.
4. If **Record Status** is set to inactive, edit the server and set to **Active**. If you change the record status, ensure that you reconfigure that server again.
   You have successfully configured the servers.

Configure Servers for Advanced Availability

The advanced availability configuration offers more resilience to server outages, higher application availability, and supports rolling maintenance with minimal end-user disruption. This configuration requires one background server, one or more standby servers, and one or more application servers, all of which you need to configure.

Follow these steps:

1. Configure the Background Server.
2. Add a Server.
3. Configure the Standby or Application Servers.
4. Verify the Server Details.

Configure the Background Server

Configure the background server before configuring the application or standby servers.

Follow these steps:

1. Log in to the server that you want to configure as the background server.
2. Use the pdm_configure command to start the configuration.
   The **Select Server Configuration** screen opens.
3. Select **Advanced Availability** as the configuration type and follow the prompts to complete the configuration. For more information, see *Server Configuration Utility (see page 869)*.
   The background server is configured.

Add a Server

If you want to install a new server in your CA SDM deployment, you must first add the corresponding server record before you configure it.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server
2. Select System, Servers from the Administration tab.
3. Click Create New to add a server record for the following server, depending on CA SDM configuration:
   - Conventional: Secondary server
   - Advanced availability: Application or standby server
4. Complete the fields as appropriate for the server.
5. Click Save to add the server detail.

Create Server Fields

The following fields appear when you create or update a server:

- **Host Name**
  Specifies the local host name of the server. The local host name is stored in the usp_servers table in local_host column.

  Important! Ensure that host name is entered as case-sensitive in the usp_servers table.

- **Attachment Servlet Path**
  You must specify the fully qualified domain name of a server using this field:
  http://<host>:<port>/CAisd/Upload/Servlet
  Where <host> is the fully qualified domain name of a server.
  We recommend that you configure this field.

- **Time Zone**
  Specifies the time zone where the server is located. This time zone value is used to trigger events in the application. This value is used only if the Use End User Time Zone option is not selected, or if no time zone is specified for the service type.

- **Record Status**
  Indicates the state of the server. Active status indicates that the server is a part of the CA SDM deployment.

  Important! If you have inactivated any server, it is recommended not to start CA SDM services on that server. This action may result in unexpected behaviour.

- **Server Type**
  Specifies the type of server that you want to configure. Following server types can be selected, depending on your CA SDM configuration:
  - Advanced Availability: Application or standby server
  - Conventional: Secondary server
- **Configured**
  Available only for advanced availability configuration. This field indicates the state of the configured server. The default value of this field is No. The value is updated to Yes after you successfully run pdm_configure on that server. If you edit any of the automatically entered field values of a server record, the Configured field turns to No.

Configure the Standby or Application Servers

You configure each standby and application server after configuring the background server. This configuration is required to establish communication with the background server.

Important! (Recommended) Ensure that both background server and all other standby servers have similar configuration. This process ensures that during a failover when a standby server becomes the new background server, it can function exactly like the old background server.

Follow these steps:

1. (If you are adding a new standby or application server) Ensure that you added the server record of the standby or application server that you are configuring. For more information, see the Add a Server section.
2. Log in to the server that you want to configure as the standby or application server.
3. Use the pdm_configure command to start the configuration.
   The **Select Server Configuration** screen opens.
4. Select **Advanced Availability** as the configuration type and follow the prompts to complete the configuration. To enable and use the federated search feature, select the federated search option. For more information, see *Server Configuration Utility (see page 869)*.
5. Repeat steps 1-3 on each of the servers that you want to configure as the standby and application server.
   You have configured the standby and application servers.
6. Suppose that you have one or more application servers. You can configure a load balancer (see page 511) to track the requests to and from the different application servers.

Note: To use a load balancer URL or an application server URL for the links in the CA SDM notifications, complete the following steps:

a. Log in to the background server.

b. Select **Options Manager**, **Notifications** on the **Administration** tab.

c. Change the value of the web_cgi_url option to point to:

- The load balancer if you have more than one application servers.
- The application server, if you have only one application server.

Verify the Server Details

After you have configured all the servers, ensure that each one is properly configured and available.

Follow these steps:

1. Make sure that all background, standby, and application servers are running.
2. Log in to the background server Web UI.
3. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.
4. Verify that the **Configured** field displays Yes for the standby and application server records.
5. If **Record Status** is set to inactive, edit the server and set to Active. If you change the record status of any server, reconfigure it.
   You have successfully configured servers for the advanced availability configuration.

Note: You can click any of the Local Host entries on the Server Details page to view the details of the server.

Configure the Load Balancer

If you have one or more application servers, configure the load balancer to monitor the traffic on these application servers.

Follow these steps:

1. Install Apache Tomcat on an application server.

Note: Ensure that Tomcat is using JRE 1.7 and ensure that the Tomcat is not using the port number that is configured for the CA SDM components.

2. (Optional) Configure SSL on the Tomcat servers that you have installed. For more information about configuring SSL, see How to Configure SSL Authentication (see page 935).

3. Deploy the health servlet. Complete the following steps:

   a. Copy the HealthServlet.war file from the $NX_ROOT/samples/HealthServlet folder to the *TOMCAT_HOME*/webapps folder.

   b. Restart Tomcat.

Note: The HealthServlet.war file is deployed in the webapps folder. To confirm the deployment, verify that the HealthServlet folder is created in the same webapps folder. After the successful deployment, the health servlet is ready to perform the health checks. It includes checking the status of the SLUMP and health of the CA SDM processes that are defined in the health.xml file. Find the health.xml file at TOMCAT_HOME/webapps/HealthServlet/WEB-INF/classes directory.

You can modify this health.xml file, based on your organization needs. Ensure that the XML does not have any errors and that you restart Tomcat to reflect the changes that are made to the XML.

Example: Modify the health.xml File to Monitor the Webengine Process

4. Repeat steps 1-3 on all the other application servers.

5. Configure the load balancer to monitor the following healthservlet URL on each application server:

   ```
   http://<Machine_name>:<Port_number>/HealthServlet/GetHealth
   ```

6. Each application server has its own set of processes.

   - If the SLUMP and all the CA SDM processes are working properly, the load balancer tool receives an HTTP 200 response from the application server with a predefined payload as follows:

     ```
     AA-Server-Status: All OK!

     AA-Server-Role: APP
     ```

   - If a SLUMP or any of the CA SDM processes (listed in health.xml) stop working and cannot resume, the third-party tool receives an HTTP 503 response from the application server with a predefined payload as:

     ```
     AA-Server-Status: NOT OK!

     AA-Server-Role: APP
     ```

- If the healthservlet URL of an application server sends a quescing response, the load balancer must redirect requests from that server to the other application servers. For example, the following response is received when the application server is quesced for 58677 seconds.

  ```
  Quiesce time remaining :58677 seconds
  ```

- If an application server is healthy and no quescing is required, then the following response is received from the healthservlet of the server:

  ```
  Currently no Quiesce time set. Return code : -1
  ```

7. Configure the session persistence on each load balancer. For more information, see your load balancer document. This process ensures that a request coming from one application server is routed back to the same application server.

Example: Modify the health.xml File to Monitor the Webengine Process

Add the process in the health.xml file with the correct tagname, as defined in CA SDM. Complete the following steps to find the tagname:

1. a. Open the pdm_startup.i and pdm_startup files from the $NX_ROOT/pdmconf directory.

   b. Look for the process that you want to monitor in both the files.

   c. Find the corresponding tagname by matching the variables in both the files. For example, webengine process is defined in the pdm_startup.i file as follows:

   ```
   #define WEBENGINE(_TAG,_HOST,_SLUMP_NAME,_DOMSRVR, _CFG, _WEBDIRECTOR,
   _RPC_NAME)
   ```

   The webengine process is defined in the pdm_startup file as follows:

   ```
   WEBENGINE(webengine, $NX_LOCAL_HOST, web:local, domsrvr, $NX_ROOT/bopcfg
   /www/web.cfg, "", "rpc_srvr:%h")
   ```

   From the example, we can find out that the tagname for webengine process is webengine.

   Important! For creating a new process, the existing process is commented out in the pdm_startup file and new entries are added. Ensure that you look for the tagname in the new process entrie

At the end of this topic, you have successfully configured the load balancer.

Convert from Advanced Availability to Conventional Configuration

You can revert to conventional configuration from the advanced availability configuration. Similarly, you can convert a conventional configuration to advanced availability. This article gives the procedures for both types of conversions.

Convert from Advanced Availability to Conventional

Follow these steps:

1. Verify the Prerequisites (see page 514)
2. Stop all services on the application and standby servers.
3. Inactivate all Application and Standby Servers (see page 514).
4. Configure the Primary Server (see page 515).
5. Change the Application and Standby Server Types (see page 515).
6. Configure the Secondary Servers (see page 515).
7. Verify Server Details (see page 516)

Verify the Prerequisites

Complete planning for the conventional configuration. For more information, see Plan the CA SDM Installation (see page 450).

Note: You can configure only the background server as the primary server. You can configure only the standby and application servers as the secondary servers.

Inactivate All Application and Standby Servers

Before you configure the servers for the conventional configuration, ensure that you inactivate all the application and standby servers.

Follow these steps:

1. Log in to the web interface of the background server.
2. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.
3. Click the host name of the application server.
   The **Server Detail** page opens.
4. Click **Edit**.

5. Change the **Record** status to **Inactive**.

> **Important!** If you have inactivated any server, it is recommended not to start CA SDM services on that server. This action may result in unexpected behaviour.

6. Click **Save**.
   The application server is set to inactive.

7. Perform steps 3-6 for all the other application and standby servers.
   All application and standby servers are set to inactive.

Configure the Primary Server

Primary server must be configured before you configure any secondary servers.

Follow these steps:

1. Log in to the background server web interface and inactivate it.

2. Use the pdm_configure command and start the configuration.
   The **Select Server Configuration** screen opens.

3. Select **Conventional** as the configuration type and follow the prompts to complete the configuration. For more information about the configuration, see the *Server Configuration Utility (see page 869)*.
   The primary server is now configured.

Change the Application and Standby Server Types

After you configure the primary server, change the server type for all the application and standby servers to secondary servers and then activate them.

Follow these steps:

1. Make sure that the primary server is running.

2. Log in to the primary server web interface.

3. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.

4. Set the **Record Status** for all application and standby servers as **Active**.

5. Change the server type of all the application and standby servers to secondary servers.
   The server type for all application and standby servers are changed.

Configure the Secondary Servers

You configure each secondary server after configuring the primary server. This configuration is required to establish communication with the primary server.

Follow these steps:

1. Log in in to the application or standby server that you want to configure as the new secondary server.

2. Use the pdm_configure command to start the configuration.
   The **Select Server Configuration** screen opens.

3. Select **Conventional** as the configuration type and follow the prompts to complete the configuration. For more information, see the *Server Configuration Utility (see page 869)*.
   The secondary server is now configured.

4. Repeat steps 1-3 on each of servers that you want to configure as the secondary server.

Verify Server Details

After you have configured all the servers, ensure that each one is properly configured and available.

Follow these steps:

1. Make sure that primary and all secondary servers are running.

2. Log in to the primary server Web UI.

3. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.

4. If **Record Status** is set to inactive, edit the server and set to **Active**. If you change the record status, ensure that you reconfigure that server again.
   You have successfully configured the servers.

Convert from Conventional Configuration to Advanced Availability

Before converting from the conventional to the advanced availability configuration, upgrade to or install CA SDM 12.9 on all the servers.

Follow these steps:

1. Plan for the Advanced Availability Configuration. For more information, see the CA SDM Installation Planning (see page 450).

2. Stop all services on the secondary servers.

3. Inactivate All the Secondary Servers (see page 517).

4. Configure the Background Server (see page 517).

5. Change Secondary Server Type (see page 517).

6. Configure the Standby and Application Servers (see page 518).

7. Verify Server Details (see page 519).

Inactivate All the Secondary Servers

Before you configure the servers for the advanced availability configuration, ensure that you inactivate all the secondary servers.

Follow these steps:

1. Log in to the web interface of the primary server.

2. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.

3. Click the host name of the secondary server.
   The **Server Detail** page opens.

4. Click **Edit**.

5. Change the **Record** status to **Inactive**.

   Important! If you have inactivated any server, it is recommended not to start CA SDM services on that server. This action may result in unexpected behaviour.

6. Click **Save**.
   The secondary server is set to inactive.

7. Perform steps 3-6 for all the other secondary servers.
   All secondary servers are set to inactive.

Configure the Background Server

Configure the background server before configuring the application or standby servers.

Follow these steps:

1. Log in to the primary server.

2. Use the pdm_configure command to start the configuration.
   The **Select Server Configuration** screen opens.

3. Select **Advanced Availability** as the configuration type and follow the prompts to complete the configuration. For more information, see the *Server Configuration Utility (see page 869)*.
   The background server is configured.

Change Secondary Server Type

After you configure the background server, change the server type for all the secondary servers to application and standby servers and activate them.

Follow these steps:

1. Make sure that the background server is running.
2. Log in to the web interface of the background server.
3. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.
4. Set the Record Status for all secondary servers as Active.
5. Change the server type of all the secondary servers to application or standby servers, as required.
   The server type of all the secondary servers is changed.

Configure the Standby and Application Servers

You configure each standby and application server after configuring the background server. This configuration is required to establish communication with the background server.

Important! (Recommended) Ensure that both background server and all other standby servers have similar configuration. This process ensures that during a failover when a standby server becomes the new background server, it can function exactly like the old background server.

Follow these steps:

1. Log in to a secondary server.
2. Use the pdm_configure command to start the configuration.
   The **Select Server Configuration** screen opens.
3. Select **Advanced Availability** as the configuration type and follow the prompts to complete the configuration. For more information, see the *Server Configuration Utility (see page 869)*.
4. Repeat steps 1-3 on each of the servers that you want to configure as the standby and application server.
   You have configured the standby and application servers.
5. If you want to use a load balancer to track the requests to and from the different application servers, configure the load balancer (see page 511).

Note: To use a load balancer URL or an application server URL for the links in the CA SDM notifications, complete the following steps:

a. Log in to the background server.

b. Select **Options Manager**, **Notifications** on the **Administration** tab.

c. Change the value of the web_cgi_url option to point to:

- The load balancer if you have more than one application servers.
- The application server, if you have only one application server.

6. Verify the Server Details (see page 519).

Verify Server Details

After you have configured all the servers, ensure that each one is properly configured and available.

Follow these steps:

1. Make sure that all background, standby, and application servers are running.
2. Log in to the background server Web UI.
3. Select **System**, **Servers** on the **Administration** tab.
   The **Server List** page opens.
4. Verify that the **Configured** field displays Yes for the standby and application server records.
5. If **Record Status** is set to inactive, edit the server and set to Active. If you change the record status of any server, reconfigure it.
   You have successfully configured servers for the advanced availability configuration.

Note: You can click any of the Local Host entries on the Server Details page to view the details of the server.

Step 6- Verify the Installation

After you install CA SDM, use the following information to verify that the installation was successful.

1. (If you have selected to install Unified Self-Service along with CA SDM) After the installation is complete, to verify the Unified Self-Service installation, log in to the following URL as an administrator:

   `http://<CA_Unfied_Self_Service_Server_Name>:<Port_Number>/`

   The default tenant Home Page is displayed.

2. Verify that a system environment variable for the path is set for the product to the installation directory you specified. The default home directory is C:\Program Files\CA\Service Desk Manager. For a 64-bit Windows operating system, the path is C:\Program Files (x86) \CA\Service Desk Manager. For a non-Windows operating system, the path is /opt/CAisd/.

3. Verify the following information:

    a. In the Control Panel (Add or Remove Programs), verify that an entry appears for the product.

    b. From the Start menu, verify that the following options appear:

    - View the documentation.
    - Start the Configuration Wizard.
    - Start the Web Interface.
    - Contact Technical Support.
    - Start the Web Screen Painter.
    - Uninstall CA SDM.

4. From the Windows Start menu, click Start, CA, Service Desk Manager, Service Desk Manager Web Client. If the Web Interface starts properly, then your installation is successful. For more information about the default user accounts created at the time of installation, see the CA SDM Default User List topic. If you cannot verify this information, the product has not been installed correctly. In this case, start the CA SDM installation again to modify the installation.

5. When CA SDM is up and running, it is recommended to check the process memory. For optimal performance, we recommend the following method:

    a. Set a notification when the process memory exceeds 1.25 GB and begin a check on the processes that are running.

    b. Set a warning notification when the process memory exceeds 1.5 GB and take corrective actions to check the memory usage.

6. Review the CA SDM Default User List (see page 520)

7. Check the Status of the Required Ports (see page 521)

Review the CA SDM Default User List

The following table lists default user information for typical CA SDM implementations:

OS	Product	Default Username	OS Level?	How it is Created
Windows	CA SDM	ServiceDesk	Yes	Automatically
	CA EEM	EiamAdmin	No	Default Password: EiamAdmin
		ServiceDesk	No	Created in the MDB during configuration

OS	Product	Default Username	OS Level?	How it is Created
	CA MDB SQL Server			
	CA MDB Oracle	mdbadmin	No	Created in the MDB during configuration
	CA SDM	CASMAdmin	No	Manually created
UNIX	CA SDM	srvcdesk	Yes	Manually created
	CA MDB Oracle	mdbadmin	No	Created in the MDB during configuration
	CA SDM	CASMAdmin	No	Manually created
Linux	CA SDM	srvcdesk	Yes	Manually created
	CA MDB Oracle	mdbadmin	No	Created in the MDB during configuration
	CA SDM	CASMAdmin	No	Manually created

Check the Status of the Required Ports

The CA SDM installation requires various ports and port ranges to be opened on your firewall. Ensure that following ports are open before you start implementing CA SDM:

The ports opened on the firewall depends on the *NX.env* file settings. By default, CA SDM chooses the port that is readily available. The system reserves ports less than 1024, but can request a port number as high as 65335.

Note: The NX.env file is located in the default CA SDM installation folder.

The following *NX.env* variables set the starting port (2100) and the incremental increase (plus 1) to find an open port:

- NX_SLUMP_FIXED_SOCKETS=1
- NX_SLUMP_SECONDARY_SOCKET=2100

The following list displays default and recommended ports (and port ranges) for a typical CA SDM installation:

- **Database**
  - Oracle: 1521
  - SQL Server: 1433
- **CA SDM**
  - FTP: 21
  - SMTP: 25

- HTTP: 80
- HTTPS: 8080
- HTTPS (secondary): 8081
- POP3: 110
- IMAP: 143
- LDAP: 389
- WebEx: 1270
- mstsc: 1389
- oaserver: 1706
- Slump Socket: 2100
- qserver: 2234
- Proctor Socket: 2300
- Communications: 2365
- Apache Tomcat: 8080
- Apache Tomcat Shutdown:
- SSL on Apache Tomcat: 8443

- **EBR Search**
  - Base Port: 13000
- **Portal Server**
  - Apache Tomcat: 8080
  - Apache Tomcat Shutdown: 8085
  - SSL Functionality: 8443
  - Portal_Safe_List: 8444
- **Support Automation**
  - Main Server (Socket Server) Internal: 7005
  - Main Server (Socket Server) External: 10443
  - Socket Proxy Server (Socket Configuration Main Server) Internal: 7005

- Socket Proxy Server (Socket Configuration Main Server) External: 10444
- Message Routing Server (Socket Configuration) External: 10444
- Apache Tomcat: 8070
- Apache Tomcat Shutdown: 8075

- **Visualizer**
  - Apache Tomcat: 9080
  - Apache Tomcat Shutdown: 9085

At the end of this step, you must have opened the required ports.

Troubleshooting the Installation

Accessing the Installation Log File

When you install CA SDM, an installation log file is created, which includes the actions, events, and system changes that occurred during the installation. If the product does not install correctly, you can view the errors in the log file and can fix the problems.
You can find the Service Desk Manager_r14_1_Install.log file in the \log folder of the installation directory. For Remote Components installations, the log is located in the %TEMP% directory. Open the file with a text editor such as Notepad or the vi editor.

Note: If you cancel the installation before it is finished, the installation log is created on your desktop for Windows. For UNIX and Linux, the log file is created in the root directory.

Troubleshooting Tips

Use the following tips to troubleshoot the installation of CA SDM:

- If you receive an Install Shield error during CA SDM installation, wait until msiexec.exe stops running. Then try installing the product.
- Suppose that you have upgraded from Argis 8.0 to CA Asset Portfolio Management r11.2 and you are sharing the CA MDB (database) with CA SDM. You may encounter problems when you add or update assets in asset families using CA SDM. To avoid errors, you must define the asset extension tables to CA SDM using one of the following methods:
- - Use WSP to define the tables and the forms to view and edit the table entries.
- - Manually edit the tables and forms using the following guidelines:
- - The file $NX_ROOT\bopcfg\majic\assetx.maj contains a template that can be used to create a majic file to identify the columns in the asset extension table to CA SDM. Copy this file and edit as appropriate, following the instructions that are available in the file.

- Create a .sch file in $NX_ROOT\site\mods directory to define the database columns. The files $NX_ROOT\site\assetx_schema.sch and $NX_ROOT\site\assetx_index.sch can be used as templates which can be copied and edited as appropriate for your asset extension tables.

  Note: References to NX_ROOT pertain to the environmental variable containing the installation path of CA SDM. This NX_ROOT variable is set in the NX.env configuration file that is used to set environmental variables for CA SDM.

  Example: NX_ROOT Definition

  @NX_ROOT=C:\Program Files\CA\Service Desk Manager

- (Internet Explorer 8 on Windows 2008) If the internet security level is set to high, the CA SDM URL and about:blank must be added as Trusted Sites.

- (Google Toolbar) The CA SDM web interface may have a problem displaying the title bar text at the top of the window.

- (Internet Explorer 8.0) You may experience periodic increased memory use when accessing the CA SDM web interface. This is a known issue with the current release of Internet Explorer. To release the memory, periodically minimize your main CA SDM web page.

- You may receive an Unprivileged Script error when you use cut, copy, and paste functionality on the HTML editor page in Knowledge Categories. Click OK to view a technical note at mozilla.org (http://mozilla.org), which shows you how to allow a script to access the clipboard.

- When viewing the content of a file attachment in which the file name contains Latin-1 extended characters, a save as popup appears. You can either save to disk or click open and select an application to open the attachment.

Secure CA SDM from Cross-Site Scripting Vulnerabilities

The CA SDM installation is susceptible to reflected cross-site scripting vulnerabilities, which might result in the infected URL being reflected back to the user. To secure CA SDM from such vulnerabilities, validation parameters exist in the web.cfg file. These parameters perform a white list validation in the webengine. Also, install the NX option on the primary and secondary servers to secure CA SDM.

Points to consider before you proceed with securing CA SDM:

- The SDM URL parameters that are defined in the web.cfg file are validated for securing CA SDM.

- You can add SDM URL parameters in the web.cfg file with required validation pattern. You can also add validation patterns, if necessary.

Secure CA SDM from Cross-Site Scripting Vulnerabilities in Conventional and Advanced Availability Mode

Follow these steps:

1. Stop the CA SDM services.

2. On the primary server, execute the following command to install the NX option.

   ```
   pdm_options_mgr -c -a pdm_option.inst -s VALIDATE_REQUEST_PARAMETER -v 1
   ```

   Note: For each secondary server, manually add or update the NX option in the *NX.env* file that is located in *$NX_ROOT* directory.

3. (Optional) To avoid losing the changes when you run the *pdm_configure* command with the *-t* flag.

   ```
   pdm_options_mgr -c -a pdm_option.inst -s VALIDATE_REQUEST_PARAMETER -v 1 -t
   ```

4. Restart the CA SDM services.

5. (Optional) In Advanced Availability mode, perform rolling maintenance to apply the NX option on all servers.

Install and Configure JRE 1.8.0_45

Complete the following steps to install and configure JRE 1.8.0_45 (32-bit) to use with CA SDM release 14.1:

1. Shut down the CA SDM Daemon or CA SDM Proctor Service, or both on the relevant CA SDM server (primary or secondary, or both).

2. Download JRE 1.8.0_45 (jre-8u45-windows-i586 via the Download JRE link) from http://www.oracle.com/technetwork/java/javase/downloads/jre8-downloads-2133155.html

3. During the installation, select the Change destination folder option and enter the destination folder as <drive>:\<install_directory>\CA\SC\JRE\1.8.45

4. Take a backup of NX.env, located at <drive>:\<install_directory>\CA\Service Desk\

5. Modify NX.env as follows:

   ```
   @NX_JRE_INSTALL_DIR=C:/Program Files (x86)/Java/jre1.8.0_45
   ```

6. Start Service Desk.

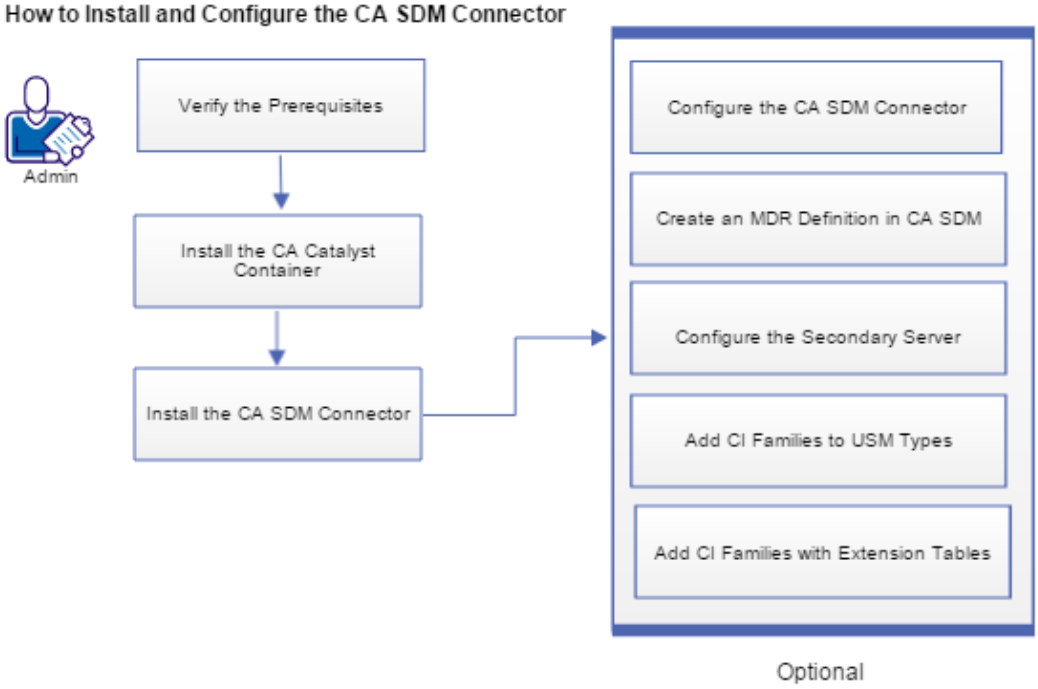
7. Install and configure Apache Tomcat 7.0.59 (see page 502) for Support Automation to work properly.

How to Install CA SDM Connector

CA SDM notifies the CA SDM connector when changes occur to incidents, problems, change orders, CIs, and relationships. The CA SDM connector queries CA SDM for information about the object (router, for example) and transmits the information through the connector framework and publishes to CA Catalyst.

The CMDB module of CA SDM provides a repository of CIs and their relationships. Organizations can use the repository to view the CIs (printers, computer systems, network services, for example). CI relationships can be viewed on the CI detail form or through the MDR Launcher in CA CMDB Visualizer. For more information about the MDR Launcher in CA CMDB Visualizer, see MDR Management (see page 2679).

The following diagram shows how to install and configure the CA SDM Connector:



Follow these steps:

1. Verify the Prerequisites to Install (see page 527)
2. If you plan to install the CA SDM Connector and the CA Catalyst Server on different computers, install the CA Catalyst Container on the same computer where you plan to install the CA SDM Connector (For more information about installing the CA Catalyst Container, see the *CA Catalyst documentation*).
3. Install the CA SDM Connector (see page 533)
4. Restart the CA Catalyst Container service on the CA Catalyst server.
5. (Optional) Configure the CA SDM Connector (see page 525)
6. (Optional) Create an MDR Definition in CA SDM (see page 3409)
7. (Optional) Configure the Secondary Server (see page 534)
8. (Optional) Add CI Families to USM Types (see page 538)

9. (Optional) Add CI Families with Extension Tables (see page 541)

Verify the Prerequisites to Install

This topic contains the following information:

Operating System Support

The CA SDM Connector supports installation on the following operating systems:

- Windows Server 2008 SP1 and SP2 (x64-bit and x86-bit)
- Windows Server 2008 R2 (x64-bit)
- Windows Server 2012 R2 (64-bit only)
- Windows Server 2012 (64-bit only)

Supported Versions of the Associated Products

The CA SDM Connector installation requires the following product versions:

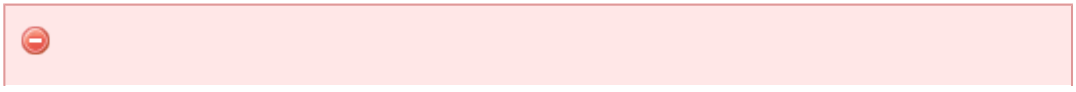
- CA Catalyst Server r3.2
- CA Catalyst Container r3.2 and r3.4.1
- CA Configuration Automation r12.8 SP1 and r12.8 SP2
- CA EEM r8.4, r12.5, r12.5.1
- CA SDM r12.9 CUM1, r14.1.01
- CA SOI r3.1, r3.2, r3.2 CUM3, r3.3, r3.3 CUM1

The supported versions of these products can be downloaded from http://support.ca.com (http://support.ca.com/).

CA SDM Connector Installation Considerations

Before you install the CA SDM Connector, verify that you have the following prerequisites:

- Install and configure the supported version of CA Catalyst. For more information about the installation procedure, see the CA Catalyst documentation.



Important! If you are using CA Catalyst Container r3.4.1, you do not need to install the CA Catalyst server.

- If you plan to install the CA SDM Connector and CA Catalyst Server on different computers, install the CA Catalyst Container on the computer where CA SDM Connector will be installed. For more information about installing procedure of the CA Catalyst Container, see the CA Catalyst documentation.

Note: Container installation cannot be performed on Windows 2012 OS. To support Windows 2012 OS, right click on <*Container Installation Location* >\Disk1\InstData\Windows\VM\install.exe and select Properties, Compatibility. Change the compatibility mode to Windows XP and then start the installation by double clicking the .exe file.

- For CA SDM connector to function for CA SDM installed in supported locales, you must first apply RO72246 (Language Independent) and RO72249 (Language Combo) patches on CA SDM 12.9. Then apply the following patches:

Language	Patch
German	T52Y442
Simplified Chinese	T52Y443
Japanese	T52Y444
English	T52Y445
French	T52Y446
French Canadian	T52Y447
Spanish	T52Y448
Italian	T52Y449
Brazilian Portuguese	T52Y450

- You must upgrade to CA SDM 14.1.01 (see page 633) and first apply RO80318 (Windows Master) patch. Then apply the following patches:

Language	Patch
German	T52Y463
Japanese	T52Y464
French	T52Y465
French Canadian	T52Y466
Spanish	T52Y467
Italian	T52Y468
Brazilian Portuguese	T52Y469

- You install the CA SDM Connector on the same server that runs CA SDM to get access to the interfaces used for the connector-management data repository (MDR) communication.

  Note: (Conventional configuration) You can configure the CA SDM connector to communicate with CA SDM on a primary or secondary server. We recommend a dedicated secondary server to serve requests of the connector and notify the connector with the updates on the objects that are processed. For more information about the secondary server configuration, see Configure the Secondary Server (see page 534).

  Important! (Advanced availability configuration) It is recommended to install the CA SDM connector on any ONE of the application servers and not on the background or standby server. So. i f the CA SDM server (application server on which this connector is installed) goes down, then the CA SDM connector service will also go down.

- You have the login credentials of a CA SDM user with either administrator privileges or belonging to an Access Type that has rights to CA SDM Web Services and APIs. In addition to the Administrator role, the Level 2 Analyst role has the appropriate rights.

- (For CA Catalyst Container r3,2) Verify that the CA Catalyst Registry Server is up and running before you start the CA SDM Connector installation.You cannot install the connector on an existing CA SDM Connector installation. Uninstall the existing CA SDM Connector and then install the supported version of the CA SDM Connector.

  Important! If you uninstall the CA SDM Connector, the existing settings (for example, configuration and policy file changes) are not restored. To restore the settings, ensure that you keep a backup of the modified files from the existing installation and migrate it to the newly installed CA SDM Connector data. For more information, see (Optional) Migrate Data from CA SDM Connector r2.5 (see page 529) or (Optional) Migrate Data from CA SDM Connector r3.1 or r3.2 (see page 530)

- (For CA Catalyst Container r3.4.1) Ensure that CA SOI r3.3 is up and running before the CA SDM Connector installation.

(Optional) Migrate Data from CA SDM Connector r2.5

If you have customized the configuration and policy files of the CA SDM Connector r2.5 and want to restore the changes for the new installation, manually migrate the existing data. The migration is a mandatory step to restore existing data since CA SDM Connector does not support upgrade upon reinstallation.

Note: The directory structure of CA SDM Connector r2.5 is different from CA SDM Connector r3.1 or r3.2. CA SDM Connector r2.5 does not store the policy and configuration files in the CA Catalyst registry.

Follow these steps:

1. Download and backup the following files:
   - ServiceDeskManager_<ComputerName>.xml from the SOI_HOME/resources /configurations directory. SOI_HOME is the path where the CA SDM Connector is installed.
   - ServiceDeskManager_policy.en, ServiceDeskManager_policy.xml, ServiceDeskManager_policySB.en, and ServiceDeskManager_policySB.xml files from the SOI_HOME/resources/core/CatalogPolicy directory.
   - USM-CMDB.xml and ServiceDeskObject.xml files from the SOI_HOME/resources directory.
2. Uninstall the existing CA SDM Connector (see page 542).
3. Install the supported version of the CA SDM Connector (see page 533).
4. Log in to the CA Catalyst Registry UI and navigate to the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\modules\configuration\
   ```

5. Compare each property from the ServiceDeskManagerConnector.xml file with the backup ServiceDeskManager_<ComputerName>.xml file.Ensure that you correctly add the customized contents from the backup file to the ServiceDeskManagerConnector.xml file.
6. Navigate to the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\modules\policy\
   ```

7. Compare the ServiceDeskManager_policy.en, ServiceDeskManager_policy.xml, ServiceDeskManager_policySB.en, and ServiceDeskManager_policySB.xml files with their respective backup files. Ensure that you correctly add the customized contents from the backup files to the new policy files.
8. Navigate to the CATALYST_CONTAINER_HOME/resources directory and compare the USM-CMDB.xml and ServiceDeskObject.xml files with their respective backup files. CATALYST_CONTAINER_HOME is the path where the CA SDM Connector is installed. Ensure that you correctly add the customized contents from the backup file to the new USM-CMDB. xml and ServiceDeskObject.xml files.
9. Restart CA SDM Connector Container service.

(Optional) Migrate Data from CA SDM Connector r3.1 or r3.2

If you have customized the configuration and policy files of the existing CA SDM Connector (for example, CA SDM Connector r3.1) and want to restore the changes for the new installation, manually migrate the existing data. The migration is a mandatory step to restore existing data since CA SDM Connector does not support upgrade upon reinstallation.

Follow these steps:

1. Log in using one of the following steps:

- (Applicable for CA Catalyst Container r3.2) Log in to the CA Catalyst Registry UI using the following URL:

  ```
  https://<registryserver:port>/registry/carbon/admin/login.jsp
  ```

- (Applicable for CA Catalyst Container r3.4.1) Log in to the CA SDM connector machine.

2. Download and backup the ServiceDeskManagerConnector.conf and ServiceDeskManagerConnector.xml files from the following directory:

   - (Applicable for CA Catalyst Container r3.2) \topology\physical\<CA_Catalyst_Server>\modules\configuration\

   - (Applicable for CA Catalyst Container r3.4.1) CA\Catalyst\CatalystConnector\registry\topology\physical\<CA_Connector_Machine>\mod

3. Download and backup the ServiceDeskManager_policy.en, ServiceDeskManager_policy.xml, ServiceDeskManager_policySB.en, and ServiceDeskManager_policySB.xml files from the following directory:

   - (Applicable for CA Catalyst Container r3.2) \topology\physical\<CA_Catalyst_Server>\modules\policy\

   - (Applicable for CA Catalyst Container r3.4.1) CA\Catalyst\CatalystConnector\registry\topology\physical\<CA_Connector_Machine>\mod

4. Download and backup the USM-CMDB.xml and ServiceDeskObject.xml files from the CATALYST_CONTAINER_HOME/resources directory. CATALYST_CONTAINER_HOME is the path where the CA SDM Connector is installed.

5. Uninstall the existing CA SDM Connector (see page 542).

6. Install the supported version of the CA SDM Connector (see page 533).

7. Log in to the CA Catalyst Registry UI and navigate to the following directory:

   a. (Applicable for CA Catalyst Container r3.2) \topology\physical\<CA_Catalyst_Server>\modules\configuration\

   b. (Applicable for CA Catalyst Container r3.4.1) CA\Catalyst\CatalystConnector\registry\topology\physical\<CA_Connector_Machine>\r

8. Compare each property from the ServiceDeskManagerConnector.conf and ServiceDeskManagerConnector.xml files with the respective backup files. Ensure that you correctly add the customized contents from the backup files to the new ServiceDeskManagerConnector.conf and ServiceDeskManagerConnector.xml files.

9. Navigate to the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\modules\policy\
   ```

10. Compare the ServiceDeskManager_policy.en, ServiceDeskManager_policy.xml, ServiceDeskManager_policySB.en, and ServiceDeskManager_policySB.xml files with their respective backup files. Ensure that you correctly add the customized contents from the backup files to the new policy files.

11. Navigate to the following directory:

    - (Applicable for CA Catalyst Container r3.2) CATALYST_CONTAINER_HOME/resources
    - (Applicable for CA Catalyst Container r3.4.1) CA\Catalyst\CatalystConnector\registry\topology\physical\<CA_Connector_Machine>\mod

12. Compare the USM-CMDB.xml and ServiceDeskObject.xml files with their respective backup files. Ensure that you correctly add the customized contents from the backup files to the new USM-CMDB.xml and ServiceDeskObject.xml files.

13. Restart CA SDM Connector Container service.

(Optional) Map the Unknown Classes in CMDB

The following families have been identified to have “Unknown” class. Since CA SDM has unique class names, these are not included in the policy files.

- Hardware.DiskPartition
- Hardware.VMDataStore
- Hardware.Processor
- Hardware.File
- Hardware.Memory

If you require these classes to be mapped and created in the CA SDM CMDB, you must create a new class in CA SDM and provide the mapping in the policy files.

Example: Create a class for Hardware.File

Follow these steps:

1. Create a new class in CA SDM. For example, UnknownFile.

2. Edit and provide the following mapping in ServiceDeskManager_policySB.xml (SouthBound) file:

```
<Normalize>
<Field output="class" type="map" input="FileType" >
<mapentry mapin="Unknown" mapout="UnknownFile" />
</Field>
</Normalize>
```

3. Edit and provide the following mapping in ServiceDeskManager_policy.xml (NorthBound) file:

```
<Normalize>
<Field output="FileType" type="map" input="class">
```

```
<mapentry mapin="UnknownFile" mapout="Unknown" />
</Field>
</Normalize>
```

Note: Similarly there are two classes, “Linux” and “AIX” under Hardware.Diskpartition which are not mapped as these have the same name as in Hardware.Server family. If you require these, you must add in policy files similar to that of “Unknown” classes.

Install CA SDM Connector

Ensure that you follow the CA SDM Connector Installation Considerations (see page 527) correctly before installing the CA SDM Connector.

Note: Based on the language in which CA SDM is installed, the appropriate connector policy files are now installed by the modified CA SDM connector installer. However, the connector installation screens will still remain in English.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:

   Important! Verify that the user has complete administrative privileges, such as the ServiceDesk user.

   - (Advanced availability) Application server
   - (Conventional) Primary or Secondary server

2. Go to http://support.ca.com (http://support.ca.com/) and complete the following steps:

   a. Download and unzip the Connector_CAServiceDeskManager zip file.

   b. Execute the Connector_CAServiceDeskManager.exe file.
   The Introduction screen appears.

3. Click Next, accept the terms of the License Agreement, and click Next.
   The Choose Container Node screen appears.

4. Select a custom container node and click Next.
   The CA SDM Configuration screen appears.

5. Enter the following CA SDM information and click Next.

   - **CA Service Desk Manager User**
     Specifies the CA SDM user.

- **CA Service Desk Manager Password**
  Specifies the corresponding password of the CA SDM user.

- **Enable TWA Flag**
  Specifies to enable or disable the Transaction Work Area (TWA) flag. TWA (see page 2531)is an intermediate storage system for the data.

The Service Startup screen appears.

6. Keep the check box selected to start the CA SDM Connector services automatically after the installation. To perform the post installation steps, clear the check box. Click Next.
   The Installation Summary screen appears.

7. Review your selections and click Install.
   The CA SDM Connector installs on the system and integrates with the appropriate product database and CA Catalyst instance.
   The Install Complete screen appears.

8. Click Done.

Note: If the installation summary page displays installation errors, view the CATALYST_*HOME\CA_ Service_Desk_Manager_Connector_Install_<Date (MM-DD-YYYY)> <Time(HH:MM:SS)>.log* file to troubleshoot the installation. CATALYST_HOME specifies the folder where you installed the CA SDM Connector. This file is created after you complete the installation.

The CA SDM Connector is installed.

Note: For more information about USM data mapping, see USM Data Mapping for CA Service Desk Manager Connector (see page 4730).

(Optional) Configure the Secondary Server

If you installed the CA SDM Connector on a secondary CA SDM server, complete the following post-installation steps:

1. Complete the following steps to locate the Domsrv name of the secondary server:

   a. Open a command prompt on the CA SDM server (primary or secondary) and navigate to the *SDM_HOME/bin* directory.

   b. Execute pdm_status (see page 3889) from the command line. This command shows the status of all the processes on the system.

   c. Locate the Domsrvr name that corresponds with the secondary server host name.

2. Launch the CA Catalyst Registry UI by entering the following URL:

   ```
   https://<registryserver:port>/registry/carbon/admin/login.jsp
   ```

3. Open the ServiceDeskManager_Connector.xml file from the following directory in the CA Catalyst Registry UI:

   ```
   /topology/physical/<NODE-NAME>/module/configuration/
   ```

   Note: <NODE-NAME> displays the host name where you installed CA SDM Connector.

4. Click Edit as Text.

5. Locate Domsrvr_name in the file and specify the name identified by pdm_status in step 1.

6. Click Save Content.
   The secondary server is configured.

7. (Optional) Follow these steps to change the Domsvr name after the CA SDM Connector is online:

   a. Click Administration, Connector Configuration.

   b. In the Domsrv field on the connector details page, specify the Domsvr name of the secondary server.
      The configuration settings are updated.

   c. Click Stop, Start.

   The CA SDM Connector is restarted.

(Optional) Configure the CA SDM Connector

After the CA SDM Connector installation, you can modify the CA SDM Connector properties that you defined during the installation. You can customize the integration by introducing new CMDB families to participate in the integration, deploying the CA SDM Connector on the secondary server, excluding certain CI types, and so on.

Follow these steps:

1. Log in to the CA Catalyst Registry UI using the following URL:

   ```
   https://<registryserver:port>/registry/carbon/admin/login.jsp
   ```

   - **registryserver**
     Specifies the name of the server where you installed the CA Catalyst Registry.

- **port**
  Specifies the CA Catalyst Registry port.

The Registry Browse page appears.

2. Click ServiceDeskManagerConnector.xml from the following directory:

```
/topology/physical/<NODE-NAME>/modules/configuration
```

> **Note:** <NODE-NAME> indicates the hostname where you installed the CA SDM Connector.

3. Click Edit as Text.

4. Change any of the following properties from the Connection Details table and click Save:

   - **deviceXXXFamilies**
     Specifies the list of CMDB families with mapped USM CI types that require device properties defined by USM import standards in CA Catalyst. When device properties are not defined for the CI, the CA SDM Connector uses this property to obtain the information from the system on which the CI is hosted.
     For example, the application configuration manager discovers the software that uses the COTS class and Software.COTS family and populates the system with the host name (or DNS name) of the computer on which the application is running. If the system name is not found, the CA SDM Connector uses this property to retrieve the information.
     Default: Software.Application, Software.Operating System, Software.COTS, Software. Database, Software.Application Server, Hardware, Network.Port, Software, Network. Network, Interface Card, Hardware.Storage

   - **deviceXXXRelationships**
     Specifies the list of CMDB CI relationship types. CA SDM Connector queries the CI to obtain its device properties based on the relationship type.
     Default: runs, runs on, hosts, is hosted by, contains, is contained by.

   - **domsrv_name**
     Specifies the Domserver name to which the CA SDM Connector sends queries and registers for change notifications.
     Default: Primary server name.
     Format: Domsrv name specified for the Object Manager during the CA Service Desk Manager configuration.

   - **database query parameter size**
     Specifies the CA SDM database parameter list size (integer only) in the where clause query. For more information about the database parameter list size, see your database documentation.

   - **childtoparent**
     Specifies the relationship of the service CI and associated CIs. In CMDB, you can configure a service CI for either consumption or composition. If configured for consumption, the

service CI is the provider to consumers and the associated CIs are dependents in the service graph. If the service CI is configured for composition, the service is the ultimate dependent and the provider CIs impact the service.
Specify True if the service CI is configured for composition (child-to-parent).
Specify False if the service CI is configured for consumption (parent-to-child).

Note: For more information about configuring CI services, see the Configuration Items (see page 2470)

- **exclude_usm_ci_types**
  Specifies the USM entity name that the CA SDM Connector excludes from processing. You can exclude any CMDB supported CI type.
  Default: Incident, Problem, Request, Change Order, Alert

- **exclude_cmdb_relationship_types**
  Specifies the CMDB relationship types that the CA SDM connector excludes from processing. (For each relationship type, provide both Provider-to-Dependent and Dependent-to-Provider attributes separated by comma (,)).

- **class**
  Specifies the CMDB class which refers to the service CI type (separated by comma (,)).
  Default: Business Service, Infrastructure Service, Other Service

- **family**
  Specifies the CMDB family which refers to the service CI type (separated by comma(,)).
  Default: Enterprise Service

- **open_incident_threshold**
  Specifies the threshold value for the total number of open Incidents per service (including the graph CIs) and a "Too Many Open Incident" alert is sent to CA SOI.
  Default: 1

- **Password**
  Specifies the password that is associated with the CA SDM user.

- **User name**
  Specifies the user name for connecting to CA SDM.
  Default: The value entered during installation

- **window_offset**
  Specifies the offset value which is used to calculate the predicted maintenance windows and an alert is sent to CA SOI. The CA SDM Connector will not alert CA SOI about the predicted maintenance windows until the next day from the present time.
  Default: 1440 (one day in minutes).

- **enable_twa**
  Specifies whether the incoming CIs and CI relationships should be saved to TWA or to CMDB.
  Default: false (The data is loaded in the CMDB module of CA SDM)

- **excluded_activity_types**
  Specifies the activities in CA SDM that the CA SDM Connector excludes from publishing to the Catalyst. Provide the activity codes separated by comma (,).
  Default: INIT

- **time_reporting_min_allowed_value**
  Specifies the minimum value (in seconds) to be entered for the time spent on any activity in CA SDM.
  Default: 180

- **enable_SDI**
  Specifies whether CA SDI functionalities can be accessed while using the CA SDM connector. Enter **true** to enable the use of CA SDI.

- **scope_enabled_relationship_types_startup**
  Specifies to publish the relationship scopes of the selected property at the startup or restart of CA SDM. Provide the property values separated by comma (,).

  Important! Ensure that you provide only the CA SDM ProviderToDependent relationship type as the property value, irrespective of the childtoparent value. For example, financially belongs to.

5. Import the CA SDM server certificate to the client-truststore.jks keystore file located under $CATALYST_HOME\registry on the CA SDM server. The password for the keystore is located in the $CATALYST_HOME\registry\repository\conf\axis2.xml file.

6. Set the NX.env file on the CA SDM server to the following value:

   ```
   @NX_SERVLET_SERVER_URL=https://sdm_server_host:8443
   ```

7. Restart the CA SDM Connector Container.
   The changes are applied and the configuration is updated.

(Optional) Add CI Families to USM Types

This topic contains the following information:

Important! Adjustment of the Service Desk Policy is a customization, and not specifically supported by CA Support.

To add a CMDB family to a USM type, enter the family name in the configuration file and policy file.

Follow these steps:

1. Locate the USM-CMDB.xml configuration file in the following directory:

   ```
   CATALYST_HOME/container/resources
   ```

2. Add the CI families to the file and save your changes.

3. Launch the CA Catalyst Registry UI by entering the following URL:

   ```
   https://<registryserver:port>/registry/carbon/admin/login.jsp
   ```

4. Locate the ServiceDeskManager_policy.xml file in the following directory:

   ```
   /topology/physical/<NODE-NAME>/modules/policy
   ```

   Note: <NODE-NAME> displays the host name where you installed the CA SDM Connector.

5. Add the CI families to the file and save your changes.

6. Restart the CA Catalyst Container service running on the CA SDM Connector host.

Example Add the Hardware.TestSystem CMDB Family to the ComputerSystem USM Type

The following example shows how to add the Hardware.TestSystem CMDB family to the ComputerSystem USM type.

Follow these steps:

1. Open the USM-CMDB.xml configuration file and complete the following steps to add the CMDB to the file:

   a. Click Edit as Text.
   The list of USM names and CMDB families appear.

   b. Locate "ComputerSystem" and add the Hardware.TestSystem family delimited by a comma as shown in the following example:

   ```
   <usm name="ComputerSystem" cmdbFamilies="Hardware.Server,Computer,
   Hardware.TestSystem" cmdbClasses="*" />
   ```

   c. Click Save Content.

2. Launch the CA Catalyst Registry UI by entering the following URL:

   ```
   https://<registryserver:port>/registry/carbon/admin/login.jsp
   ```

3. Open the ServiceDeskManager_policy.xml file and complete the following steps to add the CMDB family to the file:

a. Click Edit as Text.

b. Locate outval="ComputerSystem" and add the Hardware.TestSystem family as shown in the following example:

```
<Field input="familyName" pattern="^Hardware.Server$|^Hardware.
Mainframe$|^Hardware.Workstation$|^Hardware.Virtual Machine$|Hardware.
TestSystem" output="eventtype" outval="ComputerSystem" />
```

c. Navigate to EventClass name="ComputerSystem" as shown in the following example:

```
<EventClass name="ComputerSystem" extends="GenericIPDevice">
```

d. Locate outval="GenericIPDevice" and add the Hardware.TestSystem family as shown in the following example:

```
Field input="familyName" pattern=" ^Hardware.Server$|^Hardware.
Mainframe$|^Hardware.Workstation$|^Hardware.Printer$|^Hardware.Virtual
Machine$|^Network.Router$|^Network.Switch$|^Network.Hub$|Hardware.
TestSystem" output="eventtype" outval="GenericIPDevice"
```

e. Locate local.ENTITY_NR.Classify.pattern and add the Hardware.TestSystem family as shown in the following example:

```
local.ENTITY_NR.Classify.pattern.^Hardware.Server$|^Hardware.
Mainframe$|^Hardware.Workstation$|^Hardware.Printer$|^Hardware.Virtual
Machine$|^Network.Router$|^Network.Switch$|^Network.Hub$|Hardware.
TestSystem=^Hardware.Server$|^Hardware.Mainframe$|^Hardware.
Workstation$|^Hardware.Printer$|^Hardware.Virtual Machine$|^Network.
Router$|^Network.Switch$|^Network.Hub$|Hardware.TestSystem
```

f. Click Save Content.

4. Restart the CA Catalyst Container service running on the CA SDM Connector host.
The Hardware.TestSystem CI family is added to the CA SDM Connector configuration.

Example Add the Hardware.CustomSystem Custom CMDB Family to the USM-A Custom USM Type

The following example shows how to add the Hardware.CustomSystem custom CMDB family to the USM-A custom USM type.

Follow these steps:

1. Open the USM-CMDB.xml configuration file and complete the following steps to add the custom CMDB family:

   a. Click Edit as Text.
   The list of USM names and CMDB families appear.

   b. Insert a new line and add the custom USM name and CMDB family name as shown in the following example:

```
<usm name="USM-A" cmdbFamilies="Hardware.CustomSystem" cmdbClasses="*" />
```

c. Click Save Content.

2. Launch the CA Catalyst Registry UI by entering the following URL:

   ```
   https://<registryserver:port>/registry/carbon/admin/login.jsp
   ```

3. Open the ServiceDeskManager_policy.xml file.

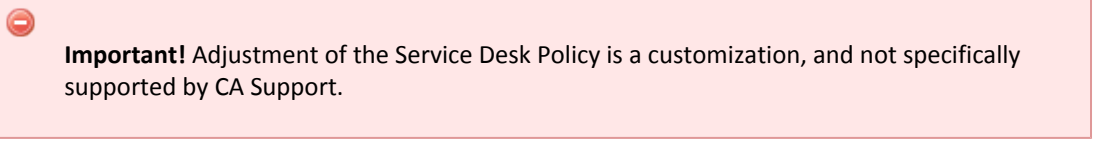
4. Click Edit as Text and add the CMDB family name, as appropriate.

5. Click Save Content.

6. Restart the CA Catalyst Container service running on the CA SDM Connector host.
   The Hardware.CustomSystem CI family is added to the CA SDM Connector configuration.

(Optional) Add CI Families with Extension Tables

Each CI family has a set of family-specific attributes that reside in an extension table in the MDB. The family-specific attributes describe the unique characteristics of each type of CI. When you configure the CA SDM Connector, you can add CI families with extension tables through a configuration file.



Important! Adjustment of the Service Desk Policy is a customization, and not specifically supported by CA Support.

Follow these steps:

1. Locate the ServiceDeskObject.xml configuration file in the following directory:

   ```
   CATALYST_HOME/container/resources
   ```

2. Add the extension table attributes to the CMDB family in the file.

3. Save the file.

4. Restart the CA Catalyst Container service running on the CA SDM Connector host.

Example Add the HAR_TESX Extension Table to the Hardware.TestSystem CI Family

The following example shows how to add the HAR_TESX Extension Table to the Hardware.TestSystem CI Family.

Follow these steps:

1. Open the ServiceDeskObject.xml configuration file for editing.
   The configuration file opens.

2. Add the extension table attributes to the CMDB family. For example, if the extension_table for the Hardware.TestSystem family is HAR_TESX, then the entry appears as shown in the following example:

```
<factory name=" HAR_TESX_extension   ">
      <attribute type="UUID" name="id"/>
      <attribute type="String" name="name"/>
      <attribute type="Date" name="last_mod_dt"/>
   </factory>
```

3. Save your changes and close the file.

4. Restart the CA Catalyst Container service running on the CA SDM Connector host.
   The HAR_TESX extension table is added to the Hardware.TestSystem CI family.

Uninstall the CA SDM Connector

You uninstall the CA SDM Connector when it is no longer required in your environment.

Follow these steps:

1. Click Start, All Programs, CA Catalyst, and uninstall in the following order:

   a. Uninstall CA SDM Connector.

   b. Uninstall CA Catalyst Container (You *must* uninstall the CA Catalyst Container only when the CA SDM Connector is installed standalone and not installed with any CA Catalyst component).

2. If you have installed the CA SDM Connector and CA Catalyst on different computers, complete the following step to delete the CA SDM node from the CA Catalyst Registry UI:

   Important! Perform this deletion step only if no other connectors are installed on the same container containing CA SDM Connector.

   a. Delete the Catalyst folder from the machine where CA SDM connector is installed.

   b. (Applicable for CA Catalyst Container r3.2) Delete the CA SDM node from the CA Catalyst Registry UI.

3. (Applicable for CA Catalyst Container r3.2) If you have installed the CA SDM Connector and CA Catalyst on the same computer, delete specific files from the CA Catalyst Registry UI after uninstalling the CA SDM Connector. Complete the following steps:

   a. Delete the ServiceDeskManagerConnector.conf and ServiceDeskManagerConnector.xml files from the following directory:

      ```
      \topology\physical\<CA_Catalyst_Server>\modules\configuration\
      ```

   b. Delete the ServiceDeskManager_policy.en, ServiceDeskManager_policy.xml, ServiceDeskManager_policySB.en, and ServiceDeskManager_policySB.xml files from the following directory:

```
\topology\physical\<CA_Catalyst_Server>\modules\policy\
```

c. Click the connector-modules.xml file name from the following directory:

```
\topology\physical\<CA_Catalyst_Server>\
```

d. Complete the following steps to edit the connector-modules.xml file.

i. Click Edit as Text.

ii. Delete the lines from the <feature name="ServiceDeskManager-connector"...> tag to the </feature> tag.

iii. Delete the lines from the <feature name="Slump...> tag to the </feature> tag.

iv. Click Save Content.

e. Click the startup.properties file name from the following directory:

```
\topology\physical\<CA_Catalyst_Server>\
```

f. Complete the following steps to edit the startup.properties file.

i. Click Edit as Text.

ii. Delete the Slump;12.7,ServiceDeskManager-connector;3.2.0 text.

iii. Click Save Content.

4. (Applicable for CA Catalyst Container r3.2) Revert CA Catalyst Server Configuration Steps (see page 543)

5. (Applicable for CA Catalyst Container r3.2) Restart the CA Catalyst Container service on the CA Catalyst server.
The CA SDM Connector is uninstalled.

Revert CA Catalyst Server Configuration Steps

The steps that the CA SDM Connector installation performs to configure the CA Catalyst server *must* revert to its original state. Complete the following steps:

- Remove the Reconciled Instance for CMDB (see page 543)
- Remove the Synchronization Policy for the Custom Reconciled Instance (see page 544)
- Remove the Inbound Filter Used for Suppressing the CMDB Projection Updates (see page 545)
- Remove the Customized Correlation Rules for the ProvisionedSoftware (see page 546)

Remove the Reconciled Instance for CMDB

To complete the CA SDM Connector uninstallation, remove the reconciled instance that is created for CMDB. For more information about reconciled views, see the *CA Catalyst Administration Guide*.

Follow these steps:

1. Log in to the CA Catalyst Registry UI and click the reconciledViews.xml file name from the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\reconciler
   ```

2. Click Edit as Text.

3. Delete the following code from the file:

   ```
   <reconciledView>
       <instanceName>CMDB-view</instanceName> <defaultSheetURL>registry:///topology
   /physical/${catalyst.container.name}/reconciler/cmdb_defaultsheet.xml<
   /defaultSheetURL>   <existenceURL>registry:///topology/physical/${catalyst.
   container.name}/reconciler/existenceSourcesOfTruth.xml</existenceURL>
   <!--     The default correlation rules do not update the co-relatable
   attributes across MDRs, for example, serviceName of Service CI type. The
   <handleDecorrelation/> tag allows the catalyst to update such co-relatable
   attributes -->
   <handleDecorrelation />
   </reconciledView>
   ```

4. Click Save Content.

5. Click the reconciler folder from the path on the top pane to navigate to the /topology/physical /<CA_Catalyst_Server>/reconciler directory.

6. Locate the cmdb_defaultsheet.xml registry file.

7. Click Actions, Delete.
   The reconciled instance for CMDB is removed.

Remove the Synchronization Policy for the Custom Reconciled Instance

To complete the uninstallation of the CA SDM Connector, remove the synchronization policy that is created for the custom reconciled instance.

Important! If you reinstall the CA SDM Connector without removing the synchronization policy during the uninstallation, the file containing the policy is appended with duplicate policies. If these duplicate policies exist, the CA SDM Connector does *not* work properly.

Follow these steps:

1. Log in to the CA Catalyst Registry UI and click the plannerpolicy.xml file name from the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\synchronizer
   ```

2. Click Edit as Text.

3. Delete the following code from the file:

```
<tns:plannerPolicy id="CMDB-sync">
    <tns:plannerPolicyConfig xsi:type="tns:InnerPlannerPolicyConfig">
      <tns:reconciledInstanceName>CMDB-view</tns:reconciledInstanceName>
      <tns:mdr>
        <tns:MdrProduct>CA:00020</tns:MdrProduct>
      </tns:mdr>
    </tns:plannerPolicyConfig>
  </tns:plannerPolicy>
```

4. Click Save Content.
   The synchronization policy is removed.

Remove the Inbound Filter Used for Suppressing the CMDB Projection Updates

To complete the uninstallation of the CA SDM Connector, remove the inbound filter that is added to suppress the updates from the CMDB projections.

Important! If you reinstall the CA SDM Connector without removing the Inbound filter during the uninstallation, the file containing the filter is appended with duplicate filters. If these duplicate filters exist, the CA SDM Connector does *not* work properly.

Follow these steps:

1. Log in to the CA Catalyst Registry UI and click the plancontrol.xml file name from the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\synchronizer
   ```

2. Click Edit as Text.

3. Locate the following line between the <planControl> and </planControl> tags:

   ```
   <defaultAction defaultBehavior="send">
   ```

4. Delete the following code that is added before the <defaultAction defaultBehavior="send"> line:

   ```
   <filter name="blockCMDBUpdates">
       <condition>
           <operationSet shouldMatch="true">
               <operation>update</operation>
           </operationSet>
         <xpath>
           <namespace value="http://ns.ca.com/2009/07/usm-core" prefix="usm"/>
           <path>//*[local-name()='MdrProductLastUpdated']</path>
           <value>CA:00020</value>
         </xpath>
       </condition>
       <action defaultBehavior="drop" />
   ```

```
</filter>
```

5. Click Save Content.
   The inbound filter is removed.

Remove the Customized Correlation Rules for the ProvisionedSoftware

To complete the uninstallation of the CA SDM Connector, remove the customized correlation rules that are assigned for the ProvisionedSoftware.

Follow these steps:

1. Log in to the CA Catalyst Registry UI and click the correlation.properties file name from the following directory:

   ```
   \topology\physical\<CA_Catalyst_Server>\correlation
   ```

2. Click Edit as Text.

3. Add the comment character (#) at the beginning of following line:

   ```
   ruleForInstanceNameComparision=registry:///topology/logical/tenant0/usmschema
   /InstanceNameRules.json
   ```

4. Click Save Content.

5. If you have added a custom content in the InstanceNameRules.json file that you need for some other integration, then complete the following steps:

   a. Browse to the following directory:

      ```
      \topology\logical\tenant0\usmschema\InstanceNameRules.json
      ```

   b. Locate, edit, remove the following line in the InstanceNameRules.json file:

      ```
      "ProvisionedSoftware":{"OR":["InstanceName",{"AND":["ProductName",
      {"ANDALLEXIST":["DeviceDnsName","SoftwarePathUrl"]}]}]}
      ```

   c. Click Save Content.

   The customized correlation rules are removed.

Step 5 - Finalize the Integration with the Common Components

If one of the product installed is integrated with any common component, for example CA Process Automation then all the other products are also integrated with the same CA Process Automation. A new product installed is automatically integrated with all the existing products.

Note: Restart the services for CA Asset Portfolio Management, CA Service Desk Manager, and CA Service Catalog for auto-integration changes to come into effect after installing these products.

Auto-Integration Considerations:

Consider the following, if you are integrating:

- **CA EEM and CA Process Automation Considerations:** If you have installed CA EEM and CA Process Automation and integrate one or more CA Service Management products with these common components, ensure that you provide the same CA EEM information that you provided while installing CA Process Automation for auto-integration to be successful.

- **CASM_Policy File**: Do not modify or edit the CASM_Policy file from **CA SDM**, **Administration**, **SOAP Web Services Policy**, **Policies**, **CASM_Policy File**. If you modify the file, generate a new CASM_policy file and manually copy this file from the CA SDM installation directory to the installation directory of all CA Service Management products.

Depending upon your deployment, see the following sections for some additional manual steps to be performed to finalize the integration:

- Integrate CA Asset Portfolio Management with the Common Components (see page 547)
- Integrate CA Service Desk Manager with the Common Components (see page 548)
- Integrate CA Service Catalog with the Common Components (see page 553)

Integrate CA Asset Portfolio Management with the Common Components

The integration between CA Asset Portfolio Management and all the common components is completely automated. You do not have to perform any manual steps to finalize this integration.

However, if you are migrating from CA Business Intelligence 3.3 to 4.1, you have to update the custom universe as follows:

Important! This step applies only if you are migrating from CA Business Intelligence 3.3 to CA Business Intelligence 4.1.

If you have Custom Universe based on the OOTB Universe, refresh the link with CA Service Management 14.1 Universe.

1. Launch Universe Design Tool from the machine where CA Business Intelligence Release 4.1 SP3 client tools are installed.

2. Copy the backup Custom Universe to this machine.

3. Click File, Open.

4. Click File, Parameters.

5. Click the Links Tab

6. From the Name column, click the universe of your product,
   The Change Source button is enabled.

7. Click the Change Source button.

8. Select the location of the universe file.

   Note: The .unv file is typically located in the CA Universes folder.

9. Click Open, OK.
   The universe link is updated.

10. Export the custom universe.

Integrate CA Service Desk Manager with the Common Components

After the auto-integration steps performed by the CA Service Management installer, you need to perform few manual steps to finalize the integration of CA SDM with other components or products. Perform the following integration steps, depending on the products that you have selected for integration:

- Integrate CA Service Desk Manager with CA EEM on Solaris (see page 548)
- Integrate CA Service Desk Manager with CA Business Intelligence (see page 549)

Integrate CA Service Desk Manager with CA EEM on Solaris

If you are planning to auto-integrate CA SDM with CA EEM on Solaris, install the CA SDM Secondary or Application Server on Windows or any other Operating System other than Solaris. If you are planning to upgrade CA SDM on Solaris to CA Service Management, upgrade the CA SDM Primary or Background server. Move the bopuath_nxd authentication module daemon to the Secondary Server. Complete the following based on your CA SDM configuration:

- Move the Authentication Module Daemon for CA SDM Conventional Configuration (see page 548)
- Move the Authentication module Daemon for CA SDM Advanced Availability Configuration (see page 549)

Move the Authentication Module Daemon for CA SDM Conventional Configuration

On the CA SDM Conventional Setup, complete the following:

1. Upgrade CA SDM Primary Server to CA Service Management.
   or
   Install CA SDM Secondary on Windows.
   You can perform a fresh CA SDM Installation or upgrade an earlier CA SDM release to CA Service Management.

2. Log in to CA SDM web user interface as an administrator on the Primary server with srvcdesk credentials of the local host.

3. Navigate to System, Configurations on the Administration tab.
4. Click Create New to add the primary server details.
5. In the Host Name field, specify the primary host name for the configuration. Click Save.
6. On the Configuration Detail page, select the Additional Processes tab.
7. Select and edit the Login User Authentication and in the Update Process page provide the secondary server name.
8. Launch the *pdm_configure* on the Primary Server.
   The Config Options page drop-down has the last configuration that you created. Select the configuration and click Finish.
   After successful configuration, user login is successfully authenticated by CA EEM.

Move the Authentication module Daemon for CA SDM Advanced Availability Configuration

For CA SDM Advanced Availability, move the bopauth_nxd authentication daemon from the background server to any other server (such as application server). Complete the following:

Follow these steps:

1. Log in to the CA SDM background server web interface as an administrator.
2. Select the Administration tab. Expand Options Manager, Security.
3. Click *the bopauth_nxd_host* entry in the Options List. Click Edit.
4. Select the host name of the target server from the Option Value drop-down list. Click Save.
5. Restart the background server after changing the default value of *bopauth_host*.
6. Start version control as a client on the application server using the following command:
   pdm_ver_nxd -c
7. Restart the application server.
   You have successfully configured the redirection of authentications requests to an external server.
   Note: By default, the authentication module runs on the background server.

Integrate CA Service Desk Manager with CA Business Intelligence

This step loads the CA SDM universe and reports and creates groups. The step also optionally creates one user for each group and establishes group authorizations.

(For Linux/ UNIX/ AIX/ Solaris) After CA SDM installation, you need to create srvcdesk user in CA Business Intelligence Release 4.1 SP3 and assign it to the following groups manually:

- Change Manager
- Customer Service Manager

- Incident Manager
- Knowledge Analyst
- Knowledge Manager
- Problem Manager
- Service Desk Manager
- Support Automation Admin
- Support Automation Analyst

Follow these steps:

1. Launch the CA Service Management installer.
2. Select **CA Business Intelligence (CA BI) Configuration for CA Service Desk Manager** option from the **Select the required Installer** screen.

   Depending on the server where you run CA Business Intelligence configuration, the configuration performs the following tasks and you need the following DNS:

   - (Server where CA Business Intelligence 4.1 SP3 is only installed) Configuration imports the OOTB Universe, Reports, Groups/Users and installs 32 bit ODBC or 64 bit ODBC Client. Create 32bit/64bit DSNs pointing to the CA SDM machine.
   - (Server where CA Business Intelligence 4.1 SP3 and CA SDM are installed) Configuration imports the OOTB Universe, Reports, Groups/Users and installs 64 bit ODBC Client. Create 64bit DSN pointing to CA SDM machine.
   - (Server where CA Business Intelligence 4.1 SP3 and Client Tools are installed) Configuration imports the OOTB Universe, Reports, Groups/Users and installs 32 bit ODBC /64 bit ODBC Client. Create 32bit/64bit DSNs pointing to CA SDM machine.
   - (Server where CA Business Intelligence 4.1 Client Tools is installed) Configuration installs 32 bit ODBC Client. Create 32bit DSN pointing to CA SDM machine.
   - (Server where CA Business Intelligence 4.1 Client Tools and CA SDM are installed) Configuration does not perform any action. Required 32 bit ODBC Client and DSN are already available.

3. Complete the fields on the CA Business Intelligence configuration UI. If you installed CA Business Intelligence on a different computer than CA SDM, the following fields appear on the CA Business Intelligence configuration:

   Service Desk Primary Host: Provide the host name of the CA SDM server depending on your configuration:

   - **For conventional:** primary server

- **For advanced availability:** application server

ODBC Port: Specifies the port number of the CA SDM ODBC driver. **Recommended:** 19987.
ODBC Install Location: Specifies the custom location for the ODBC installation when it is different from the default location.

4. Verify the CA Business Intelligence configuration.

Configure Failover Settings

This process is only applicable for advanced availability configuration. If multiple application servers are configured, you can configure failover settings. You configure failover to redirect active user sessions to the other application server. You can also configure load balancing between multiple application servers.

Follow these steps:

1. Invoke the command prompt as an administrator.
2. Execute odbcad32.exe from the following location on the CA Business Intelligence server:
   - (For 32bit DSN) C:\Windows\System32
   - (For 64bit DSN) C:\Windows\SysWOW64

   The DataDirect OpenAccess SDK ODBC Driver Setup dialog opens
3. Enter the application server details in the **General** tab.
4. Enter the alternate application server details in the **Failover** tab with the following syntax: (Host=AppServer1:Port=19987,Host=AppServer2:Port=19987,..)
5. Select **Load Balancing** to distribute the load among the server. The load is balanced between servers whose details are provided in the **General** tab and the **Failover** tab. The servers are picked randomly.

   Note: Select Force SQL_DRIVER_NOPROMPT for failover or load balancing configuration.

6. Click **Apply** and **OK**.
   You have configured the post configuration settings for the advanced availability configuration.

How to Configure Date Range Values and Join Parameters

After you install CA Business Intelligence, complete the following tasks:

- Configure the date range values so that the date range filters in CA Business Intelligence work correctly.

- Configure the join parameters so that universe outer joins are supported.

Follow these steps:

1. On the computer on which CA Business Intelligence server has been installed, navigate to the following location:

   ```
   C:\Program Files (x86)\CA\SC\CommonReporting4\SAP BusinessObjects Enterprise XI 4.0\dataAccess\connectionServer\odbc\extensions\qt
   ```

2. Using a text editor, open the odbc.prm file and navigate to the <Configuration> section. Locate the following line to configure date range values:

   ```
   <Parameter Name="USER_INPUT_DATE_FORMAT">{\d 'yyyy-mm-dd'}</Parameter>
   ```

3. Modify the line to include "hh:mm:ss am/pm" as shown in the following example:

   ```
   <Parameter Name="USER_INPUT_DATE_FORMAT">{\d 'yyyy-mm-dd hh:mm:ss am/pm'}</Parameter>
   ```

4. Open odbc.prm from the Program Files (x86)\CA\SC\CommonReporting4\SAP BusinessObjects Enterprise XI 4.0\dataAccess\connectionServer\odbc directory.

5. Locate the following line to configure join parameters:

   ```
   <Parameter Name="EXT_JOIN">NO </Parameter>
   ```

6. Locate the following and replace NO with YES:

   ```
   <Parameter Name="FULL_EXT_JOIN">NO</Parameter>
   <Parameter Name="LEFT_EXT_JOIN">NO</Parameter>
   <Parameter Name="RIGHT_EXT_JOIN">NO</Parameter>
   ```

7. Add the following three lines after the OUTERJOINS_GENERATION parameter:

   ```
   <Parameter Name="LEFT_OUTER"></Parameter> <Parameter Name="RIGHT_OUTER"></Parameter> <Parameter Name="OUTERJOINS_COMPLEX">Y</Parameter>
   ```

8. Save the odbc.prm file.

9. Restart the Business Objects Enterprise services.
   Date range values and join parameters are configured. Date range filters work with CA Business Intelligence and universe outer joins are supported.

Update the Custom Universe Link

Important! This step applies only if you are migrating from CA Business Intelligence 3.3 to CA Business Intelligence 4.1.

If you have Custom Universe based on the OOTB Universe, refresh the link with CA Service Management 14.1 Universe.

1. Launch Universe Design Tool from the machine where CA Business Intelligence Release 4.1 SP3 client tools are installed.
2. Copy the backup Custom Universe to this machine.
3. Click File, Open.
4. Click File, Parameters.
5. Click the Links Tab
6. From the Name column, click the universe of your product,
   The Change Source button is enabled.
7. Click the Change Source button.
8. Select the location of the universe file.

   Note: The .unv file is typically located in the CA Universes folder.

9. Click Open, OK.
   The universe link is updated.
10. Export the custom universe.

Integrate CA Service Catalog with the Common Components

After you install CA Service Catalog and the common components, review the following sections to understand how to integrate the common component with CA Service Catalog

- Integrate CA Service Catalog with CA EEM (see page 553)
- Integrate CA Service Catalog with CA Process Automation (see page 553)
- Integrate CA Service Catalog with CA Business Intelligence (see page 554)

Integrate CA Service Catalog with CA EEM

CA EEM is a mandatory component for CA Service Catalog. Hence, CA EEM is automatically integrated with CA Service Catalog.

Integrate CA Service Catalog with CA Process Automation

After the CA Process Automation processes are loaded and configured, update the CA Service Catalog login credentials in the CA Process Automation Dataset, to complete the integration between the two products. For more information, see the Integrate CA Service Catalog with CA Service Desk Manager (see page 560) topic.

Integrate CA Service Catalog with CA Business Intelligence

Follow these steps after you have installed both CA Service Catalog and CA Business Intelligence, to complete the integration between the two products:

Step 1 - Update the Custom Universe Link

Important! This step applies only if you are migrating from CA Business Intelligence 3.3 to CA Business Intelligence 4.1.

If you have Custom Universe based on the OOTB Universe, refresh the link with CA Service Management 14.1 Universe.

1. Launch Universe Design Tool from the machine where CA Business Intelligence Release 4.1 SP3 client tools are installed.
2. Copy the backup Custom Universe to this machine.
3. Click File, Open.
4. Click File, Parameters.
5. Click the Links Tab
6. From the Name column, click the universe of your product,
   The Change Source button is enabled.
7. Click the Change Source button.
8. Select the location of the universe file.

   Note: The .unv file is typically located in the CA Universes folder.

9. Click Open, OK.
   The universe link is updated.
10. Export the custom universe.

Step 2 - Update the CA Service Catalog Universe Connection

Important! If both your CA Service Catalog and CA Service Desk Manager are configured to use the same instance of CA Business Intelligence server, and the date format in odbc.prm file is changed to the CA SDM date format, perform the following steps.

The following procedure applies to MS SQL Server only

Update the CA Service Catalog Universe connection Database Middleware after you run the CA Service Management installer to integrate CA Service Catalog with CA Business Intelligence. In the following procedure, you update the connection Database Middleware for MS SQL Server 2008.

1. Log in to the Universe Design tool.
2. Go to **File**, **Import**.
3. Navigate to CA Universes, CA Service Catalog.
4. Go to **File**, **Parameters**.
5. Click **Edit** to edit the login parameters in the **Edit CA SLCM connection** screen.
6. Click **Back**.
7. Navigate to Microsoft, MS SQL Server 2008, ODBC Drivers to select the Data Access driver.
8. Click **Next**.
9. Provide the appropriate MDB credentials and test the Connection.
10. Click **Next**.
11. Click **Next**, **Finish**.
12. Click **OK** to close the Parameters window
13. Click **File**, **Save**.
14. Click **File**, **Export**.
15. Navigate to CA Universes, CA Service catalog
16. Click OK
17. Click OK when you see the message.
    You have updated the CA Service Catalog Universe connection Database Middleware for MS SQL Server 2008. Follow a similar procedure for other supported versions of MS SQL Server.

The following procedure applies to Oracle only

Update the CA Service Catalog Universe connection Database Middleware after you run the CA Service Management installer to integrate CA Service Catalog with CA Business Intelligence. In the following procedure, you update the connection Database Middleware for Oracle.

1. Log in to the Universe Design tool.
2. Go to **File**, **Import**.
3. Navigate to CA Universes, CA Service Catalog.
4. Go to **File**, **Parameters**.
5. Click **Edit** to edit the login parameters in the **Edit CA SLCM connection** screen.
6. Click **Back**.
7. Navigate to Oracle 11, Oracle ODBC Drivers to select the Data Access driver.
8. Click **Next**.
9. Provide the appropriate MDB credentials and test the Connection.
10. Click **Next**.
11. Click **Next**, **Finish**.
12. Click **OK** to close the Parameters window
13. Click **File**, **Save**.
14. Click **File**, **Export**.
15. Navigate to CA Universes, CA Service catalog
16. Click OK
17. Click OK when you see the message.
18. Update the oracle.prm file at <CABI_Home>\SAP BusinessObjects Enterprise XI 4.0 \dataAccess\connectionServer\odbc\extensions\qt as follows:

    a. Replace <Parameter Name="USER_INPUT_DATE_FORMAT">'dd-Mmm-yyyy'< /Parameter> with existing USER_INPUT_DATE_FORMAT tag.

    b. Restart the Apache Tomcat for BI 4 and Server Intelligence Agent services in Central Configuration Manager.

    You have updated the CA Service Catalog Universe connection Database Middleware for Oracle.

Step 3 - Configure Trusted Authentication

Configure CA Service Catalog and CA Business Intelligence to use trusted authentication for the integration between the two products. Trusted authentication provides Single Sign-On. Single Sign-On enables CA Service Catalog users to access the Launch Pad application of CA Business Intelligence directly from the CA Service Catalog GUI.

CA Service Catalog uses standard CA Business Intelligence login if trusted authentication is not set up or if it is not working properly.

Note: The following login methods do *not* apply to CA Business Intelligence: CA EEM token, CA SiteMinder Integration, and NTLM authentication on Windows.

Follow these steps:

1. Log on to the CA Business Intelligence Central Management Console as a user with administrative rights.
2. Go to **Manage**, **Authentication** area of the Central Management Console.
3. Click the **Enterprise** tab.
4. Check **Trusted Authentication is Enabled** to enable trusted authentication.
5. Click **New shared secret** and you see that **Download Shared Secret** is enabled.

   Note: The CA Business Intelligence client and the Central Management Console use the shared secret password to create a trusted authentication password. The value of this password and the frequency with which you update it meet your password security standards.

6. Click **Download Shared Secret** to generate TrustedPrincipal.conf file.
7. Perform the remaining steps on *every* Catalog Component computer.
8. Open the file that is named USM_HOME\reporting\CABI\TrustedPrincipal.conf using a text editor.
9. Scroll to the following line and specify the same shared secret password that you downloaded on the CA Business Intelligence Central Management Console.

   ```
   SharedSecret=password
   ```

10. Save the TrustedPrincipal.conf file.

11. Restart the Catalog Component computer.

Important! Whenever you update the password on the CA Business Intelligence Central Management Console, make the same change to the password in the TrustedPrincipal.conf file on every Catalog Component computer.

Step 4 - Run Pre-Defined Reports

Before you run the pre-defined reports, you must create a DSN and ODBC Connection for the MDB on either SQL Server or Oracle. For more information, see Import the BIAR File (see page 3299) topic. Now, to verify the CA Service Catalog - CA Business Intelligence integration, run the pre-defined reports from CA Service Catalog.

Optionally view the pre-defined reports in localized format. To do so, set the language configuration in the **Preferences**, **Locales and Time Zone**, **Preferred Viewing Locale** section of CA Business Intelligence.

Note: Some fields remain in English even when you view reports in localized format. These fields include Request Status, Billing Status, Account Status, Account Type, and fields related primarily to payment and adjustment. In addition, in both English and localized reports, custom status values do appear in the reports; however, their descriptions do not.

Follow these steps:

1. Select **Home**, **DashBoards**, **Administration Quick Start**, **BI Launch Pad** in CA Service Catalog.
2. Click **Documents**, **Folders**, **Public Folders**, **CA Reports**, **CA Service Management, CA Service Catalog**.
3. Click **Admin Reports** or **User Reports**, as required.
   The Admin Reports folder and its reports are visible only to users who are members of the Administrator groups.
   The User Reports folder and its reports are visible only to users who are members of either the Administrator groups or the End User groups.
4. Double-click the report which you want to run.
5. Specify the parameters for your report.
6. Click Run Query and view the report.

> **Note:** In a multi-tenant (business unit) implementation, your reports display only the data of tenants to which you have access. If you run a report for an integrated product (such as CA Service Desk Manager or CA Asset Portfolio Management), but that product has not been integrated with CA Service Catalog, then the report typically fails.

(For Linux/ UNIX/ AIX/ Solaris) After CA SDM installation, you need to create srvcdesk user in CA Business Intelligence Release 4.1 SP3 and assign it to the following groups manually:

- Change Manager
- Customer Service Manager
- Incident Manager
- Knowledge Analyst
- Knowledge Manager
- Problem Manager
- Service Desk Manager
- Support Automation Admin
- Support Automation Analyst

Step 6 - Finalize the Integration with the Products

This section contains the following articles:

Integrate CA Asset Portfolio Management with CA Service Catalog

The integration between CA Asset Portfolio Management and CA Service Catalog is completely automated. You do not have to perform any manual steps to finalize this integration.

In the rare event that the integration between the two products fail, see integrate CA Asset Portfolio Management with CA Service Catalog manually (see page 3470) to troubleshoot the integration.

Integrate CA Service Desk Manager with CA Asset Portfolio Management

The integration between CA Service Desk Manager and CA Asset Portfolio Management is completely automated. You do not have to perform any manual steps to finalize this integration.

In the rare event that the integration between the two products fail, see integrate CA Service Desk Manager with CA Asset Portfolio Management manually (see page 3251) to troubleshoot the integration.

Integrate CA Service Catalog with CA Service Desk Manager

Ensure that you have selected both CA SDM and CA Service Catalog during the CA Service Management installation. After the successful installation of CA Service Management, perform the following manual steps to ensure that CA SDM and CA Service Catalog are integrated successfully.

- Update Login Credentials in CA Process Automation Dataset (see page 560)
- Create Groups in CA Service Desk Manager (see page 561)

Update Login Credentials in CA Process Automation Dataset

Important! Ensure that you have CA SDM Connector installed before you proceed with the following procedure.

Follow these steps:

1. Log in to CA Process Automation as an Administrator.
2. Click Library from the Home page.
3. Select the CA SDM folder and double click SDM_GlobalDataset.
4. Click Check out and enter the CA Service Catalog user credentials.
5. Click Save.
6. Click Check in and Close.
7. From the CA SDM SRF folder, double click HWSW_FilledFormInventory.
8. Click Check Out from the Common menu.
9. On the properties tab, enter the details of Tags field as chgcat and save.
10. Click Check in and Close.
11. From the CA Service Catalog folder, double click CA SLCM.
12. Click Check out and enter the CA Service Catalog user credentials
13. Click Save.
14. Click on Check in and close.

Important! Ensure that you have CA SDM connector installed to complete steps 15 and 16.

15. On the Configuration tab, click Modules.
16. Click Lock and double click CA ServiceDesk.
17. Give the CA SDM Host name In the Default ServiceDesk WebService URL.
18. Enter the password for Default User.
19. Save and close.
20. Click Unlock.

Create Groups in CA Service Desk Manager

Follow these steps:

1. Log in to CA SDM as an Administrator.
2. From the Administrator tab select Security and Role Management, Groups.
3. Click Create New and enter the group name for CA Service Catalog
4. Click Members, Service contracts, Auto Assignment.
5. Click Update Members.
6. Search and update the members.
7. Click OK and Save.
8. Associate this group with the following categories, and add CA SDM administrator as the assign of these categories:
   - SLCM.HWFFI
   - SLCM.SWFFI

Important! Ensure that you restart CA SDM and CA Service Catalog services after performing all the steps.

At the end of this topic, you have successfully integrated CA Service Catalog with CA Service Desk Manager.

In the rare event that the integration between the two products fail, see integrate CA Service Catalog with CA Service Desk Manager manually (see page 3255) to troubleshoot the integration.

Rules Enabled in Integrated Environment

When you auto-integrate CA Service Management components, some of the rules that are defined in the Event-Rule-Action page of CA Service Catalog are enabled. The rules that are enabled are required for the common administration components and for the integration to work properly. The rules are enabled in the following scenarios:

- When you install CA Service Management for the first time and auto-integrate the components
- When you upgrade from a standalone CA Service Catalog to the integrated environment
- When you upgrade from a standalone CA SDM to the integrated environment

When you upgrade to the integrated environment, some of the rules that you had disabled may also be enabled. We recommend that you do not disable such rules, as disabling them may cause the common administration and the integration to not work properly.

The following table gives the list of rules that are enabled:

Rule with filter that fires once for each HW request item when status goes from approval range to Pending Fulfillment (WFHWCheckAvailability)

Rule	Description
Common Administration and Content Pack Related rules	
CASM Auto Integration Rule	Rule with filter that fires once for CASM Auto Integration service
CASM Common Configuration Rule	Rule with filter that fires once for CASM Common Configuration service
CASM Contact Sync Rule	Rule with filter that fires once for each CASM Contact Sync service
CASM Create LDAP Rule	Rule with filter that fires once for each CASM add LDAP service
CASM Create Role Rule	Rule with filter that fires once for each CASM Custom Role service
CASM Custom Role Mapping Rule	Rule with filter that fires once for each CASM Custom Role Mapping service
CASM Custom Tenant Mapping Rule	Rule with filter that fires once for each CASM Custom Tenant Mapping service
CASM Import LDAP Users Rule	Rule with filter that fires once for each CASM import LDAP users service
CASM Manage LDAP Rule	Rule with filter that fires once for each CASM manage LDAP service
CASM Tenant Mapping Rule	Rule with filter that fires once for each CASM tenant onboarding service
CASM Tenant Onboarding Rule	Rule with filter that fires once for each CASM tenant onboarding service
CASM Update MT Options	Enable Multi Tenancy Options for Common Administration
CASM Update Role Rule	

Rule	Description
	Rule with filter that fires once for each CASM Create Role Service
CASM Update Tenant	Rule with filter that fires once for each CASM tenant update service
CASM Update User Rule	Rule with filter that fires once for each CASM update user service
CASM User Onboarding Rule	Rule with filter that fires once for each CASM user onboarding service
When Category is Service Management Content and Status is Canceled	Rule with filter that fires once for each service option of Service Management Content category when status updates to Canceled
When Category is Service Management Content and Status is Completed	Rule with filter that fires once for each service option of Service Management Content category when status updates to Completed
When Category is Service Management Content and Status is Pending Fulfillment	Rule with filter that fires once for each service option of Service Management Content category when status updates to Pending Fulfillment
Out-of-The-Box rules The out-of-the-box rules include multiple actions and only the actions mentioned here are enabled.	
When Category is Hardware and Status is Filled from Inventory Action: Launch HWSWFilledFromInv_SDM_SYNC SRF	Rule with filter that fires once for each HW request item when status goes to Filled From Inventory (WFHWFulfillment)
When Category is Hardware and Status is Pending Fulfillment Actions: Launch CheckAvailability SRF for Hardware Auto assign the selected asset to the user	Rule with filter that fires once for each HW request item when status goes from approval range to Pending Fulfillment (WFHWCheckAvailability)
When Category is Software and Status is Filled from Inventory Action: Launch HWSWFilledFromInv_SDM_SYNC SRF for Software	Rule with filter that fires once for each SW request item when status goes to Filled From Inventory (WFSWFulfillment)
When Category is Software and Status is Pending Fulfillment Action: Launch CheckAvailability SRF for Software availability	Rule with filter that fires once for each SW request item when status goes from approval range to Pending Fulfillment (WFSWCheckAvailability)
When Status is Submitted and Approval Process is driven by Workflow Action: Launch Approval SRF	Rule with filter that fires once for each service when a request is submitted for approval (WFAllSubmit)
Notes and Attachment Synchronization rules	

Rule	Description
When notes is added to Service Catalog request	When notes are added to CA Service Catalog request, add them to the corresponding CA Service Desk ticket
When attachment is added to Service Catalog request	When attachment is added to CA Service Catalog request, add it as a link to the corresponding CA Service Desk ticket

Implementing CA Service Catalog

The CA Service Catalog products and components are an integrated set of business applications that a Service Delivery Manager uses to manage services. To optimize your use of CA Service Catalog and the system resources that it uses, carefully prepare to install or upgrade the product. Plan for CA Service Catalog Installation by following the instructions outlined in Plan your CA Service Catalog Installation (see page 564). Determine the following:

- Understand your current Business process and requirements.
- System architecture you plan to use.
- Determine the CA EEM authentication method to use.
- The CA Service Catalog components you plan to install.
- Review the Hardware and Software Requirements.

After you complete the planning for installing CA Service Catalog , install or upgrade CA Service Catalog, using the scenario that applies to your implementation:

- Install CA Service Catalog
- Upgrade CA Service Catalog on Existing Computers (traditional upgrade)
- Upgrade CA Service Catalog on New Computers (migration-model upgrade)

Follow these steps:

- Step 1 - Plan your CA Service Catalog Installation (see page 564)
- Migrate Data Between CA Service Catalog Systems (see page 576)
- How to Upgrade CA Service Catalog (see page 579)
- Step 2 - Install CA Service Catalog (see page 590)
- Step 3 - Perform CA Service Catalog Post-Installation Tasks (see page 596)

Step 1 - Plan your CA Service Catalog Installation

CA Service Catalog products and components are an integrated set of business applications that a Service Delivery Manager uses to manage services. To optimize your use of CA Service Catalog and the system resources that it uses, prepare to install the product. Ensure that the following implementation planning tasks are implemented before you install CA Service Catalog:

CA Service Catalog 14.1 Installation Planning Checklist
▪ Determine the Type of Business Process and System Architecture (see page 565) to Use.

CA Service Catalog 14.1 Installation Planning Checklist
▪ .Determine the Failover Mechanisms and Session Management (see page 572).
▪ Determine the Number of Servers required for installation.
▪ Ensure that at least one CA EEM is installed (see page 283) in the environment.
▪ (If you have CA Business Intelligence 3.3 and if you want reporting capability) Installed CA Business Intelligence Release 4.1 SP3 (see page 285) and then install CA Service Catalog.
▪ (If you want process automation) Installed CA Process Automation (see page 292).
▪ Ensure that the required ports are open.
▪ Ensure that the hardware requirements (see page 573) are met.Ensure that at least one CA EEM is installed (see page 283) in the environment.
▪ Install the Database Server of your choice (MS SQL or Oracle Database Server). Ensure that you have the database information depending upon the database you are using: ▪ ▪ SQL Server ▪ SQL Serverdatabaseusernameandpassword ▪ SQL Server database port number ▪ Oracle ▪ Whether the Oracle database is local or remote ▪ Whether you need to create tablespaces ▪ The Net Service Name ▪ The DBAusernameandpassword ▪ The data and index tablespace name ▪ The complete path for the tablespace ▪ JDBC connection information, including the system identifier (SID) and listener port
▪ Decided to use widgets for Request Management (see page 2176).
▪ (If you plan to install Unified Self-Service with CA Service Catalog) Downloaded Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases). ⚠ **Note:** Do not Install Liferay manually as the installer unzips the downloaded file and installs Liferay.
▪ Review the CA Service Catalog Hardware Requirements (see page 573).

Step 1a - Determine your Business Process and System Architecture to Use

This article contains the following topics:

Business Process

Implementing CA Service Catalog requires an understanding of your current business processes. Often this effort requires a discovery process to research and obtain this information. During this process, you ask questions and collate information about your business processes. Use top-down analysis to define your business and your business needs. After you determine your business needs, implement the catalog system to address them.

Review CA Service Catalog components (see page 571) to determine the catalog components that are required for your implementation.

System Architecture

The number of *catalog requests per minute* is the key criterion for determining the size of the architecture as small (see page 566), medium (see page 567), or large (see page 569). This criterion is much more important than the number of users in the system or other criteria. The higher the number of catalog requests per minute, the larger the recommended architecture.

Availability refers to the ability of an organization to deliver consistent, predictable access to applications and data.

Demonstration-Only Deployment

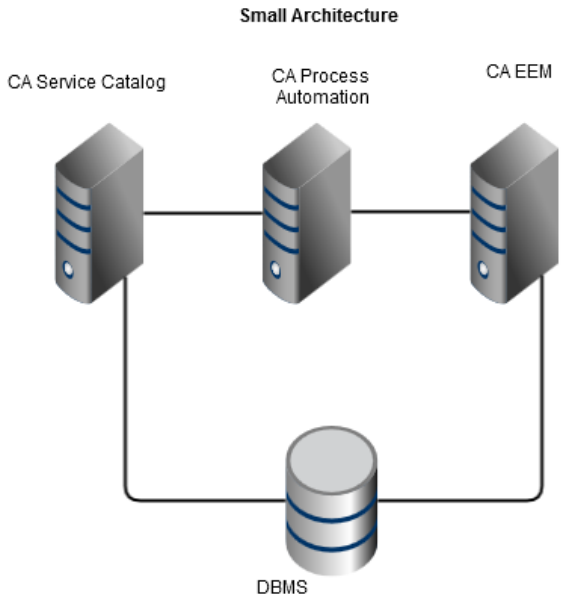
In addition to small, medium, and large architectures, CA Service Catalog also supports a standalone deployment. In a standalone deployment, all the components, including the database server, are installed on a single physical computer. This deployment is for demonstration *only* and is *not* suitable for a production environment.

Important! Verify that the DBMS is tuned for maximum performance. This directive applies to all size architectures.

Small Architecture

An small architecture can include the following servers:

- Server 1 hosts CA Service Catalog, including Service Accounting Component.
- Server 2 hosts CA Process Automation.
- Server 3 hosts the DBMS.
- Server 4 hosts CA EEM. You use configuration parameters to connect CA Service Catalog and CA Process Automation with CA EEM.



This model applies to systems with an expected average load of 1 to 10 catalog requests per minute. Clustering does *not* apply to small architecture.

Also consider, any performance-related information and other stress test data that you have from implementing previous releases of CA Service Catalog

Medium Architecture

If you expect more than a small percentage of the requests to be complex, consider moving to medium architecture. Complex requests include one or more of the following items:

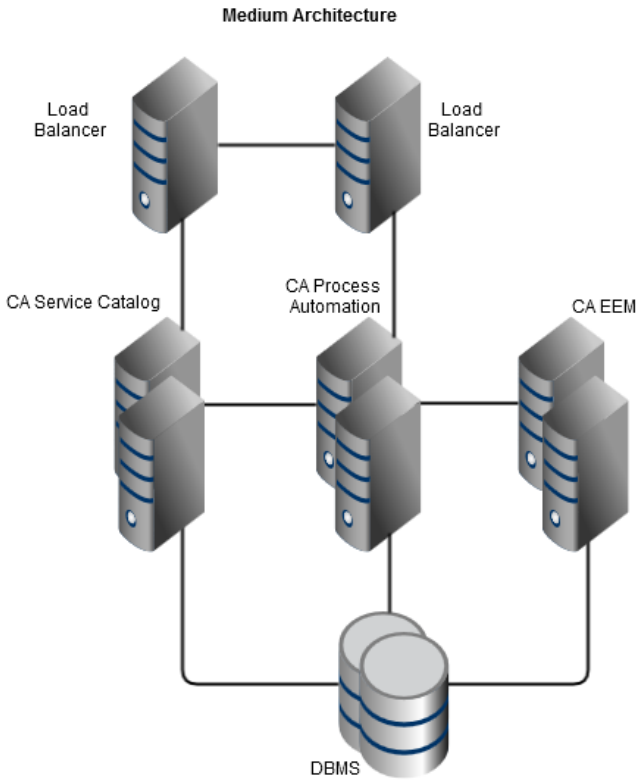
- Multiple (two or more) services or service options.
- Attachments.
- Long forms or multiple forms.
- Long web service calls or multiple web service calls.
- Multiple CA Process Automation processes.

Similarly, consider moving to a medium architecture if both of the following conditions exist:

- Your implementation includes more than 5,000 users.
- You expect more than a small percentage of these users to access the catalog simultaneously.

The medium architecture can efficiently process a load of 11-50 catalog requests per minute. The medium architecture expands the small architecture by implementing clustering and adding load balancers.

The following diagram illustrates an example of medium architecture:



The medium architecture setup is as follows: *Two clustered servers* refers to two virtual computers that are clustered.

- Two clustered servers host CA Service Catalog.
- Two clustered servers host CA Process Automation. Install and cluster CA Process Automation according to the specifications in the CA Process Automation documentation.
- One or preferably two load balancers are the front ends to the clusters for CA Process Automation and CA Service Catalog, respectively. Both the CA Process Automation and CA Service Catalog clusters require a load balancer, which can be an existing instance. CA Process Automation and CA Service Catalog can share a load balancer.
- Two clustered servers host CA EEM. CA EEM is clustered but is not used with a load balancer. We recommend clustering CA EEM to provide failover protection. You use configuration parameters to connect CA Service Catalog and CA Process Automation with the CA EEM cluster. You can increase CA EEM performance by pointing each CA Process Automation domain server to different CA EEM servers. Install and cluster CA EEM according to the specifications in the CA EEM documentation (https://wiki.ca.com/display/eem1251/Failover+Configuration).
- Two clustered servers host the DBMS. You cluster the DBMS to improve throughput and responsiveness. Verify that you cluster your DBMS using a method that improves performance. For example, using an active-active database cluster can reduce performance, especially on write operations. For more information about clustering your DBMS, see its documentation.

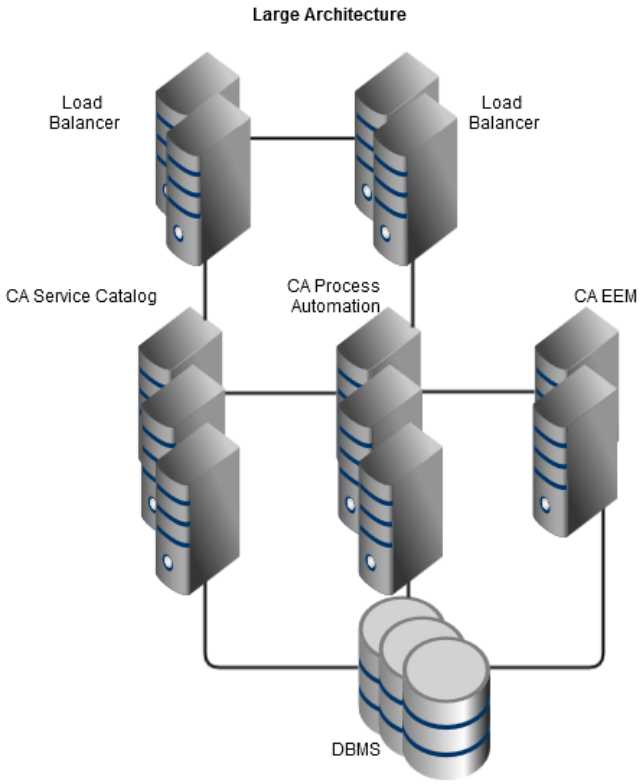
- Some virtual machine software uses scheduling algorithms that result in decreased performance when the number of CPUs increases. This performance loss is most noticeable when the virtual machines are sharing systems with other virtual machines that also have a lower number of CPUs allocated. Typically, in such cases, increasing the number of virtual machines in the cluster improves performance more than increasing the number of CPUs per virtual machine.

Large Architecture

Consider the factors for moving from a small architecture to a medium architecture. The same factors in greater magnitude can cause you to add computers and clusters to a large architecture. The large architecture can efficiently process an average load of 50 or more catalog requests per minute.

The large architecture includes multiple web server clusters and a database cluster.

The following diagram illustrates an example of large architecture:



The large architecture setup is as follows:

- Two or more clustered servers host CA Service Catalog.
- Two or more clustered servers host CA Process Automation.
- You install and cluster CA Process Automation according to the specifications in the CA Process Automation documentation. Alternatively, you install CA Process Automation on three physical computers and place them in a separate cluster.

- Two or more load balancers are the front ends to the clusters for CA Process Automation and the Catalog Component of CA Service Catalog, respectively. Both the CA Process Automation and CA Service Catalog clusters require a load balancer, which can be an existing instance.

- Two or more clustered servers host CA EEM. CA EEM does not *use* a load balancer. We recommend clustering CA EEM to provide failover protection and high availability. You use configuration parameters to connect CA Service Catalog and CA Process Automation with the CA EEM cluster. You can increase CA EEM performance by pointing each CA Process Automation domain server to different CA EEM servers.

- Two or more clustered servers host the DBMS.

- Some virtual machine software uses scheduling algorithms that result in decreased performance when the number of CPUs increases. This performance loss is most noticeable when the virtual machines are sharing systems with other virtual machines that also have a lower number of CPUs allocated. Typically, in such cases, increasing the number of virtual machines in the cluster improves performance more than increasing the number of CPUs per virtual machine.

- A filestore serves as the single location for all shared files.

Review CA Service Catalog Architecture Example (see page 570)for more information about a typical catalog implementation.

CA Service Catalog Architecture Example

This article contains the following topics:

This topic explains how to architect the CA Service Catalog system to meet the requirements for the following scenario:

I have 60,000 end users who are distributed across the country. My system is located in a centralized data center that the service provider owns. We want to integrate with CA Service Desk Manager, CA Asset Portfolio Management, and other products. Our expected load is about 100 requests per day with an average of 1000 concurrent connections. We are planning to define CA Process Automation processes to meet our requirements.

This scenario is common. Because of the variability around usage patterns and architecture there is no simple calculator that can generate sizing estimates. However, the CA Service Catalog components are dynamically scalable.

The CA Service Catalog architecture is n-tier, stateless, and web-based. Users make HTTP requests. These HTTP requests are passed to one or more application servers. The application server performs the processing logic using a pool of connections to the database. The web server can be co-located with application server instances. Also, several computational engines run independently from any user interactions; examples include the billing and SLA correlation engines. Other web servers, application servers, and computational engines can be added, as required. The database, where state is maintained, is the potential performance bottleneck. The scalability of the database platform is important. Therefore, the sizing and architecture of the MDB is the most critical factor.

Metrics

First, consider the concurrent connection metric: Because HTTP is connectionless, there is no "concurrent user" metric.

Next, consider the metric of 100 requests per day: This metric does not provide the peak usage, a critical factor. If the 100 requests are evenly distributed through the day, system impact would be minimal. However if the 100 requests are all made at the same time of day, then the system could be challenged. Also, the type of request has a direct impact on the resource utilization.

Variations

Variations in usage and architecture are important. Consider them carefully and tune your system. Adjust your tuning over time as changes in demand or system load occur, if necessary.

Business Requirements and Updates

When you are implementing CA Service Catalog, it is critical to capture accurate business requirements. Use the business requirements to formulate efficient technical architectures. Therefore, you start an implementation with a discovery phase per module to capture the business requirements. Next, you study the limitations and capabilities of the client operational infrastructure, and you formulate an efficient implementation architecture. Once you obtain all the information, you can formulate an initial sizing estimate.

Based on the possible variations in usage and architecture, organizations must start with two instances of each component. One component for fail-over and one component for load balancing. Because the components can be co-located, start with at least two server class machines in addition to the database servers. If computational engines are heavily used during peak activity times, they require their own server or servers. The usage-patterns typically change over time as the clients grow to understand the features and use them more heavily. As you discover usage patterns over time, you can dynamically add and distribute components as needed.

CA Service Catalog Components

The CA Service Catalog components are as follows:

- **Service Catalog**
  Service Catalog provides a container that consists of services for one, several, or all business units. Services are built of one or more service option groups that describe IT services and how to charge for them. The service catalog also enables an organization to model its business units or departments and manage the users accounts contained within those units. Services in the service catalog can be organized into folders. The services contain detailed information about the price of a service. Services can represent one or more metrics and can include Service Level Agreements (SLAs).
  Service Catalog provides required common functions such as management of users, business units and accounts, reporting, and event handling.

- **Service Catalog Accounting**
  Service Catalog Accounting is the financial component of CA Service Catalog. You can use it to for billing, chargeback, cost allocation, budgeting, and planning of services in the catalog.

- **Service Catalog Content**
  Service Catalog Content is a set of best practice model services to help you start your catalog quickly. Using these model services helps you better align your services with business goals, improve internal customer satisfaction, and standardize your processes to achieve greater operational efficiency.

Step 1b - Determine the Authentication Methods to use

Administrators can authenticate users in CA Service Catalog by any one of the following methods:

- CA EEM alone
- CA EEM with an external directory. For example: an LDAP directory, such as Microsoft Active Directory
- Windows NTLM authentication

You specify whether to use CA EEM standalone or with an external directory. When you use CA EEM standalone, CA EEM stores the user information and passwords in its data store. When you use CA EEM with an external directory, such as Microsoft Active Directory, the external directory stores the users and passwords in its data store. If the client system uses a Windows domain, you can configure CA Service Catalog to use NTLM authentication. NTLM authentication enables a user who has been authenticated to the domain to skip the login page.

Step 1c - Understand Failover Mechanisms and Session Management

This article contains the following topics:

Failover Mechanisms

As part of your implementation, you can perform the following tasks to provide failover mechanisms:

- Deploy CA Service Catalog in a cluster.
- If you use CA Process Automation, deploy clustering in CA Process Automation.
- Use *database* clusters. CA Service Catalog components are also compatible with database clusters which are recommended for environments experiencing heavy load.

  Note: For information about database clustering, see your DBMS documentation.

- Use a load balancer. Clustering requires a load balancer. To maximize the uptime of CA Service Catalog, include the load balancer and cluster computers in your failover plan.
- Implement clustering on the load balancer computer.
- Move user-generated files from the local file system to a filestore (see page) (a central location) on a high-availability network shared file system. CA Service Catalog maintains several user-generated files on the local file system. These files include forms and XSL and XML customizations.
- If you are using CA EEM for authentication, cluster CA EEM, using operating system level clustering.

Note: For information about clustering and implementing failover with CA EEM, see CA EEM documentation (https://wiki.ca.com/display/eem1251/Failover+Configuration).

- Improve the robustness of the hardware used in your environment, by using all applicable means, including RAID hard disks, redundant power supply, and network cards. For more information, see your hardware documentation.

Session Management

Session management is very important for performance. Use a process automation tool such as CA Process Automation to handle session management effectively.

Effective use of web service sessions is crucial for maintaining throughput as your environment scales up. Creating a web service session is a task which requires multiple invocations of authentication and authorization logic and accounts for the majority of time and effort spent when using web services. Design CA Process Automation processes and other web service clients to avoid creating extra web service sessions. Exception handling should create a session only when the exception is known to be the result of an invalid or expired session.

Step 1d - Review the Hardware Requirements

Ensure that your system meets the following hardware requirements before proceeding with the CA Service Catalog installation:

- CPU: Intel Platform —3 GHz Processor or higher (Multi-processor recommended)
- Memory: 4 GB or higher recommended. Additional 2 GB, if you plan to install Unified Self-Service.
- Hard disk: Minimum 80 GB with at least 4 GB free space

Important! For production, we strongly recommended that you install each required application on its own computer. For example, you install Catalog Component on server 1, CA Process Automation on server 2, and Accounting Component on server 3. You install the DBMS server software on server 4.

Step 1e - Verify the Prerequisites for CA Service Catalog Installation

The term *CA Service Catalog computer* means the DBMS server and any computer on which you plan to install any CA Service Catalog product or component.

The following installation considerations and requirements typically apply to all implementations.

- As a best practice, verify that all CA Service Catalog computers are *geographically collocated* - that is, are located in the same building, in the same room. Geographically collocated CA Service Catalog computers prevent possible performance problems caused by network latency.
- Record the following data for every installation of CA Service Catalog. The installation program prompts you to provide this data.

- Installation path name, if you do not want to use the default path name
  Default: C:\Program Files\CA\Service Catalog

- Startup and shutdown port numbers, if you do not want to use the default ports 8080 and 8085.

  Important! We recommend that you do *not* use port 7777 as the startup or shutdown port. Port 7777 is reserved for Java Messaging Service (JMS).

  If you must use port 7777 for the startup or shutdown port, reset the JMS port number after you have finished running the setup utility. Otherwise, port conflicts occur, and the product does not function correctly.

- No host name is needed because you install the product locally.

- Record the CA EEM Server details.

  Note: Ensure that you have at least one CA EEM in your environment because CA EEM is mandatory for CA Service Catalog.

- If you are planning to use Oracle database, ensure that you identify the system identifier (SID) and verify that the ORACLE_HOME and ORACLE_SID variables are set correctly.

- In a distributed implementation, any computer on which you install CA Service Catalog must have either your DBMS server or DBMS client installed. This requirement applies to both SQL Server and Oracle.

- When you install CA Service Catalog products and components on a network share, map a drive letter to this share. Alternatively, copy the installation image to a local folder with a short path name, for example, C:\ or C:\Temp. Run the installation programs locally from this folder.

  Note: Avoid long path names because they can cause problems during the installation process.

  The maximum length of a path name in Windows is 260 characters. If the path names exceed this limit, the installation (or upgrade) can fail. Verify that the path name where you install CA Service Catalog does not exceed this limit.

- If you want to install Unified Self-Service, we recommend that you install Unified Self-Service and CA Service Catalog on different computers.

- If you want to integrate CA Service Catalog with CA Process Automation, ensure that:

- - The CA Service Catalog computer name does not begin with a number.

- The computer name of the load balancer does not begin with a number, if you are using a load balancer for CA Service Catalog or CA Process Automation.

If you do not meet these requirements, web service calls for the integration can result in errors, for example:

```
Caused by: com.sun.xml.messaging.saaj.util.JaxmURI$MalformedURIException: Host is
not a well formed address!
```

Required Open Ports

On each host computer where you install CA Service Catalog, specify the port number for CA Service Catalog to communicate with the web server. You can change the default values during installation. If these ports are not available, have other non-conflicting port numbers available.

- 8080 and 8085 - For the Catalog Component service for communication

After the installation, if applicable, you also specify the port number for CA Service Catalog to communicate with other CA products, when you configure the integration with them.

The following port number is the default value for use by CA EEM. You cannot change it during installation.

- 5250 - for the iTechnology iGateway service

CA Service Catalog requires the following ports for communication with products and components. If you have disabled these ports, for hardening purposes or for any other reasons, enable them.

Note: For more information about how to enable ports, see your Windows documentation.

Product or Component	Default Port
CA Service Catalog startup port (includes access for CA Service Catalog and Service Accounting Component)	8080
CA Process Automation, CA Service Desk Manager, CA Business Intelligence, and other CA products that integrate with CA Service Catalog	8080
CA Service Catalog shutdown port	8085
Visualizer port for CA Service Desk Manager	9080
SQL Server server	1433
Oracle server	1521
CA EEM	5250
IMQ port of CA EEM	7676

If you are not using the default ports, verify that they are open. You do not need to open the shutdown ports for the products and components listed.

If you plan to implement clustering for CA Service Catalog, open all Apache JServ Protocol (AJP) and load balancing ports.

Decide the Service Provider Business Unit ID

During the CA Service Catalog installation, you specify a “service provider” business unit ID. This ID specifies the top level (root) business unit. All other business units are structured under the root business unit. As a best practice, specify your company domain name or a short version of your company name for this ID.

Note: After you have installed CA Service Catalog, you cannot change the business unit ID of the service provider. But, you can change the business unit login ID and the business unit name service provider.

Migrate Data Between CA Service Catalog Systems

You can migrate CA Service Catalog from one system to another system, to replicate your environment. You perform such a migration to move from a test system to a production system or as part of disaster recovery. You can also perform such a migration as part of upgrading using a migration model.

For clarity, use these terms:

- *test system* refers to all computers *from* which you are migrating
- *production system* refers to all computers *to* which you migrating

Thus, these terms describe a typical scenario where you migrate from a test system to a production system. If you are migrating for other reasons, the test system is the *source* system. The production system is the *target* or *destination* system.

This documentation assumes a multi-computer system architecture. For example, one computer for the DBMS, one computer for CA Service Catalog and Service Accounting Component and one computer for CA Process Automation. Unless indicated otherwise, *system* refers to *all* CA Service Catalog computers in your test or production, including the DBMS computer. If you are migrating one stand-alone CA Service Catalog system to another stand-alone system, ignore references to multiple computers.

Follow these steps:

- Step 1 - Verify Prerequisites for Data Migration (see page 576)
- Step 2 - Migrate the Data (see page 577)

Step 1 - Verify Prerequisites for Data Migration

Perform the following prerequisite tasks before you migrate CA Service Catalog. These tasks are required to help ensure that you can complete the migration process successfully.

1. Verify that the setup on the production system matches the setup on the test system. Verify that the production system has CA Service Catalog installed on the same number of computers as the test system. Verify that the same products and components are installed on each computer in the production system as its "matching" computer in the test system. You migrate from the old system to the new system incrementally in pairs.
   For example, suppose that the first test computer has installed CA Service Catalog, the Catalog Content, and Service Accounting Component. In that case, the first production computer must also have each of these components installed. Moreover, the production computer must not have any *additional* CA Service Catalog products and components installed.

2. Verify that the business unit ID of the service provider is *the same* in both systems.

   Important! The service provider business unit ID for the new installation *must match* the previous installation.

Verify that all computers in both systems are at the same patch level for all important software.

- Verify that the CA EEM Application Name for CA Service Catalog is the same on both the test and production systems. By default, the name is *Service Catalog*.
  If necessary, update the Application Name, on either or both systems.

- Stop the CA Service Catalog services on all CA Service Catalog computers using the Windows Control Panel.

- Back up the MDB of your *production* system and also your *test* system, on the computer where the MDB is installed. This requirement applies, regardless of whether the system is installed on one computer or multiple computers.

You have performed the prerequisite tasks for migrating CA Service Catalog.

Step 2 - Migrate the Data

You can migrate CA Service Catalog products and components from one system to another.

Follow these steps:

1. Restore the MDB database backup of the test system into your production system. During this process, select the option for overwriting the existing MDB database.

Unregister the CA EEM application that the production system uses, as follows:

1. Log in to the Global Application of CA EEM as the EiamAdmin user.
   If your systems use a different name than *Service Catalog* for the CA Service Catalog application name, use that name.

2. Select Configure, Applications, Service Catalog application and click the UnRegister button.

- Back up the CA EEM data on the CA Service Catalog computer in your test system, as follows.
  If you have multiple CA Service Catalog computers, perform this step on the *first* CA Service Catalog computer. You run this command once, regardless of how many CA Service Catalog computers your system has.

  1. Open the CA Service Catalog command prompt by clicking Start, Programs, CA, Service Catalog, Service Catalog Command Prompt.
  2. Run the following command at the command prompt:

     ```
     ant backup-eem-app
     ```

     This action generates a file that is named eem-backup.xml in the USM_HOME directory.

- Copy the following files from the test CA Service Catalog computer to the production CA Service Catalog computer.
  If you have multiple CA Service Catalog computers, perform this step on the *first* CA Service Catalog computer in each system. You copy these files once, regardless of how many CA Service Catalog computers your system has.

  - USM_HOME\seeddata.properties
  - USM_HOME\filestore folder
    This folder can exist on a different computer than the current computer. To verify its location, select Administration, Configuration, Filestore Information. As a best practice, soon after the migration, set up a single location for shared files (see page).
  - USM_HOME\eem-backup.xml

- Run the following commands on all CA Service Catalog computers in the production system, one computer at a time.

  1. Update the password of the database user (see page 1514) to ensure that CA Service Catalog continues to run efficiently throughout your environment. (see page 1511)
  2. Update the database host, password, instance, service name, or port (see page 1511) for the database, as needed.

     Important! The database host name that you specify must be different from the one used in the test system. Updating the other settings is optional.

  3. Run the ant restore-eem-app command.
     This command restores the CA EEM database from test to production, using the eem-backup.xml that you copied.
  4. Run the ant update-usm-host command.
     This command enables you to change the host name and port number for a computer running CA Service Catalog.

Important! All host names for production CA Service Catalog must be different from the ones in the test system. Updating the other settings is optional.

For more information about this command, see Update the Host Name and Port Number Using the ant Command (see page 1513) section.

- Start all CA Service Catalog services on all computers in the production system.
- Log in to CA Service Catalog in the production system. Select Administration, Configuration. Update the configuration sections for Filestore, CA Service Desk Manager Integration, and CA CMDB Integration.

Important! If your post-migration environment does *not* include any option in the list, update the configuration settings to *remove* the integration! Similarly, if your post-migration environment *does* include any of these options, perform the following step: Verify that the host names, port numbers, and other configuration data are correct for your post-migration environment. Remember that setting up a filestore location is a best practice.

- Test by verifying that the same users, services, and requests, that existed in test also exist in production.

How to Upgrade CA Service Catalog

Decide whether to perform a traditional or migration model upgrade (see page 580). Note the value of all parameters for all business units in your implementation before you upgrade. After you upgrade, set the parameters accordingly.

- If you are running CA Service Catalog 12.6 through 12.9, you can upgrade directly to the current release using *either* a traditional model or migration model upgrade (see page 580).
- If you are running CA Service Catalog 12.5, the following options apply:
  - Upgrade directly to the current release using a migration model.
  - *First* upgrade to 12.6. Next, use a traditional model to upgrade to the current release.
- You *cannot* upgrade from one DBMS to another. For example, you cannot upgrade a CA Service Catalog 12.7 installation running SQL Server to the current release of CA Service Catalog installation running Oracle.
- The installer upgrades CA Service Catalog in its existing installation directory, except in the following case: If you perform a migration model upgrade to the current release of CA Service Catalog on a 64-bit computer, CA Service Catalog is upgraded to a 64-bit application, and its default installation directory is updated accordingly. (CA Service Catalog Release 12.6 and 12.7 were supplied as 32-bit applications.)

If required, also review the Hardware Requirements (see page 573) and Installation Prerequisites (see page 573) before you proceed with upgrading CA Service Catalog.

Traditional and Migration Model Upgrades

You can upgrade CA Service Catalog to the current release using *either* a migration model or a traditional model.

- In a traditional model, you upgrade on existing CA Service Catalog computers.
- In a migration model, you install the current release of CA Service Catalog on *new* computers. When you install CA Service Catalog on the new computers, you use the Catalog database and CA EEM computers.

The migration model works as follows:

Consider this sample scenario: Your setup has Catalog Component and the Catalog database on existing Computer 1. Catalog Component and Service Accounting Component are on existing Computer 2, and CA Process Automation on existing Computer 3. Perform the following actions:

- Verify that the current release of CA Service Catalog Release supports the DBMS version on existing Computer 1.
- Verify that the DBMS client software is installed on the new computers on which you plan to run the upgrade.
- Install Catalog Component on new Computer 4, pointing to the existing Catalog database on existing Computer 1. Similarly, install Catalog Component and Service Accounting Component on new Computer 5. When you are prompted for information about the Catalog database or CA EEM, use the *existing* Catalog database and CA EEM specifications, such as the CA EEM host name and application name.
- Utilize CA Process Automation on Computer 3.

> **Note:** Do *not* upgrade or delete CA Service Catalog on existing Computer 1 until all other computers are upgraded to the current release of CA Service Catalog and are running successfully.

Follow these steps :

- Step 1 - Plan your CA Service Catalog Upgrade (see page 580)
- Step 2 - Upgrade CA Service Catalog (see page 586)
- Step 3 - Perform CA Service Catalog Post-Upgrade Tasks (see page 587)

Step 1 - Plan your CA Service Catalog Upgrade

This article contains the following topics:

Preparing for the upgrade is a required task whether you upgrade using a migration model or a traditional model.

Follow these steps:

1. Find and list all computers in your implementation that have one or more CA Service Catalog components installed. Use this list to help verify that you upgrade all required computers efficiently and in the correct sequence.

2. Stop all Windows services for your existing release of CA Service Catalog.

3. Review whether you have shared any of the folders under CA Service Catalog and Shared Components. If the folders are shared, unshare them before the upgrade and restore the share after the upgrade is finished.

4. Verify that your *user ID* is defined as an administrator with *elevated privileges* on each *applicable Windows computer*, as follows:

   - ***user ID***
     Specifies your administrative user ID for the Windows computer (*not* your user ID for CA Service Catalog).

   - ***elevated privileges***
     Specifies additional rights in Windows that are available to administrative users only. To install or upgrade CA Service Catalog, administrators require the elevated privilege named Log on as Service.

   - ***applicable Windows computer***
     Specifies a Windows computer on which you plan to install or upgrade CA Service Catalog and which supports elevated privileges for administrators.

5. Verify that your administrative user ID has Log on as Service rights on each applicable Windows computer, as follows:

   a. Click Start, All Programs, Administrative Tools, Local Security Policy, Security Settings, Local Policies, User Rights Assignment, Log on as Service.

   b. Verify that your administrative user ID is listed.

6. (Migration Model Upgrade Only) If you have an existing filestore that you want to continue using after the upgrade, perform this step. Otherwise, skip this step.
   Record the computer name and the complete pathname of the filestore. Save them for reference after the upgrade.
   For traditional upgrades, the filestore is backed up to the following location:
   C:\Program Files (x86)\CA\Service Catalog\SCA_Backup\previous_release\r12.*n*\Service Catalog
   r12.*n* is 12.6, 12.7, 12.8, or 12.9 depending on the version from which you are upgrading.

7. Perform the following actions in your current implementation:

   - Prepare the catalog database and the DBMS (see page 582)

   - Back up CA EEM data (see page 584)

8. Record any customizations that you made to XML, XSL, or other CA Service Catalog files, for example, server.xml. The upgrade program installs new versions of these files. After the upgrade, you can make the same customizations to the new versions of these files. Follow the same process for any customizations that you made to related third-party files such as Tomcat files.

9. If you have copied the installation media to a network share, map a drive letter to this share. This mapping is required because a batch file runs as part of the upgrade, and batch files cannot run from a UNC path.

You have prepared for the upgrade.

Prepare the Catalog Database and the DBMS

Prepare the Catalog database and the DBMS for the upgrade.

Follow these steps:

1. Review the contents of the Catalog database:
   - The Management Database (MDB) tables that apply to CA Service Catalog; their names typically begin with a CA_ prefix. The MDB is the common, shared database for CA Technologies products. The MDB provides the database schema for CA Service Catalog and other CA Technologies products.
   - The CA Service Catalog-specific tables; their names typically begin with a USM_ prefix. These tables are not included in the MDB.
2. Back up your existing Catalog database on the computer where it currently resides.
3. Optimize the System Change Detail tables (see page 583).
4. If applicable, on your DBMS server, upgrade your Oracle or SQL Server software to a supported version.
5. Apply all patches and other maintenance for your DBMS (SQL Server or Oracle).

Note: For more information, see your SQL Server or Oracle documentation.

6. Remove replication in your DBMS.

Important! When replication has been added, the database tables are locked from any schema changes, even if replication is turned off. As a result, the upgrade cannot run successfully. For information about how to remove replication, see your DBMS documentation. Also see that documentation for more information about how to add it again, after you have completed the upgrade.

7. Verify that the DBMS client software is installed on the computer from which you plan to run the installation program.

Optimize the System Change Detail Tables

The System Change Detail tables are important for auditing and database performance. You can optimize the System Change Detail tables by eliminating redundant or obsolete records. This procedure helps optimize the performance of the database and CA Service Catalog.

Follow these steps:

1. Determine the number of each type of record, as follows:

    a. Enter the following command to determine the number of useful records:

    ```
    select count(*) from usm_system_change_detail where old_value!=new_value
    ```

    b. Enter the following command to determine the number of obsolete records:

    ```
    select count(*) from usm_system_change_detail where old_value=new_value
    ```

    Complete the remaining steps if a significant number of obsolete records exist, especially If more obsolete records than useful records exist. Otherwise, skip the remaining steps and finish preparing the Catalog database and the DBMS.

2. Enter the following command to filter the useful records from usm_system_change_detail table into a temporary table:

    ```
    Select * into usm_system_change_detail_temp from usm_system_change_detail where old_value!=new_value
    ```

3. Drop usm_system_change_detail table, as follows:

    a. Back up the indexes and database constraints for the following tables:

    - usm_system_change_detail
    - usm_system_change_detail_ext

    Note: For more information about how to perform the backup, see your DBMS documentation. For a sample script that restores indexes and constraints, see the sample script for SQL Server that follows these steps.

    b. Drop the foreign key constraints for the usm_system_change_detail_ext table.

    c. Drop the usm_system_change_detail table.

4. Rename the usm_system_change_detail_temp table to usm_system_change_detail.

5. Use the script that you created in Step 3a to restore the indexes and database constraints for the following tables.

   - usm_system_change_detail
   - usm_system_change_detail_ext

Sample Script

The following sample script applies to SQL Server. This script backs up indexes and database constraints. You can use this script as a model for backing up the indexes and database constraints in Step 3a.

```
ALTER TABLE [dbo].[usm_system_change_detail]
ADD CONSTRAINT [XPKusm_system_change_detail] PRIMARY KEY CLUSTERED
(
[id] ASC,
[name] ASC
)
WITH
(
PAD_INDEX = OFF,
STATISTICS_NORECOMPUTE = OFF,
SORT_IN_TEMPDB = OFF,
IGNORE_DUP_KEY = OFF,
ONLINE = OFF,
ALLOW_ROW_LOCKS = ON,
ALLOW_PAGE_LOCKS = ON
)
ON [PRIMARY]
ALTER TABLE [dbo].[usm_system_change_detail]
WITH CHECK ADD CONSTRAINT [$usm_s_r00002c5700000000] FOREIGN KEY
(
[id]
)
REFERENCES [dbo].[usm_system_change] ([id])
ALTER TABLE [dbo].[usm_system_change_detail]
CHECK CONSTRAINT [$usm_s_r00002c5700000000]
ALTER TABLE [dbo].[usm_system_change_detail_ext]
WITH CHECK ADD CONSTRAINT [$usm_s_r00002c6100000000] FOREIGN KEY
(
[id],
[name]
)
REFERENCES [dbo].[usm_system_change_detail] ([id], [name])
ALTER TABLE [dbo].[usm_system_change_detail_ext]
CHECK CONSTRAINT [$usm_s_r00002c6100000000]
```

Back Up CA EEM Data

Backing up CA EEM data is a required task whether you upgrade using a migration model or a traditional model.

Important! If CA EEM is configured with high availability, perform these steps on the Primary CA EEM server.

Follow these steps:

1. Back up your existing CA EEM on the computer where it currently resides, as follows:
    a. If other CA Service Catalog components exist on the same computer, shut down their Windows services.
    b. Log in to CA EEM; on the login page, select your current CA Service Catalog release as the application instance.
2. Click Configure, EEM Server, Export Application.
3. Perform the following steps:
    a. Select all check boxes under Object List, and verify that Override the Max Search Size is *not* selected.
    If CA EEM is configured with External Directory, clear these options: Global Users, Global User Groups, Global Folders, and Global Settings.
    b. Click Export.
    c. On the File Download prompt, select a location to save the ServiceCatalog.xml file. Record the location where you saved the file, for future reference.
4. Log out of CA EEM.
5. Back up the CA EEM data on the Catalog Component computer in your test system, as follows.

    Note: If you have multiple Catalog Component computers, perform this step on the *first* (formerly *primary*) Catalog Component computer *only*. You run this command once, regardless of how many Catalog Component computers your system has.

    a. Open the CA Service Catalog command prompt by clicking Start, Programs, CA, Service Catalog, Service Catalog Command Prompt.
    b. Run the following command at the command prompt:

    ```
    ant backup-eem-app
    ```

    This action generates a file named eem-backup.xml in the %USM_HOME% directory. USM_HOME is the documentation convention that specifies the local CA Service Catalog installation directory. For 32-bit computers, the default path name is C:\Program Files\CA\Service Catalog. For 64-bit computers, the default path name is C:\Program Files (x86)\CA\Service Catalog for 32-bit installations or C:\Program Files\CA\Service Catalog for 64-bit installations.

You have backed up CA EEM data.

Step 2 - Upgrade CA Service Catalog

This article contains the following topics:

Important! If you have an existing CA Business Intelligence 3.3, review this section (see page 285) before proceeding with the CA Service Catalog upgrade. Ensure that you have prepared CA Service Catalog for upgrade (see page 580) as well.

Upgrade From Release 12.8 or 12.9

If you are upgrading from CA Service Catalog 12.8 or 12.9, use the CA Service Management Installer to install CA Service Catalog (see page 590) on all CA Service Catalog computers, in any order. Follow the prompts to complete the upgrade.

Note: If you want to use custom port numbers, specify them in the fields provided. This requirement applies even if you specified custom port numbers in the previous release.

Upgrade from Release 12.6 or 12.7

Typically, your implementation includes multiple instances of CA Service Catalog installed on multiple computers. If you are upgrading CA Service Catalog in such an environment, upgrade the computers in the correct sequence.

Follow these steps:

1. If you are upgrading in a non-clustered environment, follow this sequence:
   a. Use the CA Service Management Installer to install CA Service Catalog (see page 590) on all computers that have Accounting Component or CA Workflow installed.

      Important! The current release of CA Service Management does not support CA Workflow. However, because you cannot upgrade Service View component without upgrading CA Workflow, you run the CA Service Management Installer even on the CA Workflow computers.

   b. Use the CA Service Management Installer to install CA Service Catalog (see page 590) on all computers that have the Service View component installed.

> **Note:** In a non-clustered environment, you can upgrade the first (primary) Service View computer and the additional (secondary) Service View computers in any order.

2. If you are upgrading in a clustered environment, follow this sequence:

1. a. Determine the the first (primary) Service View computer by checking the registry entries.

   - On 32-bit systems, the registry entry for the first Service View computer is as follows:
     HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\Service Catalog\View
     This key has the following value:
     PRIMARY VIEW - Yes

   - On 64-bit systems, the registry entry for the first Service View computer is as follows:
     HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\ComputerAssociates\Service Catalog\View
     This key has the following value:
     PRIMARY VIEW - Yes

   b. Use the CA Service Management Installer to install CA Service Catalog (see page 590) on all computers that have Accounting Component or CA Workflow installed.

> **Important!** If one of those computers is the first Service View computer, do not upgrade it now. Instead, upgrade it after you have completed the next step.

   c. Use the CA Service Management Installer to install CA Service Catalog (see page 590) on all additional (secondary) Service View computers and then on the first (primary) Service View computer.

You have upgraded CA Service Catalog to the current release.

Step 3 - Perform CA Service Catalog Post-Upgrade Tasks

Finalizing the upgrade is the last required task when you upgrade CA Service Catalog.

Follow these steps:

1. If you upgraded to CA EEM Release 12.51 in a clustered setup, you updated the MaxKeepAliveRequests property in the Apache proxy.conf file to meet the CA EEM installation requirements. In that case, reset the MaxKeepAliveRequests property to its original value.

2. Reset the JMS port number, (see page 598)if necessary.

3. Log in to the root business unit of CA Service Catalog as a Service Delivery administrator.

4. If you are performing a migration model upgrade from CA Service Catalog 12.5, perform this step. Otherwise, skip this step.

    a. Click Catalog, Configuration, System Configuration.
    The System Configuration page appear.

    b. Set the value of the **Use Service Provider Catalog Only** option to Yes or No. You decided the value when you prepared for the upgrade (see page 580). For more information about this option, see System Configuration (see page 1461).

    Note: The value that you set applies to the entire Catalog system.

5. Verify that you and other users can log in to CA Service Catalog on the new computers. Verify that the CA Service Catalog components are working properly.

6. If you integrated CA Service Catalog with CA Service Desk Manager in the previous release, update the host computer names. Also reconfigure the other connection details between the two products.

7. If you enabled the following features in the previous release, to continue using them, enable them for this release:

    - Secure Socket Layer (SSL)
    - Windows NTLM authentication

    Note: These options are disabled by default, for both new installations and upgrades. Verify that your configuration specifications were retained and reset them, if necessary.

8. Set up shared and customized files (see page 588). This step can include re-applying customizations from the previous release and setting up the filestore, if applicable.

9. (Migration Model Upgrades Only) Uninstall (see page 626) the previous versions of CA Service Catalog products and components from the "old" CA Service Catalog computers. If you installed a new version of CA EEM, uninstall the old version of CA EEM from the old CA Service Catalog computers.

You have finalized the upgrade.

Set Up Shared and Customized Files

Setting up shared and customized files is a required task when you finalize the upgrade. For example, re-apply any customizations that you recorded for XML, XSL, or other CA Service Catalog files when you prepared for the upgrade.

Follow these steps:

1. (Multiple Catalog Component Computers) Perform the following steps:

    a. If you have not already done so, set up the filestore (the single location for shared files). Otherwise, skip this step.

    b. Click Administration, Configuration, Filestore on any Catalog Component computer. Verify that the filestore location is correct. If necessary, correct the location.

    c. Access the filestore computer and verify that the filestore folder includes the themes folder. If necessary, copy the themes folder to the filestore folder.

2. To use the old filestore location, if applicable, proceed as follows. Otherwise, skip this step.

    a. Copy the themes folder from the local filestore to the old filestore.

    b. Click Administration, Configuration, Filestore.

    c. Specify the original filestore location. You recorded this location when you prepared for the upgrade (see page 580).

3. Copy all filestore contents (files shared by all users in the environment) from the previous filestore location to the new location, as follows:

    - Documents: Copy from USM_HOME\view\documents to % USM_HOME\filestore\documents
    - Images:
        - Copy from USM_HOME\view\webapps\usm\images\offerings to % USM_HOME\filestore\images\offerings
        - Copy from USM_HOME\view\webapps\usm\images\rateplans to USM_HOME\filestore\images\rateplans
    - Forms: Copy from USM_HOME\view\forms to USM_HOME\filestore\forms
    - Custom directory: Copy any files that you want to update or replace from USM_HOME\view\webapps\usm\custom to USM_HOME\filestore\custom

    Note: Your installation can have some or all of these folders, depending on the previous version of CA Service Catalog that was installed.

4. Re-apply any customizations that you recorded for XML, XSL, or other CA Service Catalog files, such as category.xml or requestshared.xml. Restore or verify your customizations, as follows:

- (Migration model upgrade only) Compare each customized file that you backed up earlier with the files supplied in this release. Update the new file with your customizations from the backup file.
  Follow the same process for any customizations that you made to related third-party files such as Tomcat files.

  Important! You can replace certain new files with your backup files, in certain cases. However, *before* doing so, contact Technical Support and verify each file that you want to replace.

- (Traditional upgrade only) Review any CA Service Catalog files that you customized, such as custom.xml or requestshared.xml. Verify that your customizations are intact and are applicable for this release.
  The traditional upgrade automatically backs up customized files before the upgrade and restores them after the upgrade.

5. Perform this step if you customized the CA Service Repository Agent in the previous release and you want to continue using the same customizations for this release:

   Note: The CA Service Repository Agent is also named the Data Mediation Data Repository Agent. This repository agent automates the process of importing usage data in Delimiter Separated File format or Fixed Length File format.

You have set up shared and customized files.

Step 2 - Install CA Service Catalog

Important! Ensure that you have reviewed the CA Service Catalog Planning (see page 564) section before proceeding with this installation.

Use the CA Service Management Installer to install either only the CA Service Catalog product or Integrate CA Service Catalog with Unified Self-Service. Integration with CA Unified Self-Service lets you open a request and monitor the progress of this request.

Note: To connect to MS SQL database while installing the Unified Self-Service console, use the MS SQL server authentication method. Windows authentication is not supported.

Follow these steps:

1. Ensure that you complete the following steps by running the CA Service Management Installer (see page 296):

    a. Select a language and **CA Service Management** from the **Select the required installer** screen

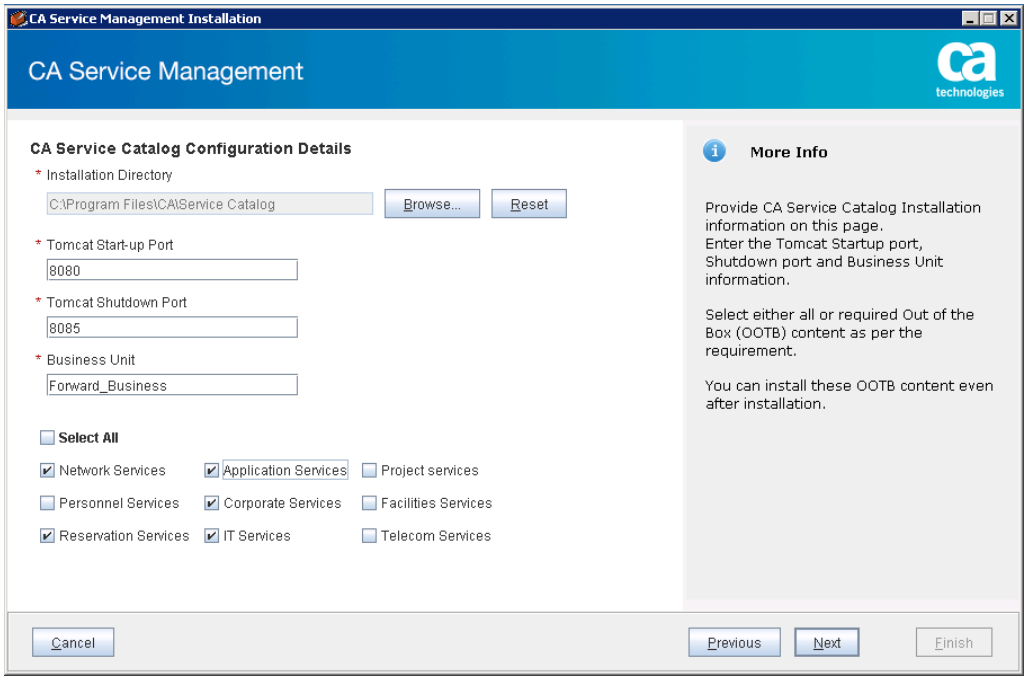
    b. Accept the license agreement.

    c. Enter the database information correctly.

    d. Select **CA Service Catalog** from the **Select the Products and Integrations** screen. If you want to integrate Unified Self-Service with CA Service Catalog, keep the check box for Unified Self-Service selected.

    e. Review the **Installation Prerequisites** report and taken corrective measures, if required, to proceed with the installation.

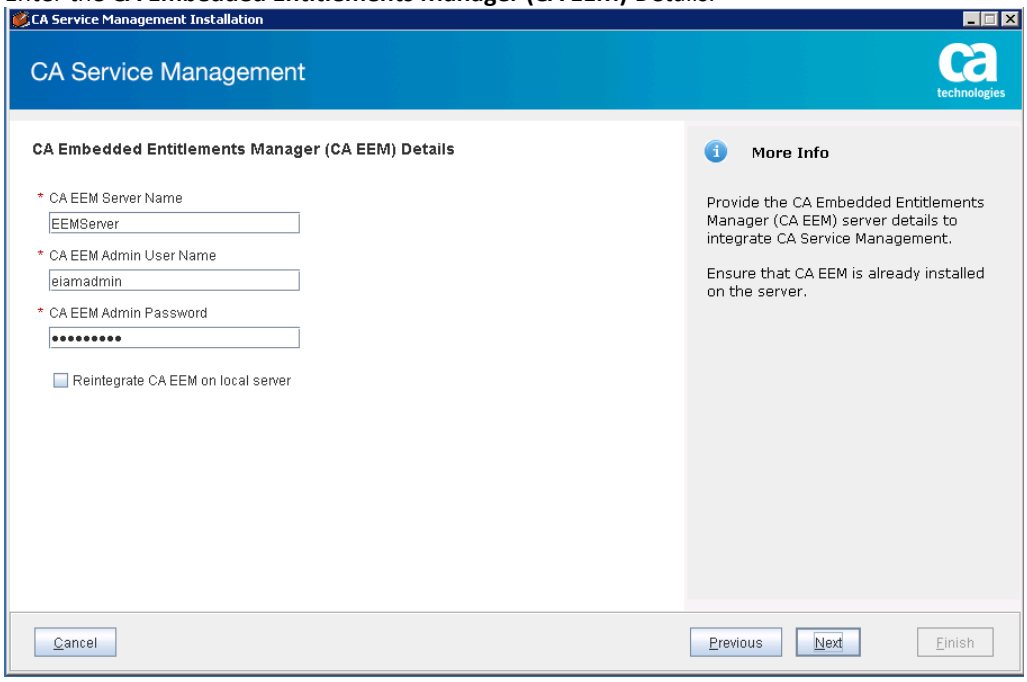
2. Specify the services you want to configure at the time of installation in the **CA Service Catalog Configuration Details** screen.



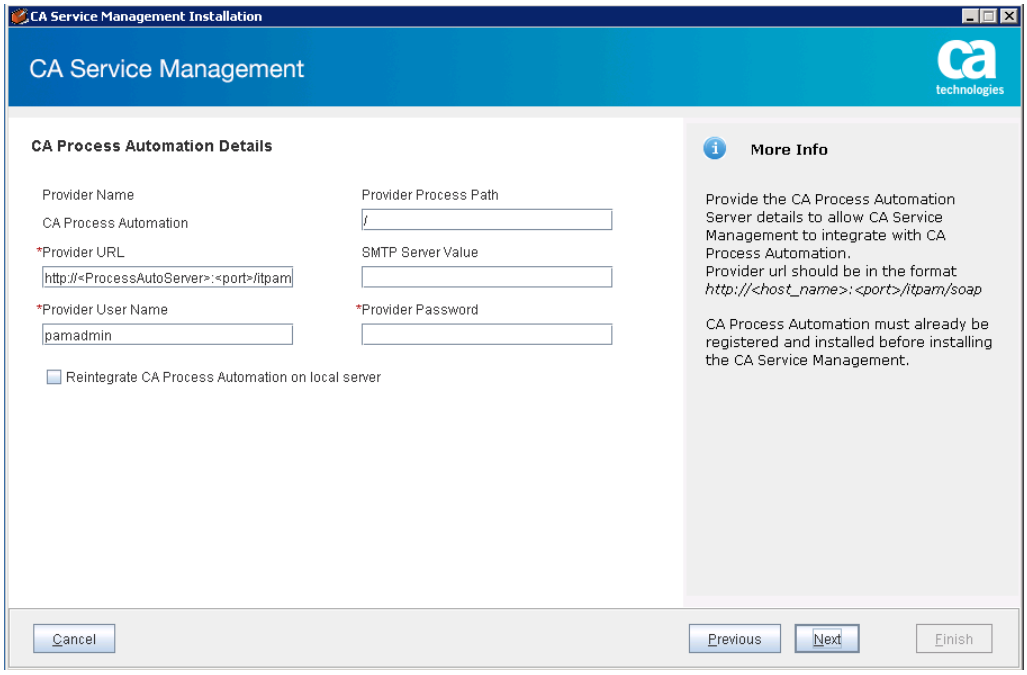
CA Service Catalog Configuration Details

3. (Optional). Enter details if you plan to integrate CA Service Catalog with Unified Self-Service. For more information, see the Install Unified Self-Service with CA Service Catalog (see page 593).

4. Enter the **CA Embedded Entitlements Manager (CA EEM)** Details.

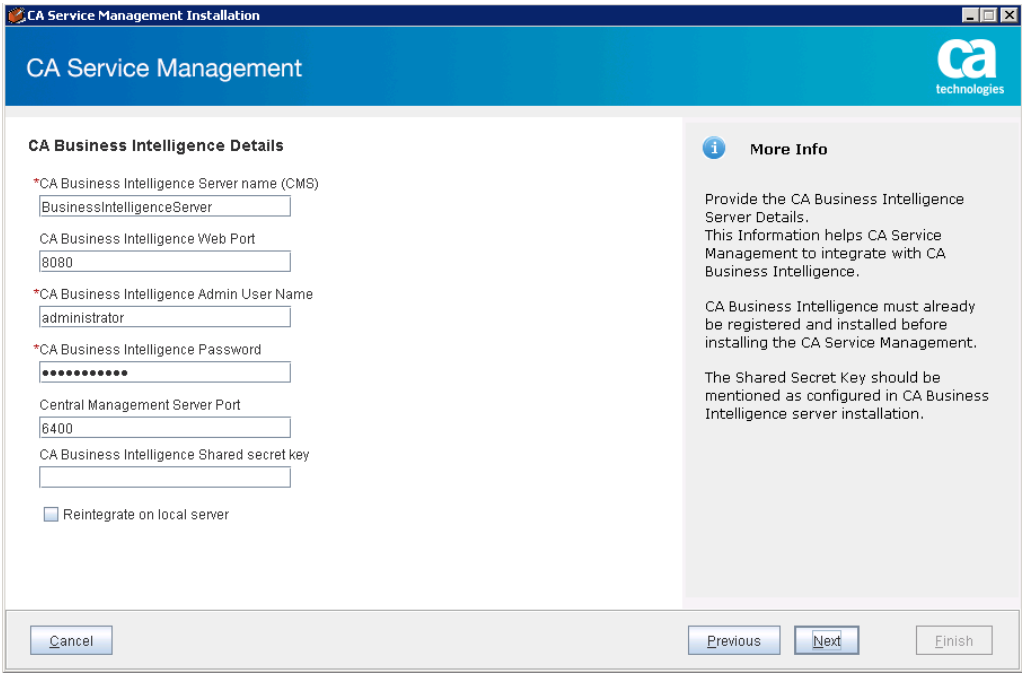


5. (Optional). Enter the CA Process Automation information in the **CA Process Automation Details** screen, if you intend to integrate CA Service Catalog with CA Process Automation.



CA Process Automation Details

6. (Optional). Enter the CA Business Intelligence information in the **CA Business Intelligence Details** screen to integrate CA Business Intelligence with CA Service Catalog.



CA Business Intelligence Details

7. Review the **Pre-Installation Configuration Summary** and verify that all the server and port information is correct.

8. Review the **Installation progress** information and click **Install** to install CA Service Catalog.

9. Review the log files stdout.txt and stderr.txt in the C:\ directory, if the installation failed. Fix the errors and click **Retry Install**.

10. Review the Installation Guidance Report summary to ensure that the installation was successful.

After the installation is complete, verify the CA Service Catalog installation by logging into the following URL as a Catalog administrator to view the CA Service Catalog User Interface:

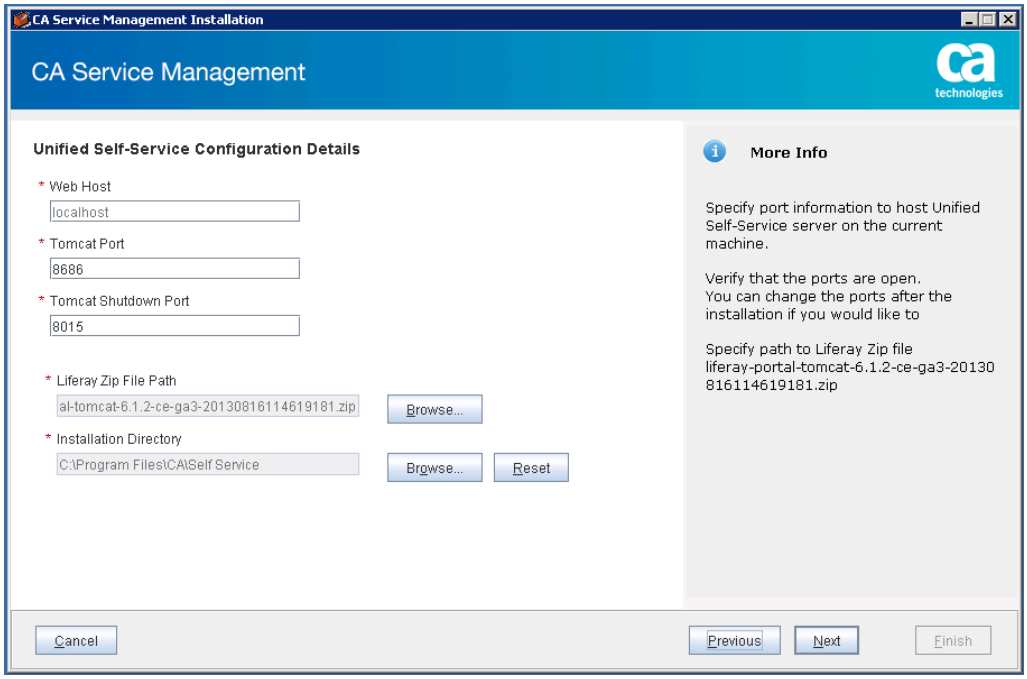
`http://<CA_Service_Catalog_Server_Name>:<Port_Number>/usm/`

You have successfully installed CA Service Catalog.

Install Unified Self-Service with CA Service Catalog

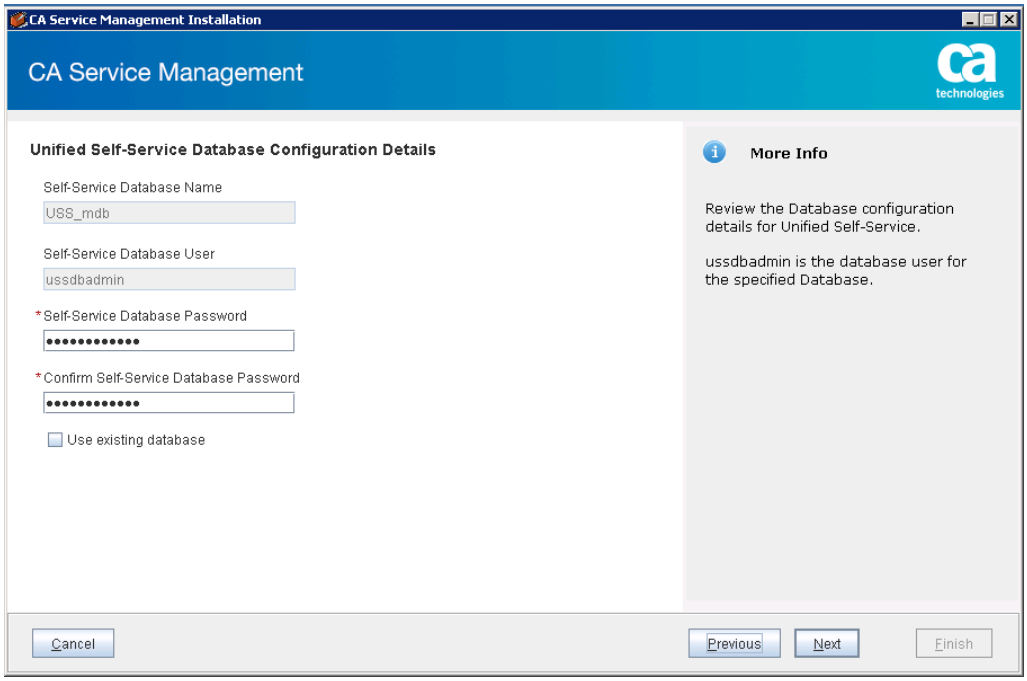
1. Enter the configuration details in the **Unified Self-Service Configuration Details** screen. Enter the Web Host as the host name of the machine where you are installing Unified Self Service.

> **Note:** Before you install Unified Self-Service, download Liferay CE 6.1.2 GA3 edition zip file (https://www.liferay.com/downloads/liferay-portal/available-releases). Do not Install Liferay manually as the installer unzips the downloaded file and installs Liferay.



Unified Self-Service Configuration Details

2. Enter the database information in the **Unified Self-Service Database Configuration Details** screen. If you have already set up a database, select the Use existing database check box and select the backup file. The database for Unified Self-Service is created during this installation.



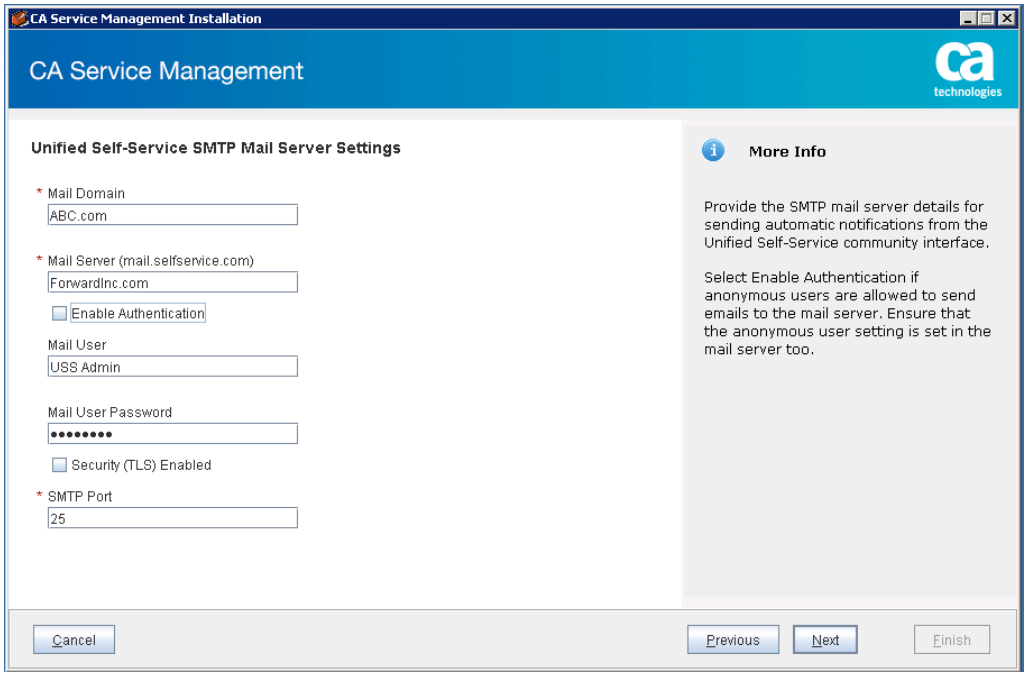
Unified Self-Service Database Configuration Details

3. Enter the SMTP mail server details to send automatic notifications from the Unified Self-Service community interface in the **Unified Self-Service SMTP Mail Server Settings** screen:

   - **Mail User**
     Defines the name of the mail user using which you want to send automatic notifications.

   - **Mail User Password**
     Defines the password of the mail user.

   - **Security (TLS) enabled**
     Specifies whether the TLS security is enabled or not for the mail server.



Unified Self-Service SMTP Mail Server Settings

You have entered all the Unified Self-Service information.

(Optional). After the installation is complete, verify the Unified Self-Service installation by logging into the following URL as an administrator to see the default tenant Home Page:

`http://<CA_Unfied_Self_Service_Server_Name>:<Port_Number>/`

Note: For optimal performance, consider setting up Unified Self-Service in a clustered environment (see page 619).

You have successfully installed the Unified Self-Service Console.

Step 3 - Perform CA Service Catalog Post-Installation Tasks

As part of implementing CA Service Catalog, review the following post-installation tasks and perform the tasks that apply:

- Update MaxKeepAliveRequests (see page 596)
- Assign the Service Delivery Administrator Role to a User (see page 596)
  - Change Your Password (see page 597)
- Create Users and Services (see page 598)
- Reset the JMS Port Number (see page 598)
- Install and Integrate Additional Process Automation Tools (see page 599)
- Configure JRE 1.8.0_45 (see page 599)
- Enhance Security (see page 600)
- Set Up Single Location for Shared Files (see page 601)
  - Retain the Default Location for Shared Files (see page 601)
  - Set Up a Custom Location for Shared Files (see page 602)
- Verify that Browser Security Settings Permit Login (see page 603)

After you perform the post-installation tasks that apply, you can also implement clustering (see page 604).

Update MaxKeepAliveRequests

If you installed CA EEM 12.51 in a clustered setup, you updated the MaxKeepAliveRequests property in the Apache proxy.conf file to meet the CA EEM installation requirements. Now, reset the MaxKeepAliveRequests property to its original value.

Note: The installation or upgrade program backs up your existing CA EEM data to the following location:

USM_HOME\conf-backup\upgrade-eem-backup.xml

Assign the Service Delivery Administrator Role to a User

Typically, the CA Service Catalog installation creates a user named *spadmin* and assigns it the Service Delivery administrator role. This user has complete control of the Catalog system. By default, the user name and the password are the same.

However, if *all* of the following conditions exist, then the installation *cannot* create this user.

- You have installed CA Service Catalog for the first time (*not* upgraded).
- CA EEM is already installed.
- CA EEM is already configured to use an external store, such as Microsoft Active Directory.

In this case, assign the Service Delivery Administrator role to another user. Doing so enables this user to log in to CA Service Catalog using the Service Delivery Administrator role. You can also assign the Service Delivery Administrator role to additional users. Doing so is optional but is beneficial if redundancy is important in your organization.

Follow these steps:

1. Open the CA Service Catalog command prompt by clicking Start, Programs, CA, Service Catalog, Service Catalog Command Prompt.

2. Enter the following command at the CA Service Catalog command prompt:

   ```
   ant add-spadmin-user
   ```

   Note: For a list of ant commands and their descriptions, enter ant -p.

3. Follow the prompts to add the spadmin administrator role to a specific user, using the following information:

   - If CA EEM *is* configured to use an external directory (such as Microsoft Active directory), specify an existing user name.
   - The command utility creates the user in the CA Service Catalog user database, if both of the following conditions exist:
     - CA EEM is *not* configured to use an external directory.
     - The user name that you specify is new.
   - The command utility does *not* prompt you for the password of the new or updated user.
   - If CA EEM *is* configured to use an external directory, the password is defined and stored in the external directory.
   - The new password is the same as the user name, if both of the following conditions exist:
     - CA EEM is *not* configured to use an external directory.
     - The user name that you specify is new.

4. If necessary, cancel and rerun the ant add-spadmin-user command to correct any errors.

5. Verify that the new or updated user can log in to CA Service Catalog as a Service Delivery Administrator and perform the spadmin functions.

6. (Optional) Instruct the new user to change the password (see page 597).

You have assigned the Service Delivery Administrator role to a user.

Change Your Password

Changing the password is especially recommended for the user named spadmin (the Service Delivery administrator). In addition, you can also change it at any time, for various security-related reasons.

Follow these steps:

1. Log in to CA Service Catalog with your current user name and password.
2. Click Profile.
3. Click the Change Password button at the top right of the page.
4. Enter your old and new passwords in the fields provided.
5. Click OK.

You have changed your password.

Create Users and Services

Once you have installed CA Service Catalog:

- Set up users, user groups, business units, and accounts.
- Create and customize services that users can request from the catalog.
- Configure the processes for managing, approving, and billing for requested services.

For more information about how to perform these tasks, see Manage Business Units and Tenant Administration (see page 1395), Manage Users and Assign Roles (see page 1408), Manage Services (see page 2987), and Service Accounting (see page 3108).

Note: Do not add users, delete users, or change user information using CA EEM. We recommend that you use CA Service Catalog for managing users. CA EEM is then updated accordingly.

Reset the JMS Port Number

Reset the JMS port number only if you specified 7777 as the CA Service Catalog startup or shutdown port when you ran the installation program. We recommend that you do *not* use port 7777 as the startup or shutdown port. Port 7777 is reserved for Java Messaging Service (JMS).

Important! If you must use port 7777 for the startup or shutdown port, reset the JMS port number after you have finished running the setup utility. Otherwise, port conflicts occur, and the product does not function correctly.

Follow these steps:

1. Open the file that is named USM_HOME/config.properties in a text editor.
2. Update the value of the jms.port property to a new value.
3. Restart the Windows service named CA Service Catalog.

You have reset the JMS port number.

Install and Integrate Additional Process Automation Tools

For best performance, CA Service Catalog requires a process automation tool. You can use CA Process Automation to automate processes in CA Service Catalog. Even though you can *install* CA Process Automation at any time, we recommend that you install CA Process Automation with CA Service Catalog using the CA Service Management Installer.

Important! If you install two or more instances of CA Service Catalog, implement clustering *before* you integrate CA Service Catalog with CA Process Automation.

Configure JRE 1.8.0_45

The CA Service Catalog installation program automatically installs the Java Runtime Environment (JRE). We recommend that you use the JRE version *1.8.0_45* that is installed by CA Service Catalog. You can configure CA Service Catalog to use or replace the JRE version, if required, as follows.

Follow these steps:

1. Install the JRE version 1.8.0_45, if not already installed.
   For example, install the JRE version from www.java.com (http://www.java.com) or one of its affiliated sites.
2. Open the Service Delivery Command Prompt from the CA Service Catalog section of the Windows Start menu. Enter the following command:

   ```
   ant upgrade-jre
   ```
3. Close all CA Service Catalog Windows services when prompted.
4. Enter the path name where you have installed the new JRE version.
5. Enter the new JRE version number. For example, 1.8.0_45.

   Wait for the CA Service Catalog system to verify that it supports the new JRE version.

   Note: If you receive a failure message, check the file Build.xml under Catalog home and check for statement new.jre.is (http://new.jre.is)**.supported**.

Check the JRE version again. If it remains unchanged even after you complete the upgrade process, change it manually.

6. Perform steps 2, 3, and 4 again. In case of failure, try using a different JRE version that is supported by CA Service Catalog.

   Note: For 32 bit JRE, change the path of jvm.dll from *<available file=${new.jre.dir} /bin.server" property="new.jre.has.server" /> to <available file="${new.jre.dir}/bin" property="new.jre.has.server" />*.

   The 64-bit JRE, jvm.dll is located in *C:\Program Files\Java\jre1.8.0_45\bin\server* and the 32-bit JRE is located in *C:\Program Files (x86)\Java\jre1.8.0_45\bin\client*.

   Close the command prompt.

7. Restart all CA Service Catalog Windows services and verify that you can log into CA Service Catalog.

   Note: If services fail to start, check the folder path *C:\Program Files\Java\jre1.8.0_45\bin*. Create a folder and name it as **Server**. Copy the contents of the **Client** folder in the **Server** folder. For 32-bit JRE, jvm is located in *C:\Program Files (x86)\Java\jre1.8.0_45\bin\client*. Check the service catalog.log in *C:\Program Files (x86)\Java\jre1.8.0_45\bin\server\jvm.dll*.

   You can log in and access CA Service Catalog using a different version of JRE.

Enhance Security

To enhance security in your CA Service Catalog implementation, *consider* making the following configuration changes:

- Disable the Apache JServ Protocol (AJP) port, port 8009 while performing the initial setup, if you are *not* implementing clustering.
  To disable AJP, edit the USM_HOME\view\conf\server.xml file and verify that the AJP tags are commented out.

- Reduce the timeout of CA Service Catalog user sessions. By default, sessions time out after 60 minutes of inactivity.
  To reduce the timeout, log in to CA Service Catalog, click Administration, Configuration, User Default. Adjust the **Session Timeout** parameter.

- Configure the CA EEM password policies to be more secure, if CA EEM is *not* configured to use an external directory.
  Specifically, consider locking user accounts after three to five failed login attempts. To set this value, log in to CA EEM and click Configure, EEM Server, Password Policies.

- Update the list of roles that can run web services. By default, only the Certificate user and users with the service provider (SP) administrator role can run web services.
  To change this list, log in to CA EEM with the Application set to Service Catalog. Click Manage Access Policies, Policies, Acess Policies, USM_Resource. Edit the policy whose permissions you want to update, and add the resource that is named usm_webservice__all to that policy.

  Note: For more information about editing these policies, see your CA EEM documentation (https://wiki.ca.com/display/eem1251/Policies).

- Enable Secure Socket Layer (SSL) for web services so that passwords are not sent in plain text when you use the logIn(String,String,String) method. If SSL is not available, consider using the logInToken(String) method instead. This method takes a CA EEM artifact as a parameter and is encrypted.

- Install antivirus software on the filestore computer, if you are using a filestore (see page) (a single location for shared files). We recommend that you use a filestore.

- Harden CA Service Catalog computers.
  Hardening is the process of securing a computer by removing or disabling components or access points, to render the computer less vulnerable to outside attacks. Hardening can include disabling all ports on a computer initially and afterwards manually enabling individual ports as needed. Other basic hardening steps include the following: Limit the number of users permitted access to a computer, strengthen password and access control, install intrusion-detection software, and close ports.

Set Up Single Location for Shared Files

If you have installed Catalog Component on multiple computers (either clustered or non-clustered), we recommend that you set up a single location for shared files. Shared files can include documents, reports, images of services, data mediation files, customizations, and forms.

By default, the location for shared files is the USM_HOME\filestore folder on *every* Catalog Component computer. This folder contains several subfolders. However, for optimal efficiency, you can specify *one* location on a single computer that all Catalog Component computers share. This single location is named the *central filestore* or *filestore*. The computer on which the filestore resides can have Catalog Component installed. However, Catalog Component is not required on that computer.

If you have installed Catalog Component on multiple computers and you do not set up a filestore, then verify that the individual filestores on all Catalog Component computers are synchronized.

If you have installed Catalog Component on a single computer, this entire process does not apply, so you can skip it.

Retain the Default Location for Shared Files

Setting up a single location for shared files helps improve the accuracy and efficiency of sharing files between computers.

Follow these steps:

1. Verify that all computers on which CA Service Catalog is installed have a trusted domain relationship. This trusted relationship enables user accounts and global groups to be used in a domain other than the domain where the accounts are defined.

2. Start the CA Service Catalog service with the login credentials of the Windows user that has read/write access to the shared location. If necessary, change the login credentials for the CA Service Catalog service to meet these requirements, as follows:

    a. Select Administrative Tools, Services.

    b. Right-click the service, click Properties, click the Log On tab, and enter the login credentials.

    c. Save the changes and restart the service.

3. Share the USM_HOME\filestore folder on the first CA Service Catalog computer as the filestore for all CA Service Catalog computers.

Set Up a Custom Location for Shared Files

You can create a custom location for shared files.

Follow these steps:

1. Share the folder to use as the filestore.

2. Verify that the Windows operating system users who are updating the filestore have read /write access to this folder.

3. Use the UNC path in the format *computer-name**folder-name* to specify the location of the filestore.

4. Start the Catalog Component service with the logon credentials of the Windows user who requires access to the folder.

5. Select Administration, Configuration, Filestore Information.

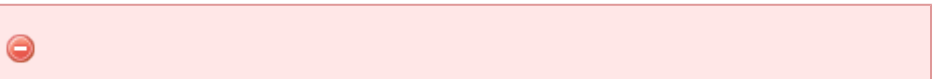
6. Perform the following steps:

    a. Click the Edit icon for the Filestore Location variable.

    b. In the Filestore Location field, specify the UNC path name of the shared drive you defined in a previous step, for example: \\big-computer\Shared_USM\filestore or \\big-computer\filestore.

    c. Click Update Configuration.

    d. Click Test to verify the validity of the share.
    This test returns a successful connection test message if the filestore can be used to store files that are uploaded by users.



Important! Testing the filestore is mandatory.

7. Perform the action that applies:
   - If the test succeeds, copy the entire contents of the USM_HOME\filestore folder to the new location.
   - If the test fails, reconfigure the share. Also, verify that all the CA Service Catalog services that are accessing the share have the same, valid credentials.
8. Recycle all CA Service Catalog services on all computers.

Verify that Browser Security Settings Permit Login

This topic applies *only* if you are using Internet Explorer to access CA Service Catalog. Your browser security settings can prevent you from seeing the user name and password prompts when you attempt to log in to CA Service Catalog. Therefore, verify your browser security settings to ensure that you can access CA Service Catalog.

Follow these steps:

1. Open Internet Explorer on the computer you want to use for accessing CA Service Catalog.
2. Enter the URL to start CA Service Catalog in the browser address field, in the following format:
   http://computer-name:port number/usm/
   - ***computer-name***
     Specifies the name of the computer that you want to log in to.
   - ***port number***
     Specifies the CA Service Catalog port number of that computer.
3. Verify that you see the CA Service Catalog login page, including the user name and password prompts.
   If Yes, this verification procedure is complete, and you can skip the remaining steps.
   If No, complete the remaining steps.
4. In Internet Explorer, open Internet Options, click Security, and perform *one* of the following steps:
   - Change the security level for the Local Intranet to Medium-High or Medium
   - Add the login URL for CA Service Catalog to your Trusted sites
5. Close and reopen your browser.
6. Enter the URL to start CA Service Catalog in the browser address field. Verify that you see the CA Service Catalog login page with the user name and password prompts.

You have verified your browser security settings to ensure that you can access CA Service Catalog.

(Optional) Implement Clustering

A *cluster* is two or more interconnected computers that create a solution to provide higher availability, higher scalability, or both.

A CA Service Catalog administrator can optionally use clustering for CA Service Catalog to improve performance and provide failover protection. Clustering means multiple computers in a group that perform the same or similar function, essentially acting as one virtual computer. Failover protection means that if one computer malfunctions, becomes heavily loaded, or loses power, its workload is transferred to the other computers in the cluster. These computers retain and complete the active sessions.

Another advantage of clustering is load-balancing. If one of the cluster components is processing a request, the load is redirected to another component in the cluster. Users of the system see no interruption of access. The loss of performance on users and business functions is minimized, even when computer availability is lost or reduced.

Clustering for CA Service Catalog is accomplished through the Catalog Component clustering. All user communications with catalog and accounting functions are accomplished through the Catalog Component. Thus, the term *Catalog Component clustering* includes both Catalog Component clustering and Service Accounting Component clustering.

In *horizontal clustering*, different physical computers comprise a cluster. As a result, the load balancer forwards requests to different computers having different IP addresses. All Catalog Component installations on all computers must use the same cluster of the MDB.

You can optionally install and cluster multiple instances of CA EEM and CA Process Automation.

Important! These instructions apply *only* to the Apache Tomcat web server version supplied with CA Service Catalog. If you are using any other web server instead, see your web server documentation for information about clustering.

Follow these steps:

- Step 1 - Verify Prerequisites for Clustering (see page 604)
- Step 2 - Set Up Horizontal Clustering for CA Service Catalog (see page 606)
- Step 3 - (Optional) Set Up NTLM Authentication for Each Cluster (see page 608)
- Step 4 - Set Up Load Balancing (see page 609)

Step 1 - Verify Prerequisites for Clustering

Perform the following preliminary tasks before you implement clustering:

1. Decide how many cluster nodes to create, depending on your design concerns and availability of resources.

2. Verify that the time and time zone on all clustered computers are the same.

3. Verify that the IPV6 protocol is disabled on all clustered computers.

4. Verify that no other application uses the following ports.
   By default, CA Service Catalog uses these ports for clustering, using the AJP protocol:

   - 8009 - for CA Service Catalog communicating with Apache HTTP Server
   - 8019 - for Service Fulfillment communicating with Apache HTTP server

5. Perform the following step if applicable:

   a. If another application uses one of these port numbers, eliminate the duplication. Use a different port number for either CA Service Catalog or the other application.

   b. If you use a different port number for CA Service Catalog, then also replace the old port number with the new port number. For example, if you change 8009 to a different port number, use the new port number instead of 8009.

6. Locate the multicast address for Tomcat in the server.xml file that is located in the USM_HOME\view\conf folder. This address is the value of the address attribute within the Membership tag.
   Default: 228.0.0.4

7. Locate the multicast address for Java Messaging Service (JMS) in the config.properties file that is located in the USM_HOME folder.
   Default: 239.255.2.3:6155

8. Run the following command at the DOS prompt of each clustered computer:

   ```
   netsh interface ip show joins
   ```

   The command lists all multicast addresses applicable to this computer.

9. Verify that this list includes the multicast addresses that you recorded from the server.xml and config.properties files:

   - If Yes, then skip the remaining steps in this topic.
   - If No, then use the list to determine a common multicast address applicable to all clustered computers. Complete the remaining steps.

10. Follow these steps:

    a. Update the multicast addresses in the server.xml files on all clustered computers and use this common address.

    b. In the config.properties files on all clustered computers, edit the JMS-related configuration section. Specify this common address, as shown in the following example.

    Important! The port number *must* be the same on each computer in the cluster.

```
#multicast://default = multicast://239.255.2.3:6155
#static:(tcp://<host1>:<port>,tcp://<host2>:<port>,...)
jms.networkConnectorUri = multicast://custom-ip-address:custom-port
jms.discoveryUri = static: multicast://custom-ip-address:custom-port
#jms.port = 7777
jms.port = custom-port
```

c. If you want to specify your nodes statically instead of using a multicast address, perform this step instead of step b.
In the config.properties files on all clustered computers, edit the JMS-related configuration section. Specify the host and port for all other computers in the cluster, as shown in the following example.
The port number can be the same value on each computer in the cluster, or it can be different.

```
#multicast://default = multicast://239.255.2.3:6155
#static:(tcp://<host1>:<port>,tcp://<host2>:<port>,...)
jms.networkConnectorUri = static:(tcp://host:custom-port)
jms.discoveryUri = static:(tcp://host:custom-port)
#jms.port = 7777
jms.port = custom-port
```

Note: Update the server.xml and config.properties files on all clustered computers before proceeding to the next step.

11. Restart the CA Service Catalog Windows service on all clustered computers.

Step 2 - Set Up Horizontal Clustering for CA Service Catalog

Perform this process on *every* computer on which you want to set up a horizontal cluster node for CA Service Catalog, including the first CA Service Catalog computer.

Note: Before you perform this procedure, verify that CA Service Catalog is installed locally.

Follow these steps:

1. As a prerequisite, if this computer is not the first-installed CA Service Catalog computer, perform the following steps:

   a. Verify that its host name is unique.

   b. Verify that its database is pointing to the database of the CA Service Catalog computer installed first.

2. Open the USM_HOME\view\conf\server.xml file for editing. Uncomment the Cluster tags, if they are commented:

3. Specify a unique port in the <Cluster> section for each CA Service Catalog computer:

```
<Receiver className="org.apache.catalina.tribes.transport.nio.NioReceiver"
      address="auto"
      port="4000"
      autoBind="100"
      selectorTimeout="5000"
      maxThreads="6"/>
```

4. Uncomment the Apache JServ Protocol (AJP) tags shown in the following lines, if they are commented:

```
<Connector port="8009" enableLookups="false" redirectPort="8443"
tomcatAuthentication="false"
      maxThreads="400" minSpareThreads="25" maxSpareThreads="100" protocol="AJP
/1.3" />
```

5. (Optional) Comment the HTTP ports Connector tags to improve security as follows:

```
<Connector port="8080" enableLookups="false" redirectPort="8443"
tomcatAuthentication="false"
      maxThreads="400" minSpareThreads="25" maxSpareThreads="100" debug="0"
connectionTimeout="15000"
      disableUploadTimeout="true" compression="on" compressionMinSize="2048"
      compressableMimeType="text/html,text/plain,text/xml,text/css,text
/javascript,image/png,image/gif,image/jpeg,application/json"
      useBodyEncodingForURI="false" URIEncoding="UTF-8" />
```

6. Save the file.

7. Review the ServiceCatalog.log file of each CA Service Catalog computer and verify that the replication cluster was added. For example:

```
INFO Cluster-MembershipReceiver org.apache.catalina.cluster.tcp.
SimpleTcpCluster - Replication member added:org.apache.catalina.cluster.mcast.
McastMember[tcp://141.202.143.77:4013,catalina,141.202.143.77,4013, alive=0]
```

8. Restart the CA Service Catalog Windows services: CA Service Accounting and CA Service Catalog.

9. If you are using NTLM authentication to enable single sign-on to CA Service Catalog, set up NTLM authentication for each cluster (see page 608).

You have set up clustering for CA Service Catalog.

Remove a Cluster

When necessary, you can remove a horizontal CA Service Catalog cluster. Sample reasons for doing so include the following conditions:

- This computer becomes obsolete.
- You want to install clustering on a different computer.
- This cluster is no longer needed.

Follow these steps:

1. Open the server.xml file of the horizontal cluster node that you want to remove.
2. Comment the cluster tag.
3. Restart the CA Service Catalog Windows service.

You have removed the cluster node. Next, verify that the load balancer setup no longer references this cluster.

Step 3 - (Optional) Set Up NTLM Authentication for Each Cluster

If you are clustering CA Service Catalog and you are using NTLM authentication to enable Single Sign-On to CA Service Catalog, then set up the cluster for Single Sign-On.

Follow these steps:

1. Perform *one* of the following actions on each cluster:
   - If you are using Apache Load Balancer, perform the following steps on each cluster to set up NTLM Authentication.
     a. Download the mod_auth_sspi module from the sourceforge web site, sourceforge.net.
     b. Copy the mod_auth_sspi.so module to the <APACHE_Home>\modules directory of the Apache web server that you use for CA Service Catalog.
     c. Append the following configuration section to the <APACHE_Home>\conf\httpd.conf file.

```
LoadModule sspi_auth_module modules/mod_auth_sspi.so

<Location ~ "/usm/(wpf|documents|FileStore)">

AuthName "domain_name"

AuthType SSPI

SSPIAuth On

SSPIOfferBasic On

SSPIAuthoritative On

SSPIDomain "domain_name"

SSPIofferSSPI off

require valid-user

</Location>
```

d. Replace *domain_name* with the name of your network domain or Windows domain in the file.

e. Verify that the tomcatAuthentication="false" attribute is set for the Tomcat connectors that this Apache load balancer uses.

2. If you *are* using a load balancer *other than* Apache Load Balancer, configure NTLM authentication for your load balancer first. Then configure Tomcat to use NTLM authentication for CA Service Catalog for each catalog cluster node, if both of the following conditions exist:

   - Your load balancer is not configured to perform NTLM authentication.
   - Your load balancer uses the HTTP Port (default 8080) to connect to Tomcat instances of CA Service Catalog. For more information about how to set up NTLM authentication, see your load balancer documentation.

3. Log in to any CA Service Catalog computer in the cluster.

4. Click Administration, Configuration, Single Sign On Authentication.

   Note: Perform this step and the remaining steps *once* in your implementation. You do not need to repeat these steps for individual clusters, because performing them once affects all clusters.

5. a. Locate the property that is named **Single Sign On Type** and click the Modify icon.

   b. Select the option that is named **Artifact Based Single Sign On** and click Update Configuration.
   The dialog closes, and you return to the Sign On Authentication page.

   c. Locate the property that is named **Artifact Type** and click the Modify icon.

   d. Set **Artifact Type** to the appropriate option for your load balancer, and click Update Configuration. For Apache Load Balancer, select Request.

6. Restart the CA Service Catalog Windows services to ensure that you have set up NTLM Authentication for the clusters.

Step 4 - Set Up Load Balancing

To load balance the existing nodes using Apache HTTP Server, follow these instructions. Perform this process *after* you have set up all cluster nodes.

Note: If you are implementing horizontal clustering on multiple computers, use the computers that have the same default gateway. To obtain the default gateway, enter the ipconfig command at the DOS prompt.

1. Install Apache Web Server load balancer for Windows version 2.2.25. You can download it from the Apache web site, apache.org.
   The default installation folder is C:\Program Files\Apache Software Foundation\Apache2.2.
2. Configure Apache HTTP Server. (see page 610)
3. (Optional) Disable Web Server Features. (see page 610)
4. Create and Configure the workers.properties File. (see page 611)
5. Create the uriworkermap.properties file. (see page 613)
6. Update the httpd.conf file. (see page 614)
7. Verify load balancing. (see page 616)

Configure Apache HTTP Server

Configuring Apache HTTP Server is a required task when you set up load balancing.

Follow these steps:

1. Access the Apache website, www.apache.org.
2. Find and download the file that is named mod_jk-1.2.30-httpd-2.2.3.so. CA Service Catalog supports mod_jk 1.2.30.
3. Rename the mod_jk-1.2.30-httpd-2.2.3.so file to *mod_jk.so*.
4. Copy the mod_jk.so file to the modules folder in the Apache Server installation.

You have configured Apache HTTP Server.

(Optional) Disable Web Server Features

Disabling the web server features of Apache HTTP Server improves performance and reduces potential security risks.

Follow these steps:

1. Delete the following folders under C:\Program Files\Apache Software Foundation\Apache2.2:
   - \cgi-bin
   - \errror
   - \htdocs
   - \icons
   - \manual

> **Note:** The "C:\Program Files\" portion of the path names reflect the typical location that is specified at installation time. This portion of your path names can vary depending on the installation directory that is specified for the \Apache Software Foundation folder at installation time.

2. Rename httpd.conf to _httpd.conf.bak in the C:\Program Files\Apache Software Foundation\Apache2.2\confdirectory.

3. Find the httpd.minimal.conf file.
   This minimal configuration file is included in the Utilities/Apache Webserver directory of the CA Service Catalog installation media.

4. Copy the httpd.minimal.conf file to C:\Program Files\Apache Software Foundation\Apache2.2\conf.

5. Rename the httpd.minimal.conf file to httpd.conf in that directory.

6. Delete all files in that directory *except* the following files:

   - httpd.conf
   - _httpd.conf.bak

7. Change to the C:\Program Files\Apache Software Foundation\Apache2.2\modules directory.

8. Delete all files in that directory *except* the following files:

   - mod_jk.so
   - mod_log_config.so
   - mod_setenvif.so

You have disabled web server features.

Create and Configure the workers.properties File

Creating and configuring the worker.properties file is a required task when you set up load balancing.

Follow these steps:

1. Create the workers.properties file manually in the \conf directory of the Apache installation folder.

2. Verify that the file lists all the Tomcat instances to include in the clustered environment.

3. Obtain the following information for each cluster node:

   - The host name of the clustered node
   - The ajp port of the clustered node. Obtain it from the connector port in the following line in the server.xml file of each cluster node:

```
<Connector port="8009"  maxThreads="150" tomcatAuthentication="false'
```

- The jvmRoute name of the node. Obtain it from the following line in the server.xml file of each cluster node:

  ```
  <Engine name="Standalone" defaultHost="localhost" debug="0" jvmRoute=
  ```

  For example, for the CA Service Catalog cluster node on the computer that is named XYZ, the jvmRoute name is XYZ_USMView.

  Important! Verify that the jvmRoute name is unique for each CA Service Catalog cluster. This name must be unique, because the load balancer uses it to identify each cluster. This name is case-sensitive.

4. Review the following sample worker.properties file sections for the types of clustering that you can perform. In all cases, the worker.properties file defines a load balancer node named loadbalancerview. This node balances CA Service Catalog requests among the CA Service Catalog cluster nodes. For example, this node load balances the /usm context between the workers defined. The context path /usm is defined in the USM_HOME\view\conf\server.xml file pointing to the CA Service Catalog web application.

5. Review the example (see page 613).

   a. Add a worker to the cluster, as follows:

      i. Create a worker section at the end of the worker.properties file, using the following lines as a model:

      ```
      worker.jvmRouteName.port=ajpport
      worker.jvmRouteName.host=HOSTNAME
      worker.jvmRouteName.type=ajp13
      worker.jvmRouteName.lbfactor=1
      ```

      ii. Verify that its jvmRouteName is unique.

      iii. Add the new cluster at the end of the list of balance workers for a loadbalancer node.
      For example, suppose that the jvmRoute name of the new worker is COMPUTER3_caff and its ajpport is 8019. In that case, enter the following new worker section to add the new cluster to the selected loadbalancer node:

      ```
      worker.COMPUTER3_caff.port=8019
      worker.COMPUTER3_caff.host= COMPUTER3
      worker.COMPUTER3_caff.type=ajp13
      worker.COMPUTER3_caff.lbfactor=1
      ```

      iv. Remove an existing cluster from the loadbalancer setup in the worker. properties file, as follows:

      1. Delete the section for the worker.

      2. Remove any references to the deleted worker from the list of balance workers.

The list of balance workers begins with the following line:

```
worker.<loadbalancernode>.balance_workers
```

You have created and configured the worker.properties file.

Horizontal Clustering Example for CA Service Catalog

This example illustrates how to use clustering to load balance the /usm context of CA Service Catalog between two workers. The cluster specifications are as follows:

Worker1:

- Hostname: Computer1
- JVMroutename: Computer1_USMView
- AJP port: 8009

Worker 2:

- Hostname: Computer2
- JVMroutename: Computer2_USMView
- AJP port: 8009

In these examples, Computer1 and Computer2 are the host names (computer names) of the workers.

Use the loadbalancerview node to load balance between the workers Computer1 and Computer2 as horizontal clusters for CA Service Catalog. To do so, define the loadbalancerview node sections of the worker.properties as follows.

```
worker.list=loadbalancerview
worker.status.type=status
worker.loadbalancerview.method=Busyness
worker.loadbalancerview.type=lb
worker.loadbalancerview.balance_workers=COMPUTER1_USMView,COMPUTER2_USMView
worker.loadbalancerview.sticky_session=1
worker.COMPUTER1_USMView.port=8009
worker.COMPUTER1_USMView.host=COMPUTER1
worker.COMPUTER1_USMView.type=ajp13
worker.COMPUTER1_USMView.lbfactor=10
worker.COMPUTER2_USMView.port=8009
worker.COMPUTER2_USMView.host=COMPUTER2
worker.COMPUTER2_USMView.type=ajp13
worker.COMPUTER2_USMView.lbfactor=10
```

Create the uriworkermap.properties File

Creating and configuring the uriworkermap.properties file is a required task when you set up load balancing. This file specifies which context the load balancer node selects and forwards to its cluster nodes.

Note: If the file exists already, update it to match the text in the following steps.

Follow these steps:

1. Manually create the uriworkermap.properties file in the \conf directory of the Apache installation folder.
2. Enter the following lines in the file:

   ```
   /usm|/*=loadbalancerview
   ```

3. Save the file.

You have created the uriworkermap.properties file.

Update the httpd.conf File

Updating the httpd.conf file is a required task when you set up load balancing.

Follow these steps:

1. Open the conf/httpd.conf file in the Apache HTTP Server installation directory and update it to include the following specifications:

   ```
   Listen 89
   LoadModule jk_module modules/mod_jk.so
   JkWorkersFile conf/workers.properties
   <VirtualHost *:89>
    ServerName load balancer host name
    JkMountFile conf/uriworkermap.properties
    JkLogFile logs/mod_jk.log
    JkLogLevel debug
   </VirtualHost>
   ```

2. Find the following lines:

   ```
   JkLogFile logs/mod_jk.log
   JkLogLevel debug
   ```

3. (Optional) Replace the lines in the previous step with the following lines:

   ```
   JkLogFile "|bin/rotatelogs.exe logs/mod_jk.log.%Y-%m-%d-%H_%M_%S 10M"
   JkLogLevel emerg
   ```

   This action modifies the mod_jk.log file on your production server to record only critical errors. The action also enables automatic rollover when the log file size reaches 10 MB.

4. Add a Listen directive with the port number for every VirtualHost port in the file.
   For example, suppose that you have defined a virtual host at port 89, as follows:

   ```
   <VirtualHost *:89>
   ```

   In that case, add the Listen directive for this port in the httpd.conf file, for example:

   ```
   Listen 89
   ```

   Note: The commonly used port is 89.

This specification enables the Apache HTTP Server to listen on this port and accept incoming requests.

5. Change the Default Type from text/plain to text/html.

   Note: This setting works well on most browsers. If you experience any difficulty with performance or display quality after changing this option, return it to its original value.

6. Save and close the conf/httpd.conf file.

7. Adjust related settings (see page 615) in other locations.

8. Disable the HTTP ports of the cluster computers (see page 615).

9. Configure the server information for the cluster computers (see page 616).

Adjust Related Settings

Adjusting related settings is a required task when you update the httpd.conf file.

Follow these steps:

1. Open your web browser. Set the proper values for the ServerAdmin and ServerName options.

2. Restart the Apache service, as follows:

   a. Open the Apache Service Monitor.

   b. Highlight the service to restart.

   c. Click Restart.

3. Test by accessing the link http://*hostname*:89/usm.
   Here, *hostname* specifies the load balancer computer, the computer on which the Apache HTTP Server is configured for load balancing.

4. Review the mod_jk.log file under the logs folder in the Apache directory to determine which jvmRoute node was called. An example follows:

   ```
   found worker HOST1__USMView (HOST1__USMView) for route COMPUTER1__USMVi
   ```

(Optional) Disable HTTP Ports

To enhance security, disable the HTTP ports of the cluster computers when you update the httpd.conf file. Doing so routes users directly to the load balancer computer rather than directly to a cluster.

Follow these steps:

1. Comment the connector tag that includes HTTP port information, in the server.xml files of each cluster computer. This port is the startup node that is provided during installation, typically 8080.

2. Recycle the CA Service Catalog Windows services of the clusters whose server.xml files were changed. The Windows services are named CA Service Accounting and CA Service Catalog.

Configure Server Information

Configuring the server information of the cluster computers is a required task when you update the httpd.conf file.

Follow these steps:

1. Click **Administration**, **Configuration**, **Server Information**, in the CA Service Catalog GUI.

2. Replace the server host name and port number with the load balancer host name and port number.

3. Recycle the CA Service Catalog Windows services of the clusters whose Server Information options were changed.

You have configured the server information of the cluster computers.

Note: If you do not perform this task, the following error occurs for users who request CA Service Catalog services using Internet Explorer 8.0: Forms that include a lookup field that calls a report object do not populate correctly when the user clicks the Search icon.

Verify Load Balancing

To test load balancing, verify that the load is distributed to other nodes when one of the nodes in the same cluster becomes busy. To test failover functionality, verify that the load is distributed to other nodes when one of the nodes in the same cluster shuts down.

Verify that *all* clustered nodes communicate efficiently with *all* load balancer computers using the telnet utility. If the clusters do not run efficiently, verify that this communication exists and check for any network configuration problems. For example, suppose that your load balancer host name is abc and the port is 89. Verify that you can successfully connect from all your clustered nodes using the following command from each node:

```
telnet abc 89
```

We recommend that you cluster your load balancer computers to help avoid single-point-of-failure problems with an individual load balancer computer. For more information, see the Apache website and other resources about how to cluster load balancer computers.

You can also record cluster-related logging information in the tomcat_view.log file.

Follow these steps:

1. Add the following section to the log4j.xml file for each CA Service Catalog computer:

```
<logger name="org.apache.catalina.cluster" additivity="false">
  <level value="TRACE" />
  <appender-ref ref="tomcat_view" />
</logger>
```

2. Set the log level for each log4j.xml file appropriately. For example, use a high log level while you are troubleshooting. Conversely, use a low log level, or comment out the previous lines, at other times.

Step 7 - (Optional) Enable Secured Sockets Layer (SSL) Authentication

Configuring the SSL authentication provides enhanced login security while allowing users to access a higher performance connection.

Perform the following steps to enable SSL authentication in CA Service Management.

1. Configure SSL Authentication in the Products of the Solution (see page 617).
2. Run the SSL Authentication Batch File (see page 617).
3. Enable SSL Integration (see page 618).

Configure SSL Authentication in the Products of the Solution

You must first configure SSL authentication in each product you installed as part of the solution.

For information on how to configure SSL authentication in the products of the solution see the following information:

- Configure SSL Authentication in CA SDM (see page 935)
- Configure SSL Authentication in CA Service Catalog (see page 1432)
- Configure SSL Authentication in CA APM (see page 318)

Run the SSL Authentication Batch File

After you installed CA Service Management and configured SSL authentication, you must the run the SSL authentication batch file.

Follow these steps:

1. Navigate to [ISO_ROOT]\\DBCleanupUtility.
2. Run the UpdateScriptUSS.bat batch file.

Enable SSL Integration

After you configured SSL authentication in each of the products, you must enable SSL integration through the common administration user interface.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Product Integrations.

5. Under each product tab, check the **HTTPS** check box and specify the SSL port numbers.

6. Click Submit.

Upgrade to the Supported JRE Version for Unified Self Service

You must upgrade to the supported JRE version to successfully implement Unified Self Service.

Follow these steps:

For Windows

1. Download the supported JRE version.

2. Shut down the following services:

   - CA Unified Self-Service jetty server

   - CA Unified Self-Service server

3. Take a backup of wrapper.conf, located at <drive>:\Program Files\CA\Self Service\OSOP\tomcat-7.0.40\bin.

4. Edit wrapper.conf using the text editor and modify **set.JAVA_HOME=** with the JRE Installed location. **Example:** \Program Files\Java\jre1.8.0_45\bin

5. Save the file.

6. Start the following services:

   - CA Unified Self-Service jetty server

- CA Unified Self-Service server

For Linux

1. Download the supported JRE version.
2. Shut down all the services for Unified Self Service.
3. Take a backup of startup.sh, located at opt/CA/Self Service/bin.
4. Open startup.sh.
5. Look for **Export JAVA_HOME=** and update with the JRE installed location.
6. Look for **Export PATH= /bin:** and update with the JRE installed location.
7. Start all the services for Unified Self Service.

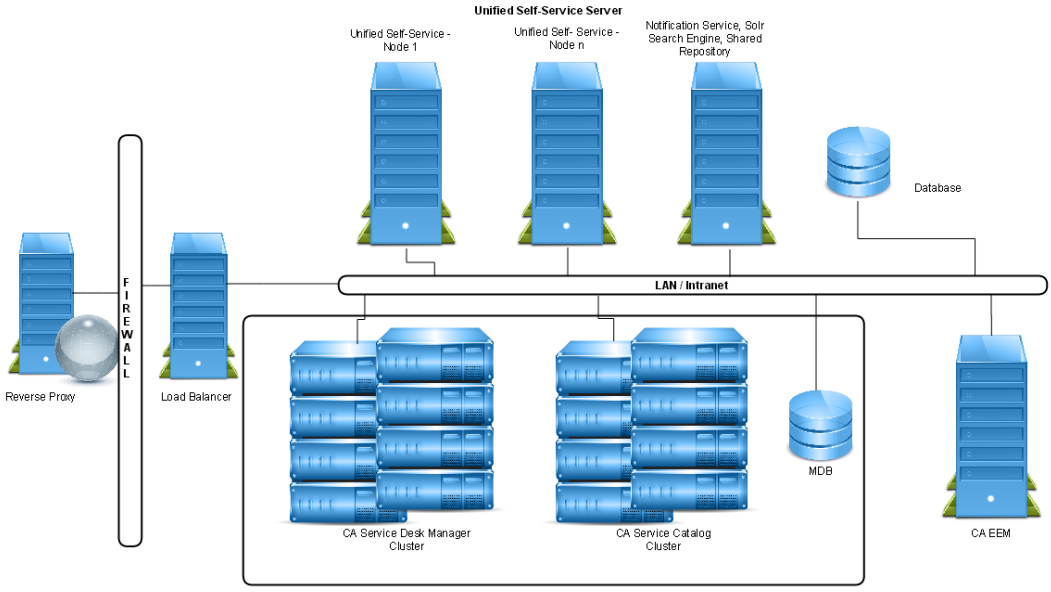
How to Set up the Cluster Environment for Unified Self-Service

For the optimal performance, set up Unified Self-Service on a cluster environment. In an ideal cluster environment, multiple server instances with identical configuration span across multiple nodes. All instances in a cluster work together to provide high availability, reliability, and scalability.

You need the following minimum requirements for the cluster environment:

- Two machines to set up the Unified Self-Service nodes
- One machine to set up Solr 1.4.1, Notification Server, and Shared Repository
- One Database server
- One machine for Load Balancer

The following diagram shows an ideal cluster environment for Unified Self-Service:



Follow these steps:

1. Set up and Configure Node 1 (see page 620)
2. Set up and Configure Node 2 (see page 623)
3. Configure the Load Balancer (see page 624)

Set up and Configure Node 1

Set up Unified Self-Service on node 1 and configure it for the cluster environment.

Follow these steps:

1. Install Unified Self-Service on a machine or node 1. Ensure that you give the Database Host as the machine name.
2. Onboard a tenant and configure the CA SDM data source. For more information, see Onboard Tenants (see page 1679).
3. Shutdown Unified Self-Service in services.msc.
4. Open the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory.
5. Append the file with the following lines:

```
#cluster
cluster.link.enabled=true
ehcache.cluster.link.replication.enabled=true
lucene.replicate.write=false
net.sf.ehcache.configurationResourceName=/custom-ehcache/hibernate-clustered.xml
```

```
ehcache.multi.vm.config.location=/custom-ehcache/liferay-multi-vm-clustered.xml
```

6. Extract the custom-ehcache.zip file from the OSOP\tools folder to the OSOP\tomcat-7.0.40 \webapps\ROOT\WEB-INF\classes\ folder.

   Important! Ensure that after the extraction, the custom-ehcache folder is created in the same path as the **hibernate-clustered.xml** and **liferay-multi-vm-clustered.xml** files.

7. Open the server.xml file from the OSOP\tomcat-7.0.40\conf\ folder.

8. Replace <Engine name="Catalina" defaultHost="localhost"> with <Engine name="Catalina" defaultHost="localhost" jvmRoute="node1">.

9. Restart Unified Self-Service services.

10. Install and Configure Apache Solr (see page 621) and Configure Liferay to use Solr for Searching (see page 622).

11. Configure the common repository for attachments on the Unified Self-Service common server. For more information, see the Liferay documentation.

12. Copy the OSOP\jetty-7.2.2.v20101205 folder to the Unified Self-Service common server to configure the notification server on the common Unified Self-Service server.

13. Configure the notification server on the Unified Self-Service node:

    a. Open portal-ext.properties file and search for *cometd*.

    b. Replace localhost with the hostname or IP address of Unified Self-Service common server and port with the port number on which Jetty is running. For example,

    ```
    #cometd configurations begin
    cometd.enable=true
    cometd.contextPath=/notification-server
    #internal properties are used by java client
    cometd.internal.host=localhost
    cometd.internal.port=18686
    cometd.internal.protocol=http
    #external properties are used by jquery clients
    cometd.external.host=localhost
    cometd.external.port=18686
    cometd.external.protocol=http
    #cometd configurations end
    ```

    c. Stop Unified Self-Service Jetty server from service.msc.

Unified Self-Service node 1 is configured.

Install and Configure Apache Solr

Install Apache Solr on the Unified Self-Service common server.

Follow these steps:

1. Download Solr 1.4.1 on the Unified Self-Service common server. For more information, see any Solr website, example, http://archive.apache.org/dist/lucene/solr/1.4.1.

2. From the Solr distribution, copy example folder so that Unified Self-Service is also at the same level.

3. Define the environment variable as the location for Solr to store the search index.
   Example: $SOLR_HOME=/openspace/solr

   > **Note:** This environment variable can be defined on the start up sequence of the operating system, in the environment for the user who is logged in, or in the start-up script for your application server. If you are using Tomcat to host Solr, modify setenv.sh or setenv.bat and add the environment variable there.

4. Use this environment variable as a parameter for JVM during the start up configuration of the application server.

   > **Note:** If you are using Tomcat, edit catalina.sh or catalina.bat and add the -Dsolr.solr.home=$SOLR_HOME to the $JAVA_OPTS variable.

5. Install Solr on the Unified Self-Service common server. For more information, see http://lucene.apache.org/solr.

   > **Note:** Install the Solr search engine on a separate machine from Liferay. To integrate Solr search engine with Liferay, restart the application server.

6. Shut down Solr.

7. From the Solr distribution, copy **solr.war** to the webapps directory of your servlet container.

8. Start Solr on the Jetty server:

   a. Go to $SOLR_HOME on the command prompt.

   b. Run java -Dsolr.solr.home=/openspace/solr -jar start.jar to set the java system property solr.solr.home.

Configure Liferay to use Solr for Searching

Do not run Liferay and Solr search engine on the same machine.

Follow these steps:

1. Install the Solr Liferay plugin on Unified Self-Service node 1.
2. Copy solr-web.war file from OSOP\tools to the OSOP\deploy folder of the Unified Self-Service installation directory.
3. Open solr-spring.xml from the WEB-INF/classes/META-INF folder.
4. Modify the following value to point to the server where Solr is up and running:

   ```
   <constructor-arg type="java.lang.String" value="http://localhost:8080/solr" />
   ```

5. Save the solr-spring.xml file and place it back in the plugin archive.
6. Copy the schema.xml file from the extracted solr-web folder (docroot/WEB-INF/conf) to $SOLR_HOME/conf folder of the Unified Self-Service common server.
7. Restart Solr on the Unified Self-Service common server.
   Liferay server search is now upgraded to use Solr.
8. From Unified Self-Service, select Control Panel, Server, Server Administration.
9. Click Execute button next to reindex all search indexes at the bottom of the page.
   Liferay will begin sending indexing requests to Solr for execution. Once Solr has indexed the data, a search server runs independently of all the Unified Self-Service nodes.The Unified Self-Service search now uses the Solr as the search index. This is ideal for a clustered environment, as it allows all the Unified Self-Service nodes to share one search server and one search index, and this search server operates independently of all the nodes.

Set up and Configure Node 2

Set up and configure Unified Self-Service on node 2 for the cluster environment.

Follow these steps:

1. Stop the Unified Self-Service services on node 1.
2. Create backup of node 1:
   - (Windows) Run TakeBackup.bat from the bin folder of the Unified Self-Service installation directory.
   - (Linux) Run TakeBackup.sh

   Backup is created in Unified Self-Service_installation\CAOpenSpaceBackup.car file of the Unified Self-Service installation directory.

3. On node 2, install the similar configuration Unified Self-Service as set up in node 1:

    a. Select Use existing database option.

    b. Ensure that you use the same database host name as used during the Unified Self-Service node1 setup.

    c. Select node1 backup CAOpenSpaceBackup.car.**Note:** Ensure user has all the privileges according to the basic installation.

    d. Ensure that you extracted the custom-ehcache.zip file in the OSOP\tomcat-7.0.40\webapps\ROOT\WEB-INF\classes\ folder of the Unified Self-Service installation directory.

    > **Important!** Ensure that after the extraction, the custom-ehcache folder is created in the same path as the **hibernate-clustered.xml** and **liferay-multi-vm-clustered.xml** files.

    e. Open the server.xml file from the OSOP\tomcat-7.0.40\conf\ folder and replace <Engine name="Catalina" defaultHost="localhost"> with <Engine name="Catalina" defaultHost="localhost" jvmRoute="node2">.

After the successful configuration, two Unified Self-Service nodes run with the same database in a cluster.

Configure the Load Balancer

Configure the load balancer to increase scalability and to maintain performance.

Follow these steps:

1. Download and install Apache HTTP server 2.2.
2. Download mod_jk.so (http://mod_jk.so) and copy it to APACHE_HOME\modules\ directory.
3. Modify the APACHE_HOME\conf\httpd.conf file:
    - Append the file with the following lines:

```
JkWorkersFile conf/workers.properties

JkLogFile logs/mod_jk.log

JkLogLevel info

JkLogStampFormat "[%a %b %d %H:%M:%S %Y]"

JkMount /* loadbalancer
```

    - Add the following entry in the httpd.conf file (if not added):

```
# Load the mod_jk connector

LoadModule jk_module modules/mod_jk.so
```

4. Define the IP addresses of node1 and node 2 in the APACHE_HOME\conf\workers.properties file:

   ```
   worker.node1.host = <IP ADDRESS OF NODE1>
   worker.node2.host = <IP ADDRESS OF NODE2>
   ```

5. Start load balancer.

6. On the client machine (from where you are accessing Unified Self-Service) modify C:\Windows\System32\drivers\etc\host file to point to the IP address of the Load Balancer. For example, if you on boarded a tenant with virtual host as test.openspace.com (http://test.openspace.com) and the IP address of the Apache server is 10.11.12.13, then you have to add 10.11.12.13 test.openspace.com (http://test.openspace.com) line in the host file. This allows access to the virtual host from the client machine.
   Load balancer is configured.

7. Stop the Unified Self-Service services on node 1 and verify that requests are getting mapped to node 2 even if node 1 is down.

Uninstall CA Service Management 14.1

This article contains the following topics:

After you have uninstalled CA Service Management product or products from a system, you must remove the database details from that system. To remove the database details, see Run the Database Cleanup Utility (see page 627)topic

Uninstall CA Asset Portfolio Management

You can uninstall the CA Asset Portfolio Management 14.1 components except CA MDB. CA MDB cannot be uninstalled.

Follow these steps:

1. From the Start menu on a CA Service Management Release 14.1 server, navigate to **Control Panel**, **Programs**.

2. Select **Programs and Features**. Locate and double-click CA Asset Portfolio Management.

3. Select Uninstall and follow the on-screen wizard instructions.
   CA APM 14.1 is uninstalled.
   If you have installed CA APM on multiple servers, uninstall these installations in a similar way.

Uninstall CA Service Catalog

You can uninstall CA Service Catalog and CA EEM from one or more computers.

Follow these steps:

1. Stop all CA Service Catalog Windows services on all computers.

2. Open the Windows Control Panel, select CA Service Catalog, and click Uninstall.

   Note: The CA Service Catalog data in the MDB is saved for any future CA Service Catalog installations in your enterprise. If you delete the MDB data, you cannot recover it.

3. If no other CA Technologies products in your enterprise use CA EEM, use the Windows Control Panel to uninstall it.

   Important! Before you uninstall CA EEM, unregister all registered applications. For more information, see your CA EEM documentation.

4. (Optional) Review the uninstallation log files in the Windows Temp directory:

   - CA_Service_Catalog_view.log
   - CA_Service_Catalog_Uninstall.log

Note: Tomcat and the JRE are installed automatically during the CA Service Catalog installation. They are also uninstalled automatically during the CA Service Catalog uninstallation.

After Uninstalling Service Catalog, you must uninstall CA Service Management Administration.

Uninstall CA Service Desk Manager

To uninstall CA Service Desk Manager,

1. Depending upon the operating system,
   - (Windows) From the Start menu, select All Programs, CA, Service Desk Manager, Uninstall.
   - (Linux/ UNIX) Go to the directory where you installed CA SDM (NX_ROOT/SDUninstall) and use ./SDUninstall.

   A message window appears.
2. Click Next.
3. Choose the option to keep all the files or to remove them during the uninstallation, and click Next.
4. Choose the services that you want to shutdown and click Next.
5. After the services are stopped, click Uninstall.
   The uninstallation process starts.
6. Select the option to restart the system (recommended for Windows) after the uninstallation and click Done.

At the end of the topic, you have successfully uninstalled CA SDM. Proceed to run the UninstallCleanup utility (see page 627).

Uninstall Unified Self-Service

Uninstall Unified Self-Service, if you no longer need it. Before uninstalling, ensure that you install JRE 1.7.51 or later and set JAVA_HOME to the JRE path. Make sure to add JAVA_HOME in the Environment PATH variable.

Follow these steps:

- (Windows) Click Start, All Programs, CA, Unified Self-Service, Change Unified Self-Service Installation, and select Uninstall Product. You are prompted to take the backup. Click OK.
  A CAOpenSpaceBackup.car backup file is created under the path C:\CA_Open_Space_Backup.
- (Linux) Navigate to the install directory, run Change Unified Self-Service Installation, and select Uninstall Product. You are prompted to take the backup. Click OK.
  A CAOpenSpaceBackup.car backup file is created under the path \CA_Open_Space_Backup.
  The installed directories and files are deleted from the system but the database is not deleted.

Run the Database Cleanup Utility

During the installation of CA Service Management 14.1 products, each of the installed product is registered in a common mdb table that is reflected in the deployment summary of the selected environment. These entries must be cleared in the following cases:

- Uninstallation of any CA Service Management products

- Moving Database or migration from one server to another

Run the CA Service Management database cleanup utility on a Windows or a Non-Windows environment. The database cleanup utility removes the entries and adds these to the following tables:

Table Name from where the entries are removed	Table Name to which the removed entries are added
al_cdb_componentinstallstate	al_cdb_comp_installstate_bkup
al_cdb_configurationparameters	al_cdb_config_params_backup

Note: On a Non-Windows Platform, before running the **DBCleanup.sh** Utility, you must export the Oracle Environment variables on the terminal.

Follow these steps:

1. Navigate to *DVD1\DBCleanupUtility* directory.
2. For Windows, double-click the **DBCleanupUtility.bat** to launch the DBCleanup utility.
   On a Non-Windows platform, you must run the **DBCleanupUtility.sh** file.
3. Enter the following details:
   a. **Database Server Type**: Specify the type of server, MS SQL or Oracle.
   b. **Database Host Name:** Enter the host name of the server where the database resides.
   c. **Database User Name**:
      - **SQL Server**: Enter the privileged user detail that has permission to create and modify schema.
      - **Oracle**: Provide the mdbadmin user name.
   d. **Database Password**:
      - **MS SQL**: Enter the database password used by the database admin user.
      - **Oracle**: Enter the password for the Oracle database user.
   e. **Database Port Number:** Provide the database port number.
   f. **Enter Database Name:** Enter the database name. For example, mdb.
   g. **System Name**: Provide the host name of the system from where you want to uninstall the CA Service Management product or products.
4. Select any of the following products that you want to uninstall:

- **SDM -** CA Service Desk Manager.
- **SLCM-** CA Service Catalog.
- **ITAM -** CA IT Asset Manager.
- **USS -** Unified Self-Service.
  The utility cleans up the database and removes the entries of the selected product installed on the server.

Implementing CA Service Management Release 14.1.01

This topic contains the following information:

CA Service Management 14.1.01 is a cumulative patch that has several enhancements and bug fixes (see page 91) on top of CA Service Management 14.1. All the necessary files that are required for the patch installation are packaged as a .CAZ or .tar.Z files available at CA Support Online.

Installation on Windows Operating System

- Navigate to the folder where you downloaded the cumulative patch .tar.Z file and run the following command run the following command: CA Service Desk Manager
- CA Asset Portfolio Management
- CA Service Catalog
- Unified Self-Service

Note: CA Service Desk Manager (Windows) users need to apply the mandatory patch RO80745 after applying the cumulative patch.

Follow these steps:

1. Download the Cumulative Patch (.caz) file from http://ca.com/support.

2. Download the cazipxp.exe (available inside the APPLYPTF) utility from http://supportconnectw.ca.com/public/ca_common_docs/latest_applyptf.asp.
   Copy the cazipxp.exe file to the same folder as the downloaded cumulative .CAZ file. Ignore this step if you already have cazipxp.exe file.

3. In the Windows command prompt, navigate to the folder where you downloaded the cumulative patch .caz file and run the following command:

   ```
   cazipxp.exe –u <Cumulative Patch.caz>
   ```

4. After the command is executed, the following files are available in the same folder:
   RO80231.caz
   Contains the necessary patch installation files for CA SDM.
   RO80262.caz
   Contains the necessary patch installation files for CA APM.
   RO80252.caz
   Contains the necessary patch installation files for CA Service Catalog.
   RO80300.caz
   Contains the necessary patch installation files Unified Self-Service.
   Product Readme Files
   The readme files contain information about the new features in the patch, the installation instructions, and other important information about the patch.

   Note: CA SDM users can also use APPLYPTF for applying the patch. The respective patches are copied to :

   - $NX_ROOT\patches\SDM_CUM1
   - $NX_ROOT\patches\APM_CUM1
   - $NX_ROOT\patches\CATALOG_CUM1
   - $NX_ROOT\patches\USS_CUM1

   Depending on the product patch you want to install, you must extract the corresponding .caz file. For example, for CA SDM, extract RO80231.caz file.

5. To extract the patch installation files, in the Windows command prompt, run the following command:

   ```
   cazipxp.exe –u <.caz file of the product>
   ```

   For example, for CA Service Catalog, run the following command:

   ```
   cazipxp.exe –u RO80252.caz
   ```

6. The patch installation procedure depends on the product you want to install. The extracted files contain a readme file that has all the necessary installation instructions. Follow the steps and complete the patch installation.

Installation on Linux Operating System

On a Linux operating systems, you can apply the patch for the following products:

- CA Service Desk Manager
- Unified Self-Service

Note: CA Service Desk Manager(Linux) users need to apply the mandatory patch RO80746 after applying the cumulative patch.

Follow these steps:

1. Download the Cumulative Patch (.tar.Z) file from http://ca.com/support.
   Copy the files for the cumilative patch in the $NX_ROOT/Patches directory. The $NX_ROOT /Patches directory may not exist if this is the first patch you are applying on your environment. You must manually create the folder and copy the files.

2. Navigate to the folder where you downloaded the .tar.Z file and run the following command:

   ```
   tar -xvzf <Cumulative_Patch.tar.Z>
   ```

3. After the command is executed, the following files are available in the same folder:
   RO80302.tar.Z
   Contains the necessary patch installation files for CA SDM.
   RO80301.tar.Z
   Contains the necessary patch installation files Unified Self-Service.
   CA_SDM_14_1_01_Readme.pdf
   The readme file contains information about the new features in the patch, the installation instructions, and other important information about the patch.

   Depending on the product patch you want to install, you must extract the corresponding .tar. Z file. For example, for CA SDM, extract the RO80302.tar.Z file.

4. The patch installation procedure depends on the product you want to install. The extracted files contain a readme file that has all the necessary installation instructions. Follow the steps and complete the patch installation.

5. To apply the patch run the following command:

   ```
   applyptf.<OS type> -r $NX_ROOT/Patches/RO80302.jcl -e $NX_ROOT
   ```

Installation on AIX or Solaris Operating System

On AIX and Solaris operating systems, you can apply the patch for CA Service Desk Manager.

Note: CA Service Desk Manager users need to apply the mandatory patch RO80747(For Solaris) and RO80748 (For AIX) after applying the cumulative patch.

Follow these steps:

1. Download the Cumulative Patch (.tar.Z) file from http://ca.com/support.

2. Copy the files for the cumulative patch in the $NX_ROOT/Patches directory. The $NX_ROOT /Patches directory may not exist if this is the first patch you are applying on your environment. You must manually create the folder and copy the files.

3. Navigate to the folder where you downloaded the cumulative patch .tar.Z file and run the following command:

   ```
   uncompress $NX_ROOT/Patches/<Cumulative_Patch.tar.Z>
   tar -xvf $NX_ROOT/Patches/<Cumulative_Patch.tar.Z>
   ```

4. After the command is executed, the following files are available in the same folder:

   For Solaris: **RO80304.tar.Z**

   For AIX: **RO80305.tar.z**

   CA_SDM_14_1_01_Readme.pdf
   The readme file contains information about the new features in the patch, the installation instructions, and other important information about the patch.

   Depending on the product patch you want to install, you must extract the corresponding .tar. Z file. For example, for CA SDM, extract the RO80304.tar.Z file.

5. The patch installation procedure depends on the product you want to install. The extracted files contain a readme file that has all the necessary instructions. Follow the steps and complete the patch installation.

6. To apply the patch run the following command:
   For AIX:

   ```
   applyptf.<OS type> -r $NX_ROOT/Patches/RO80305 .jcl -e $NX_ROOT
   ```

   For Solaris:

   ```
   applyptf.<OS type> -r $NX_ROOT/Patches/RO80304 .jcl -e$NX_ROOT
   ```

Install CA Service Desk Manager Release 14.1.01

Important! All components of the cumulative patch are supplied and implemented in English and all supported languages. However, the updates from the patch to the UI elements, utilities, messages, and so on appear in their respective language based on the product installation. Please go through the readme before applying the patch and ensure that you perform the post installation steps.

To help you plan for a successful implementation of Cumulative Patch, you must meet the following prerequisites:

- To install and use the cumulative patch, ensure that CA Service Desk Manager 14.1 is already installed. For information, visit CA Technical Support (http://ca.com/support). (http://ca.com/support.)
- Ensure that you read the enhancements and new features (see page 109) available for CA SDM, after applying this patch.
- Back up your system and database before installing the cumulative patch. This is necessary in case any problems are encountered during the cumulative patch installation.

Complete the following steps to apply the cumulative patch to CA Service Desk Manager 14.1:

For Windows:

1. Apply RO80231.caz which is extracted from CASM 14.1.01 cumulative patch.
2. If you do not have the ApplyPTF utility, download it from CA Technical Support (http://ca.com/support).
3. Shutdown the CA SDM services in all the servers.
4. Depending on the CA SDM configuration, complete one of the following steps:
   - (Advanced availability configuration) Log in into the standby server, which you are planning to promote as the new background server.
   - (Conventional configuration) Log in to the primary server.
5. Run the APPLYPTF command.
6. Select the ApplyPTF to local or remote nodes option and click Next.
7. Click Browse and select RO80231.caz file from $NX_ROOT\Patches\SDM_CUM1\ or from the location where the caz file has been extracted.
8. Leave all other options unchanged unless the node name is incorrect.

9. Click Next to install the patch.
   Once this patch is installed successfully, find the following files under the $NX_ROOT\Patches folder:

   - Language independent patch: RO80230
   - Language dependent patch: RO802229
   - Language independent patch readme: RO80230.TXT
   - Language dependent patch readme: RO80229.TXT

10. Apply the language independent patch first and then apply the language dependent patch (follow the instructions provided in the respective readmes).

For Non-Windows:

1. Apply the following patch (which is extracted from CASM 14.1.01 cumulative patch), depending on your non- windows environment:

   - (Linux) RO80302.tar.Z
   - (AIX) RO80305.tar.Z
   - (Solaris) RO80304.tar.Z

2. If you do not have the ApplyPTF utility, download it from CA Technical Support (http://ca.com/support). (http://ca.com/support.)

3. Depending on your non-windows environment, extract the patch file in the $NX_ROOT/Patches/SDM_CUM1/ directory:

   Note: The $NX_ROOT/Patches/SDM_CUM1/ directory may not exist, if you are applying the fix for the first time. In such a case, you must create it manually.

   - For Linux, unzip the patch file using tar -xvzf RO80302.tar.Z
   - For AIX, uncompress and untar the patch file as follows:

     a. i. uncompress $NX_ROOT/Patches/RO80305.tar.Z

        ii. tar -xvf $NX_ROOT/Patches/RO80305.tar

   - For Solaris, uncompress and untar the patch file as follows:

     a. i. uncompress $NX_ROOT/Patches/RO80304.tar.Z

        ii. tar -xvf $NX_ROOT/Patches/RO80304.tar

4. To apply the patch, run the following command, depending on your non-windows environment:
   - (Linux) applyptf.<OS type> -r $NX_ROOT/Patches/RO80302 .jcl -e $NX_ROOT
   - (AIX) applyptf.<OS type> -r $NX_ROOT/Patches/RO80305 .jcl -e $NX_ROOT
   - (Solaris) applyptf.<OS type> -r $NX_ROOT/Patches/RO80304 .jcl -e $NX_ROOT
5. When this patch is installed successfully, find the following files under the $NX_ROOT/Patches folder:
   a. For Linux:
      - Language independent patch: RO80249
      - Language dependent patch: RO80248
      - Language independent readme: RO80249.TXT
      - Language dependent readme: RO80249.TXT
   b. For AIX:
      - Language independent patch: RO80271
      - English language patch: RO80272
      - Language independent readme: RO80271.TXT
      - English readme: RO80272.TXT
   c. For Solaris:
      - Language independent patch: RO80258
      - Language dependent patch: RO80278
      - Language independent readme: RO80258.TXT
      - Language dependent readme: RO80278.TXT
6. Apply the language independent patch first and then apply the language dependent patch (follow the instructions provided in the respective Readmes).

Note: When the patch is successfully applied, before uploading any attachments, check ALL repositories and re-select the correct Servlet Server if needed. If the files that are replaced during the patch application process are not available in the expected locations then the patch was not applied properly. Review the Applyptf log file for additional information or contact CA Technical Support (http://ca.com/support) for assistance.

See the respective Post_Installation_and_Backout_Steps located in $NX_ROOT/doc folder to complete the patch installation process.

You may find the following known issues associated with this patch:

- Unable to Batch Import Knowledge Documents Using the keit_daemon Command (see page 152)
- Auto Refresh does not work when an existing attachment or URL is deleted or detached from a Configuration Item (see page 178)

Implementing CA IT Asset Manager Release 14.1.01

Complete the following steps to apply the cumulative patch to CA IT Asset Manager 14.1:

Verify the Prerequisites

- To apply cumulative patch 14.1.01, you must have already installed CA APM 14.1 GA.
- If you have installed CA APM 12.9, you must first upgrade to CA APM 14.1 and then apply the cumulative patch.

Install the Patch

Follow these steps:

1. Download the CA APM 14.1.01 cumulative patch from CA Support Online to the CA APM application server in the APM_14_1_01 folder.
2. Run the cazipxp.exe –u RO80262.caz command to unzip the CA APM 14.1.01 cumulative patch (caz file) in the same folder:
3. Verify that the following files are available:

- MDB.exe
- Setup.bat
- Patch.msp

4. Double click and extract ‘MDB.exe’ to get MDB folder.
5. Complete the following steps to u pdate the web server, application server components and database.

> **Note:** Please apply the Database patch first and then apply the patch in the application and webserver components.

- Log in to the application server where you downloaded and extracted the patch. From the command prompt, go to the APM_14_1_01 folder. To apply the database patch, use the following command.

> **Important!** We recommend that you back up your MDB database before you perform the MDB update. If your MDB update fails, restore the backup and start the installation again. We do not recommend that you reinstall the MDB update in the same environment where the MDB update failed.

For **SQL Server**, execute the following command:

```
setup.bat -SERVERTYPE=DB -DBVENDOR=mssql -DBNAME=<mdb_name> -DBHOST=<database_hostname> -
DBUSER=<database_username> -DBPASSWORD=<database_password> -MANIFEST=Unicenter_Asset_Portfolio_Management -
WORKSPACE=UAPM
```

SERVERTYPE
SERVERTYPE is DB, for database patch application.

DBVENDOR
Specifies the database vendor name. Enter mssql for SQL Server.

DBNAME
Specifies the existing CA APM Release 14.1 MDB database name.

DBHOST
Specifies the database server system host name.

DBUSER
Specifies the existing CA APM Release 14.1 MDB database user name.

DBPASSWORD
Specifies the existing CA APM Release 14.1 MDB database password.

Important! The -DBUSER and -DBPASSWORD parameter values must match your existing CA APM Release 14.1 database user name and password.

MANIFEST
Specifies the name of the manifest file. Do not change the default value for this parameter.

WORKSPACE
Specifies the name of the workspace. Do not change the default value for this parameter.

For **Oracle Server**, execute the following command:

```
setup.bat -SERVERTYPE=DB -DBVENDOR=oracle -DBNAME=<oracle_service_name> -DBHOST=<database_hostname> -
DBUSER=<database_username> -ORA_TBLSPACE_PATH=<tablespace_path> -DBPASSWORD=<database_password> -
MDB_ADMIN_PSWD=<mdb_administrator_password> -MANIFEST=Unicenter_Asset_Portfolio_Management -WORKSPACE=UAPM
```

SERVERTYPE
SERVERTYPE is DB, for database patch application.

DBVENDOR
Specifies the database vendor name. Enter oracle for Oracle.

DBNAME
Specifies the existing Oracle Service name.

DBHOST
Specifies the database server system host name.

DBUSER
Specifies the existing Oracle database user name.

ORA_TBLSPACE_PATH
Specifies the path to the Oracle tablespace.

DBPASSWORD
Specifies the existing Oracle database password

Important! The -DBUSER and -DBPASSWORD parameter values must match your existing CA APM Release 14.1 database user name and password.

MDB_ADMIN_PSWD
Specifies the existing MDB administrator password.

MANIFEST
Specifies the name of the manifest file. Do not change the default value for this parameter.

WORKSPACE
Specifies the name of the workspace. Do not change the default value for this parameter.

6. To update the application server, copy the folder APM_14_1_01 to the Application server. In the command prompt, go to the APM_14_1_01 folder and run the following command.

   ```
   Setup.bat -SERVERTYPE=APP
   ```

   Note: If the Application server and the Web server components reside on the same Machine, you can ignore step 7.

7. To update the web server, copy the folder APM_14_1_01 to the Web server. In the command prompt, go to the APM_14_1_01 folder and run the following command.

   ```
   Setup.bat -SERVERTYPE=WEB
   ```

Verify the Cumulative Patch Installation

After you have completed all installation procedures, you can verify that CA APM 14.1.01 and the database upgrade were performed successfully.

Database upgrade verification

1. Login to the server where you downloaded and extracted the CA APM 14.1.01 cumulative patch.
2. Navigate to the folder where you downloaded and extracted the CA APM 14.1.01 cumulative patch (APM_14_1_01).
3. Navigate to the MDB\mdb1.5 folder.
4. Open the install_<databasename>.log file with a text editor.

   Note: In the log file name, database name is replaced with the name of the database. For example, if the database name is test, the log file name is install_test.log.

5. Verify that a message similar to the following message appears at the end of the log file:

   'MDB setup completed successfully'.

Cumulative Patch verification

1. Login to APM application.

2. After a successful login click on ‘About’ link (top-right).
   The display should be:
   Release: 14.1.1.28

3. Verify the ITAMMSP.log file in the system drive.

4. In the Add/Remove Programs, click View Installed Updates and verify the entry **CA ITAM 14.1.01.**

Install Localization Update on the Cumulative Patch

After you verify the cumulative patch installation, you must install the localization update for languages other than English.

Follow these steps:

1. Log in to the Application Server.

2. In the Windows command prompt, navigate to <ITAM installation folder>\L10N\language_pack.

3. Run the following command:

   ```
   SetSeeddata.exe <language code-country code>
   ```

   For example, SetSeeddata.exe de_DE. The language codes are same as the folder names present at this location.

4. Verify the LOGSetSeeddata.log file.

Uninstall CA APM 14.1.01

You can decide to uninstall CA APM from a computer for various reasons. For example, you can uninstall CA APM because you decided to use the computer for a different purpose or to move the components to another computer.

Note: The MDB upgrade cannot be reverted. To revert the MDB changes, restore the previous database backup.

Follow these steps:

1. Login to the servers (Application & Web) where you installed CA APM 14.1.01.

2. Go to Control Panel > Programs and Features and click View installed updates.

3. Right-click on CA ITAM 14.1.01 and select Uninstall to uninstall this cumulative patch.

Enhancements

Ensure that you read the enhancements and new features (see page 91) available for CA APM, after applying this patch.

Maintenances

Cumulative#	Testfix#	Title	Description
APM 14.1.01	T5E2402	NON ADMIN USERS FAILS TO LOG IN	Issue with non admin users logging into APM.
	T5M7130	CAN'T UPDATE COST RECORD	Unable to update cost record extensions.
	T5E2402	METADATA DOESN'T FRESH ON ALL SERVERS IN LOAD BALANCING ENVIRONMENT.	In NLB environment, extensions created from one server are not available from other server without resetting IIS.
	NA	INTERNET EXPLORER RENDERING.	Internet explorer rendering issues.
	NA	PATCH OVERRIDING IIS SETTINGS AND ENABLING WINDOWS AUTHENTICATION.	Patch overriding IIS settings and enabling windows authentication.
	NA	IP ADDRESSES NOT SHARED	IP no synced with SAM and APM.
	T5E2404	UNABLE TO UPDATE ASSET SECONDARY LOOKUP	Unable to update Location and Contact as secondary lookup of an asset.
	NA	MAC ADDRESS FIELD SMALL	MAC address coming from SAM update.
	T5E2402	INACTIVATE ROLE	Unable to save set role to inactive.
	T5GJ134	CLEAR EXCEPTION MESSAGE NOT DISPLAYED	Import job errors out with inappropriate Exception message.
	T5E2408	ITAM-12.9-INVALID CA_ASSET ROWS	Data importer job fails to create an asset.
	T5XU059	DATA IMPORT LOG FILES LINE NUMBER ISSUE	Issue with data importer log files.
	T5E2404	UNABLE TO UPDATE ASSET SECONDARY LOOKUP	Unable to update Location and Contact as secondary lookup of an asset.
	T5GJ138	[CONFIGURATION] CANNOT REMOVE FOREIGNGROUP LEVEL 2 OR MORE REQUIRED FIELDS.	Unable to remove from the configuration the additional fields associated to related objects.
	T5E2402	ITAM - 12.9 - ERROR WHEN CREATING FILTER	Date filter saving issues.

Cumulative#	Testfix#	Title	Description
	T5GJ133	DATA IMPORTER - IMPROPER LOG RESULTS	Data importer doesn't show log results correctly as processed.
	T5M7120	UNABLE TO CLEAR DATE FIELD	Try to import by giving null values for any date field. Get the exception in the log.
	T5M7120	ERROR CREATING SEARCHES	The search does not give the Save successful message and also throws an exception when the search is brought up.
	T5UM103	LIFECYCLE STATUS DATE CHANGE	The life cycle status date is not changing when the life cycle status is updated.
	T5UM103	UNHANDLE SQL EXCEPTION	Infrequent error when using APM.
	T5GJ140	UNABLE TO SAVE ANY EXISTING CONTACT RECORDS	The application encountered an error while saving an object that references other objects. Contact ID contains invalid reference key.
	T5M712	EXTENDED FIELD NOT SHAREABLE	The extended field should be available for selection.
	T5GJ137	HARDWARE RECONCILIATION THROWING ERROR LAST_UPDATE_DATE=NULL	A reconciled computer deleted from ITCM interface and the ITAM Hardware Engine is executed last_update_date to NULL.
	T5EM232	CANNOT DELETE FIELD ON ASSET	Can not delete field from GUI.
	T5E2406	ITAM - 12.9 -EVENT SERVICE LIFECYCLE STATUS	NA
	NA	[WCF] USER SHOULD BE ABLE TO UPDATE LAST UPDATE OR CREATION DATES AS NEEDED.	Last update user set up.
	T5M7125	UNABLE TO ADD FIELD IN CONF	In Asset Configuration ON mode, we are unable to add Legal Status History Fields to Legal Documents for Assets.
	T5GJ135	HIDE INTERNAL ATTRIBUTES FROM 'ADD EXISTING FIELDS' POPUP - CONFIGURATION	ITAMService.log shows that the code is attempting to add data into the arg_allocation_summary_view table, even though these fields are hidden on the configuration.
	NA	IMPORT JOB ERROR	Import job errors out with inappropriate Exception message.
	T5XU050	READ-ONLY PERMISSIONS ISSUE FOR NON-ADMIN USERS	Read-Only permissions issue for Non-Admin users.
	T5GJ134	NULL EXCEPTION MESSAGE IN WEB SERVICE	Exception Message: Web Service threw exception in data importer.
	T5M7120	UNABLE TO CLEAR DATE FIELD	When importing by giving null values for any date field. Get the exception in the log.

Cumulative#	Testfix#	Title	Description
	T5JH194	SORTING IMPORTER JOBS ON JOB ID IN ASCENDING ORDER	Unable to sort Import Jobs on Job Id in Ascending direction.
	T5EM232	ERROR ON DEAUTHORIZE	Unable to de authorise user from user management.
	T5EM232	AUTHORIZE USERS SEARCH	When searching for authorise users are performing an Or as opposed to an And.
	T5EM232	ERROR ON CHANGE MODEL WIZARD	APM fails to run change model wizard, tried to execute a model change from/to the same asset family.
	T5GJ138	CANNOT FIND CONTACT /ROLE	Unable to search for the user already existing.
	NA	HW RECON-LIFECYCLE STATUS ERR	updates are failing and ITAMHWEngine.log is throwing numerous errors.
	T5UM105	ISSUE WITH ASSET AUDITS	NA
	T5UM104	ISSUE WITH CONFIGURATION: ASSET ENTITLEMENTS	All links in Asset Entitlements do not show in configuration ON mode in software asset.
	T5UM092	FILTER VALUES CASE SENSITIVE	Organisation save throws error"The User is not authorized to modify the asset due to the filter".
	T5EM227	IMPORT JOB ERROR	Data Importer fails to import assets when main destination object is set to 'Asset (All Families)'
	T5EM226	AUTOCOMPLETE NOT WORKING	The autocomplete function is not working on lookup fields in the 'additional information' section of the asset details page.

Upgrade to CA Service Catalog Release 14.1.01

This Readme contains instructions on how to download and install the CA Service Catalog 14.1.01 patch updates.

Note: All components of the CA Service Catalog 14.1.01 patch are supplied and implemented in English only. For example, the installation program for the patch runs in English only. However, the updates from the patch to the CA Service Catalog UI elements, utilities, messages, and so forth appear in the chosen product installation language. These updates function the same way in both English and non-English environments. Therefore, you can install the patch in both environments to obtain the latest updates to the product.

We strongly recommend that in addition to applying the patch, you must also configure the Secure Socket Layer (SSL). Instructions for enabling SSL can be found in the CA Service Catalog documentation wiki (https://wiki.ca.com/display/CASM1401/Configure+CA+Service+Catalog+to+Use+Secure+Socket+Layer)along with other general security considerations. In addition, administrators must disable login using the HTTP GET method. To disable, set the Allow Login with GET configuration in CA Service Catalog Administration, Configuration, Single Sign On Authentication to No.

For information on Poodle Vulnerability and remediation steps to secure the Apache Tomcat server used by CA Service Catalog SSL (HTTPs), refer to technical document posted on CA Support: http://www.ca.com/us/support/ca-support-online/product-content/knowledgebase-articles/tec1155961.aspx

Prerequisites

To help you plan for a successful implementation of the CA Service Catalog 14.1.01 patch, ensure that your environment meets the following prerequisites:

- To install and use the patch, ensure that you have installed CA Service Catalog 14.1. For information on this, visit http://ca.com/support.

- Back up your system and database before installing the patch. This is necessary in case any problems are encountered during the installation of the patch.
  For instructions, see Technical Document TEC472303, “Backup and Restore Procedures for CA Service Catalog Products” which is posted on http://ca.com/support.

How to Install the Patch

Follow these instructions to apply the patch on top of the CA Service Catalog 14.1 base version.

1. If you do not have the cazipxp.exe utility, download it from the CA Technical Support at http://ca.com/support.

2. Extract the patch setup file CA_SLCM_r14_1_01_Setup.exe from <Rxxxx.caz> by running the following command:

   ```
   cazipxp.exe –u < Patch cazip file>
   ```

3. Run the *CA_SLCM_r14_1_01_Setup.exe* on all the systems where you have installed the base version of CA Service Catalog 14.1. Follow the installation wizard to install the patch.

How to Uninstall the Patch

Follow these instructions to uninstall the patch:

1. Click **Control Panel**, **Programs and Features**.

2. Double click the CA Service Catalog r14.1.01 and follow the uninstallation wizard instructions to uninstall the patch.

CA Service Catalog Patch Enhancements

Note: For more information related to Patch enhancements, new features, new certifications, fixes, and other updates provided with the CA Service Catalog 14.1.01 patch, see CA Service Management Release 14.1.01 Enhancements (see page 91).

Files Affected

This section lists the files that are affected with the application of CA Service Catalog 14.1.01 Patch. Some of the files listed may not be present in your system depending on the CA Service Management products and components that you have installed.

Note: USM_HOME refers to the CA Service Catalog product install path.

If you have customized CA Service Catalog using the Customization Framework, note the following two locations where the files may get affected by this patch application:

- As a best practice, the customization of files must be implemented under USM_HOME\filestore\custom folder (and its sub folders). As such, after applying the patch, you may be required to merge the files from this folder (and its sub folders) with the new files delivered by the Patch. A list of the files being updated by the patch is documented in this section.
- Customizations outside the USM_HOME\filestore\custom folder (and its sub folders) must be backed up before applying the CA Service Catalog 14.1.01 patch. After applying the patch, you must re-implement the customizations on the new files delivered with the patch. The following files are updated with the patch application.

List of Files Affected

Following are the list of files that are replaced:

- USM_HOME\version.properties
- USM_HOME\accounting\scripts\MDB\SQL\seeddata_de_DE.properties
- USM_HOME\accounting\scripts\MDB\SQL\seeddata_fr_FR.properties
- USM_HOME\accounting\scripts\MDB\SQL\seeddata_it_IT.properties
- USM_HOME\accounting\scripts\MDB\SQL\seeddata_zh_CN.properties

- USM_HOME\catalog\content\ApplicationServices.xml
- USM_HOME\catalog\content\ApplicationServices_da_DK.properties
- USM_HOME\catalog\content\ApplicationServices_da_DK.xml
- USM_HOME\catalog\content\ApplicationServices_de_DE.properties
- USM_HOME\catalog\content\ApplicationServices_de_DE.xml
- USM_HOME\catalog\content\ApplicationServices_es_ES.properties
- USM_HOME\catalog\content\ApplicationServices_es_ES.xml
- USM_HOME\catalog\content\ApplicationServices_fi_FI.xml
- USM_HOME\catalog\content\ApplicationServices_fr_FR.properties
- USM_HOME\catalog\content\ApplicationServices_fr_FR.xml
- USM_HOME\catalog\content\ApplicationServices_it_IT.properties
- USM_HOME\catalog\content\ApplicationServices_it_IT.xml
- USM_HOME\catalog\content\ApplicationServices_ja_JP.properties
- USM_HOME\catalog\content\ApplicationServices_ja_JP.xml
- USM_HOME\catalog\content\ApplicationServices_nl_NL.xml
- USM_HOME\catalog\content\ApplicationServices_pt_BR.xml
- USM_HOME\catalog\content\ApplicationServices_sv_SE.xml
- USM_HOME\catalog\content\ApplicationServices_zh_CN.xml
- USM_HOME\catalog\content\CorporateServices.xml
- USM_HOME\catalog\content\CorporateServices_da_DK.xml
- USM_HOME\catalog\content\CorporateServices_de_DE.xml
- USM_HOME\catalog\content\CorporateServices_es_ES.xml
- USM_HOME\catalog\content\CorporateServices_fi_FI.xml
- USM_HOME\catalog\content\CorporateServices_fr_FR.xml
- USM_HOME\catalog\content\CorporateServices_it_IT.properties
- USM_HOME\catalog\content\CorporateServices_it_IT.xml
- USM_HOME\catalog\content\CorporateServices_ja_JP.xml

- USM_HOME\catalog\content\CorporateServices_nl_NL.xml
- USM_HOME\catalog\content\CorporateServices_pt_BR.xml
- USM_HOME\catalog\content\CorporateServices_sv_SE.xml
- USM_HOME\catalog\content\CorporateServices_zh_CN.xml
- USM_HOME\catalog\content\FacilitiesServices.xml
- USM_HOME\catalog\content\FacilitiesServices_da_DK.xml
- USM_HOME\catalog\content\FacilitiesServices_de_DE.xml

Implementing CA Service Management 14.1.02

CA Service Management 14.1.02 is a cumulative patch for CA Service Management 14.1 and 14.1.01, which provides new features, enhancements, and bug fixes.

The following patches are available for Windows and Non-Windows environment to download from CA Support (https://support.ca.com/irj/portal/newhome):

- RO86281 (Windows)
- RO86285 (Linux)
- RO86282 (Solaris)
- RO86295 (AIX)

Note: To install CA Service Management 14.1.02, it is mandatory to have CA Service Management 14.1 or 14.1.01 installed in the system.

Prerequisites for CA Service Management 14.1.02 Installation

Verify and complete the following prerequisites before proceeding with CA Service Management 14.1.02 installation :

- To install and use cumulative patch, ensure that CA Service Management 14.1 or 14.1.01 is installed in your environment. For more information, visit CA Technical Support (http://ca.com/support).
- Back up your system database (MDB) before installing the cumulative patch. This is mandatory and ensures safe data recovery if any problems are encountered during the installation process.
- Before installing the patch, ensure that you have read the CA Service Management 14.1.02 Release notes for *What's New in this Release*, fixes, and known issues. For more information, see CA Service Management Release 14.1.02 Enhancements . (see page 69)

Prerequisites for CA Service Desk Manager and Unified Self-Service Installation

Do not invoke ApplyPTF manually in your system while running the CA Service Management 14.1.02 patch installer. If ApplyPTF is invoked, an alert message may appear that you can run only one ApplyPTF at a time, and the task of applying CA SDM or USS patch gets completed without applying the patch.

Prerequisites for CA Asset Portfolio Management Installation

Complete the following prerequisites before proceeding with CA APM 14.1.02 installation:

- Install .NET 4.5.2 framework on Windows Server 2008 (see page)
- Add ASP.NET in IIS on Windows Server 2012 (see page 686)

Install .NET 4.5.2 framework on Windows Server 2008:

To install .NET 4.5.2 framework on Windows Server 2008, complete the following steps:

1. Navigate to .NET 4.5.2 framework *Root folder/filestore/*Prerequisite.
2. Execute **NDP452-KB2901907-x86-x64-AllOS-ENU.exe.**
3. Follow on-screen instructions. Click **Next**.

4. Review the summary screen.

5. Click **Finish** to exit the installer.
   .NET 4.5.2 framework is now installed.

Add ASP.NET in IIS on Windows Server 2012

To add ASP.NET in IIS on Windows Server 2012, perform the following steps:

1. Open Server Manager.

2. Navigate to **Manage**, **Add Roles and Features**.

3. Follow on-screen instructions. Select installation type and destination server.

4. Select **Roles** from the select server roles pane, expand **Web Server (IIS)**, **Application Development (IIS)**.

5. Select **ASP.NET 3.5** and **ASP.NET 4.5**.

6. Click **Next**.

7. Follow on-screen instructions and complete the installation.
   ASP.Net is now added in IIS.

For more information on supported operating system, databases, web browsers, and so on, see Supportability Matrix. (see page 119)

Additionally, if you want to identify and list the CA Service Management product patches installed in your system, you can run SMPatchReport utility. For more information, see Run SMPatchReport Utility to Get Installed Patches List. (see page 742)

Install CA Service Management 14.1.02

To install CA Service Management 14.1.02. perform the following based on the operating system installed in your system (Windows/Non-Windows):

- Install CA Service Management 14.1.02 (Windows) (see page 688)
- Install CA Service Management 14.1.02 (Non-Windows) (see page 692)

Install CA Service Management 14.1.02 (Windows)

This article describes how to install the CA Service Management 14.1.02 patch for Windows. Ensure that you have completed installation prerequisites (see page 686)before proceeding with patch installation.

Important: If you have applied test fixes on CA Service Management 14.1.02, you must not reapply the CA Service Management 14.1.02 patch as it may override the test fix changes.

Note: If you are installing the patch on CA SDM 14.1 or 14.1.01, consider the following based on your server configuration:

- Advanced Availability: log on to the standby server, which you plan to promote as the new background server and install the patch.
- Conventional: log on to the primary server.

Note: In a CA APM distributed environment, the CA Service Management 14.1.02 patch must be applied on all servers. However, the database screen is shown only on the component server and you must install the MDB patch from the component server.

Perform the following steps:

1. Download **RO86281. CAZ** from CA Support (http://www.ca.com/in/support.aspx).
2. Extract the file using following command:

   ```
   cazipxp.exe -u <Patch cazip file>
   ```

   Note: If you do not have the cazipxp.exe utility, download it from CA Support (http://www.ca.com/in/support.aspx).

3. Extract **CASM_14.1.02_CommonPatchInstaller_Win.zip**.
4. Perform the following steps if CA Service Catalog is installed in your environment:
   a. Download **RO86617.CAZ** from CA Support (http://www.ca.com/in/support.aspx).
   b. Copy and paste the **RO86617.CAZ** in the *CASM_14.1.02 _CommonPatchInstaller_Win\Patches\SLCM\Binaries* folder.
5. Navigate to *CASM_14.1.02_CommonPatchInstaller_Win* folder *and* double-click **Setup.exe**.
6. Review and accept the license agreement terms.
7. In Database Configuration, select Microsoft SQL Server or Oracle as the database type. Ensure that you have installed Microsoft SQL Server or Oracle database client in the system.

Note: In case of CA SDM, the installer detects and identifies if there is a primary or standby server (Conventional or Advanced Availability) and displays the MDB database screen.

Provide the database configuration details as per the selected database (Oracle or Microsoft SQL Server):

a. **Microsoft SQL Server**: Complete the following if you have installed Microsoft SQL Server database:

- **Database Server**: The host name of the database server. If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
- **Database Name**: Specifies the Database name (mdb), the name of the target DBMS. The default value is mdb.
- **Database Port**: Specifies the port identifier for the target DBMS.
- **Database Server Instance**: The database instance name. Leave this field blank if you are using the default instance.
- **Database Admin User**: For SQL Server, **sa** is the default value. Provides permission to create users and schema.
- **Database Admin Password**: Specifies the database password of users specified by the database admin user.
- **mdbadmin Password**: Specify the password for the mdbadmin user.
- **Confirm mdbadmin Password**: Confirm the mdbadmin user password.

b. **Oracle**: Complete the following if you have installed Oracle database:

- **Database Server**: Specifies the host name of Oracle database server.
  If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
- **Oracle Service Name**: Specifies the Oracle Service name.
- **Listener Port**: Specifies the listener port for database.
- **Net Service Name**: Identifies the Net Service Name of Oracle database where the database resides.
  If database is remote, use the Net Service Name that is defined in Oracle client on the local computer. CA SDM accesses the database through a local installation of the Oracle client.
- **DBA User Name**: Authenticates the name of the user with DBA access. The default value for DBA user is **SYS.**
- **DBA User Password**: Authenticates the password for DBA user.

- **mdbadmin Password**: Specify password for mdbadmin user.
- **Confirm mdbadmin Password**: Confirm mdbadmin user password.
- **Tablespace Path (on DB Server)**: Specifies the tablespace directory on the database server.
- **Oracle Home Path**: Specifies the Oracle client 32-bit path.
- **Data Tablespace Name**: Specifies tablespace name. The default value is **MDB_DATA**.
- **Index Tablespace Name**: Specifies index tablespace name: Default value is **MDB_INDEX**.

8. Click **Next.**
9. On the product selection page, the patch installer identifies the CA Service Management products installed in the system.

   Note: On the product selection page, deselect the products for which the patch is already updated.

   Verify and click **Next.**
10. If CA Service Catalog is installed in your environment, provide the CA Embedded Entitlements Manager (CA EEM) details:
    a. **CA EEM Server Name**: Specifies the CA EEM server name which is configured with CA Service Catalog.
    b. **CA EEM Admin User Name**: Authenticates the name of the user with Admin access. The default value for Admin user is **EiamAdmin.**
    c. **CA EEM Admin Password**: Specify password for CA EEM admin user.
11. Perform the following step if CA Service Catalog is installed in your environment and you are installing this patch on CA Service Management 14.1:
    a. Select one or both the options available on the CA Service Catalog Import Content page to import the content pack.
12. Review the Patch Information Summary page and click **Next**.
13. Review Installation progress. Click **Install** to install the selected product/products on your local system.
14. Review the installation task review progress bar. Once it reaches 100%, click **Next**.

15. Review patch Installation summary screen for the following:
    - Click the log folder URL link to view log information.
    - To view post-installation tasks based on your server configuration, see Post-Install Tasks (see page 700).
16. Click **Finish** to exit the installer.

> **Note:** If patch installation fails on a server where you have installed more than one CA Service Management product, retry the installation. Deselect the failed product from the installer screen and proceed with the installation.

> **Note:** If patch installation fails for a product, retry the installation by using the **Retry** option in the wizard where it fails. If retry does not work, exit the installer and relaunch it. If problem persists, contact CA Support (http://www.ca.com/in/support.aspx).

If you are installing CA Service Management 14.1.02 (CA SDM and USS) on Non-Windows, refer to the following topics:

- Install CA Service Management 14.1.02 Patch on Linux (CA SDM and USS) (see page 693)
- Install CA Service Desk Manager 14.1.02 Patch on Solaris (see page 698)
- Install CA Service Desk Manager 14.1.02 Patch on AIX (see page 695)

Install CA Service Management 14.1.02 (Non-Windows)

To install CA Service Management 14.1.02 on Non-Windows, perform the following:

> **Important:** If you have applied Test Fixes on CA Service Management 14.1.02, you must not reapply the CA Service Management 14.1.02 patch as it may override the Test Fix changes.

> **Note:** On Non-Windows, if you try to reapply CA Service Management 14.1.02 patch (CA SDM and USS) on a system, an error message is displayed that the patch is already applied. Reapplying the patch does not work.

- Install CA Service Management 14.1.02 Patch on Linux (CA SDM and USS) (see page 693)

- Install CA Service Desk Manager 14.1.02 Patch on AIX (see page 695)
- Install CA Service Desk Manager 14.1.02 Patch on Solaris (see page 698)

Install CA Service Management 14.1.02 Patch on Linux (CA SDM and USS)

Note: On Non-Windows,reapplying the CA Service Management 14.1.02 for CA SDM and USS is not allowed. To reapply, first uninstall the patch and reinstall. For more information on how to uninstall the patch, see Uninstall CA Service Management 14.1.02 . (see page 727)

Ensure that you have verified and completed the installation prerequisites (see page 398) before proceeding with patch installation. Perform the following steps for installing the patch (CA SDM and USS) on Linux:

Note: If you are installing the patch on CA SDM 14.1 or 14.1.01, consider the following based on your server configuration:

- Advanced Availability: log on to the standby server, which you plan to promote as the new background server and install the patch.
- Conventional: log on to the primary server.

1. Download **RO86285.tar.Z** file from CA Support (http://www.ca.com/in/support.aspx).
2. Untar the tar.Z by executing the following command:

   ```
   tar -xvzf
   RO86285
   .tar.Z
   ```

3. Untar **CASM_14.1.02_CommonPatchInstaller_Linux.tar.gz** using the following command:

   ```
   tar -xvzf CASM_14.1.02_CommonPatchInstaller_Linux.tar.gz
   ```

4. Set the CA SDM bin and LIB environment variables.
   For example:

   ```
   export PATH=/opt/CA/ServiceDeskManager/bin:$PATH

   export LD_LIBRARY_PATH=/opt/CA/ServiceDeskManager/lib:$LD_LIBRARY_PATH
   ```

5. Run setup file to install CA Service Management 14.1.02 using the following command:

   ```
   ./setup.sh
   ```

6. Review and accept the license agreement terms.

7. In Database Configuration, select **Oracle** as the database type. Ensure that you have installed Oracle database client in your system.

   Note: In case of CA SDM, the installer detects and identifies if there is a primary or standby server (Conventional or Advanced Availability) and displays the MDB database screen.

   Provide the following Oracle database configuration details:

   - **Database Server**: Specifies the host name of Oracle database server.
     If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
   - **Oracle Service Name**: Specifies the Oracle Service name.
   - **Listener Port**: Specifies the listener port for database.
   - **Net Service Name**: Identifies the Net Service Name of Oracle database where the database resides.
     If database is remote, use the Net Service Name that is defined in Oracle client on the local computer. CA SDM accesses the database through a local installation of the Oracle client.
   - **DBA User Name**: Authenticates the name of the user with DBA access. The default value for DBA user is **SYS.**
   - **DBA User Password**: Authenticates the password for DBA user.
   - **mdbadmin Password**: Specify password for mdbadmin user.
   - **Confirm mdbadmin Password**: Confirm mdbadmin user password.
   - **Tablespace Path (on DB Server)**: Specifies the tablespace directory on the database server.
   - **Oracle Home Path**: Specifies the Oracle client 32-bit path.
   - **Data Tablespace Name**: Specifies tablespace name. The default value is **MDB_DATA**.
   - **Index Tablespace Name**: Specifies index tablespace name: Default value is **MDB_INDEX**.

8. Click **Next.**
9. On the product selection page, the patch installer identifies the CA Service Management products installed in the system. Verify and click **Next.**
10. Review the Patch Information Summary page and click **Next**.

11. Review the Installation progress. Click **Install** to install the selected items on your local system.

12. Review the installation task review progress bar. Once it reaches 100%, click **Next**.

13. Review the patch Installation summary screen for the following:

    - For log information, copy the log folder path to a browser.
    - Copy the URL link for post-Installation tasks to see Post Installation Steps for CA SDM Conventional Configuration (see page 700) or Post Installation Steps for Advanced Availability Configuration (see page 704).

14. Click **Finish** to exit the installer.

Note: If patch installation fails on a server where you have installed more than one CA Service Management product, retry the installation. Deselect the failed product from the installer screen and proceed with the installation.

Note: If patch installation fails for a product, retry the installation by using the **Retry** option in the wizard where it fails. If retry does not work, exit the installer and relaunch it. If problem persists, contact CA Support (http://www.ca.com/in/support.aspx).

Install CA Service Desk Manager 14.1.02 Patch on AIX

Note: On Non-Windows,reapplying the CA Service Management 14.1.02 for CA SDM and USS is not allowed. To reapply, first uninstall the patch and reinstall. For more information on how to uninstall the patch, see Uninstall CA Service Management 14.1.02 . (see page 727)

Ensure that you have verified and completed CA SDM installation prerequisites (see page 398)before proceeding with patch installation. Perform the following to install CA SDM patch on AIX:

Note: If you are installing the patch on CA SDM 14.1 or 14.1.01, consider the following based on your server configuration:

- Advanced Availability: log on to the standby server, which you plan to promote as the new background server and install the patch.
- Conventional: log on to the primary server.

1. Download **RO86295.tar.Z** file from CA Support (http://www.ca.com/in/support.aspx).
2. Untar the **RO86295.tar.Z** file by executing the following command:

   ```
   Bash# gtar -xvzf RO86295.tar.z
   ```

3. Untar the CASM_14.1.02_CommonPatchInstaller_Aix.tar.gz by executing the following command:

   ```
   Bash# gtar -xvzf
   CASM_14.1.02_CommonPatchInstaller_Aix.tar.gz
   ```

4. Set CA SDM bin and LIB environment variables.
   For example:

   ```
   export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
   ```

   ```
   export LIBPATH=/opt/CA/ServiceDeskManager/lib:$LIBPATH
   ```

5. Run setup file to install CA Service Management 14.1.02 using the following command:

   ```
   ./setup.sh
   ```

6. Review and accept the license agreement terms.
7. In Database Configuration, select Oracle as the database type. Ensure that you have installed Oracle database client in your system.

   Note: In case of CA SDM, the installer detects and identifies if there is a primary or standby server (Conventional or Advanced Availability) and displays the MDB database screen.

   Provide the following Oracle configuration details:

   - **Database Server**: Specifies the host name of Oracle database server.
     If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
   - **Oracle Service Name**: Specifies the Oracle Service name.
   - **Listener Port**: Specifies the listener port for database.
   - **Net Service Name**: Identifies the Net Service Name of Oracle database where the database resides.
     If database is remote, use the Net Service Name that is defined in Oracle client on the local computer. CA SDM accesses the database through a local installation of the Oracle client.

- **DBA User Name**: Authenticates the name of the user with DBA access. The default value for DBA user is **SYS.**
- **DBA User Password**: Authenticates the password for DBA user.
- **mdbadmin Password**: Specify password for mdbadmin user.
- **Confirm mdbadmin Password**: Confirm mdbadmin user password.
- **Tablespace Path (on DB Server)**: Specifies the tablespace directory on the database server.
- **Oracle Home Path**: Specifies the Oracle client 32-bit path.
- **Data Tablespace Name**: Specifies tablespace name. The default value is **MDB_DATA**.
- **Index Tablespace Name**: Specifies index tablespace name: Default value is **MDB_INDEX**.

8. Click **Next.**
9. On the product selection page, the patch installer identifies the CA Service Management products installed in the system. Verify and click **Next.**
10. Review the Patch Information Summary page and click **Next**.
11. Review Installation progress. Click **Install** to install the selected product/products on your local system.
12. Review installation task review progress bar. Once it reaches 100%, click **Next**.
13. Review the patch Installation summary screen for the following:
    - For log information, copy the log folder path to a browser.
    - Copy the URL link for post-Installation tasks to see Post Installation Steps for CA SDM Conventional Configuration (see page 700) or Post Installation Steps for Advanced Availability Configuration (see page 704).
14. Click **Finish** to exit the installer.

Note: If patch installation fails, retry the installation by using the Retry option in the wizard where it fails. If retry does not work, exit the installer and relaunch it. If problem persists, contact CA Support.

Install CA Service Desk Manager 14.1.02 Patch on Solaris

Note: On Non-Windows,reapplying the CA Service Management 14.1.02 for CA SDM and USS is not allowed. To reapply, first uninstall the patch and reinstall. For more information on how to uninstall the patch, see Uninstall CA Service Management 14.1.02 . (see page 727)

Ensure that you verified and completed the CA SDM installation prerequisites (see page 398)before proceeding with patch installation. Perform the following to install CA SDM patch on AIX:

Note: If you are installing the patch on CA SDM 14.1 or 14.1.01, consider the following based on your server configuration:

- Advanced Availability: Log on to the standby server, which you plan to promote as the new background server and install the patch.
- Conventional: Log on to the primary server.

1. Download **RO86282.tar.Z** file from CA Support (http://www.ca.com/in/support.aspx).
2. Run the following command to untar the RO86282.tar.Z file:

   ```
   $ gtar -xvzf RO86282
   .tar.Z
   ```

3. Run the following command to untar **CASM_14.1.02_CommonPatchInstaller_Solaris.tar.gz**:

   ```
   $ gtar -xvzf CASM_14.1.02_CommonPatchInstaller_Solaris.tar.gz
   ```

4. Set CA SDM bin and LIB environment variables.
   For example:

   ```
   export PATH=/opt/CA/ServiceDeskManager/bin:$PATH

   export LD_LIBRARY_PATH=/opt/CA/ServiceDeskManager/lib:$LD_LIBRARY_PATH
   ```

5. Run setup file to install CA Service Management 14.1.02 using the following command:

   ```
   ./setup.sh
   ```

6. Review and accept the license agreement terms.
7. In Database Configuration, select Oracle as the database type. Ensure that you have installed Oracle database client in your system.

Note: In case of CA SDM, the installer detects and identifies if there is a primary or standby server (Conventional or Advanced Availability) and displays the MDB database screen.

Provide the following Oracle database configuration details:

- **Database Server**: Specifies the host name of Oracle database server.
  If the target instance is part of a clustered instance, the virtual host name of the cluster must be used.
- **Oracle Service Name**: Specifies the Oracle Service name.
- **Listener Port**: Specifies the listener port for database.
- **Net Service Name**: Identifies the Net Service Name of Oracle database where the database resides.
  If database is remote, use the Net Service Name that is defined in Oracle client on the local computer. CA SDM accesses the database through a local installation of the Oracle client.
- **DBA User Name**: Authenticates the name of the user with DBA access. The default value for DBA user is **SYS.**
- **DBA User Password**: Authenticates the password for DBA user.
- **mdbadmin Password**: Specify password for mdbadmin user.
- **Confirm mdbadmin Password**: Confirm mdbadmin user password.
- **Tablespace Path (on DB Server)**: Specifies the tablespace directory on the database server.
- **Oracle Home Path**: Specifies the Oracle client 32-bit path.
- **Data Tablespace Name**: Specifies tablespace name. The default value is **MDB_DATA**.
- **Index Tablespace Name**: Specifies index tablespace name: Default value is **MDB_INDEX**.

8. Click **Next.**
9. On the product selection page, the patch installer identifies the CA Service Management products installed in the system. Verify and click **Next.**
10. Review the Patch Information Summary page and click **Next**.
11. Review the Installation progress. Click **Install** to install the selected items on your local system.
12. Review the installation task review progress bar. Once it reaches 100%, click **Next**.

13. Review the Patch Installation summary screen.
    For log information, copy the log folder path to a browser.
    To view post-installation tasks based on your server configuration and log folder, see, Post Installation Steps for CA SDM Conventional Configuration (see page 700) or Post Installation Steps for Advanced Availability Configuration (see page 704).

14. Click **Finish** to exit the installer.

Note: If patch installation fails, retry the installation by using the **Retry** option in the wizard where it fails. If retry does not work, exit the installer and relaunch it. If problem persists, contact CA Support (http://www.ca.com/in/support.aspx).

Post-Installation Tasks

Complete the following post-installation tasks based on the CA Service Management 14.1.02 product /products installed in your system:

- Post Installation Steps for CA Service Desk Manager (see page 700)
- Post Installation Steps for CA Asset Portfolio Manager (see page 722)
- Post Installation Steps for CA Service Catalog (see page 723)
- Post Installation Steps for Unified Self-Service (see page 724)

Post Installation Steps for CA Service Desk Manager

After installing CA SDM 14.1.02, perform the following post-installation steps based on your server configuration:

- Post Installation Steps for Conventional Configuration (see page 700).
- Post Installation Steps for Advanced Availability Configuration. (see page 704)
- Optional Steps for Specific Issues when Installing CA Service Desk Manager 14.1.02 (see page 711) .

For more information on how to perform post-backout steps, see Post-Backout Steps for CA Service Desk Manager 14.1.02. (see page 733)

Post Installation Steps for CA SDM Conventional Configuration

Complete the following post installation steps for CA SDM Conventional Configuration:

- Install CA Service Management 14.1.02 on CA SDM 14.1 (see page 701)
  - Mandatory Steps (see page 701)
  - Mandatory Steps for CA Business Intelligence (see page 702)
    - Import Service Desk BIARs (see page 702)
    - Use Dashboard Reports (see page 703)
  - Mandatory Steps for CA SDM Mobility (see page 703)

- Install CA Service Management 14.1.02 on CA SDM 14.1.01 (see page 703)

Install CA Service Management 14.1.02 on CA SDM 14.1

Follow these steps:

1. To reconfigure CA SDM on primary server, run the following command:

   ```
   pdm_configure
   ```

   Important! Do not select Load Default Data.

2. Navigate to *NX_ROOT**data* folder.

3. To load data, run the following commands:

   ```
   pdm_load -f santafe_insert.dat
   pdm_load -f santafe_update.dat
   pdm_load -f tucson_insert.dat
   pdm_load -r -f tucson_delete.dat
   ```

4. Alert users to clear browser cache. Run the following command:

   ```
   pdm_webcache -Hpdm_webcache -b
   ```

5. Repeat **Step 1** and **Step 4** on the secondary server.

Mandatory Steps

Follow these steps:

1. Create a backup of *web.xml* from *NX_ROOT**bopcfg**www**CATALINA_BASE**webapps**CAisd**WEB-INF* in your local directory to perform a backout, if required.

2. Open the *web.xml* file from *NX_ROOT**bopcfg**www**CATALINA_BASE**webapps**CAisd**WEB-INF.*

3. Search for the following statement:
   <!-- Add filter here -->

4. Copy and paste the following configuration under the *<!-- Add filter here -->* statement:

   ```
   <!-- Cross-origin support for Attachments Servlet -->
   <filter>
   <filter-name>CORS</filter-name>
   <filter-class>com.thetransactioncompany.cors.CORSFilter</filter-class>
   <init-param>
   <param-name>cors.supportedMethods</param-name>
   <param-value>POST, GET, OPTIONS</param-value>
   </init-param>
   <init-param>
   <param-name>cors.allowOrigin</param-name>
   ```

```
<param-value>*</param-value>
</init-param>
</filter>
```

5. Search for the following statement:
   <!-- Add filter-mapping here -->

6. Copy and paste the following configuration under the *<!-- Add filter-mapping here -->* statement:

```
<!-- Cross-origin support for Attachments Servlet -->
<filter-mapping>
<filter-name>CORS</filter-name>
<servlet-name>UploadServlet</servlet-name>
</filter-mapping>
```

7. Verify that the configurations under the filter and filter-mapping statements are as shown in the following sample:

```
<!-- Add filter here -->
<!-- Cross-origin support for Attachments Servlet -->
<filter>
<filter-name>CORS</filter-name>
<filter-class>com.thetransactioncompany.cors.CORSFilter</filter-class>
<init-param>
<param-name>cors.supportedMethods</param-name>
<param-value>POST, GET, OPTIONS</param-value>
</init-param>
<init-param>
<param-name>cors.allowOrigin</param-name>
<param-value>*</param-value>
</init-param>
</filter>
<!-- Add filter-mapping here -->
<!-- Cross-origin support for Attachments Servlet -->
<filter-mapping>
<filter-name>CORS</filter-name>
<servlet-name>UploadServlet</servlet-name>
</filter-mapping>
```

8. Save and close the *web.xml* file.

9. Repeat the **Steps 1-8** to update *web.xml.tpl* file in the *NX_ROOT\samples\pdmconf\web.xml.tpl* folder to avoid losing these changes when pdm_configure is run.

10. Run the *pdm_configure* command.

11. Start CA SDM services.

Mandatory Steps for CA Business Intelligence

Complete the following steps if you have installed CA Business Intelligence:

- Import Service Desk BIARs (see page 702)
- Use Dashboard Reports (see page 703)

Import Service Desk BIARs

Follow these steps:

- Download the required patch from CA Support and follow the instructions provided in the Test Fix.
  - Windows: RO79125
  - Linux: RO79126
  - Solaris: RO79127
  - AIX: RO79128
    For example, download the Windows patch readme RO79125 and follow the instructions mentioned in the section *Procedure to create a backup .biar file*.

Use Dashboard Reports

Before you use dashboard reports, ensure that both CA SDM and CA Service Catalog use the same CA Business Intelligence server.

- Run the following queries if you have configured MDB with Oracle database:

```
create or replace function MDBADMIN.left(str1 varchar2 :=NULL,num1 NUMBER)
RETURN VARCHAR2
as
ascii_chr varchar2(32767);
begin
ascii_chr:= substr(str1,1, num1);
return ascii_chr;
end;

Update report_labels set language_code ='en' where language_code='en ';
Update report_labels set language_code ='De' where language_code='De ';
```

Mandatory Steps for CA SDM Mobility

Follow these steps:

1. Navigate to *NX_ROOT\bopcfg\www\CATALINA_BASE_REST\webapps*.
2. Create a backup and delete the workflow folder.
3. Verify that the workflow folder is created after the CA SDM server services are recycled.

Note: To resolve specific issues when installing CA SDM 14.1.02, see Optional Steps for Specific Issues when Installing CA Service Desk Manager 14.1.02 (see page 711).

Install CA Service Management 14.1.02 on CA SDM 14.1.01

If you are installing CA SDM 14.1.02 on CA SDM 14.1.01 installation, perform the following steps:

Important: Before you proceed, ensure that you have performed the post-installation steps mentioned in the CA SDM 14.1.01 readme.

Follow these steps:

1. To reconfigure CA SDM on primary server, run the following command:

   ```
   pdm_configure
   ```

   Important! Do not select **Load Default Data**.

2. Navigate to the *NX_ROOT*\data folder.

3. To load data, run the following commands:

   ```
   pdm_load -f tucson_insert.dat
   pdm_load -r -f tucson_delete.dat
   ```

4. To alert users to clear browser cache, run the following commands:

   ```
   pdm_webcache -Hpdm_webcache -b
   ```

5. Repeat **Step 1** and **Step 4** on the secondary server.

   Note: To resolve specific issues when installing CA SDM 14.1.02, see Optional Steps for Specific Issues when Installing CA Service Desk Manager 14.1.02 (see page 711).

Post Installation Steps for Advanced Availability Configuration

The following post-installation options are available for CA SDM Advanced Availability (AA) Configuration:

Install CA Service Management 14.1.02 on CA SDM 14.1

For this procedure, the following host name examples are considered:

- Background server host name is *sdmcahost1*
- Standby server host name is *sdmcahost2*
- Application server host name is *sdmcahost3*

Follow these steps:

1. Stop CA SDM services on all Advanced Availability servers.
2. Log on to the standby server that you want to promote as the new background server.
   For example, promote *sdmcahost2* server as the background server.
3. Run the following command on the standby server to start the CA SDM configuration wizard:

   ```
   pdm_configure
   ```

   Important: On the last configuration screen, before clicking **Finish**, uncheck the **Start service when completed** checkbox.

   For example, execute the *pdm_configure* command on the *sdmcahost2* server.
4. To promote the standby server as the new background server, perform the following steps.

1. a. To suppress version control on the standby (*sdmcahost2)* and background (*sdmcahost1)* servers, run the following command:

      ```
      pdm_server_control -v
      ```

   b. Start the services on standby server (*sdmcahost2)*.

   c. To promote the standby server (*sdmcahost2)* as the new background server, run the following command:

      ```
      pdm_server_control -b
      ```

2. To alert users to clear browser cache, run the following command:

   ```
   pdm_webcache -Hpdm_webcache -b
   ```

3. On the original background server (*sdmcahost1)*, run the CA SDM 14.01.02 patch installer.
   For more information on how to install the patch on a specific operating system, see Install CA Service Management 14.1.02 (see page 688). For example, to install CA SDM 14.1.02 on Windows, see Install CA Service Management 14.1.02 (Windows) (see page 688).
4. Run the following command on the original background server (*sdmcahost1)* to start the CA SDM configuration wizard:

   ```
   pdm_configure
   ```

   Important: On the last configuration screen, before clicking **Finish**, uncheck the **Start service when completed** checkbox.

5. Execute the following commands on the original background server (*sdmcahost1)*:

a. To suppress version control on the original background server (*sdmcahost1)*, run the following command:

```
pdm_server_control -v
```

b. Start the services on the original background server (*sdmcahost1)*.

c. To promote the original background server (*sdmcahost1)* as the background server, run the following command:

```
pdm_server_control -b
```

6. Perform the following steps:

a. Navigate to *NX_ROOT\data.*

b. To load data from CA SDM 14.1.01, run the following commands:

```
pdm_load -f santafe_insert.dat
pdm_load -f santafe_update.dat
pdm_load -f tucson_insert.dat
pdm_load -r -f tucson_delete.dat
```

c. To alert users to clear browser cache, run the following command:

```
pdm_webcache -H
pdm_webcache -b
```

7. Start the services on the original standby server (*sdmcahost2)*.

8. On all application servers (*sdmcahost3)*, run the CA SDM 14.01.02 patch installer.
For more information on how to install the patch on a specific operating system, see Install CA Service Management 14.1.02 (see page 688). For example, to install CA SDM 14.1.02 on Windows, see Install CA Service Management 14.1.02 (Windows) (see page 688).

9. Run the following command on the application server (*sdmcahost3)* to start the CA SDM configuration wizard:

```
pdm_configure
```

10. To alert users to clear browser cache, run the following command:

```
pdm_webcache -H
pdm_webcache -b
```

Mandatory Steps

Follow these steps:

1. Open *web.xml* from *NX_ROOT\bopcfg\www\CATALINA_BASE\webapps\CAisd\WEB-INF.*

2. Search for the following statement:
<!-- Add filter here -->

3. Copy and paste the following configuration under the *<!-- Add filter here -->* statement:

```
<!-- Cross-origin support for Attachments Servlet -->
<filter>
<filter-name>CORS</filter-name>
```

```
<filter-class>com.thetransactioncompany.cors.CORSFilter</filter-class>
<init-param>
<param-name>cors.supportedMethods</param-name>
<param-value>POST, GET, OPTIONS</param-value>
</init-param>
<init-param>
<param-name>cors.allowOrigin</param-name>
<param-value>*</param-value>
</init-param>
</filter>
```

4. Search for the following statement:
   <!-- Add filter-mapping here -->

5. Copy and paste the following configuration under the *<!-- Add filter-mapping here -->* statement:

```
<!-- Cross-origin support for Attachments Servlet -->
<filter-mapping>
<filter-name>CORS</filter-name>
<servlet-name>UploadServlet</servlet-name>
</filter-mapping>
```

6. Verify that the configurations under the filter and filter-mapping statements are as shown in the following sample:

```
<!-- Add filter here -->
<!-- Cross-origin support for Attachments Servlet -->
<filter>
<filter-name>CORS</filter-name>
<filter-class>com.thetransactioncompany.cors.CORSFilter</filter-class>
<init-param>
<param-name>cors.supportedMethods</param-name>
<param-value>POST, GET, OPTIONS</param-value>
</init-param>
<init-param>
<param-name>cors.allowOrigin</param-name>
<param-value>*</param-value>
</init-param>
</filter>
<!-- Add filter-mapping here -->
<!-- Cross-origin support for Attachments Servlet -->
<filter-mapping>
<filter-name>CORS</filter-name>
<servlet-name>UploadServlet</servlet-name>
</filter-mapping>
```

7. Save the *web.xml* file.

8. Restart tomcat.

9. Repeat the **Steps 1-8** to update the *web.xml.tpl* file located in *NX_ROOT\samples\pdmconf\web.xml.tpl.*

10. Run the *pdm_configure* command.

11. Start CA SDM services.

Mandatory Steps for the CA Business Intelligence

Complete the following steps if you have installed CA Business Intelligence:

- Import Service Desk BIARs (see page 708)
- Use Dashboard Reports (see page 708)

Import Service Desk BIARs

Follow these steps:

- Download the required patch from CA Support and follow the instructions provided in the Test Fix.
  - Windows: RO79125
  - Linux: RO79126
  - Solaris: RO79127
  - AIX: RO79128
    For example, download the Windows patch readme RO79125 and follow the instructions mentioned in the section *Procedure to create a backup .biar file*.

Use Dashboard Reports

Follow these steps:

1. Ensure that both CA SDM and CA Service Catalog use the same CA Business Intelligence server.
2. If you have configured MDB with Oracle database, run the following commands:

```
create or replace function MDBADMIN.left(str1 varchar2 :=NULL,num1 NUMBER)
 RETURN VARCHAR2
 as
 ascii_chr varchar2(32767);
 begin
 ascii_chr:= substr(str1,1, num1);
 return ascii_chr;
 end;

Update report_labels set language_code ='en' where language_code='en ';
Update report_labels set language_code ='De' where language_code='De ';
```

Mandatory Steps for CA SDM Mobility

Follow these steps:

1. Navigate to *NX_ROOT\bopcfg\www\CATALINA_BASE_REST\webapps*.
2. Create a backup and delete the workflow folder.
3. Verify that the workflow folder is created after CA SDM server services are recycled.

Note: To resolve specific issues when installing CA SDM 14.1.02, see Optional Steps for Specific Issues when Installing CA Service Desk Manager 14.1.02 (see page 711).

Install CA Service Management on CA SDM 14.1.01

Perform the following post-installation steps, if you have installed CA SDM 14.1.02 on CA SDM 14.1.0:

Important: Ensure that you have performed the post-installation steps mentioned in patch installation on 14.1 (see page 704).

1. Stop CA SDM services on all Advanced Availability servers.
2. Log on to the standby server to promote it as the new background server.
   For example, promote the *sdmcahost2* server as the background server.
3. Run the following command on the standby server (*sdmcahost2)* to start the CA SDM configuration wizard:

   ```
   pdm_configure
   ```

   Important: On the last configuration screen, before clicking **Finish**, uncheck the **Start service when completed** checkbox.

4. To promote the standby server (*sdmcahost2)* as the new background server, perform the following steps:
   a. To suppress version control on the standby (*sdmcahost2)* and background servers (*sdmcahost1)*, run the following command:

      ```
      pdm_server_control -v
      ```

   b. Start the services on standby server (*sdmcahost2)*.
   c. To promote the standby server (*sdmcahost2)* as the new background server, run the following command:

      ```
      pdm_server_control -b
      ```

5. To alert users to clear browser cache, run the following commands:

   ```
   pdm_webcache -Hpdm_webcache -b
   ```

6. On the original background server (*sdmcahost1)*, run the CA SDM 14.01.02 patch installer. For more information on how to install the patch on a specific operating system, see Install CA Service Management 14.1.02 (see page 688). For example, to install CA SDM 14.1.02 on Windows, see Install CA Service Management 14.1.02 (Windows) (see page 688).
7. Run the following command on the original background server (*sdmcahost1)* to start the CA SDM configuration wizard:

   ```
   pdm_configure
   ```

Important: On the last configuration screen, before clicking **Finish**, uncheck the **Start service when completed** checkbox.

8. Execute the following commands on the original background server (*sdmcahost1)*:

    a. To suppress version control on the original background server (*sdmcahost1)*, run the following command:

    ```
    pdm_server_control -v
    ```

    b. Start the services on the original background server (*sdmcahost1)*.

    c. To promote the original background server (*sdmcahost1)* as the background server, run the following command:

    ```
    pdm_server_control -b
    ```

9. Perform the following steps:

    a. Navigate to the *NX_ROOT**data* folder.

    b. To load data from CA SDM 14.1.01, run the following commands:

    ```
    pdm_load -f tucson_insert.dat
    pdm_load -r -f tucson_delete.dat
    ```

    c. To alert users to clear browser cache, run the following command:

    ```
    pdm_webcache -H
    pdm_webcache -b
    ```

10. Start the services on the original standby server (*sdmcahost2)*.

11. On all application servers (*sdmcahost3)*, run the CA SDM 14.01.02 patch installer.
    For more information on how to install the patch on a specific operating system, see Install CA Service Management 14.1.02 (see page 688). For example, to install CA SDM 14.1.02 on Windows, see Install CA Service Management 14.1.02 (Windows) (see page 688).

12. Run the following command on the application servers (*sdmcahost3)* to start the CA SDM configuration wizard:

    ```
    pdm_configure
    ```

13. To alert users to clear browser cache, run the following command:

    ```
    pdm_webcache -H
    pdm_webcache -b
    ```

Note: To resolve specific issues when installing CA SDM 14.1.02, see Optional Steps for Specific Issues when Installing CA Service Desk Manager 14.1.02 (see page 711).

Optional Steps for Specific Issues when Installing CA Service Desk Manager 14.1.02

This section lists how to resolve specific issues when installing CA Service Desk Manager 14.1.02:

Optional Steps for Specific Issues when Installing CA SDM 14.1.02 on CA SDM 14.1

Prob# USRD 2113

KT_DAEMON MAY TERMINATE WITH STRING TOO BIG ERROR

Resolution:

This fix introduces an NX variable **NX_ALLOW_COMMENT_VIA_UPDATE_STATUS**. Set the value of the variable to **Yes**, to insert comments without changing the status via Update Status window.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s ALLOW_COMMENT_VIA_UPDATE_STATUS -v yes -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s ALLOW_COMMENT_VIA_UPDATE_STATUS -v yes -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 2971

SORT FAILS IN DETAIL PAGE FOR ASCENTED CHARACTERS IN ORACLE

This fix introduces an NX variable **@NX_ORCL_SORTING**. Set this variable to **BINARY_CI** then the CA Service Desk Manager sorts the values according to BINARY_CI. You can also use JAPANESE_M_CI for sorting the Japanese or kana sensitive values and GENERIC_M_CI for polish or Czech characters.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s ORCL_SORTING -v BINARY_CI -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s ORCL_SORTING -v BINARY_CI -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 2991

EXPORTING MORE THAN 5000 CONFIGURATION ITEMS FAILS

This fix introduces an NX variable, **@NX_EXPORT_STATUS_TIMEOUT**. Set this variable to a value greater than 300 milliseconds, which is used if there are more than 5000 configuration items.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s EXPORT_STATUS_TIMEOUT –v 1800 –a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s EXPORT_STATUS_TIMEOUT -v 1800 -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 2992

KD EMAIL NOTIFICATION SENT WITH HIGH URGENCY LEVEL

This fix introduces an NX variable **@NX_KT_EMAIL_NOTIFY_LEVEL**. Set this variable to the new notification urgency level as: 1-Low, 2-Normal, 3-High, 4-Emergency

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s KT_EMAIL_NOTIFY_LEVEL -v 1 -a pdm_option.inst

Where, 1 is the Low urgency level
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s KT_EMAIL_NOTIFY_LEVEL -v 1 -a pdm_option.inst -t
 Where, 1 is the Low urgency level
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3024

HEALTHSERVLET MAKES TOMCAT FILE SIZE HUGE

If HealthServlet webapp is already deployed, perform the following steps:

1. Stop the Apache Tomcat server on which HealthServlet webapp is hosted.
2. Take a backup of the file: */webapps/HealthServlet/WEB-INF/classes/health.xml*
3. Delete the HealthServlet */webapps/HealthServlet* folder.
4. Copy the file *$NX_ROOT/samples/HealthServlet/HealthServlet.war* to *webapps* folder.
5. Restart the Apache Tomcat server.
6. Copy back the *health.xml* file to the folder: */webapps/HealthServlet/WEB-INF/classes*

Prob# USRD 3029

SQL ERROR MAY OCCUR WHEN OPENING KNOWLEDGE DOCUMENT

This fix introduces an NX variable **@NX_KD_TICKET_ACCURACY**. This variable is used to specify the maximum number of tickets for which the CA Service Desk Manager guarantees an accurate count when displaying a Knowledge Document. These are tickets that have either been solved by the Knowledge Document or that were opened based on the Knowledge Document. The count of these tickets is free from canceled tickets up to the number specified in the NX_KD_TICKET_ACCURACY variable. By default, this value is set to 300.

Note: Setting this value too high may impact performance when opening up Knowledge Documents, depending on your environment. This fix requires that the NX variable **@NX_IGNORE_CANCELED** also be installed and set to **Yes**.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s KD_TICKET_ACCURACY -v 300 -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s KD_TICKET_ACCURACY -v 300 -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3055

ALLOW STRICT SURVEYS TO BE SENT TO MULTIPLE TICKETS

This fix introduces an NX variable **@NX_ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS**. Set this variable to **Yes**, to ensure that strict surveys allow one response per ticket per contact.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS -v Yes -a pdm_option.
inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS -v Yes -a pdm_option.
inst –t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3067

REPORTED BY FIELD NOT FOCUSABLE

This fix introduces an NX variable **@NX_FOCUS_REPORTED_BY**. Set this variable to **Yes**.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s FOCUS_REPORTED_BY -v <XXX> -a pdm_option.inst
```

Where '<XXX>' is set to **Yes**

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s FOCUS_REPORTED_BY -v <XXX> -a pdm_option.inst -t
 Where '<XXX>' is set to Yes
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3200

TWO WORKFLOW TASKS STATUS MAY SHOW PENDING

The fix introduces an NX variable **@NX_INSERT_WF_PREVIOUS** to avoid the status of workflow task to become pending.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s INSERT_WF_PREVIOUS -v YES -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s INSERT_WF_PREVIOUS -v YES -a pdm_option.inst –t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3148

LDAP SERVER CONTACTED WHILE LOGGING IN SSO

This correction introduces an NX variable **@NX_STRIP_DOMAIN_NAME**. Set this variable to **Yes**, to strip the domain name from the login name of the NTLM authenticated user during login to CA Service Desk Manager.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s STRIP_DOMAIN_NAME -v Yes -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s STRIP_DOMAIN_NAME -v Yes -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3124

SLOW PERFORMANCE DUE TO QUEUED TRANSACTIONS ON

This fix introduces an NX variable **@NX_VIRTDB_LOCK_AGENTS**. This variable should be assigned an number equivalent to the number of locking update agents. By default, the value is 1.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s VIRTDB_LOCK_AGENTS -v <XXX> -a pdm_option.inst
 Where, <XXX> is number of locking agent.
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s VIRTDB_LOCK_AGENTS -v <XXX> -a pdm_option.inst -t

Where, <XXX> is number of locking agent.
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 2975

MISSING HTML MESSAGE IN TICKET NOTIFICATION

The fix to this problem introduces an **NX_INSERT_NLH_MSG_HTML** variable that can be tweaked to avoid the problem. Set this variable to **YES**, then the html message body of the notification can be inserted into not_log table. If the *Notification Message Body* is removed from the Default initial message template for request/incident/problem Message Template, the html message will replace the message body of the notification.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s INSERT_NLH_MSG_HTML -v YES -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s INSERT_NLH_MSG_HTML -v YES -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3258

UNEXPECTED BEHAVIOUR ON CLICKING CAB CONSOLE B

Follow these steps:

1. Start the CA Service Desk Manager service.
2. From the command prompt, navigate to the *NX_ROOT**data* folder.
3. Backup the *current usp_pdmMacro* and *usp_pdmMacroParam* tables by running the following commands on the command prompt.

   ```
   pdm_extract usp_pdmMacro > USRD_2789_backup_macro.dat
   ```

   ```
   pdm_extract usp_pdmMacroParam > USRD_2789_backup_param.dat
   ```
4. Verify that these files are successfully created.
5. Update the *usp_pdmMacro* and *usp_pdmMacroParam* tables by running the following commands on the command prompt:

   ```
   pdm_load -u -f data_USRD_2789_UPDATE.dat
   ```

   ```
   pdm_load -i -f data_USRD_2789_INSERT_en-US.dat
   ```
6. Then clear the cache of these tables by executing the following commands:

   ```
   pdm_cache_refresh -t usp_pdmMacro
   ```

```
pdm_cache_refresh -t usp_pdmMacroParam
```

Prob# USRD 2976

PDM_ISQL RETURNS ERROR WHEN PDMWEB.EXE IS RENAMED

- This fix introduces an NX variable **@NX_PDMWEB_RENAMED_TO**. Set the variable to the new cgi name of the webengine.
  To install the option, run the following command from the command prompt on the primary server:

  ```
  pdm_options_mgr -c -s PDMWEB_RENAMED_TO -v <XXX> -a pdm_option.inst
  ```

  Where, <XXX> is the input name used instead of *pdmweb*

  To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

  ```
  pdm_options_mgr -c -s PDMWEB_RENAMED_TO -v <XXX> -a pdm_option.inst -t
  ```

  Restart the server.

- This fix introduces an NX variable **@NX_EXE_EXCLUDE**. Set this variable to **Yes**.
  To install the option, run the following command from the command prompt on the primary server:

  ```
  pdm_options_mgr -c -s EXE_EXCLUDE -v <XXX> -a pdm_option.inst
  ```

  Where, <XXX> is set to **Yes**.

  To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

  ```
  pdm_options_mgr -c -s EXE_EXCLUDE -v <XXX> -a pdm_option.inst -t
   Where, <XXX> is set to Yes.
  ```

  Restart the server.

Prob# USRD 3283

PERFORMANCE ISSUES WITH SUPPORT AUTOMATION DOM

This fix introduces an NX variable **@NX_STOP_SA_DOMSRVR_MASS_UPDATES**. This variable is used to specify whether to send mass updates to NX_SA_DOMSRVR process. Set the value to **Yes** to stop sending the mass updates to NX_SA_DOMSRVR process.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s STOP_SA_DOMSRVR_MASS_UPDATES -v Yes -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s STOP_SA_DOMSRVR_MASS_UPDATES -v Yes -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 3297

KNOWLEDGE REPORT CARD FOR ALL DAYS FAILS

Follow these steps:

1. Copy the contents of *$NX_ROOT\doc\Validation_Patterns_and_Parameters.txt* to the end of *NX_ROOT\bopcfg\www\web.cfg* and *NX_ROOT\bopcfg\www\web.cfg.tpl*, replacing the existing contents of these values in the *web.cfg* and *web.cfg.tpl* files.
   NX_ROOT represents the Service Desk Application Installation folder.

   Note: The contents of *Validation_Patterns_and_Parameters.txt* need to be added to the *web.cfg* file of the desired webengine. For example, if you want to **only** protect the secondary server webengine and the *web.cfg* filename for that webengine is: *secondaryservername-web1.cfg*, then, the contents need to be added to this file and **not** to the default *web.cfg*.

   Important: If the NX_VALIDATE_REQUEST_PARAMETER variable is already installed, you may skip this step.

2. To install the option, run the following command from the command prompt on the primary server:

   ```
   pdm_options_mgr -c -a pdm_option.inst -s VALIDATE_REQUEST_PARAMETER -v 1
   ```

3. To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

   ```
   pdm_options_mgr -c -a pdm_option.inst -s VALIDATE_REQUEST_PARAMETER -v 1 -t
   ```

   For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

4. Restart the CA Service Desk Manager services.

Optional Steps for Specific Issues when Installing CA SDM 14.1.02 on CA SDM 14.1.01

Prob# USRD 2113

KT_DAEMON May Terminate with the STRING TOO BIG Error

Resolution:

The fix introduces a new optional NX variable **NX_ALLOW_COMMENT_VIA_UPDATE_STATUS**. Set the value to **Yes** to insert comments without changing the status through the Update Status window.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s ALLOW_COMMENT_VIA_UPDATE_STATUS -v yes -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s ALLOW_COMMENT_VIA_UPDATE_STATUS -v yes -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 2971

Sorting of Accented Characters in Oracle Fails

Resolution:

The fix introduces a new optional NX variable **@NX_ORCL_SORTING**. Set the value to **BINARY_CI** to sort the values according to BINARY_CI, **JAPANESE_M_CI** to sort the Japanese or kana sensitive values, or **GENERIC_M_CI** to sort the Polish or Czech characters.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s ORCL_SORTING -v BINARY_CI -a pdm_option.inst
```

To avoid losing the change when you run the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s ORCL_SORTING -v BINARY_CI -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Prob# USRD 2991

Export of 5000 and More Configuration Items Fails

Resolution:

The fix introduces a new optional NX variable **@NX_EXPORT_STATUS_TIMEOUT**. The variable is used if there are more than 5000 configuration items. You can set the varible to a value greater than 300 milliseconds.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s EXPORT_STATUS_TIMEOUT –v 1800 –a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s EXPORT_STATUS_TIMEOUT -v 1800 -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the NX_ROOT directory and restart the server.

Prob# USRD 2992

KD Email Notification is Sent with High Urgency Level

Resolution:

Run the following commands to uninstall the NX variables:

```
pdm_options_mgr -c -s KT_EMAIL_NOTIFY_LEVEL -v 1 -a pdm_option.deinst
where 1 is the Low urgency level.

pdm_options_mgr -c -s KT_EMAIL_NOTIFY_LEVEL -v 1 -a pdm_option.deinst -t
where 1 is the Low urgency level.
```

Note: For each secondary CA SDM server you have configured, manually add or update the NX variable above in each secondary CA SDM server machine within its *NX.env* file located under the NX_ROOT directory. A CA SDM product recycle is normally needed for the new NX variable to take effect.

Prob# USRD 3024

HEALTHSERVLET Increases the Size of the TOMCAT File

Resolution:

If the HealthServlet webapp is already deployed, perform the following steps:

1. Stop the tomcat server where the HealthServlet webapp is hosted.
2. Take a backup of the file */webapps/HealthServlet/WEB-INF/classes/health.xml*
3. Delete the HealthServlet/webapps/HealthServlet folder.
4. Copy the file *NX_ROOT/samples/HealthServlet/HealthServlet.war* to the webapps folder.
5. Restart the tomcat server.
6. Copy the *health.xml* file to the folder */webapps/HealthServlet/WEB-INF/classes.*

Prob# USRD 3029

SQL Error May Occur when Opening the Knowledge Document

Resolution:

This fix introduces a new NX variable @NX_KD_TICKET_ACCURACY. This variable is used to specify the maximum number of tickets to which Service Desk will guarantee an accurate count when displaying a Knowledge Document. These are tickets that have either been solved by the Knowledge Document or that were opened based on the Knowledge Document. The count of these tickets will be guaranteed to be free from canceled tickets up to the number specified in

NX_KD_TICKET_ACCURACY. By default, this value is set to 300. Please note that setting this value too high may impact performance when opening up Knowledge Documents, depending on your environment. As well, please note that this correction requires that the NX variable @NX_IGNORE_CANCELED also be installed and set to “Yes”.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s KD_TICKET_ACCURACY -v 300 -a pdm_option.inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s KD_TICKET_ACCURACY -v 300 -a pdm_option.inst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the NX_ROOT directory and restart the server.

Prob# USRD 3055

Allow Strict Surveys to be Sent to Multiple Tickets

Resolution:

The fix introduces a new NX variable **@NX_ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS**. Set the value to **Yes** to let strict surveys allow one response per ticket per contact.

To install the option, run the following command from the command prompt on the primary server:

```
pdm_options_mgr -c -s ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS -v Yes -a pdm_option.
inst
```

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS -v Yes -a pdm_option.
inst –t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the NX_ROOT directory and restart the server.

Prob# USRD 3067

REPORTED BY FIELD NOT FOCUSABLE

Resolution:

The fix introduces a new NX variable **@NX_FOCUS_REPORTED_BY**. You must set the value to **Yes**.

To install the option, run the following command from the command prompt on the primary server::

```
pdm_options_mgr -c -s FOCUS_REPORTED_BY -v <XXX> -a pdm_option.inst
```

where <*XXX*> is set to **Yes**.

To avoid losing changes when you execute the pdm_configure command, run the command with the -t option as follows:

```
pdm_options_mgr -c -s FOCUS_REPORTED_BY -v <XXX> -a pdm_option.inst -t
```

where <*XXX*> is set to **Yes**.

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the NX_ROOT directory and restart the server.

pdm_options_mgr -c -s STOP_SA_DOMSRVR_MASS_UPDATES -v Yes -a pdm_option.inst -t

Post Installation Steps for CA Asset Portfolio Manager

After installing CA Asset Portfolio Management 14.1.02, perform the following post-installation steps:

- Modify the Configurations on Windows Server 2012: (see page 722)
- Modify Event Service (see page 722)
- Modify Import Driver (see page 723)
- Modify Web Server Component (see page 723)

Modify the Configurations on Windows Server 2012:

1. Log in to the CA ITAM web server.
2. Navigate to the *Root/Web Server* folder.
3. Open the *Web.config* file and locate the *system.web* section.
4. Modify the Current Key with the New Key as shown next.
   Current Key:

   ```
   compilation
   ```

   New Key:

   ```
   compilation targetFramework="4.5"
   ```
5. Execute the following command to stop and restart IIS services on the web servers:

   ```
   iisreset
   ```

Modify Event Service

1. Log in to the CA ITAM application server.
2. Navigate to the *Root/Event Service* folder.
3. Open the *CA.Applications.EventService.exe.config* file.
4. Modify the Current Key with the New Key as shown next.
   Current Key:

   ```
   maxNameTableCharCount="16384"
   ```

New Key:

```
maxNameTableCharCount="2147483647"
```

5. Save the file.

Modify Import Driver

1. Log in to the CA ITAM application server.
2. Navigate to the *Root/Import Driver* folder.
3. Open the *ImportDriver.exe.config* file.
4. Modify the Current Key with the New Key as shown next.
   Current Key:

   ```
   maxNameTableCharCount="16384"
   ```

   New Key:

   ```
   maxNameTableCharCount="2147483647"
   ```

5. Save the file.

Modify Web Server Component

1. Log in to the CA ITAM web server.
2. Navigate to the *Root/Web Server* folder.
3. Open the *Web.config* file.
4. Modify the Current Key with the New Key as shown next.

   Current Key:

   ```
   <binding name="st_importBinding"/>
   ```

   New Key:

   ```
   <!--<binding name="st_importBinding" />-->
   <binding name="st_importBinding" maxBufferSize="2147483647"
   maxReceivedMessageSize="2147483647" maxBufferPoolSize="524288" transferMode="
   Buffered">
   <readerQuotas maxDepth="32" maxStringContentLength="2147483647" maxArrayLength="
   2147483647"
   maxBytesPerRead="4096" maxNameTableCharCount="2147483647" />
   </binding>
   >
   ```

5. Save the file.

Post Installation Steps for CA Service Catalog

After installing CA Service Catalog 14.1.02, perform the following post-installation steps:

Enable CORS filter

Perform the following steps to enable CORS filter:

1. Open the *USMHOME/view/webapps/usm/WEB-INF/web.xml* file.
2. Modify the Current Key with the New Key as shown next.
   Current Key:

   ```
   <param-name>cors.allowed.origins</param-name>
   <param-value>*</param-value>
   ```

   New Key:

   ```
   <param-name>cors.allowed.origins</param-name>
   <param-value><http/https>://<Catalog Host Name>:<Catalog Port No>,
   <http/https>://<USS Host Name>:<USS Port No></param-value>
   ```

3. Save the file.
4. Restart the CA Service Catalog Windows Service.

(Optional) Form Cache

Form definitions are cached for better response time with use case like submitting a request and viewing a request. This configuration is ideal for production deployments as form definitions seldom change. However for deployments on development or test environments the form definitions change frequently, it becomes imperative to read the form definition every time instead of using the cache.

Perform the following steps to disable form definition cache:

1. Open the *USMHOME/view/conf/ehcache.xml* file.
2. Modify the Current Key with the New Key as shown next.
   Current Key:

   ```
    <cache name="system.form.cache" maxBytesLocalHeap="100M" eternal="false"
   overflowToDisk="false" timeToIdleSeconds="86400" timeToLiveSeconds="120000"/>
   ```

   New Key:

   ```
    <cache name="system.form.cache" maxBytesLocalHeap="100M" eternal="false"
   overflowToDisk="false" timeToIdleSeconds="2" timeToLiveSeconds="2"/>
   ```

3. Save the file.
4. Restart the CA Service Catalog Windows Service.

Post Installation Steps for Unified Self-Service

Perform the following optional post-installation steps for USS 14.1.02:

Prerequisites

Create a backup of the *US4SM\OSOP\portal-ext.properties* file.

Note: *US4SM* is the default Unified Self-Service installation directory.

Customize CA SDM Data Source Property

Perform the following steps to customize the CA SDM Data Source Property:

1. Open the *US4SM\OSOP\portal-ext.properties* file and copy the following content at the end of the file:

```
# SDM Datasource Config Fields
# Maximum number of the SDM Fields that can be shown in SDM Datasource config
Fields sections
# If no value/invalid value/ value less than 4 is specified, it will default to
10
sdm.configFields.maxFieldsToShowInConfigOptionsPage = 10
# If you want this property to be tenant specific, prefix the Web ID of the
tenant to the property. It is case-sensitive
# (Web Id can be obtained from the http(s)://server-name:<port-no>/group
/control panel > Portal Instances)
# Example Format:
# someCompany.com.sdm.configFields.maxFieldsToShowInConfigOptionsPage = 10
```

2. Save the file and restart (see page 1704) the services.

Enable or Disable the Community

Follow these steps:

1. Open *US4SM\OSOP\portal-ext.properties* and copy the following content at the end of the file:

```
# Community On/Off
# Community/Message board feature can be disabled by the setting property
disable.uss.community to true (case sensitive)
# Example - with Multi tenancy
# For a specific tenant, prefix the property with the tenant webID
# For tenants, if the value is not defined or the property is missing,Community
is enabled, by default.

# someCompany.com.disable.uss.community = true

# Example - All other tenant Community will be disabled if the value for the
property is true (case sensitive).
# If the value is not defined or the property is missing, Community is enabled,
by default.
```

```
# disable.uss.community = true
```

2. Save the file and restart (see page 1704) the services.

Enable Clickjacking Filter

Follow these steps:

1. Open the *US4SM\OSOP\tomcat-7.0.40\conf\web.xml* file.

2. Search for the text: *Built In Filter Definitions*
   The Built In Filter section appears as follows:
   <!-- ================== Built In Filter Definitions ==================== -->

   <filter>
   .
   .
   .
   </filter>

3. Add the following filter at the end of the *Built In Filter Definitions* section:

```
<!-- Filter :Restricts framing of USS application in all domains expect the
current domain in which USS is hosted -->
<filter>
<filter-name>ClickjackFilterSameOrigin</filter-name>
<filter-class>org.owasp.esapi.filters.ClickjackFilter</filter-class>
<init-param>
<param-name>mode</param-name>
<param-value>SAMEORIGIN</param-value>
</init-param>
</filter>
<filter-mapping>
<filter-name> ClickjackFilterSameOrigin </filter-name>
<url-pattern>/*</url-pattern>
</filter-mapping>
```

4. Save and close the file and restart (see page 1704) the services.

USS Announcements are Formatted Incorrectly for Windows

1. Navigate to the *US4SM\OSOP\tomcat-7.0.40\bin* folder and edit the file *wrapper.conf:*

   a. Modify the variable *wrapper.java.additional.20* value from *-Duser.timezone=GMT* to *-Duser.timezone=sdm-time-zone*
      For Example: '-Duser.timezone=America/Denver'. (Mountain Time)

   b. Save and close the file.

2. Navigate to *US4SM\OSOP* folder and *a*ppend the following content at the end of the *portal-ext.properties* file.

```
#set this to show the announcement date format in 24/12 hr
#format:
# dd-MMM-yy hh.mm.ss aa for 12 hr format
# dd-MMM-yy HH.mm.ss for 24 hr format
announcement.date.format=dd-MMM-yy hh.mm.ss aa
```

3. Save the file and restart (see page 1704) the services.

USS Announcements are Formatted Incorrectly for Linux

1. Navigate to the *US4SM\OSOP\tomcat-7.0.40\bin* folder and edit the file *setupenv.sh*

   a. Modify the variable *Duser.timezone* value from *-Duser.timezone=GMT* to *-Duser.timezone=sdm-time-zone*
   For Example: '-Duser.timezone=America/Denver'. (Mountain Time)

   b. Save and close the file.

2. Navigate to *US4SM\OSOP* folder and *a*ppend the following content at the end of the *portal-ext.properties* file.

```
#set this to show the announcement date format in 24/12 hr
#format:
# dd-MMM-yy hh.mm.ss aa for 12 hr format
# dd-MMM-yy HH.mm.ss for 24 hr format
announcement.date.format=dd-MMM-yy hh.mm.ss aa
```

3. Save the file and restart (see page 1704) the services.

For more information about USS enhancements, see CA Service Management Release 14.1.02 Enhancements (see page 69).

Uninstall CA Service Management 14.1.02

This article contains the following:

To uninstall CA Service Management 14.1.02, perform the following steps as per the product /products installed in your system:

Uninstall CA Service Desk Manager 14.1.02

To uninstall CA SDM 14.1.02, perform the following based on the type of operating system used by you:

Uninstall CA Service Desk Manager 14.1.02 (Windows)

Perform the following steps to uninstall the patch if you have installed CA SDM on Windows:

1. Log into CA SDM as an Administrator.
2. Shut down CA Service Desk Manager Server.
3. Navigate to the location *where you have extracted the CA Service Management Installer zip package*.
4. Locate *CASM_14.1.02_CommonPatchInstaller _Win\Installer\filestore\utils\ApplyPTF*.
5. Click **APPLYPTF**.
6. Select **Backout PTF** from the local or remote nodes option.
7. Click **Next**.
8. Enter the binary for language-independent patch or the language-dependent patch name. The following binary and language-dependent patches are supported:
   - Binary: **RO86155**
   - Language Master CAZ**: RO86157**
   - English:**RO86158**
   - French: **RO86161**
   - French Canadian: **RO86163**
   - German: **RO86159**
   - Italian:**RO86165**
   - Japanese: **RO86166**
   - Portuguese Brazil: **RO86164**
   - Simplified Chinese: **RO86167**
   - Spanish: **RO86160**
9. Leave all other options intact unless the node is incorrect
10. Click **Next** to uninstall CA SDM 14.1.02. Repeat steps **6-9** to remove the required language-dependent patch.
11. To restore MDB database, revert to database backup that you took before applying the patch. For more information, see Prerequisites (see page 686) .

12. To perform the post-backout steps, see Post-Backout Steps for CA Service Desk Manager 14.1.02 (see page 733).

Uninstall CA Service Desk Manager 14.1.02 (Linux)

Perform the following steps to uninstall the patch, if you have installed CA SDM 14.1.02 on Linux:

1. Log into CA SDM as root user.
2. Shut down the CA Service Desk Manager Server.
3. Navigate to the location where you have extracted the CA Service Management Installer tar.gz package.
4. Navigate to the *CASM_14.1.02_CommonPatchInstaller _Linux\Installer\filestore\utils\ApplyPTF* folder.
5. The following binary and language-dependent patches are supported:
   - Binary name: **RO86202**
   - Language Master: **RO86203**
   - English: **RO86204**
   - French: **RO86206**
   - German: **RO86205**
   - Japanese: **RO86207**
6. Execute the following command to remove the binaries or the language-dependent patches. Replace the <patch_name> with the binary or language-dependent patch name:

   ```
   ./applyptf.<platform> -b <patch_name>  -e <NX_ROOT>
   ```

   Here, <platform> specifies the operating system and <NX_ROOT> specifies the CA SDM installed location.

   For example:

   ```
   ./applyptf.linux -b RO86202 -e /opt/CA/ServiceDeskManager
   ```

7. To restore MDB database, revert to database backup that you took before applying the patch.
8. To perform the post-backout steps, see Post-Backout Steps for CA Service Desk Manager 14.1.02 (see page 733).

Uninstall CA Service Desk Manager 14.1.02 (Solaris)

Perform the following steps to uninstall if you have installed CA SDM 14.1.02 on Solaris:

1. Log into CA SDM as root user.
2. Shut down the CA Service Desk Manager Server.
3. Navigate to the location where you have extracted the CA Service Management Installer tar.gz package.
4. Navigate to the *CASM_14.1.02_CommonPatchInstaller _Solaris\Installer\filestore\utils\ApplyPTF* folder.
5. The following binary and language-dependent patches are supported:
   - Binary name: **RO86196**
   - Language Master: **RO86197**
   - English:**RO86198**
   - French: **RO86200**
   - German: **RO86199**
   - Japanese: **RO86201**
6. Execute the following command to remove the binaries or the language-dependent patches. Replace the <patch_name> with the binary or language-dependent patch name:

   ```
   ./applyptf.<platform> -b <patch_name> -e <NX_ROOT>
   ```

   Here, <platform> specifies the operating sytsem and <NX_ROOT> specifies the CA SDM installed location.
   For example:

   ```
   ./applyptf.sun -b RO86196 -e /opt/CA/ServiceDeskManager
   ```

7. To restore MDB database, revert to database backup that you took before applying the patch.
8. To perform post-backout steps, see Post-Backout Steps for CA Service Desk Manager 14.1.02 (see page 733).

Uninstall CA Service Desk Manager 14.1.02 (AIX)

Perform the following steps to uninstall if you have installed CA SDM 14.1.02 on AIX:

1. Log into CA SDM as root user.
2. Stop the CA Service Desk Manager Server.
3. Navigate to the location where you have extracted the CA Service Management Installer tar.gz package.
4. Navigate to the *CASM_14.1.02_CommonPatchInstaller _AIX\Installer\filestore\utils\ApplyPTF* folder.

5. The following binary and language-dependent patches are supported:

   - Binary name: **RO86216**
   - English: **RO86217**

6. Execute the following command to remove the binaries or the language-dependent patches. Replace the <patch_name> with the binary or language-dependent patch name:

   ```
   ./applyptf.<platform> -b <patch_name> -e <NX_ROOT>
   ```

   Here, <platform> specifies the operating sytsem and <NX_ROOT> specifies the CA SDM installed location.
   For example:

   ```
   ./applyptf.aix -b
   RO86216
    -e /opt/CA/ServiceDeskManager
   ```

7. To restore MDB database, revert to database backup that you took before applying the patch. For more information, see Prerequisites (see page 686).

8. To perform post-backout steps, see Post-Backout Steps for CA Service Desk Manager 14.1.02 (see page 733).

Uninstall CA Asset Portfolio Manager 14.1.02

You can uninstall CA Asset Portfolio Management components except CA MDB. CA MDB cannot be uninstalled. Perform the following steps:

1. From Windows **Start** menu, navigate to **Control Panel**, **Programs, Programs and Features, View Installed Updates** on the left pane.

2. Under CA Asset Portfolio Management, select **CA ITAM 14.1.02** .

3. Follow on-screen wizard instructions to uninstall.
   CA APM 14.1.02 is uninstalled.

4. If you have installed CA APM on multiple servers, follow steps **1-3** to uninstall.

5. To restore MDB database, revert to database backup that you took before applying the patch.

Uninstall Unified Self-Service 14.1.02

To uninstall Unified Self-Service, perform the following steps:

1. Log into USS as an Administrator.

2. Stop the USS Server and Jetty Server.

3. Navigate to the location *where you have extracted the CA Service Management Installer zip package.*

4. Locate *CASM_14.1.02_CommonPatchInstaller _Win\Installer\filestore\utils\ApplyPTF*.

5. Click **APPLYPTF-64bit.exe**.
6. Select the **Backout PTF** on local or remote nodes option.
7. Click **Next**.
8. Enter **RO86148** in the first field.
   Leave all other options intact unless the node is incorrect.
9. Click **Next** to uninstall USS 14.1.02.
10. To restore MDB database, revert to database backup that you took before applying the patch.
11. To perform post-backout steps, see Post-Backout Steps for Unified Self-Service 14.1.02 . (see page 736)

Uninstall Unified Self-Service 14.1.02 (Linux)

Perform the following steps to uninstall the patch, if you have installed USS 14.1.02 on Linux:

1. Log into USS as root.
2. Shut down the Unified Self-Service Server and Jetty Server.
3. Navigate to the location where you have extracted the USS Installer tar.gz package.
4. Navigate to the *CASM_14.1.02_CommonPatchInstaller _Linux\Installer\filestore\utils\ApplyPTF* folder.
5. The following binary and language-dependent patches are supported:
   - Binary name: **RO86149**
6. Execute the following command to remove the binaries or the language-dependent patches. Replace the <patch_name> with the binary or language-dependent patch name:

   ```
   ./applyptf.<platform> -b <patch_name>  -e <NX_ROOT>
   ```

   Here, <platform> specifies the operating system and <NX_Root> specifies the USS installed location.

   For example:

   ```
   ./applyptf.linux -b  RO86149 -e /opt/CA/Self Service
   ```

7. To restore MDB database, revert to database backup that you took before applying the patch.
8. To perform post-backout steps, see Post-Backout Steps for Unified Self-Service 14.1.02 . (see page 736)

Uninstall CA Service Catalog 14.1.02

To uninstall CA Service Catalog, perform the following steps:

1. Click **Control Panel**, **Programs and Features**.
2. Double-click the CA Service Catalog r14.1.02 and follow the uninstallation wizard instructions.

Post-Backout Steps for CA Service Desk Manager 14.1.02

Perform the following post-backout steps based on your server configuration:

Post-Backout Steps for CA SDM (Conventional)

Ensure that you are logged in as Administrator to uninstall CA SDM 14.1.02. Perform the following steps:

1. Navigate to the *NX_ROOT**site* folder from the command prompt window.
2. Run the following commands on primary and secondary servers.

   ```
   pdm_perl -pi.old -e "s/resources.created=1/resources.created=0/g" config.
   properties
   ```

3. To reconfigure the primary and secondary server run the following command:

   ```
   pdm_configure
   ```

Note: Do not select *Load Default Data*.

4. Start CA SDM services.

Post-Backout Steps (Advanced Availability)

For CA SDM Advanced Availability configuration, perform the following post-back steps on standby and application servers:

1. Stop CA SDM Services on all Advanced Availability servers.
2. Log on to the standby server that you will promote as the new background server:
3. Run the following command on the standby server:

   ```
   pdm_configure
   ```

4. Promote the standby server as the new background server by executing the following commands:

   a. To suppress version control on the standby and background servers, run the following command:

   ```
   pdm_server_control -v
   ```

   b. To promote the standby server as the new background server, run the following command:

   ```
   pdm_server_control -b
   ```

5. Run *pdm_configure* command on the new standby server.
6. Run *pdm_configure* command on all application servers.

Optional Steps for Specific Issues when Uninstalling CA Service Desk Manager 14.1.02 on 14.1 or 14.1.01

Optional steps below are required only if you installed them during the patch installation process as shown in Optional Steps for Specific Issues when Installing CA SDM 14.1.02 (see page 711).

This list is common when you uninstall CA SDM 14.1.02 on CA SDM 14.1 or CA SDM 14.1.01.

KT_DAEMON MAY TERMINATE WITH STRING TOO BIG ERROR (Prob# USRD 2113)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -sALLOW_COMMENT_VIA_UPDATE_STATUS -v yes -a pdm_option.deinst
```

```
pdm_options_mgr -c -s ALLOW_COMMENT_VIA_UPDATE_STATUS -v yes -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

SORT FAILS IN DETAIL PAGE FOR ASCENTED CHARACTERS IN ORACLE (Prob# USRD 2971)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s ORCL_SORTING -v BINARY_CI -a pdm_option.deinst
```

```
pdm_options_mgr -c -s ORCL_SORTING -v BINARY_CI -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

EXPORTING MORE THAN 5000 CONFIGURATION ITEMS FAILS (Prob# USRD 2991)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s EXPORT_STATUS_TIMEOUT –v 1800 –a pdm_option.deinst
```

```
pdm_options_mgr -c -s EXPORT_STATUS_TIMEOUT -v 1800 -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

KD EMAIL NOTIFICATION SENT WITH HIGH URGENCY LEVEL (Prob# USRD 2992)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s KT_EMAIL_NOTIFY_LEVEL -v 1 -a pdm_option.deinst
```

```
pdm_options_mgr -c -s KT_EMAIL_NOTIFY_LEVEL -v 1 -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

SQL ERROR MAY OCCUR WHEN OPENING KNOWLEDGE DOCUMENT (Prob# USRD 3029)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s KD_TICKET_ACCURACY -v 300 -a pdm_option.deinst
```

```
pdm_options_mgr -c -s KD_TICKET_ACCURACY -v 300 -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

ALLOW STRICT SURVEYS TO BE SENT TO MULTIPLE TICKETS (Prob# USRD 3055)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS -v Yes -a pdm_option.
deinst
```

```
pdm_options_mgr -c -s ALLOW_STRICT_SURVEY_FOR_MULTIPLE_TICKETS -v Yes -a pdm_option.
deinst –t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

REPORTED BY FIELD NOT FOCUSABLE (Prob# USRD 3067)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s FOCUS_REPORTED_BY -v <XXX> -a pdm_option.deinst
```

```
pdm_options_mgr -c -s FOCUS_REPORTED_BY -v <XXX> -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

Optional Steps for Specific Issues when Uninstalling CA Service Desk Manager 14.1.02 only on 14.1

TWO WORKFLOW TASKS STATUS MAY SHOW PENDING (Prob# USRD 3200)

Execute the following command to uninstall the NX variable:

```
pdm_options_mgr -c -s INSERT_WF_PREVIOUS -v Yes -a pdm_option.deinst
```

```
pdm_options_mgr -c -s INSERT_WF_PREVIOUS -v Yes -a pdm_option.deinst -t
```

For each secondary CA SDM server that you configured manually, add or update the NX variable in each secondary CA SDM server in the NX.env file located in the *NX_ROOT* directory and restart the server.

UNEXPECTED BEHAVIOUR ON CLICKING CAB CONSOLE B (Prob# USRD 3258)

Follow these steps:

1. From the command line, execute the following commands from the $NX_ROOT\data folder:

   ```
   pdm_load -u -f USRD_2789_backup_macro.dat
    pdm_load -u -f USRD_2789_backup_param.dat
   ```

2. Clear the cache, by executing the following commands:

   ```
   pdm_cache_refresh -t usp_pdmMacro
    pdm_cache_refresh -t usp_pdmMacroParam
   ```

Post-Backout Steps for Unified Self-Service 14.1.02

Post-Backout Steps for Unified Self-Service 14.1.02 (Windows)

Ensure that you have administrator privileges to uninstall USS 14.1.02. Perform the following post-backout steps:

1. Stop USS Services.

2. Execute the following command:

   ```
   APPLYPTF-64 bit
   ```

3. Select ***Backout PTF*** on local or remote nodes.
4. Click **Next**.
5. Enter the fix number in the first field.
6. Leave all other options intact.
7. Click **Next** to uinstall.
8. Start USS services.

Post-Backout Steps for Unified Self-Service 14.1.02 (Linux)

Ensure that you have root user privileges. Perform the following steps:

1. Stop USS Services.
2. Run the following command to uninstall the patch:

   ```
   applyptf -b T51R166 -e $US4SM
   ```

   Note: *US4SM* is the default Unified Self-Service install directory.

3. Start USS services.

(Optional) Upgrade Apache Tomcat

To upgrade Apache Tomcat for Unified Self-Service, perform the following steps:

- (Optional) Upgrade Apache Tomcat to 7.0.59 for Unified Self-Service (Linux) (see page 737)
- (Optional) Upgrade Apache Tomcat to 7.0.59 for Unified Self-Service (Windows) (see page 740)

(Optional) Upgrade Apache Tomcat to 7.0.59 for Unified Self-Service (Linux)

Unified Self-Service (USS) provides out-of-the box Apache Tomcat 7.0.40. You can upgrade to Apache Tomcat 7.0.59 (Linux) by performing the following steps:

1. Stop USS services.
2. Navigate to *$US4SM/OSOP*.

   a. Create a backup of the *tomcat-7.0.40* folder.

b. Rename folder *tomcat-7.0.40* to *tomcat-7.0.40_original*

c. Create an empty folder *tomcat-7.0.40* at *$US4SM\OSOP*

> **Note:** *$US4SM* is the default Open Space installation directory.

3. Click here (http://archive.apache.org/dist/tomcat/tomcat-7/v7.0.59/bin/apache-tomcat-7.0.59.zip) and download the Apache Tomcat 7.0.59 version:

   a. Unzip the *apache-tomcat-7.0.59.zip* file.

   b. Copy the content of *apache-tomcat-7.0.59* folder to *$US4SM/OSOP/tomcat-7.0.40* folder and provide the permissions and access rights of *tomcat-7.0.40_original* to *tomcat-7.0.40*.
   The folder tomcat-7.0.40 contains the following files and folders:

   - bin
   - jre
   - LICENSE
   - NOTICE
   - RUNNING.txt
   - webapps
   - conf
   - lib
   - logs
   - RELEASE-NOTES
   - temp
   - work

4. Copy the following files to the *$US4SM/OSOP/tomcat-7.0.40* folder:

   - *$US4SM/OSOP/tomcat-7.0.40_original/bin/setenv.bat*
   - *$US4SM/OSOP/tomcat-7.0.40_original/bin/setenv.sh.backup*
   - *$US4SM/OSOP/tomcat-7.0.40_original/bin/setenv.sh*

5. Copy the *$US4SM/OSOP/tomcat-7.0.40_original/conf/Catalina* folder to *$US4SM/OSOP /tomcat-7.0.40/conf*

6. Open the *$US4SM/OSOP/tomcat-7.0.40/conf/catalina.properties* file and replace:

   common.loader=${catalina.base}/lib,${catalina.base}/lib/.jar,${catalina.home}/lib,${catalina. home}/lib/*.jar*

   with

   common.loader=${catalina.base}/lib,${catalina.base}/lib/.jar,${catalina.home}/lib,${catalina. home}/lib/*.jar,${catalina.home}/lib/ext,${catalina.home}/lib/ext/*.jar*

7. Save and close the file.

8. Navigate to *$US4SM/OSOP/tomcat-7.0.40_original/conf* folder and copy the *server.xml* and overwrite the file existing in *$US4SM/OSOP/tomcat-7.0.40/conf/* .

9. Navigate to *$US4SM /OSOP/tomcat-7.0.40_original/* and copy the *jre* folder to *$US4SM/OSOP /tomcat-7.0.40*

10. Copy the files and folder from *$US4SM/OSOP/tomcat-7.0.40_original/lib/ext* to *$US4SM /OSOP/tomcat-7.0.40/lib* folder:

11. Delete the following folders in *$US4SM/OSOP/tomcat-7.0.40/webapps:*

    - docs
    - example
    - host-manager
    - manager
    - ROOT

12. Copy the *$US4SM/OSOP/tomcat-7.0.40_original/webapps* folder to *$US4SM/OSOP/tomcat-7.0.40*

13. Copy the *$US4SM/OSOP/tomcat-7.0.40_original/.donotdelete* folder to *$US4SM/OSOP /tomcat-7.0.40*

14. Delete content from the following folders:

    - *$US4SM /OSOP/tomcat-7.0.40/temp*
    - *$US4SM /OSOP/tomcat-7.0.40/work*

15. Start the USS services.

(Optional) Upgrade Apache Tomcat to 7.0.59 for Unified Self-Service (Windows)

Unified Self-Service (USS) provides out-of-the box Apache Tomcat 7.0.40. To upgrade to Apache Tomcat 7.0.59 on Windows, perform the following steps:

1. Stop USS services.
2. Navigate to the *$US4SM\OSOP* folder or the location where you have installed USS.
    a. Create a backup of the *tomcat-7.0.40* folder.
    b. Rename *$US4SM\OSOP\tomcat-7.0.40* to *$US4SM\OSOP\tomcat-7.0.40_original*
    c. Create an empty folder for tomcat-7.0.40 at *$US4SM\OSOP*

    > **Note:** *$US4SM* is the default Open Space installation directory.

3. Click here (http://archive.apache.org/dist/tomcat/tomcat-7/v7.0.59/bin/apache-tomcat-7.0.59.zip) to download Apache Tomcat 7.0.59.
    a. Unzip the downloaded file.
    b. Copy the content of *apache-tomcat-7.0.59* folder to *$US4SM\OSOP\tomcat-7.0.40*
    The folder tomcat-7.0.40 contains the following files and folders:

- bin
- conf
- lib
- logs
- temp
- webapps
- work
- LICENSE
- NOTICE
- RELEASE-NOTES
- RUNNING

4. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original\bin* and copy the following files to *$US4SM\OSOP\tomcat-7.0.40:*
   - InstallTomcat-NT.bat
   - setenv.bat
   - setenv.bat.backup
   - setenv.sh
   - StartTomcat-NT.bat
   - StopTomcat-NT.bat
   - Tomcat.bat
   - UninstallTomcat.bat
   - wrapper.conf
   - wrapper.conf.backup
   - wrapper.exe
   - wrapper-license-app.conf
5. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original\conf\,* copy and replace the *Catalina* folder in *C:\Program Files\CA\Self Service\OSOP\tomcat-7.0.40\conf\Catalina*
6. Navigate to *$US4SM\OSOP\tomcat-7.0.40\conf* and edit the *catalina.properties* file and and replace the following line:
   common.loader=${catalina.base}/lib,${catalina.base}/lib/.jar,${catalina.home}/lib,${catalina.home}/lib/*.jar*
   with
   common.loader=${catalina.base}/lib,${catalina.base}/lib/.jar,${catalina.home}/lib,${catalina.home}/lib/*.jar,${catalina.home}/lib/ext,${catalina.home}/lib/ext/*.jar*
7. Save and close the file.
8. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original\conf* and copy the *server.xml* file and replace with the *server.xml* file in *$US4SM\OSOP\tomcat-7.0.40\conf*
9. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original\ folder* and copy the *jre* folder to *$US4SM \OSOP\tomcat-7.0.40*
10. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original\lib* and copy the following files and folder to *$US4SM\OSOP\tomcat-7.0.40\lib:*
    - ext
    - wrapper.dll

- wrapper.jar

11. Navigate to *$US4SM\OSOP\tomcat-7.0.40\webapps* folder and delete the following folders from*:*
    - docs
    - example
    - host-manager
    - manager
12. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original* and copy the *webapps* folder to *$US4SM \OSOP\tomcat-7.0.40*
13. Navigate to *$US4SM\OSOP\tomcat-7.0.40_original\ folder* and copy *.donotdelete* folder to *$US4SM\OSOP\tomcat-7.0.40*
14. Navigate to *$US4SM\OSOP\tomcat-7.0.40* and delete the content in the following folders:
    - temp
    - work
15. Start USS services.

Run SMPatchReport Utility to Get Installed Patches List

The SMPatchReport Utility automatically identifies and lists the CA Service Management product patches (CA SDM, CA APM, CA Service Catalog, and USS) that are installed on your local system. It provides you the option of generating a PDF or emailing the patch report summary. To email the patch report summary, you must configure the SMTP mail server properties. For more information, see Set the SMTP Server Configuration Properties (see page) .

Note: If you have multiple systems in your environment with different versions of CA Service Management product patches installed, you must run this utility on each system individually to generate the patch report summary.

Prerequisites

1. Setting 32-bit Java is mandatory for Windows and Non-Windows
2. For Windows, you must set the path variable under Environment Variables.
3. For Non-Windows, export Java path till bin/java/ in JAVA_HOME.

Run SMPatchReport Utility (Windows)

1. Navigate to *common patch installer/filestore/SMPatchReport* location on your local system.

2. Double-Click **Report.exe** to run the utility.
   The utility identifies and lists all the CA Service Management product patches that are installed in the system.

3. Select **PDF** or **E-Mail** options to generate a PDF or email the patch report summary respectively.

> **Note:** To view the generated PDF, ensure that you have a PDF reader installed in your system. For example, Adobe Acrobat Reader.

Run SMPatchReport Utility (Non_Windows)

1. Change directory to *common patch installer/filestore/SMPatchReport* location on your local system.

2. Execute **Report.sh** to run the utility.

   The utility identifies and lists all the CA Service Management product patches that are installed in the system.

3. Select **PDF** or **E-Mail** options to generate a PDF or email the patch report summary respectively.

> **Note:** To view the generated PDF, ensure that you have a PDF reader installed in your system. For example, Adobe Acrobat Reader.

Set the report.config.property File

The report.config.property file is located under *common patch installer/filestore/SMPatchReport*. Set the following properties to configure smtp mail server and other properties:

- **smtp.mail.to**: Specifies the email address to which email notifications are sent. In case of multiple email addresses, separate the values using a comma (,).

- **smtp.mail.from**: Specifies the email address from which email notifications are sent.

- **smtp.mail.authenticate**: Authenticates the user with SMTP server.
  The default value is **false**, which allows you to send email without authentication. If the value is set to **true**, the system attempts to authenticate the user. In this case, *smtp.mail.username* and *smtp.mail.password* must be set.

- **smtp.mail.username**: Specifies the user name of the account that connects to the SMTP server.
- **smtp.mail.password**: Specifies the password for the user name used in the *smtp.mail.username* property. The password must be encrypted. For more information on encrypting a password in the report.config.properties file, see Encrypt Password (see page 744) .
- **smtp.mail.host**: Specifies the host name of the SMTP server to connect to or the IP address of the server to which the email is sent.
- **smtp.mail.port**: Specifies the port number on which the SMTP service runs. This property value defaults to TCP port number 25, which is reserved for SMTP. Email administrators can change this value.
- **report.log.path**: Specifies the location where the SMPatchReport log is created. By default, it is created in your current directory.

Encrypt a Password

To encrypt password*,* set the value for *smtp.mail.password* property in the report.config,properties file. Perform the following steps to encrypt a password :

1. Open the Command Prompt window.
2. Change your working directory to SMPatchReport.
3. Ensure that 32-bit java is available on the system.
4. (Windows) Execute the following command to encrypt the password:

   ```
   java -cp ./lib/SMPatchReport.jar;./lib/sd-utils.jar;./lib/jsafeFIPS.jar;./lib
   /log4j-1.2.15.jar;. com.ca.patch.Util.StringEncrypter encrypt TextToEncrypt
   ```

5. (Non-Windows) Execute the following command to encrypt the password:

   ```
   Java -cp ./lib/sd-utils.jar:./lib//SMPatchReport.jar:./lib/jsafeFIPS.jar:./lib
   /log4j-1.2.15.jar:. com.ca.patch.Util.StringEncrypter encrypt TextToEncrypt
   ```

6. The Encrypted password is displayed on the console. Copy the password from the console and set the value in the *smtp.mail.password* property.

Troubleshooting the Installation Process

Issue: CA SDM Database Patch Fails

Sometimes, ApplyPTF fails to apply the CA Service Management 14.1.02 patch as some files are used by another process. As a result, the *Cum2* folder is not created under the *CASDM/Patches* folder.

Resolution:

Exit and launch the installer again.

Deploying Oracle RAC with CA Service Management

This section describes how to deploy the CA Service Management Products (CA Service Desk Manager, CA Service Catalog, CA IT Asset Manager, and Unified Self-Service) with Oracle Real Application Clusters (RAC). You can deploy one or combination of these products as required. Oracle RAC provide high availability to applications by removing the single server as a single point of failure.

Oracle Real Application Clusters (RAC) Install Requirements

Note: For more information about installing Oracle RAC, see Oracle documentation.

Ensure to verify and complete the following Oracle RAC installation prerequisites:

- Download Oracle Database 11g Release 2 (11.2.0.3.0 and above) (Oracle Grid infrastructure and database) software from Oracle (http://www.oracle.com/technetwork/database/enterprise-edition/downloads/112010-win64soft-094461.html) Downloads. Create the Oracle database (SID).
- The Single Client Access Name (SCAN) must be defined in the Domain Name Service (DNS) or Oracle Grid Naming Service (GNS).
- Create at least one single DNS or GNS name that resolves to three IP addresses using a round-robin algorithm. For the installation to succeed, the SCAN must resolve to at least one IP address.
- SCAN Virtual IP (VIP) addresses must be on the same subnet as the virtual IP addresses and public IP addresses.
- The virtual machines can be limited to 2 GB of swap but results in a prerequisite install check failure. The best practice define a 3+ GB of swap.
- Ensure that you have the 64-bit version of Windows Server and Oracle 11g Release 2.
- Install the Oracle Grid Infrastructure following the Oracle Documentation installation procedures.

How to Install Oracle RAC With CA Service Management

To install Oracle RAC with CA Service Management (CA Service Desk Manager, CA Service Catalog, CA IT Asset Manager, and/or Unified Self-Service), complete the following steps:

Follow these steps:

1. Install Oracle 11gr2 32-bit client software on system or systems where you plan to install the CA Service Management products.

2. Create a TNS entry on the system or systems.

3. Enable the client-side connect-time failover by setting FAILOVER=ON in the corresponding client-side TNS entry:

```
TESTRAC =
(DESCRIPTION =
(ADDRESS_LIST=
(FAILOVER = ON)
(ADDRESS = (PROTOCOL = TCP)(HOST = <scan_host_name>)(PORT
= <1521>))
)(CONNECT_DATA = (SERVICE_NAME = <netservice name>))
```

Install the CA Service Management Products with Oracle RAC

For Installing the CA Service Management Product or products with Oracle RAC, perform the following steps:

Follow these steps:

1. Launch the CA Service Management installer.
   For more information, see Install CA Service Management. (see page 296)

2. Select **CA Service Management** from Select the Required Installer screen.

3. Review and accept the license agreement information.

4. Select **Oracle** as the database type in the Database Configuration Screen and enter the following Oracle database details

   a. **Database Server**: Enter the Oracle database host name <SCAN_HOST_NAME>.

   b. **Tablespace Path (on DB Server)**: Enter +DATA.
      Complete all fields on the Oracle Database Configuration Screen. For more information, see Install CA Service Management (see page 296).

5. Select the required CA Service Management product or products.

6. Follow the on-screen instructions on the installer wizard and complete the CA Service Management installation.
   For more information about Oracle RAC Failover issue with CA Service Catalog, see Release Notes (see page 210).
   For more information about Oracle RAC Failover issue with CA SDM, see Release Notes (see page 184).
   For more information about Oracle RAC Failover issue with CA ITAM, see Release Notes (see page 257).

How to Move the CA MDB Data from the Source to the Target Systems

You can move the CA MDB database from the source system and configure it to work on the target system.

Important! We recommend that you test the procedure in a test environment before implementing on a production system. Currently, moving the CA MDB data is not supported for clustered database, load balancer, and application cluster.

Prerequisites

Before you move the CA MDB data, perform the following tasks:

1. Back up the CA MDB database on your target system.
2. Install the following products on the source and target systems:
   - CA Service Desk Manager 14.1 and above
   - CA Service Catalog 14.1 and above
   - CA Asset Portfolio Manager 14.1 and above
   - Unified Self-Service 14.1 and above
3. Ensure that the source and target systems have an identical installation configuration setup.

CA Service Management Tables

Affected CA Service Management Tables

The following tables are impacted when you move the CA MDB database on Microsoft SQL Server or Oracle:

Common Tables	CA SDM	CA Service Catalog	CA APM	CA Unified Self-Service Tables
	ci_mdr_provider	usm_configuration	al_meta_refresh_state	os_ExternalSource

Common Tables	CA SDM	CA Service Catalog	CA APM	CA Unified Self-Service Tables
al_cdb_comp_installstate_bkup			**Note:** This table is applicable only for CA Service Management 14.1.01 installation.	
al_cdb_componentinstallstate	options		al_meta_binary_store	os_ExternalSourcePropertiesUser_
al_cdb_config_params_bkup	sapolicy		al_process_account	PortalPreferences
al_cdb_configurationparameters	usp_servers object_promotion promo_hist **Note:** These tables are displayed only if CA Service Management 14.1.02 is installed in your environment.		al_apmp_def al_apmp_operation al_apmp_content_types al_apmp_progress_status al_apmp_progress al_apmp_record_filter al_apmp_run_stage	
al_cdb_files	usp_domsrvr		**Note:** These tables are displayed only if CA Service Management 14.1.02 patch is installed in your environment.	
ca_application_registration	usp_configuration usp_webeng-domsrvr usp_webengine usp_webengine_alias usp_domsrvr			

Move the CA MDB Database on Microsoft SQL Server

If you have installed Microsoft SQL Server database in your system, perform the following steps:

1. Review CA Service Management Tables (see page 747) to verify the tables that are impacted when you move the CA MDB database on Microsoft SQL Server.

2. Stop the following CA Service Management services on both the source and target application servers:

   Note: Some of these services might not be applicable if the associated products or components are not installed in your environment.

   a. **Common Admin Service**:

      - CA Service Management Admin

   b. **CA SDM**:

      Note: If you have any shared UNC paths, ensure that you copy the paths from the source system to the target system.

      - CA Service Desk Manager ODBC Data Access
      - CA Service Desk Manager ODBC Agent
      - CA Service Desk Manager Server

   c. **CA Service Catalog Services**:

      - CA Service Accounting
      - CA Service Catalog

   d. **CA Asset Portfolio Management Services**:

      - IIS Admin Service
      - CA Asset Portfolio Management - Data Importer Engine
      - CA Asset Portfolio Management - Event Service
      - CA Asset Portfolio Management - Export Service
      - CA Asset Portfolio Management - HW Reconciliation Engine
      - CA Asset Portfolio Management - LDAP Import Service
      - CA Asset Portfolio Management - Registration Service

- CA SM Server

e. **Unified Self-Service Services**:

- CA Unified Self-Service Jetty Server
- CA Unified Self-Service Server

3. On the source system, back up the **mdb** and **uss_mdb** database, and copy the mdb back up files to the target system.
4. (Optional) If you are using a named instance (non-default MDB name), ensure that you have selected the appropriate MDB instance name for the backup.
5. On the target system, perform the following steps to back up the tables:

   a. Navigate to Microsoft SQL Management Studio, right-click **MDB** (or the appropriate MDB instance name applicable for your system), and select **Tasks**, **Generate Scripts**.

   b. Click **Select Specif ic database obj ects**.

   c. Select the **Tables** option and choose the appropriate tables.

   d. Click **Next**.

   e. Select **Advanced** and navigate to **Types of Data**.

   f. Change it from **Schema Only** to **Schema and Data**, and click **OK**.

      By default, your selection is now saved to a file **%user%\documents\script.sql**.

   g. Specify different file names for MDB and USS_MDB.

   h. Perform steps **a-f** for uss_mdb.

      Two script files are generated.

6. On the target system, perform the following steps to detach the existing *mdb and uss_mdb:*

   a. Navigate to Microsoft SQL Management Studio, right-click **MDB** (or appropriate MDB name), **Tasks**, **Detach**.

   b. On the Detach Database screen, select **Drop Connections**.

   c. Click **OK**.

7. Restore *mdb and uss_mdb* backup on the target system that was copied from the source system. Select **Overwrite the existing database** (WITH REPLACE) from the **Options** tab. Ensure that the database name on the target system is retained.

Note: Restore must complete without errors.

8. Run the following Microsoft SQL *auto_fix_user* script for user mdbadmin and ussdbadmin users:

   - sp_change_users_login 'AUTO_FIX','mdbadmin'
   - sp_change_users_login 'AUTO_FIX', 'apmdba' (Applicable only if CA APM is installed and upgraded from previous release versions)
   - sp_change_users_login 'AUTO_FIX', 'uapmadmin' (Applicable only if CA APM is installed and upgraded from previous release versions)
   - sp_change_users_login 'AUTO_FIX', 'uapmbatch' (Applicable only if CA APM is installed and upgraded from previous release versions)
   - sp_change_users_login 'AUTO_FIX', 'uapmreporting' (Applicable only if CA APM is installed and upgraded from previous release versions)
   - sp_change_users_login 'AUTO_FIX', 'usmadmin' (Applicable only if CA Service Catalog is installed and upgraded from previous release versions)
   - sp_change_users_login 'AUTO_FIX', 'ServiceDesk' (Applicable only if CA SDM is installed and upgraded from previous release versions)
   - sp_change_users_login 'AUTO_FIX','ussdbadmin' (Applicable only for USS)

9. Verify that the mdbadmin and ussdbadmin users are now mapped to **mdb**/**uss_mdb** and have the **bulkadmin**, **public** roles.

10. On the target system, delete data from the following tables and commit the changes:

    a. Use **mdb** and run the following queries to delete data from the required tables:

       Common Tables:

       - delete from al_cdb_comp_installstate_bkup
       - delete from al_cdb_componentinstallstate
       - delete from al_cdb_config_params_backup
       - delete from al_cdb_configurationparameters
       - delete from al_cdb_files
       - delete from ca_application_registration

       CA SDM Tables :

       - delete from options
       - delete from usp_servers

- delete from sapolicy
- delete from ci_mdr_provider
- delete from usp_domsrvr
- delete from usp_configuration
- delete from usp_webeng_alias
- delete from usp_webeng_domsrvr
- delete from usp_webengine
- delete from object_promotion (applicable only if CA Service Management 14.1.02 is installed)
- delete from promo_hist (applicable only if CA Service Management 14.1.02 is installed)

CA Service Catalog tables:

- delete from usm_configuration

CA APM tables:

- delete from al_meta_binary_store
- delete from al_process_account

Delete the following CA APM tables, if you have CA Service Management 14.1.02 installed in your system:

- delete from al_apmp_def
- delete from al_apmp_operation
- delete from al_apmp_content_types
- delete from al_apmp_progress_status
- delete from al_apmp_record_filter
- delete from al_apmp_run_stage

b. Select **USS_mdb** and run the following queries to delete data from the required tables:

- delete from PortalPreferences
- delete from os_ExternalSource
- delete from os_ExternalSourceProperties

- delete from User_

11. Execute the **script.sql** scripts that was created in **Step 5**.

> **Note:** Ignore the warning message, There is already an object named ... in the Database.

12. (Optional) To disable email notifications, modify the ca contact table query: **Update ca_contact set email_address = ''**.

> **Note:** If USS is installed, disabling the email notifications may cause missing announcements in the target system. We recommend that you add the email addresses for required contacts before performing **Step 13**.

13. Start the services on both the source and the target systems and on the target system, perform the following steps for each product:

    a. **Common Admin Service**:
    CA Service Management Admin

    b. **CA SDM Services**:
    Perform the following steps before you start the CA SDM services:

        i. If your environment has customized CA PAM content, export all the relevant CA PAM Content from the source CA PAM server and import to the target CA PAM server. Complete the required CA PAM content configuration.
        For more information, see CA Process Automation (see page 292) .

        ii. Copy the **site/mods** directory from the source CA SDM server to the target CA SDM server.

> **Note:** This is applicable only if your application environment is customized. This is not applicable for the out-of-the-box (OOTB) content.

        iii. Run the ***pdm_configure*** command without selecting the load default data option.

        iv. Start the following CA SDM services:

- CA Service Desk Manager ODBC Data Access
- CA Service Desk Manager ODBC Agent

- CA Service Desk Manager Server

c. **CA Service Catalog Services**:
Perform the following steps before you start the CA Service Catalog services:

- If your source system has customized CA PAM content, export all relevant PAM content from the source CA PAM server and import to the target CA PAM server. Complete the required configurations for CA PAM content.
For more information, see CA Process Automation . (see page 292)

- If your source system has customized CA EEM policies, export all the relevant CA EEM policies from the source CA EEM server and import to the target CA EEM server.
For more information, see CA Embedded Entitlements Manager . (see page 283)

- Copy filestore directory from the source CA Service Catalog server to the target CA Service Catalog server.

  Note: This is applicable only if customization is carried out on the application environment. This is not applicable for the OOTB content.

- Launch the CA PAM server and access **SLCM_Globaldataset**. and validate that the domain and the CA Service Catalog root business unit names are same.

- Start the following CA Service Catalog services:

  - CA Service Accounting

  - CA Service Catalog

d. **CA Asset Portfolio Management Services**:

- IIS Admin Service

- CA Asset Portfolio Management - Data Importer Engine

- CA Asset Portfolio Management - Event Service

- CA Asset Portfolio Management - Export Service

- CA Asset Portfolio Management - HW Reconciliation Engine

- CA Asset Portfolio Management - LDAP Import Service

- CA Asset Portfolio Management - Registration Service

- CA SM Server

e. **Unified Self-Service Services**:

- CA Unified Self-Service Jetty Server
- CA Unified Self-Service Server

14. Execute the **pdm_k_reindex** command on the CA SDM target system to index knowledge documents that are created and copied from the source system.
15. Verify that CA Service Management applications are accessible. All applications must be up and running.
16. Validate that all CA Service Management Integration scenarios are working seamlessly.

Move the CA MDB Database on Oracle

Perform the following steps to copy and restore CA MDB if you have installed Oracle database in your system:

1. Review CA Service Management Tables (see page 747) to verify the tables that are impacted when you move the CA MDB database on Oracle.
2. Stop the following CA Service Management services on both the source and target application servers.

Note: Some of these services might not be applicable if the associated products or components are not installed in your environment.

a. **Common AdminService**:

- CA Service Management Admin

b. **CA SDMServices**:

Note: If you have any shared UNC paths, ensure that you copy the paths from the source system to the target system.

- CA Service Desk Manager ODBC Data Access
- CA Service Desk Manager ODBC Agent
- CA Service Desk Manager Server

c. **CA Service Catalog Services**:

- CA Service Accounting

- CA Service Catalog

d. **CA Asset Portfolio Management Services**:

- IIS Admin Service
- CA Asset Portfolio Management - Data Importer Engine
- CA Asset Portfolio Management - Event Service
- CA Asset Portfolio Management - Export Service
- CA Asset Portfolio Management - HW Reconciliation Engine
- CA Asset Portfolio Management - LDAP Import Service
- CA Asset Portfolio Management - Registration Service
- CA SM Server

e. **Unified Self-ServiceServices**:

- CA Unified Self-Service Jetty Server
- CA Unified Self-Service Server

3. On the source system, navigate to *C:\app\Administrator\product\11.2.0\dbhome_1\BIN* path to export the database. To Create and grant permissions to the directory, execute the following commands:

```
CREATE OR REPLACE DIRECTORY test_dir AS 'C:\app\Administrator';
GRANT READ, WRITE ON DIRECTORY test_dir TO mdbadmin;
GRANT READ, WRITE ON DIRECTORY test_dir TO ussdbadmin;
```

Note: Ensure that you use the appropriate MDB instance name applicable for your system.

```
expdp mdbadmin/N0tallowed@mdb directory=test_dir dumpfile=mdb.dmp
logfile=expdbmdb.log
```

Note: Ensure that you use the appropriate uss_mdb instance name applicable for your system.

```
expdp ussdbadmin/N0tallowed@uss_mdb directory=test_dir dumpfile=ussmdb.dmp
logfile=expdbussmdb.log
```

4. Copy the **mdb.dmp** and **ussmdb.dmp** files to *C:\app\Administrator* on the target system.
   On target system, take a backup of mdb first and then, take a backup of the required tables.
   To create and grant permissions to the directory, execute the following commands for mdb and uss_mdb:

   ```
   CREATE OR REPLACE DIRECTORY test_dir AS 'C:\app\Administrator';
   GRANT READ, WRITE ON DIRECTORY test_dir TO mdbadmin;
   GRANT READ, WRITE ON DIRECTORY test_dir TO ussdbadmin;
   ```

   Note: Ensure that you use the appropriate MDB instance name.

   ```
   expdp mdbadmin/N0tallowed@mdb directory=test_dir dumpfile=mdb.dmp
   logfile=expdbmdb.log
   ```

   Note: Ensure that you use the appropriate USS MDB instance name.

   ```
   expdp ussdbadmin/N0tallowed@uss_mdb directory=test_dir dumpfile=ussmdb.dmp
   logfile=expdbussmdb.log
   ```

5. If CA Service Management 14.1.02 is installed in your system, the additional tables listed here for CA SDM and CA APM also must be included in the following query:

   - **CA SDM**: object_promotion, promo hist
   - **CA APM**: al_apmp_def, al_apmp_operation, al_apmp_content_types, al_apmp_progress_status, al_apmp_progress, al_apmp_record_filter, l_apmp_run_stage

     ```
     expdp mdbadmin/N0tallowed@mdb tables=al_cdb_comp_installstate_bkup,
     al_cdb_componentinstallstate,
     al_cdb_config_params_backup,
     al_cdb_configurationparameters,
     al_cdb_files,
     ca_application_registration,
     options,
     usp_servers,
     sapolicy,
     ci_mdr_provider,
     usp_domsrvr,
     usp_configuration,
     usp_webeng_domsrvr,
     usp_webengine,
     usp_webeng_alias,
     usm_configuration,
     al_meta_refresh_state,
     al_meta_binary_store,
     al_process_account grants=y indexes=y rows=y constraints=y triggers=y
     directory=test_dir dumpfile=expdptables.dmp logfile=expdbtables.log
     ```

6. Execute the following command for uss_mdb:

   ```
   expdp system/N0tallowed@uss_mdb tables=os_ExternalSource,
   os_ExternalSourceProperties,
   PortalPreferences, User_ grants=y indexes=y rows=y constraints=y triggers=y
   directory=test_dir dumpfile=expdpusstables.dmp logfile=expdbusstables.log
   ```

7. Import the backup database copied from the source system. Execute the following commands:

   Note: Ensure that you use the appropriate MDB instance name applicable for your system.

   ```
   impdp mdbadmin/N0tallowed@mdb directory=test_dir dumpfile=mdb.dmp
   logfile=impdbmdb.log TABLE_EXISTS_ACTION = TRUNCATE
   ```

   Note: Ensure that you use the appropriate USS MDB instance name.

   ```
   impdp ussdbadmin/N0tallowed@uss_mdb directory=test_dir dumpfile=ussmdb.dmp
   logfile=impdbussmdb.log TABLE_EXISTS_ACTION = TRUNCATE
   ```

8. Drop the tables after import by executing the following commands. Dropping the tables removes the table definitions and rows.

   - **Common Tables**:

     ```
     DROP TABLE al_cdb_comp_installstate_bkup;
     DROP TABLE al_cdb_componentinstallstate;
     DROP TABLE al_cdb_config_params_backup;
     DROP TABLE al_cdb_configurationparameters;
     DROP TABLE al_cdb_files;
     DROP TABLE ca_application_registration;
     ```

   - **CA SDM**:

     ```
     DROP TABLE ci_mdr_provider;
     DROP TABLE options;
     DROP TABLE usp_servers;
     DROP TABLE sapolicy;
     DROP TABLE usp_domsrvr;
     DROP TABLE usp_configuration;
     DROP TABLE usp_webeng_alias;
     DROP TABLE usp_webeng_domsrvr;
     DROP TABLE usp_webengine;
     ```

     If you have installed CA SDM 14.1.02, execute the following commands to drop tables:

     ```
     DROP TABLE object_promotion;
     DROP TABLE promo_hist;
     ```

     CA Service Catalog:

     ```
     DROP TABLE usm_configuration;
     ```

     CA APM:

     ```
     DROP TABLE al_meta_binary_store;
     DROP TABLE al_process_account;
     ```

     For CA APM 14.1.01 installation, execute the following commands to drop tables:

```
DROP TABLE al_meta_refresh_state;
```

For CA APM 14.1.02, execute the following commands to drop tables: :

```
DROP TABLE al_apmp_def;
DROP TABLE al_apmp_operation;
DROP TABLE al_apmp_content_types;
DROP TABLE al_apmp_progress_status;
DROP TABLE al_apmp_progress;
DROP TABLE al_apmp_record_filter;
DROP TABLE l_apmp_run_stage;
```

- **USS**

```
DROP TABLE os_externalsource;
DROP TABLE os_externalsourceproperties;
DROP TABLE portalpreferences;
DROP TABLE User_;
```

9. Restore the backup of tables from **step 4**. Execute the following command:

```
impdp mdbadmin/N0tallowed@mdb directory=test_dir dumpfile=expdptables.dmp
logfile=expdbtables.log
```

10. For USS, restore the backup of tables from **step 5**: Execute the following command:

```
impdp ussdbadmin/N0tallowed@uss_mdb directory=test_dir dumpfile=expdpusstables.
dmp logfile=impdpusstables.log
```

11. Start the services on both the source and the target systems. On the target system, perform the following steps for each product:

    a. **Common Admin Service**:

    - CA Service Management Admin

    b. **CA SDM Services**:
    Perform the following steps before you start the CA SDM services:

    - If your environment has customized CA PAM content, export all the relevant CA PAM Content from the source CA PAM server and import to the target CA PAM server. Complete the required CA PAM content configuration.
      For more information, see CA Process Automation (see page 292) .

    - Copy the **site/mods** directory from the source CA SDM server to the target CA SDM server.

      Note: This is applicable only if your application environment is customized. This is not applicable for out-of-the-box (OOTB) content.

    - Run the ***pdm_configure*** command without selecting the load default data option.

    - Now, start the following CA SDM services:

      - CA Service Desk Manager ODBC Data Access

- CA Service Desk Manager ODBC Agent
- CA Service Desk Manager Server

c. **CA Service Catalog Services**:
Perform the following steps before you start the CA Service Catalog services:

- If your source system has customized CA PAM content, export all relevant PAM content from the source CA PAM server and import to the target CA PAM server. Complete the required configurations for CA PAM content.
For more information, see CA Process Automation . (see page 292)
- If your source system has customized CA EEM policies, export all the relevant CA EEM policies from the source CA EEM server and import to the target CA EEM server.
For more information, see CA Embedded Entitlements Manager . (see page 283)
- Copy filestore directory from the source CA Service Catalog server to the target CA Service Catalog server.

  Note: This is applicable only if customization is carried out on the application environment. This is not applicable for the OOTB content.

- Launch the CA PAM server and access **SLCM_Globaldataset**.
Validate that the domain and the CA Service Catalog root business unit names are same.
- Now, start the following CA Service Catalog services:
  - CA Service Accounting
  - CA Service Catalog

d. **CA Asset Portfolio Management Services**:

- IIS Admin Service
- CA Asset Portfolio Management - Data Importer Engine
- CA Asset Portfolio Management - Event Service
- CA Asset Portfolio Management - Export Service
- CA Asset Portfolio Management - HW Reconciliation Engine
- CA Asset Portfolio Management - LDAP Import Service
- CA Asset Portfolio Management - Registration Service
- CA SM Server

e. **Unified Self-Service Services**:

- CA Unified Self-Service Jetty Server
- CA Unified Self-Service Server

12. Run the **pdm_k_reindex** command on the CA SDM target system to index knowledge documents that are created and copied from the source system.

13. Verify that CA Service Management applications are accessible. All applications must be up and running.

14. Validate that all CA Service Management Integration scenarios are working seamlessly.

Administering

Common Administration

CA Service Desk Manager

CA Service Catalog

CA Asset Portfolio Management

Administering CA Service Management

CA Service Management provides the ability to perform several administrative tasks that are common to the integrated products from a single interface. Earlier, it was required to manage tenants, users, roles, and other configurations such as CA EEM integration from the respective products' interfaces. However, with CA Service Management, you can manage all the common administrative tasks from the same interface.

Each administrative and configuration task is a service offering that you can access from Unified Self-Service or from CA Service Catalog. The configurations you make are applied to all the installed products of the solution.

As an Administrator, if you want to move MDB from the production to a pre-production environment, you can move the database from the source system and configure it to work on the target system. For more information, see How to Move the CA MDB Data from the Source to the Target Systems . (see page 747)

Note: The common administration service offerings are available only when you install CA Service Catalog as part of the solution. We recommend that you install Unified Self-Service with all combination of product installations and manage the solution administration through Unified Self-Service.

You can perform the following tasks using the service offerings:

- Manage tenants (see page 766)
  Create a new tenant and map tenant structures across integrated products to specify a single tenant structure.

- Manage roles (see page 771)
  Create service management roles and map roles across integrated products.

- Manage users (see page 776)
  Add existing users to the solution; create new users and assign roles to the users.

- Configure LDAP server settings (see page 779)
  Add LDAP servers to the solution to import and synchronize contacts from LDAP user records.

- Configure common components (see page 781)
  Manage component settings that are required to integrate CA Service Management products. Components that you can manage include CA EEM, CA Business Intelligence, CA Process Automation, and mail server.

- Manage product integrations (see page 782)
  Manage the settings of integrated products in the solution.

To view a list of available administrative service offerings and learn how to use them, see Administrative Service Offerings (see page 765).

When to Use the Solution Administration Capability

It is important to understand the scenarios in which you can leverage the solution administration capability:

Scenario 1: When you install a single product

If you install CA Asset Portfolio Management or CA Service Desk Manager, the common administration service offerings are not applicable. You must perform any administrative tasks through the respective product's administration page.

However, if you install CA Service Catalog only, you can use the administrative service offerings to perform administrative tasks of CA Service Catalog.

Scenario 2: When you install a combination of products

- CA Service Desk Manager and CA Asset Portfolio Management
  The common administration service offerings are available only when you install CA Service Catalog. In this scenario, you must use the respective product's administration pages to perform any administrative tasks. For example, to create a user you must create separate users in CA Service Desk Manager and CA Asset Portfolio Management.

- CA Service Desk Manager and CA Service Catalog (or) CA Asset Portfolio Management and CA Service Catalog
  You can use the administrative service offerings to perform administrative tasks. We recommend that you install Unified Self-Service and access the administrative service offerings through the self-service user interface.

- CA Service Desk Manager, CA Asset Portfolio Management, and CA Service Catalog
  You can use the administrative service offerings to perform administrative tasks. We recommend that you install Unified Self-Service and access the administrative service through the self-service user interface.

Any "modifications" or "adaptions" or "configurations" that are done administratively through the interface (web browser, command-line, Web Screen Painter) are "supported", meaning CA Support can assist with basic suggestions and trouble-shooting. CA Support does not do the changes for the customer, they are the customer's responsibility. For example, adding a field to a table and putting the field on a form through Web Screen Painter is a fully supported "modification". Another example, installing or uninstalling a feature through the Options Manager administration is a fully supported "configuration".

Anything to do with SPEL code, Java scripting (or any language scripting), or a customer-specific change to the underlying base code-line (done by CA Services or a Partner), is not supported by CA Support. The customer can do these things, but the customer is responsible for the support, maintenance, and trouble-shooting when things go wrong. If such "customizations" affect expected out-of-the-box behavior, CA Support will ask the customer to remove the customizations and see if the behavior persists.

Administrative Service Offerings

Administrative service offerings let you perform administrative tasks that are common to the products in the solution from a single location. Each service offering has a life cycle and has several phases. By default, the administrative service offerings life cycle has no approvals. To understand more about the request life cycle, see Request Life Cycle (see page 2115).

The table below lists the administrative service offerings and the tasks you can perform:

Service Offering	Task Description
Enable /Disable Multi-tenancy	Enable or disable tenancy management.
Add Tenant	Create a new tenant to access the capabilities of the solution.
Map Tenants	Map the existing tenant structures across integrated products to create a single logical tenant structure.
Manage Tenants	View and update tenants in your organization.
Add Role	Add a role that specifies permissions across products in the solution.
Manage Roles	Search and update service management roles to change what the user sees after logging in to the product. Map the service management roles to appropriate roles in integrated products.
Add User	Add new users to the solution and assign roles to the users.
Manage Users	Search and update details of users of the solution.
Add LDAP Server	Add an LDAP server to import a list of users from an external user store.
Synchronize Users	Automatically create users and assign roles to the users of a product in the solution, that earlier did not have any roles in other products
Manage LDAP Servers	View and update LDAP servers that you have integrated with solution.
Import Users from LDAP	Import a list of users from an external user store such as an active directory.
Configure Components	Manage settings of CA EEM, CA Business Intelligence, CA Process Automation, and mail server.
Manage Integrations	Manage the settings of integrated products in the solution.

Manage Tenants

Multi-tenancy is the ability for multiple independent tenants (and their users) to share a single implementation of CA Service Management. Through CA Service Management, you can create and manage the tenants of products in the solution from a single location. As part of tenancy management, you can perform the following tasks by using the administrative service offerings:

- Create new tenants.
- Map tenancy structures across integrated products (see page 768).
- Search for a list of available tenants.
- Update tenant details.

This article contains the following topics:

Enable or Disable Multi-tenancy

To mange tenants in the solution, you must enable multi-tenancy. You can disable multi-tenancy when you have no tenants in the solution or when you do not want to manage tenants.

Note: When you disable multi-tenancy, tenant related data is available to everyone who has access to the application.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.
2. In the Home page, click Request a Service.
   The Request Page Appears.
3. Under Categories, click Service Management Administration.
4. Click Enable/Disable Multi-Tenancy.
5. Specify whether to enable or disable multi-tenancy and click Submit.

Create Tenant

You can define as many tenants as required to manage multiple separate enterprises that provide support to clients. When you create a new tenant, the tenant views the CA Service Management implementation as solely for its own use and cannot update or view another tenant's data.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Add Tenant.

5. Specify the details and click Submit.

View and Update Tenants

You can view a list of all the tenants that you manage in your organization. When required, you can make changes to tenant details. For example, you can change the terms of usage of a tenant to meet the new terms. If you no longer want to manage the tenant, you can inactivate it.

Note: You cannot update the parent details of the tenant using the administrative service offerings. To update the parent details, you must access the respective product's user interface.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Manage Tenants.

5. Search for the list of available tenants.

6. Select the tenant that you want to update and click Update.

7. Update the tenant details and click Submit.

Map Tenancy Structures across Products in the Solution

As a solution Administrator, if you installed CA Service Management with a combination of products, you must map tenancy structures across the products to create a single tenant structure. If you already have more than one product in your environment and have implemented multi-tenancy, you can leverage your existing tenancy data for performing tenant management from a single location. It is possible that you have named your tenants differently in different products. So, as a first step, you map the tenants in different products and specify how to match them.

For example, *Tenant1* in CA SDM corresponds to *BusinessUnit3* in CA Service Catalog and *Tenant4* in CA APM. Hence, you specify the mapping information to simplify your tenancy management tasks. Once you perform the mapping, you can manage tenants from a single location.

Follow these steps:

1. Step 1: Know When to Map Tenancy Structures (see page 768).
2. Step 2: Review Your Existing Tenancy Structures (see page 768).
3. Step 3: Understand Default and Customized Tenancy Mapping (see page).
4. Step 4: Complete the Tenancy Mapping (see page 770).

Know When to Map Tenancy Structures

It is important to map tenancy structures in the following scenarios:

- You upgraded older versions of your products to CA Service Management. For example, you upgraded CA SDM 12.9 and CA Service Catalog 12.9 to CA Service Management.
- You first installed CA Service Management, but not all the products. However, you choose to integrate another product. For example, you initially installed CA SDM and CA APM as part of the solution. At a later point of time, you decided to install CA Service Catalog.

Review Your Existing Tenancy Structures

Before you perform any of the tenancy management tasks, it is important to review your existing tenant structures in each of the products you installed.

Follow these steps:

1. To view the tenants and the tenant structure in CA SDM, complete the following steps:
   a. Log in to CA SDM as an Administrator
   b. On the Administration tab, select Security and Role Management.
   c. Click the tenant to view the tenant information

   For more information, click Multi-tenancy in CA Service Desk Manager (see page 1343).
2. To view the tenants and the tenant structure in CA APM, complete the following steps:

a. Log in CA APM as an Administrator.

b. Click Administration, Tenancy Management.
The Multi-Tenancy Administration page appears.

c. On the left, click Tenant.

d. Click Go to view all the tenants.

e. Click the tenant to view the tenant information.

For more information, click Implementing Multi-tenancy (see page 1606).

3. To view the tenants and the tenant structure in CA Service Catalog, complete the following steps:

a. Log in to CA Service Catalog as an Administrator.

b. Select Administration, Business Units.

c. Expand the business unit tree and find the business unit that you want.

d. Click a business unit to view the business unit information.

For more information, click Multi-tenancy in CA Service Catalog (see page 1395).

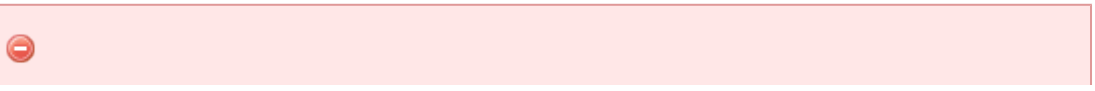
Understand Default and Custom Tenancy Mapping

When you map tenancy structures across the products in the solution, you can choose to automatically map tenants or map them manually. You must understand the different mapping processes and identify the one that better suits your requirements.

Default Tenancy Mapping

In the automatic tenant mapping process, you can choose to automatically map your tenancy structures. Tenant structures are mapped as follows:

- Service Providers of the products are first mapped to each other. In Unified Self-Service, the default tenant is the service provider.
- Based on the names and database IDs of the tenants, each tenant is mapped to tenants in the other product.
- If the number of tenants at a level are different in the products, a new tenant is created. For example, at level 2, CA SDM has four tenants but CA Service Catalog has five tenants. A new tenant is created and is mapped to the fifth tenant in CA Service Catalog.
- Tenants are mapped only if they are at the same level in the products. For example, a first-level tenant in CA Service Desk Manager is mapped only to first-level business unit in CA Service Catalog.



Important! When you choose to map tenant structures automatically, the mapping is successful only if all the products you upgraded to CA Service Management have the same database. If the products are installed on different databases, tenant information on databases other than the CA Service Management database is not migrated. For example, you installed CA SDM 12.9 and CA Service Catalog 12.9 on *database_server1* and *database_server2* respectively. While upgrading, you installed the solution on *database_server1*. Hence, tenant information on *database_server2* is not considered.

Custom Tenancy Mapping

You can map tenancy structures manually to meet your business requirements. Map your tenancy structures using the following rules:

- Do not map tenants that are at different levels. For example, do not map a seventh-level business unit in CA Service Desk Manager to a third-level tenant in CA Service Catalog.
- Do not map the same tenant more than once.
- Do not map a child without mapping all its parents. Map the parents from the tenant level directly above the child through the level directly under the Service Provider tenant.
- Verify that tenant names are unique across all products. For example, if you have a tenant named AAA in CA Service Desk Manager and CA Service Catalog, rename at least one of them to a unique, meaningful name.
- Verify that CA Service Catalog has no duplicate tenant names within its own tenant structure.

Complete the Tenancy Mapping

The Map Tenants service offering lets you perform the tenancy mapping.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.
2. In the Home page, click Request a Service.
   The Request Page Appears.
3. Under Categories, click Service Management Administration.
4. Click Map Tenants.
5. To map tenancy structures automatically, complete the following steps:
   a. Select Default Tenant Mapping.
   b. Click Submit.
6. To map tenancy structures manually, complete the following topics:

a. Select Custom Tenant Mapping.

b. Perform the mapping to meet your requirements and click Update Mapped Tenants.

c. Click Submit.

Manage Service Management Roles

User Role defines the tasks that a user typically performs. You define roles to control security and user interface navigation. Each role defines a focused view of the system by exposing only the functionality necessary for users in that role.

A user's default role determines the system view that is presented upon login. Users with multiple role assignments can switch from one role to another to see different views of the system without having to log out and log back in again.

CA Service Management lets you define service management roles that span across multiple products in the solution. A service management role is group of product roles that lets you assign multiple product roles to user at once. In the solution, you manage several service management roles. For example, System Administrator is a service management role. The System Administrator is responsible for managing configurations and administering roles and users of the individual products in the solution. Earlier, the role of an administrator was different in different products in the solution. Now, through the solution, you create a System Administrator service management role that defines the role of an administrator without having to create the roles separately in each of the products.

You can create and manage roles of integrated solutions from a single location. As part of role management, you can perform the following tasks by using the administrative service offerings:

- Define service management roles.
- Map the service management roles to appropriate roles in integrated products.
- Search for roles.
- Update role details.

This article contains the following topics:

Define a Role

You can create a service management role to meet your business requirements.

When you create a service management role, identify the corresponding roles in the integrated products. The integrated product role is either a predefined role or a role that you manually created. For example, a service management role you create must define the following:

- Name of the service management role: Business User

- Tasks performed by the role: Requests services, reports issues, and collaborates for self-help.
- Role in CA SDM: Employee, Customer
- Role in CA Service Catalog: End User
- Role in CA APM: Default User

Note: Every service management role you create must have a corresponding role in at least one of the integrated products.

The solution provides several predefined service management roles. For more information on predefined service management roles and the corresponding integrated product roles, see Predefined Service Management Roles (see page 772).

To see predefined roles in the each of the installed products, see the following information:

- Predefined roles in CA SDM (see page 1166)
- Predefined roles in CA Service Catalog (see page 1413)
- Predefined roles in CA APM (see page 1570)

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.
2. In the Menu, click My Requests.
   The Request page appears.
3. Click Create and select Request.
4. Under Categories, click Service Management Administration.
5. Click Add Role.
6. Specify the details and click Submit.

Predefined Service Management Roles

The solution provides several predefined service management roles. When you add a new role from predefined service management roles, the solution automatically identifies the corresponding roles in the integrated products.

The table details the predefined service management roles:

Service Management Role	Description	Roles in other products
System Administrator	System Administrators are responsible for managing configurations and administering roles and users of the individual products in the solution.	▪ CA SDM role: System Administrator ▪ CA Service Catalog role: Administrator ▪ CA APM role: System Administrator ▪ Unified Self-Service role: Administrator
Business User	Business users request services, report issues, and collaborate for self-help for issues related to IT.	▪ CA SDM role: Employee, Customer ▪ CA Service Catalog role: End User ▪ CA APM role: Default User ▪ Unified Self-Service role: End User
Approver	Approvers manage the change order process, but typically not the analysts who work on change order tickets.	▪ CA SDM role: Process Manager ▪ CA Service Catalog role: Request Manager ▪ CA APM role: NA ▪ Unified Self-Service role: End User
Service Catalog Administrator	Service Catalog Administrators create, define, and manage services for a specific tenant or business unit.	▪ CA SDM role: NA ▪ CA Service Catalog role: Catalog Administrator ▪ CA APM role: NA ▪ Unified Self-Service role: End User
Service Desk Administrator	Service Desk Administrators administer CA Service Desk Manager.	▪ CA SDM role: Adminstrator

Service Management Role	Description	Roles in other products
		▪ CA Service Catalog role: NA ▪ CA APM role: NA ▪ Unified Self-Service role: End User
L1 Analyst	L1 Analysts provide first-line support within your organization.	▪ CA SDM role: Service Desk Staff ▪ CA Service Catalog role: Request Manager ▪ CA APM role: Default User ▪ Unified Self-Service role: End User
L2 Analyst	L2 Analysts provide second-line support within your organization, which requires more advanced subject matter expertise.	▪ CA SDM role: IT Staff ▪ CA Service Catalog role: Request Manager ▪ CA APM role: Default User ▪ Unified Self-Service role: End User
Configuration Analyst	Configuration Analysts perform tasks within the configuration item life cycle process and second-line CMDB support within your organization.	▪ CA SDM role: CMDB Analyst ▪ CA Service Catalog role: Request Manager ▪ CA APM role: Asset Technician ▪ Unified Self-Service role: End User
Asset Manager	Asset Managers manage asset life cycle and asset fulfillment.	▪ CA SDM role: NA ▪ CA Service Catalog role: Request Manager ▪ CA APM role: Asset Fulfiller

Service Management Role	Description	Roles in other products
		▪ Unified Self-Service role: End User
Asset Management Administrator	Asset Management Administrators administer CA IT Asset Manager.	▪ CA SDM role: NA ▪ CA Service Catalog role: NA ▪ CA APM role: System Administrator ▪ Unified Self-Service role: End User
Service Owner	Service Owners are responsible for managing a specific IT service.	▪ CA SDM role: CMDB Administrator ▪ CA Service Catalog role: Catalog Administrator ▪ CA APM role: NA ▪ Unified Self-Service role: End User
Executive User	Executive users are decision makers, who would be primarily interested in metrics to understand performance and efficiency. The users must have view-only access to reports and dashboards.	▪ CA SDM role: Employee ▪ CA Service Catalog role: End User ▪ CA APM role: Default User ▪ Unified Self-Service role: End User

View and Update Roles

You can search for the available roles in the solution. When required, you can make changes to the role details. For example, you can change the name of the service management role.

You can also map the service management roles to appropriate roles in integrated products. For example, you first created a service management role with the following role definitions:

- Role in CA SDM: Employee, Customer

- Role in CA Service Catalog: End User
- Role in CA APM: Default User

However, at a later of point of time you decided to change the role in CA APM to Asset Technician.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.
2. In the Home page, click Request a Service.
   The Request Page Appears.
3. Under Categories, click Service Management Administration.
4. Click Manage Roles.
5. Search for the list of available roles.
6. Select the role that you want to update and click Update.
7. Update the role details and click Update.
8. Click Submit.

Manage Users

An important part of CA Service Management administration is to define the users accessing the solution. You must establish user security when you add new users to the product and assign a user ID and password. CA Service Management lets you create and manage users of integrated products from a single location. As part of user management, you can perform the following tasks by using the various administrative service offerings:

- Define users.
- Import user details from LDAP.
- Assign roles to users.
- Update user details.

This article contains the following topics:

Create a User

You can add a new user and define solution access rights to the user. When you create a user, the user details are available across the integrated products. For example, if you installed CA Service Desk Manager and CA Service Catalog, you can create a user and the user information is available in both the products.

When you add a new user, assign a role to the user. You can choose any predefined service management role or a custom role service management that you created.

If you have configured LDAP servers, you can also import the list of users. For more information, see Import Users Details from LDAP (see page 777).

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Add User.

5. Specify the user details and click Submit.

Import User Details from LDAP

You can import a list of users from an external user store such as an active directory. Importing users helps you save time when defining your users and makes it easy to synchronize contacts with network user data.

You can import user details from only those LDAP servers that you configure with the solution. Therefore, before you import user details from an LDAP server, ensure that you add the LDAP server to the solution. For more information, see Add LDAP Servers (see page 779).

Note: To ensure user authentication, the LDAP server from which you import user details must be integrated with CA EEM.

When you add or create user details in an active directory, ensure that the you review the user name policies (such as special characters, mandatory parameters) of all the integrated products in the solution and specify the appropriate details.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Import Users from LDAP.

5. Specify the details of the LDAP server from which you want to import users and click Submit.

Synchronize User Details across Integrated Products

You can synchronize users in the following scenarios:

- You upgraded older versions of your products to CA Service Management. For example, you upgraded CA SDM 12.9 and CA Service Catalog 12.9 to CA Service Management.
- You first installed CA Service Management, but not all the products. However, you choose to integrate another product. For example, you initially installed CA SDM and CA APM as part of the solution. At a later point of time, you decided to install CA Service Catalog.

In both the scenarios, the users of one product do not have a role assigned in other products of the solution. To ensure, that the every user has a role in the solution, you must synchronize the users.

When you use the synchronize contacts service offering, users of a product in the solution, that earlier did not have a role in other products, are automatically assigned a role. To assign a role, the service offering performs the following tasks in the order mentioned below:

- Identify the current role of the user in the product. For example, the role of User1 in CA SDM is Employee.
- Determine the service management role that the user's role corresponds to. For example, Employee in CA SDM corresponds to Business User service management role.
- Identify the corresponding role in the other products of the solution. For example, a Business User has the role of End User in CA Service Catalog, and Default User in CA APM.
- Search for the user details in the other integrated products. If the user does not exist, create the user. For example, if User1 details are not available in CA APM, User1 is created.
- Assign the respective product roles to the user.

If a user doesn't have any role assigned, you must specify the default role to be assigned to the user. For example, you imported user details from an LDAP server, but did not assign roles to the users. You specify the default role to be assigned to the user and then synchronize the users.

Note: You can assign only a service management role as a default role.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Synchronize Users.

5. Select the default role and click Submit.

View and Update User Details

You can search for the list of users and update the details, when required. For example, you initially imported users from an LDAP server and later want to change the email id of a few users. You can also inactivate a user when you do not manage the user or the user is no longer part of your organization.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Manage Users.

5. Search for the list of available users.

6. Select the user that you want to update and click Update.

7. Update the user details and click Submit.

Manage LDAP Servers

You can integrate multiple LDAP servers with CA Service Management. The administrative service offerings let you perform the following tasks:

- Add LDAP servers to the solution
- View and update LDAP server details, when required.

This article contains the following topics:

Add LDAP Server

CA Service Management allows you to import user details from an LDAP server. To import users from LDAP servers, you must first add the LDAP server to the solution. You can import users from only those LDAP servers that you added to the solution.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Add LDAP Server.

5. Specify the details of the LDAP server and click Submit

Manage LDAP Servers

You can view and modify the LDAP servers integrated with the solution. When you no longer want an LDAP server integrated with the solution, you can inactivate it.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Manage LDAP Servers.

5. Search for the list of available LDAP servers.

6. Select the LDAP server that you want to update and click Update.

7. Update the LDAP server details and click Submit.

Configure Common Components

CA Common Components are the components that are shared by all the products in the solution and have specific functions to perform. For example, you can configure CA Business Intelligence to generate reports. You can install the components through the CA Service Management solution or install them separately when required.

You can manage the settings of the following common components:

- CA Process Automation
- CA Business Intelligence
- CA EEM

This article contains the following topics:

When to configure the Common Components

You configure the CA common components in the following scenarios:

- You upgraded older versions of your products to CA Service Management and the older versions of the products already use the components.
  In this scenario, you must specify the details of the installed common components. If you integrated each product with different instances of common components, you must identify the instance that you want to integrate with the solution. For example, you integrated CA SDM with CA EEM on *server1* but integrated CA APM with CA EEM on *server2*. You must determine the CA EEM server instance that you want to integrate with the solution.
- You installed CA Service Management for the first time and installed the common components separately.
  In this scenario, you must specify the details of the installed common components to integrate with the solution.
- You already specified the common component details but want to change the settings.

For example, you installed CA Process Automation on *server1* and it is scheduled for maintenance soon. To avoid any downtime, you install CA Process Automation on *server2* and integrate the solution with *server2*.

Important! After you configure the common components, restart the CA SDM and CA Service Catalog services. If you have installed CA APM, you must recycle the Application Pool.

How to Configure the Common Components

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Configure Components.

5. To configure the settings of a component, select the respective tab.
   For example, to update CA EEM settings, click the CA EEM tab.

6. Specify the details and click Submit.
   Note: When you change CA EEM settings, you may experience issues with logging in to the products of the solution. To resolve these issues, you must manually integrate CA EEM with the individual products. For more information, see Troubleshooting (see page 3250).

Manage Product Integrations

You can manage the settings of integrated products in the solution. After you integrated products in the solution, you can change several configuration settings of the integrated products. Based on the new settings, the products are automatically integrated. For example, you changed the host name of the server on which you installed CA SDM. You specify the new host name using the service offering and integration is performed automatically.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.
   If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
   The Request Page Appears.

3. Under Categories, click Service Management Administration.

4. Click Product Integrations.

5. To configure the settings of a product, select the respective tab.
   For example, to update CA SDM settings, click the CA Service Desk Manager tab.

6. Specify the settings and click Submit.

7. (Optional) Any changes you make the CA SDM details are not updated in the *ca_registration* table in the MDB. If necessary, you must update the details in the table manually.

8. (Optional) If CA Process Automation is integrated with CA Service Catalog, any changes you make to the CA Service Catalog details are not updated in the CA SDM and CA Service Catalog datasets in CA Process Automation. You manually update the changes in CA Process Automation.

Business Value Dashboards

A Business value dashboard is a real-time graphical representation of an organization's Key Performance Indicators (KPI) that enables decision makers such as IT managers to make informed decisions. The dashboards represent detailed information about the following:

- Service support metrics such as the categories of incidents or requests, the associated volume, cost, and time spent for incident resolution.
- Operational and functional efficiency information such as, how support groups are occupied, information on ticket transfer from one group to another and the impact on time and cost.

Each dashboard is a service offering that is exposed through CA Service Catalog and accessible through the Unified Self-Service interface.

As an Administrator, you are responsible for the following:

- Configuring the business value dashboard reports
- Defining the users and user access permissions to the dashboards
- Troubleshooting any issues related to business value dashboards

Complete the following steps to implement business value dashboards:

1. Know When the Business Value Dashboards are Available (see page 783)
2. Review the Business Value Dashboards Prerequisites (see page 784)
3. Determine the Business Value Dashboards User Permissions (see page 786)
4. Configure the Business Value Dashboard Reports (see page 786)
5. (Optional) Learn How to Schedule the Business Value Dashboard Reports (see page 787)
6. (Optional) Understand the Important Metrics (see page 791)

Know When the Business Value Dashboards are Available

It is important to understand the various scenarios when you can access the business value dashboards.

Installation Scenarios

The type of installation determines the type and availability of the dashboards.

Type of Installation	Dashboards Availability
New installation For example, as part of CA Service Management, you installed CA Service Catalog and CA SDM for the first time.	Dashboards are available automatically. No configuration is required.
Upgrade For example, you upgraded older releases of CA Service Catalog or CA SDM or both to release 14.1.	Dashboards are available automatically. No configuration is required.
You first installed CA Service Catalog and at a later point installed CA SDM.	Import the the CASM.biar file manually. The file is available at the following location: [ISO_ROOT\filestore\BOXI\biconfig] **Note:** Verify that CA Service Catalog and CA SDM BIAR files are already imported.

Products Installed

The dashboards and the comprising reports that are available to you are based on the products you installed as part of the CA Service Management solution.

Products Installed	Available Dashboards
CA Service Catalog only	Service Demand - Requests
CA Service Desk Manager only	Service Demand - Incidents Operational Effectiveness
CA Service Catalog and CA Service Desk Manager	Service Demand - Requests Service Demand - Incidents Service Demand Operational Effectiveness

Review the Business Value Dashboards Prerequisites

Before you use the dashboard reports, ensure that you considered the following prerequisites:

- Both CA Service Desk Manager and CA Service Catalog must use the same CA Business Intelligence server.
- Run the following queries on an Oracle MDB:

```
create or replace function MDBADMIN.left(str1 varchar2 :=NULL,num1 NUMBER)
RETURN VARCHAR2
```

```
as

ascii_chr varchar2(32767);

begin

ascii_chr:= substr(str1,1, num1);

return ascii_chr;

end;

Update report_labels set language_code ='en' where language_code='en ';
```

- Install the Arial Unicode MS font on the server where the BIAR file will be imported. Additionally, the same font must be available on the machine from where the reports will be viewed. The font files must be copied to the Windows font folder directory.
  Following code must be added to the fontalias.xml located in below location:
  <BusinessObjects Installation Path>\ SAP BusinessObjects Enterprise XI 4.0\win64_x64\fonts

```
<FONT NAME="Arial Unicode MS">

<FONTFAMILY PLATFORM="ttf" NAME="Arial Unicode MS">

<FONTATTRIBUTE BOLD="false" ITALIC="false" LOGICAL="Arial Unicode MS" PHYSICAL="ARIALUNI.TTF"/>

</FONTFAMILY>

<FONTFAMILY PLATFORM="win" NAME="Arial Unicode MS"/>

<FONTFAMILY PLATFORM="java" NAME=" 'Arial Unicode MS', 'Arial Unicode MS'"/>

<FONTFAMILY PLATFORM="html" NAME=" 'Arial Unicode MS', 'Arial Unicode MS'"/>

</FONT>
```

- Enable the Key Performance Indicators (KPIs) for Operational Effectiveness Dashboard.
  Enabling KPI for Operational Effectives Business Objects Dashboard is mandatory to retrieve the Group information when CA SDM incidents are transferred to multiple Groups for ticket resolution. Consider the following:
  To show Support Groups Productivity and Functional Escalations in Operational Effectiveness dashboard, navigate to the CA SDM Administration tab, Options Manager, KPI and ensure that the status of kpi_ticket_data_table is installed.

- Configure the NX_KPI_TICKET_DATA_TABLE_DELAY variable to specify how frequently the incident data (for example, incident transfer) is updated in the database. The recommended value is 900 seconds.
  To configure the variable, complete the following steps in the order mentioned below:

  - Navigate to [SDM Root folder].
  - Open the NX.env file in notepad.
  - Search for @NX_KPI_TICKET_DATA_TABLE_DELAY and specify the value.
    For example, @NX_KPI_TICKET_DATA_TABLE_DELAY = 900.

- Make sure that every analyst is associated with a support group. Data related to an analyst with no support group is not displayed on business dashboard.

- Every time an analyst moves from one group to another, make sure to note down the analyst metrics in the previous group. The business dashboards display any metrics related to the older group as belonging to the new group.

Determine the Business Value Dashboards User Permissions

The role and user permissions determine the users accessing the dashboard and the users configuring the dashboards. To provide permissions to any user to configure the reports or access the dashboard, you must add the user to the CA Service Management group.

Important! You must add the *CASMAdmin* user to the CA Service Management group. The CASMAdmin user has the privileges to access the solution dashboard and also run the reports.

Follow these steps:

1. Log in Central Management Console as an administrator.
   http://cabi-hostname:Port_number/BOE/CMC
2. Under Organize, click Users and Groups.
3. Click User List.
4. Right-click the user you want to add to the CA Service Management group and click Join Group.
5. Select CAServiceManagement and move it from Available Group(s) to Destination Group(s).
6. Click Ok and save the changes.

Configure the Business Value Dashboard Reports

This article contains the following topics:

Scheduled and On-demand Reports

CA Service Management provides you the flexibility of generating reports, when required. The report generation is classified as Scheduled reporting and On-demand reporting.

Scheduled Reporting

You can use the scheduled reports when your organization requires reports to be generated at frequent intervals. Also, when you have a large data to generate reports from, you can use the scheduled reports. For example, a report is to be generated on a weekly basis. So, you use the scheduled reports and configure them to generate reports once in a week.

Note: We recommend that you use scheduled reporting when the data size is more than 10,000 records.

On-demand Reporting

You can use the On-demand reports to generate the business value dashboards when required or to process small data. For example, your organization does not require reports to be generated at frequent intervals. However, you need to generate a report whenever an executive user requires you to generate it.

Note: We recommend that you use scheduled reporting when the data size less than 10,000 records.

To know the data size, identify the count of the following tables in your MDB:

- *usm_subscription_detail* for the number of requests
- *call_req* for the number of incidents

Dashboards and the Associated Reports

Each dashboard has several reports and sub-reports associated that you can view and configure to meet your requirements. The reports are accessible through the BusinessObjects Central Management Console.

Follow these steps to access the reports associated with the dashboards:

1. Log in Central Management Console as an administrator.
   http://cabi-hostname:Port_ (http://cabi-hostnamePort_)number/BOE/CMC
2. Navigate to Folders, All Folders, CA Reports, CA Service Management.
3. Do one of the following:
   - Click View on Demand Dashboard to view the reports that you can generate on-demand.
   - Click Scheduled Dashboard to view or schedule reports as per your requirement.
   - Click Sub Reports to view the sub reports of Service Demand and Operational effectiveness dashboards.

Learn How to Schedule the Business Value Dashboard Reports

This articles explains how to schedule dashboard reports and tasks you must perform before and after scheduling the reports.

Note: Perform these tasks only if you or the end user access the dashboards from the Unified Self-Service user interface.

Complete the following:

- Configure the Business Value Dashboard Service Offerings (see page 788)
  - Identify the Report ID (see page 788)
  - Configure the Service Offering (see page 788)
- Schedule the Business Value Dashboard Reports (see page 789)
- Verify the Scheduled Dashboards (see page 791)

Configure the Business Value Dashboard Service Offerings

Each dashboard is a service offering that is exposed through CA Service Catalog and accessible through the Unified Self-Service interface.

By default, the dashboard service offerings represent data generated by on-demand reports. To display scheduled reports, you must perform several configurations on service offerings.

Complete the following steps:

- Identify the Report ID (see page)
- Configure the Service Offering (see page 788)

Identify the Report ID

Follow these steps:

1. Log in to Central Management Console as an administrator or a user with permissions to schedule report generation.
   http://cabi-hostname:Port number/BOE/CMC
2. Navigate to Folders, All Folders, CA Reports, CA Service Management, Scheduled Dashboard.
3. Right click the report that you want to schedule and select Properties.
4. From the ID, CUID field, make a note of the CUID of the report.
   For example, in **ID, CUID:17810, ATKoKrurIjlCqTvnya20W1s**, the CUID is ATKoKrurIjlCqTvnya20W1s.

Configure the Service Offering

Follow these steps:

1. Log in to CA Service Catalog as an Administrator.
2. Navigate to Catalog, Service Offerings, Offerings.
3. Expand Service Management Dashboards.
4. Select the service offering that represents the dashboard for which you want to schedule a report.
   For example, Operational Effectiveness.
5. Click the copy icon.
6. Create a copy of the service offering in the same folder and specify the name of the new service offering.
   For example, Operational Effectiveness - Scheduled Report.
7. Click the new service offering copy.
   In this example, click Operational Effectiveness - Scheduled Report.

8. In the Details tab, set the Availability date.
9. In the Permissions tab, enable permissions for the appropriate roles.
10. In the Definition tab, click Edit Service Option.
11. From the Form field, make a note of the Form name.
12. Navigate to Catalog, Forms.
13. Expand Forms, Service Management Dashboards Forms.
14. Click the form that you earlier noted and create a copy of the form as you created a copy of the service offering.
15. Click the new form and the click Script.
16. Search for the following statement. In this example, the form is the Operational Effectiveness form.

```
cabiURL = 'http://' + ca_fd.js.cabiHostName + ':' + ca_fd.js.cabiPort + '/BOE
/OpenDocument/opendoc/openDocument.jsp?
iDocID=AbEmxu8mNftBjHQIMRu2uLs&sIDType=CUID&sReportMode=weblayout&token=' + rows
[0].value;
```

17. Replace the iDocID variable with the appropriate CUID that you earlier noted.
    For example, replace AbEmxu8mNftBjHQIMRu2uLs with ATKoKrurIjlCqTvnya20W1s.
18. Click Save.
19. In the new service offering you created, update the Form name in the Definition tab to the new form name.
20. Save the changes.

Schedule the Business Value Dashboard Reports

Schedule a report when the date size is more than 10,000 records. It is important to configure both the reports and the associated sub-reports.

To know the data size, identify the count of the following tables in your MDB:

- *usm_subscription_detail* for the number of requests
- *call_req* for the number of incidents

Follow these steps:

1. Log in to Central Management Console as an administrator or a user with permissions to schedule report generation.
   http://cabi-hostname:Port_number/BOE/CMC
2. **To schedule the Service Demand-Incidents dashboard, complete the following steps:**

a. Navigate to Folders, All Folders, CA Reports, CA Service Management, Sub Reports.

b. Right-click Incident Cost Details, Incident Effort Details, Incident Volume Details and select Schedule.

c. Configure the appropriate parameters and click Schedule.

d. Navigate to Folders, CA Reports, CA Service Management, Scheduled Dashboard, Service Demand – Incidents.

e. Right-click Service Demand- Incidents and click Schedule.

f. Configure the appropriate parameters and click Schedule.
Note: Ensure you that parameter values you configure for reports and their sub-reports are the same.

3. **To schedule the Service Demand-Request dashboard, complete the following steps:**

a. Navigate to Folders, All Folders, CA Reports, CA Service Management, Sub Reports.

b. Right-click Request Volume/Cost for Services and select Schedule.

c. Configure the appropriate parameters and click Schedule.

d. Navigate to Folders, CA Reports, CA Service Management, Scheduled Dashboard, Service Demand – Requests.

e. Right-click Service Demand- Requests and select Schedule.

f. Configure the appropriate parameters and click Schedule.
Note: Ensure you that parameter values you configure for reports and their sub-reports are the same.

4. **To schedule the Service Demand dashboard, complete the following steps:**

a. Navigate to Folders, All Folders, CA Reports, CA Service Management, Sub Reports, Service Demand Scheduling.

b. Right-click on each of the reports and select Schedule.

c. Configure the appropriate parameters and click Schedule.

d. Navigate to Folders, CA Reports, CA Service Management, Scheduled Dashboard, Service Demand.

e. Right-click Service Demand and select Schedule.

f. Configure the appropriate parameters and click Schedule.
Note: Ensure you that parameter values you configure for reports and their sub-reports are the same.

5. **To schedule the Operational Effectiveness dashboard, complete the following steps:**

a. Navigate to Folders, All Folders, CA Reports, CA Service Management, Sub Reports.

b. Right-click FCR For Incident Categories, Groups By Effort Incurred On Resolution Functions, MTTR for Incident Categories and select Schedule.

c. Configure the appropriate parameters and click Schedule.

d. Navigate to Folders, CA Reports, CA Service Management, Scheduled Dashboard, Operational Effectiveness.

e. Right-click Operational Effectiveness and select Schedule.

f. Configure the appropriate parameters and click Schedule.
Note: Ensure you that parameter values you configure for reports and their sub-reports are the same.

Verify the Scheduled Dashboards

After you schedule the report generation, you must verify if the dashboards are created correctly. Each dashboard is a service offering that is exposed through CA Service Catalog and accessible through the Unified Self-Service interface.

Follow these steps:

1. Log in to Unified Self-Service as a user with permissions to access the dashboards.
If Unified Self-Service is not installed, you can access the service offerings from the CA Service Catalog user interface.

2. In the Home page, click Request a Service.
The Request Page Appears.

3. Under Categories, click Service Management Dashboards.
You must see the service offerings that you configured.

4. Click an appropriate service offering to see the related information.

Understand the Important Metrics

The three parameters related to request and incidents/categories that are significant to decision makers are cost, effort, and volume.

It is important to understand how these parameters are calculated:

Effort

Effort is the time total time spent on an incident resolution. The time spent may be by one user or multiple users in resolving an incident. The effort is calculated only when the users appropriately log in the time spent on an incident. It is important that your organization recommends time logging.

The **Time Spent** field in the incident details determines the time spent on the incident.

Volume

Volume is the total number of requests/incidents in a specific category. It is important that each incident/request has a specific category associated with it. For example, Hardware, Networking, Applications are categories.

Cost

Cost is a function of effort spent and the resource rate. It is also the cost of a service.

Each incident/request has a category associated and the total cost of a category is the sum of all costs of incidents/requests in a specific category.

- For an incident, cost is calculated as follows:

  Cost of an incident = Total time spent (in hours) by a resource * Rate (per hour) of the resource
  The following example describes how the cost parameter is calculated for an incident involving multiple resources.

Data	Analyst_1	Analyst_2
Resource Rate (per hour)	$ 100	$ 75
Time spent (in hours)	10	15

  Total cost = ($100 * 10) + ($75*15) = $ 2125
  Note: The **Cost** field in the **Contact Details** page determines the resource rate.

- For a request, the cost is the cost field that you associate for a service offering.

Offline Reporting through Microsoft SQL Server Database Replication

This section covers the the following topics:

Introduction

CA Service Management lets you generate reports that help you analyze important information. Every time that you generate a report, the application (CA SDM, CA APM, or CA Service Catalog) accesses the database to fetch information. When your database contains large volumes of data, the data retrieval process impacts the performance of your application. An effective way to reduce performance issues is to replicate or create an offline version of your database. While users continue to access the application to perform day-to-day tasks, the application accesses the replicated or offline database for any report generation activity.

Note: The database replication process is applicable only if you use Microsoft SQL Server in your environment.

This article contains the following topics:

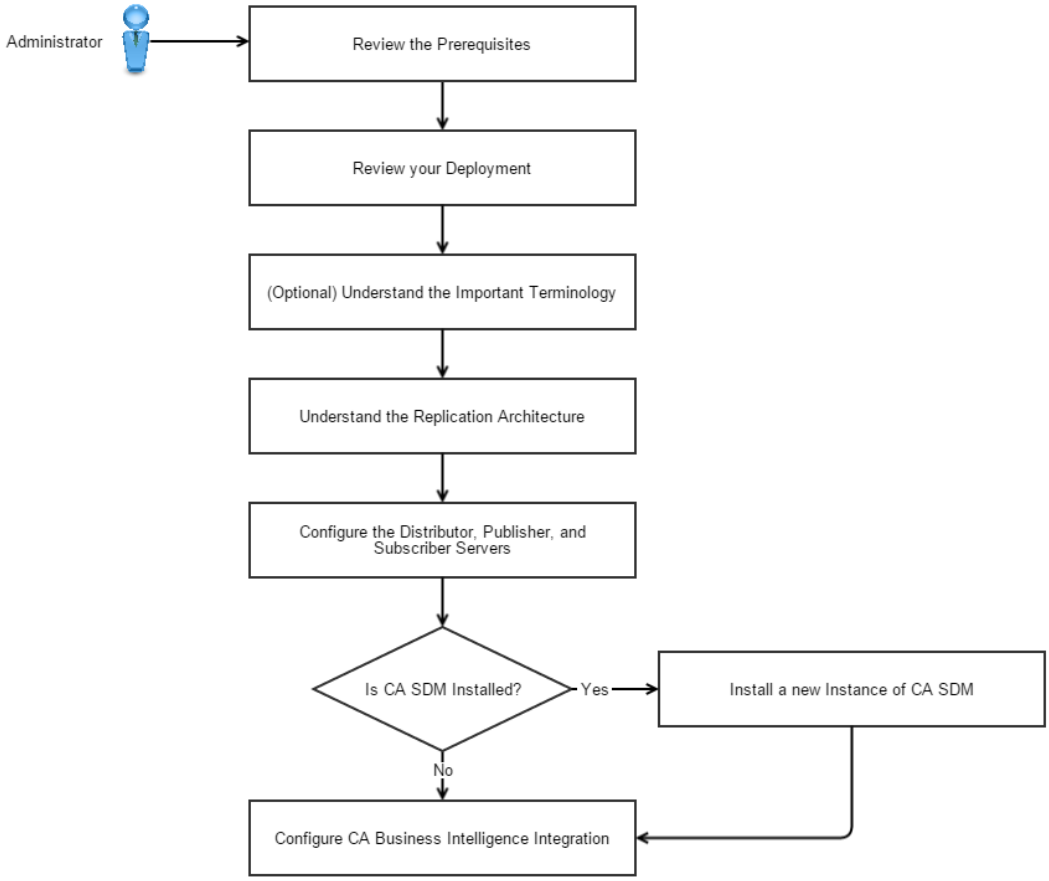
The Environment

You can implement offline reporting in the following environment:

- **Products installed:** CA Service Management 14.1 or version 12.9 of CA SDM, CA APM, and/or CA Service Catalog
- **Database:** Microsoft SQL Server 2008/2012/2014

The following diagram illustrates how a solution administrator implements database replication for offline reporting:

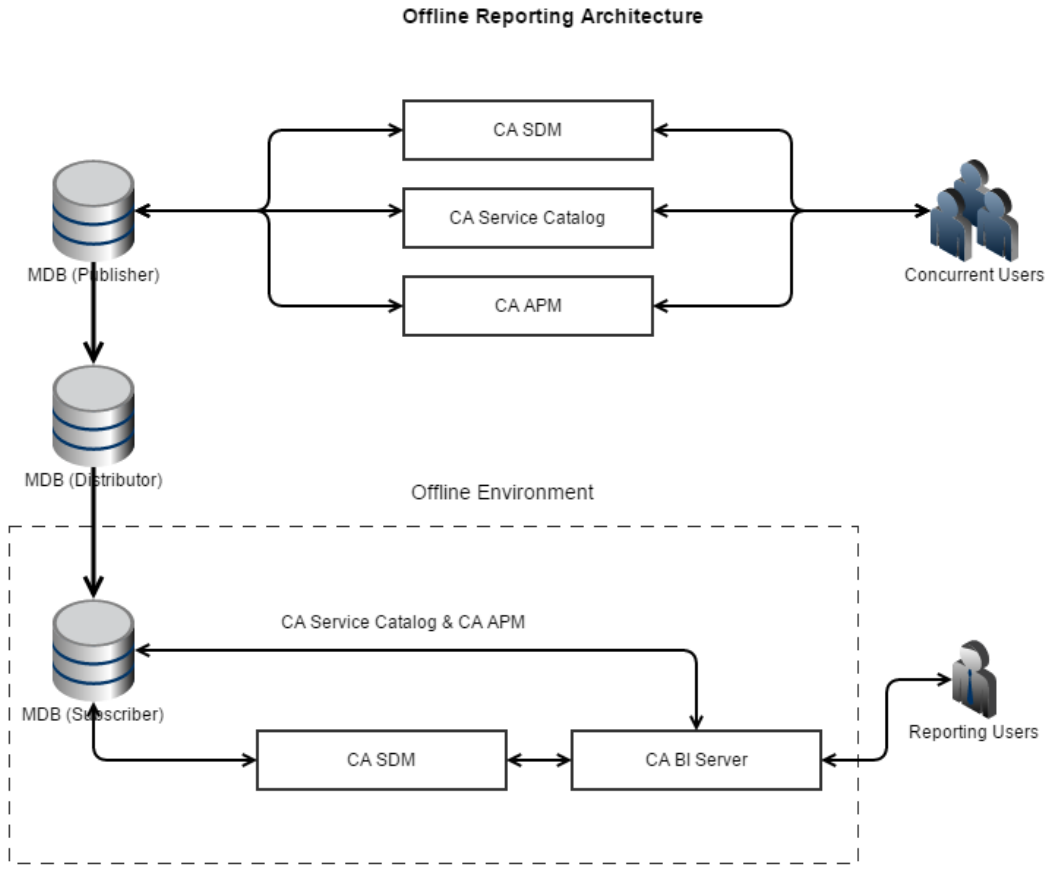
Implementing Offline Reporting through Database Replication



For more information about how to install the Replication feature, see Microsoft SQL Server documentation.

The Architecture

The following diagram illustrates the architecture of a replicated database environment for offline reporting:



Benefits

In CA Service Management, database replication is performed through the transactional replication process.

Replicating the database through transactional replication has the following benefits:

- Incremental changes are propagated to the Subscribers as they occur.
- Report generation does not require any changes to be made by the Subscriber and thus data need not be propagated back to the Publisher. In transactional replication, Subscribers are read-only and thus do not affect the performance of your environment.
- Low latency between the time changes is made at the Publisher and the changes arrive at the subscriber.
- Effective management of high insert, update, delete activity when compared to other types of replication

Note: With support for transactional replication in CA Service Management 14.1 or version 12.9 of CA SDM, CA APM, and/or CA Service Catalog, support for merge replication process is deprecated. If you already implemented merge replication on CA Service Management 14.1, we recommend you to disable it and implement transactional replication.

Best Practice

Scenario 1: New Installation of CA Service Management

If your environment is following the database replication process for the first time, it is recommended you install CA Service Management, and enable transactional replication.

Scenario 2: Upgrade CA Service Management

If your environment follows the database replication process, it is recommended you disable the replication process (merge or transactional), upgrade CA Service Management, and enable the transactional replication.

Scenario 3: Integration of CA Service Management Products

If your environment follows the database replication process, it is recommended you disable the replication process (merge or transactional), Integrate the CA Service Management products, and enable the transactional replication.

Glossary

The following terms are used frequently in the configuration information. Understand the meaning of the terms before you start configuring offline reporting:

Production Database

Production database refers to the database server that CA Service Management uses. This is the database from where you replicate another database for offline reporting.

Production database is typically the database server in a production environment.

Reporting Database

Reporting database refers to the database that you replicated from the production database. The reporting database is used only for offline reporting.

Publisher

The Publisher is a server that makes data available for replication to other servers. In addition to being the server where you specify the data to be replicated, the Publisher also detects the data that has changed and maintains information about all publications at that site.

In the offline reporting scenario, the publisher is typically the production database server.

Distributor

The Distributor is a server that contains the distribution database and stores meta data, history data, and/or transactions. The Distributor can be a separate server from the Publisher (remote Distributor), or it can be the same server as the Publisher (local Distributor).

Subscriber

Subscriber is a server that receives replicated data. Subscribers subscribe to publications, not to individual articles within a publication, and they subscribe only to the publications that they need, not necessarily all of the publications available on a Publisher.

Verify the Prerequisites

We recommend that you complete this checklist before you proceed.

1. You must have DBA privileges.
2. The following Windows services must be running. We recommend that you set the start mode to **Automatic**.
   - SQL Server
   - SQL Server Agent
   - SQL Server Browser
3. The SQL Server Agents must run on publisher, distributor, and the subscriber servers.
4. You can perform either of the following steps:
   a. **Use a domain account for every agent.** Add the domain account to the SQL Server logins and assign the sysadmin role. Set **Master** as the default database.
   b. **For each agent, create a local Windows account on the respective servers.** Add the Windows user account that you created to the SQL Server logins and assign the sysadmin role. Set **Master** as the default database.
5. Create a Snapshot Folder. Ensure that the Snapshot Folder is a network folder and not a local folder.
6. To implement replication, Microsoft mandates that every table is associated with a primary key. Hence, ensure any new table that you want to replicate has a primary key that is associated with it.
7. To connect to the database, the replication utility requires an SQL server authentication-based login credentials. We recommend the default system admin account to be used.

Review CA Service Management Deployment

Before you configure offline reporting, review the products that you installed as part of the CA Service Management solution.

Approach

Refer to the instructions in either of the following approaches depending on your deployment type.

Approach 1: Back-up and Restore the Existing Instance of MBD

The approach is a three-step procedure.
Step 1: Back up and Restore (see page 798)
Step 2: Implement Replication (see page 798)
Step 3: Set up and configure CA SDM (see page 798)

Step 1: Back up and Restore

Back up the production server database and restore to the offline server. For more information, see MSDN documentation.

Step 2: Implement Replication

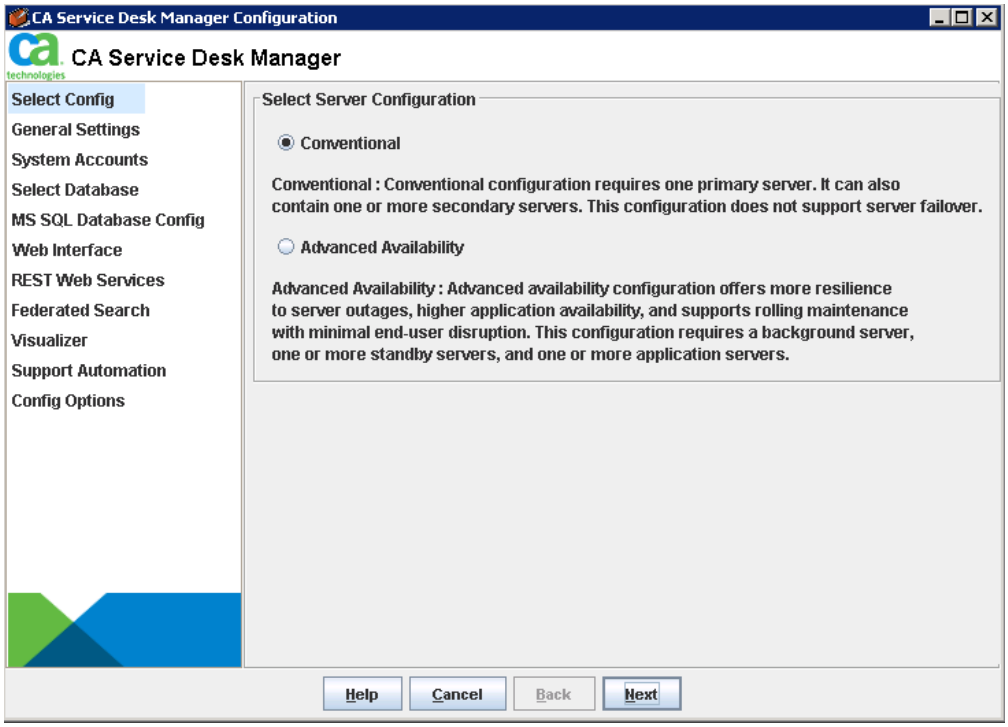
An effective way to reduce application performance issues is to replicate or create an offline version of your database. The users can continue to access the application to perform day-to-day tasks, the application accesses the replicated or offline database for any report generation activity. For more information, s ee How To Implement Replication (see page 805).

Step 3: Set up and Configure CA SDM

Follow these steps:

1. Launch the CA SDM installer from the following location:
   - **CA Service Management 14.1:** <Installation_Media_Root>\products\SDM\setup.exe
2. Follow the on-screen instructions until you reach the Configuration window.

3. Click **Cancel**



(see page 797)

4. Using a text editor, open the NX_ROOT\pdmconf\NX.env_nt.tpl file (NX_ROOT is the installation directory for CA SDM) and perform the following steps:

    a. Use the following sample code to verify that auditing is commented out:

    ```
    # Create audit log entry for field update.
    ! @NX_AUDIT_UPD=
    # Create audit log entry for deletion.
    ! @NX_AUDIT_DEL=
    ```

    b. Add the following code and parameters at the end of the file:

    ```
    @NX_EVENT_LOG_EXCLUDE=ALL
    @NX_SESSION_LOG_EXCLUDE=ALL
    ```

5. Using a text editor, open the NX_ROOT\pdmconf\pdm_startup.tpl file.

6. Edit the file by changing the line *[default procset MAIN_PROCSET]* to *[default procset OFFLINE_REPORTING]*.

7. Save and close the file.

8. Complete the following steps in Microsoft SQL Server Management Studio:

    a. Expand **Databases, mdb, Security, Users**.

b. Right-click **mdbadmin** and select **Properties**.

c. In the **Database User** window, next to **Default schema**, click the search option.

d. In the **Select Schema** window, enter *[dbo]* and click **Browse**.

e. In the **Browse for Objects** window, select the **mdbadmin** object and click **OK**.

f. In the **Database User** window, select the following entries under **Role Members** and click **OK.**

- ams_group
- db_ddladmin
- db_owner
- db_securityadmin
- regadmin
- service_desk_admin_group
- service_desk_ro_group
- usmgroup
- workflow_admin_group

9. Update the *usp_servers* table entry for local_host column. Run the following commands on the offline reporting data base server for the MDB:

```
update usp_servers
set local_host='<Offline CA SDM Server Name>'
where id=1001
```

Note: Perform this step when you install CA SDM on the restored MDB on the offline server.

10. Configure CA SDM with replicated db and do not select “load-default’ data check box. To configure CA SDM run the following command on the command prompt:

```
CMD>:\ pdm_configure
```

11. In the Windows command prompt, run the following command to view the status of the services:

```
pdm_status
```

12. To verify the installation, navigate to the following URL:

```
http://<Offline_Reporting_Server>:<SDM_Port_Number>/CAisd/pdmweb.exe
```

13. Configure CA Business Intelligence and integrate with offline MDB.

> **Note:** If multi-tenancy is enabled on the production instance of CA SDM, then manually install the same on the offline instance of CA SDM. For more information about enabling multi-tenancy, see *Administration Guide, Defining Business Structure, Multi-Tenancy, How Multi-Tenancy Works, The Multi-Tenancy Option,* available in the CA SDM Release 12.9 version bookshelf on CA Support Online (https://support.ca.com/cadocs/0/CA%20Service%20Desk%20Manager%2012%209-ENU/Bookshelf.html).

Approach 2: New MDB Instance

The approach is a three-step procedure.

- Step 1: Install MDB (see page 801)
- Step 2: Implement Replication (see page 801)
- Step 3: Set up and configure CA SDM (see page 801)

Step 1: Install MDB

Follow these steps:

1. Mount the installation media on your drive.
2. Launch the CA SDM installer from the following location:
   - **CA Service Management 14.1:** <Installation_Media_Root>\products\setup.exe

   The Installation Menu appears.
3. Click the Product Installs tab.
4. Click CA MDB.
5. Continue following the on-screen instructions to complete the installation.

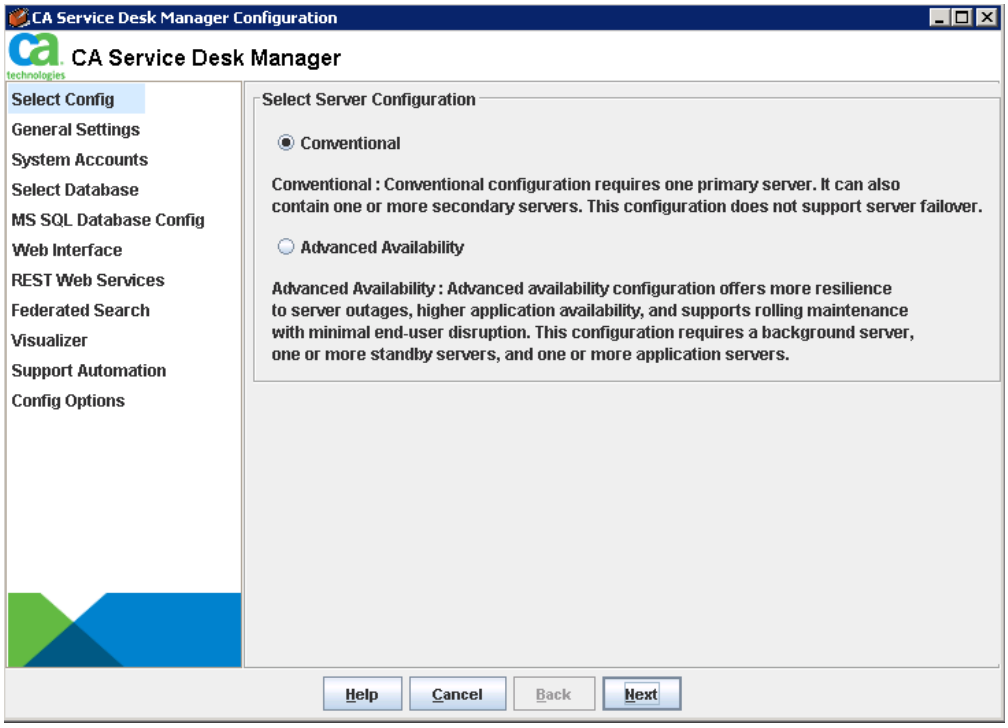
Step 2: Implement Replication

An effective way to reduce application performance issues is to replicate or create an offline version of your database. The users can continue to access the application to perform day-to-day tasks, the application accesses the replicated or offline database for any report generation activity. For more information, s ee How To Implement Replication (see page 805).

Step 3: Set up and Configure CA SDM

Follow these steps:

1. Launch the CA SDM installer from the following location:
   - **CA Service Management 14.1:** <Installation_Media_Root>\products\SDM\setup.exe
2. Follow the on-screen instructions until you reach the Configuration window.
3. Click **Cancel**.



4. Using a text editor, open the NX_ROOT\pdmconf\NX.env_nt.tpl file (NX_ROOT is the installation directory for CA SDM) and complete the following steps:
   a. Use the following sample code to verify that auditing is commented out:

```
# Create audit log entry for field update.
! @NX_AUDIT_UPD=
# Create audit log entry for deletion.
! @NX_AUDIT_DEL=
```

   b. Add the following code and parameters at the end of the file:

```
@NX_EVENT_LOG_EXCLUDE=ALL
@NX_SESSION_LOG_EXCLUDE=ALL
```

5. Using a text editor, open the NX_ROOT\pdmconf\pdm_startup.tpl file.
6. Edit the file by changing the line *[default procset MAIN_PROCSET]* to *[default procset OFFLINE_REPORTING]*.

7. Save and close the file.

8. Complete the following steps in Microsoft SQL Server Management Studio:

    a. Expand **Databases, mdb, Security, Users**.

    b. Right-click **mdbadmin** and select **Properties**.

    c. In the **Database User** window, next to **Default schema**, click the search option.

    d. In the **Select Schema** window, enter *[dbo]* and click **Browse**.

    e. In the **Browse for Objects** window, select the **mdbadmin** object and click **OK**.

    f. In the **Database User** window, select the following entries under **Role Members** and click **OK.**

    - ams_group
    - db_ddladmin
    - db_owner
    - db_securityadmin
    - regadmin
    - service_desk_admin_group
    - service_desk_ro_group
    - usmgroup
    - workflow_admin_group

9. Insert the offline server details in the *usp_servers* table. Run the following commands on the offline reporting data base server for the MDB:

```
INSERT INTO [dbo].[usp_servers]
([id],[del],[local_host],[timezone],[nx_desc],[last_mod_dt],[last_mod_by],
[server_id],[server_type],[database_type],[external_dns_name],[platform],
[linked],[slump_port],[upload_path])
VALUES(1001,0,'<Offline CA SDM Server Name>',NULL,'Local System
(<Offline CA SDM Server Name>)',NULL,NULL,14538,0,0,'',1,1,2100,NULL)
```

10. Configure CA SDM with replicated db and do not select “load-default’ data check box. To configure CA SDM run the following command on the command prompt:

```
CMD>:\ pdm_configure
```

11. In the Windows command prompt, run the following command to view the status of the services:

```
pdm_status
```

12. To verify the installation, navigate to the following URL:

    ```
    http://<Offline_Reporting_Server>:<SDM_Port_Number>/CAisd/pdmweb.exe
    ```

13. Configure CA Business Intelligence and integrate with offline MDB.

> **Note:** If multi-tenancy is enabled on the production instance of CA SDM, then manually install the same on the offline instance of CA SDM. For more information about enabling multi-tenancy, see *Administration Guide, Defining Business Structure, Multi-Tenancy, How Multi-Tenancy Works, The Multi-Tenancy Option,* available in the CA SDM Release 12.9 version bookshelf on CA Support Online (https://support.ca.com/cadocs/0/CA%20Service%20Desk%20Manager%2012%209-ENU/Bookshelf.html).

Configure CA Business Intelligence Integration

CA Business Intelligence, the reporting application that you earlier configured to access the production database must now access the reporting database. However, the way CA Business Intelligence integrates with the reporting database depends on the products you installed as part of CA Service Management.

> **Tip!** We recommend that you have the bookshelf for CA Business Intelligence available during the integration process.

- **CA SDM:** CA Business Intelligence does not access the reporting database directly. If you installed CA SDM, then configure CA BI with the CA SDM offline server to access the reporting database. For more information, see Integrate CA Service Desk Manager with CA Business Intelligence Manually (see page 3263).
- **CA Service Catalog:** CA Business Intelligence does access the reporting database directly. For more information, see Integrate CA Service Catalog with CA Business Intelligence Manually (see page 3293).
- **CA APM:** CA Business Intelligence does access the reporting database directly. For more information, see Integrate CA Asset Portfolio Management with CA Business Intelligence Manually (see page 3482).

> **Note:** Configure CA Business Intelligence to access the reporting database and not the production database.

Implement Replication

This article describes the process to implement replication.

- Configure the Distributor, Publisher, and Subscriber Servers (see page 805)
- Perform the Validation Check (see page 805)

Tip! Initiate the replication process during a planned maintenance window as it involves creating a snapshot of the database. While this process is in progress, access to your database is locked. The time period depends on the volume of data in the production database. For instance, time period for a new database is 5-6 minutes, whereas for a 112-GB database, it is 6 hours and 20 minutes.

Configure the Distributor, Publisher, and Subscriber Servers

You can configure the servers in one of the following ways:

- Run the Configuration Utility (see page 806)
- Manual Configuration (see page 808)

Perform the Validation Check

Perform the checks in Distributor/Publisher based on your configurations.

Follow these steps:

1. Navigate to Microsoft SQL Server Management Studio.
2. Expand **Databases,** and verify the new database "**Distribution**".
3. Expand **Security**, **Logins**, and verify the new login "**Distributor_admin**".
4. Expand **Server Objects**, **Linked Servers**, and verify the new linked server "**repl_distributor**".
5. Expand **SQL Server Agent, Jobs,** and verify the 6 new jobs that are created automatically.
6. Expand **Replication**, **Local Publications,** and verify the newly created publication.
7. Expand the **New Publication,** and verify the newly created subscription.
8. To confirm snapshot creation, right-click on the **Publication** and select **View Snapshot Agent Status.**

Important! Failure in the above steps indicates that the replication process is unsuccessful. In this case, the user must navigate to the log file created as part of replication and check for errors.

Run the Configuration Utility

This section explains the steps to run the configuration utility.

Download the Configuration Utility

For CA Service Management 14.1, apply the patch available on CA Support Online (http://www.ca.com/us/support/ca-support-online/product-content/recommended-reading/technical-document-index/ca-service-management-solutions-patches.aspx) .

Select a Mode

You can choose to either specify the details in the utility or perform a silent replication.

- For the interactive mode process, ensure you review the 'ReplicationInputData.csv' file to comprehend the required input values.
- For the silent replication process, ensure that you specify all the details in the 'ReplicationInputData.*csv*' file before you run the utility.

Run the Configuration Utility

Follow these steps:

1. Unzip the configuration utility file.
2. Run the *CreateReplication.bat* file.
3. Specify if you want to perform a silent replication.
   The replication process starts.
4. If you choose to specify the details in the utility, follow the on-screen instructions.
5. After to you specify all the details, the replication process starts.
   The progress is displayed
6. To understand whether the replication process was successful, view the *Replication.log* file.

Include/Exclude Tables for Replication

During the replication process, the configuration utility replicates only the tables that are part of CA Service Management. Tables that are related to other products are not replicated. For example, if you integrated CA SDM with CA Business Intelligence, the configuration utility replicates only CA SDM tables and not CA Business Intelligence tables. However, you can manually include these tables for replication.

Include a Table for Replication

Follow these steps:

1. In the configuration utility folder, open the **Creation Script** folder.
2. Open the *CreatePublication.sql* file using a text editor.
3. Copy the following code:

```
IF (EXISTS (SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME = 'Table_Na
me'))
BEGIN
exec sp_addarticle @publication = N'publication_mdb', @article = N'Table_Name',
@source_owner = N'dbo', @source_object = N'Table_Name', @type = N'logbased',
@description = null, @creation_script = null, @pre_creation_cmd = N'drop',
@schema_option = 0x000000000803509F, @identityrangemanagementoption = N'manual',
@destination_table = N'Table_Name', @destination_owner = N'dbo',
@vertical_partition = N'false', @ins_cmd = N'CALL sp_MSins_dboxent_map',
@del_cmd = N'CALL
sp_MSdel_dboxent_map', @upd_cmd = N'SCALL sp_MSupd_dboxent_map'
END
GO
```

4. Paste the code before the following entry in the file:

```
PRINT 'Publication created'
```

5. Replace 'Table_Name' in the code with the name of the table you want to include.

Exclude a Table for Replication

Follow these steps:

1. In the configuration utility folder, open the **Creation Script** folder.
2. Open the *CreatePublication.sql* file using a text editor.
3. Search for the name of the table and find the following entry. For example, if the name of the table is **xent_map**, you find the following code in the file:

```
IF (EXISTS (SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME = 'xent_map
'))
BEGIN
```

```
exec sp_addarticle @publication = N'publication_mdb', @article = N'xent_map',
@source_owner = N'dbo', @source_object = N'xent_map', @type = N'logbased',
@description = null, @creation_script = null, @pre_creation_cmd = N'drop',
@schema_option = 0x000000000803509F, @identityrangemanagementoption = N'manual',
@destination_table = N'xent_map', @destination_owner = N'dbo',
@vertical_partition = N'false', @ins_cmd = N'CALL sp_MSins_dboxent_map',
@del_cmd = N'CALL
sp_MSdel_dboxent_map', @upd_cmd = N'SCALL sp_MSupd_dboxent_map'
END
GO
```

4. Delete the code and save the file.

Manual Configuration

You can manually implement database replication if you do not want to use the utility.

Complete the following steps:

1. Configure Distribution on the Production Database Server (see page 808).
2. Create a Publication on the Production Database using Transactional Replication (see page 809).
3. Update the Publication Properties (see page 812)
4. Configure Subscription on the Reporting Database (see page 814).

Configure Distribution on the Production Database Server

For database replication, you must first configure the distributor. The distributor is the same server as the production database server.

Follow these steps:

1. In Microsoft SQL Server Management Studio, connect to the server that will be the Distributor (in many cases, the Publisher and Distributor are the same server), and then expand the server node.
2. Right-click the **Replication** folder, and then click **Configure Distribution**.
3. In the Distributor pane, select **'<ServerName>' will act as its own Distributor; SQL Server will create a distribution database and log** and click Next.
4. In the **SQL Server Agent Start** pane, select **Yes, configure SQL Server Agent service to start automatically** and click Next.
5. In the **Snapshot Folder** pane, specify a root snapshot folder (for a local Distributor) and click **Next**.
6. In the **Distribution Database** pane, review and edit the information, if necessary, and click **Next**.

7. In the **Publishers** pane, optionally enable other Publishers to use the Distributor, and click **Next**.

8. In the **Wizard Action** pane, select an appropriate action and click **Finish**.

Create a Publication on the Production Database using Transactional Replication

After you configure the distributor, you must create a publication on the publication database. The subscriber or the replication database shall subscribe to the publication for successful data replication.

Follow these steps:

1. In the Microsoft SQL Server Management Studio, connect to the production database server.

2. Expand the **Replication** folder, right-click **Local Publications** and select **New Publication**.

3. In the **Publication Database** pane, select the database you want to replicate and click **Next**.

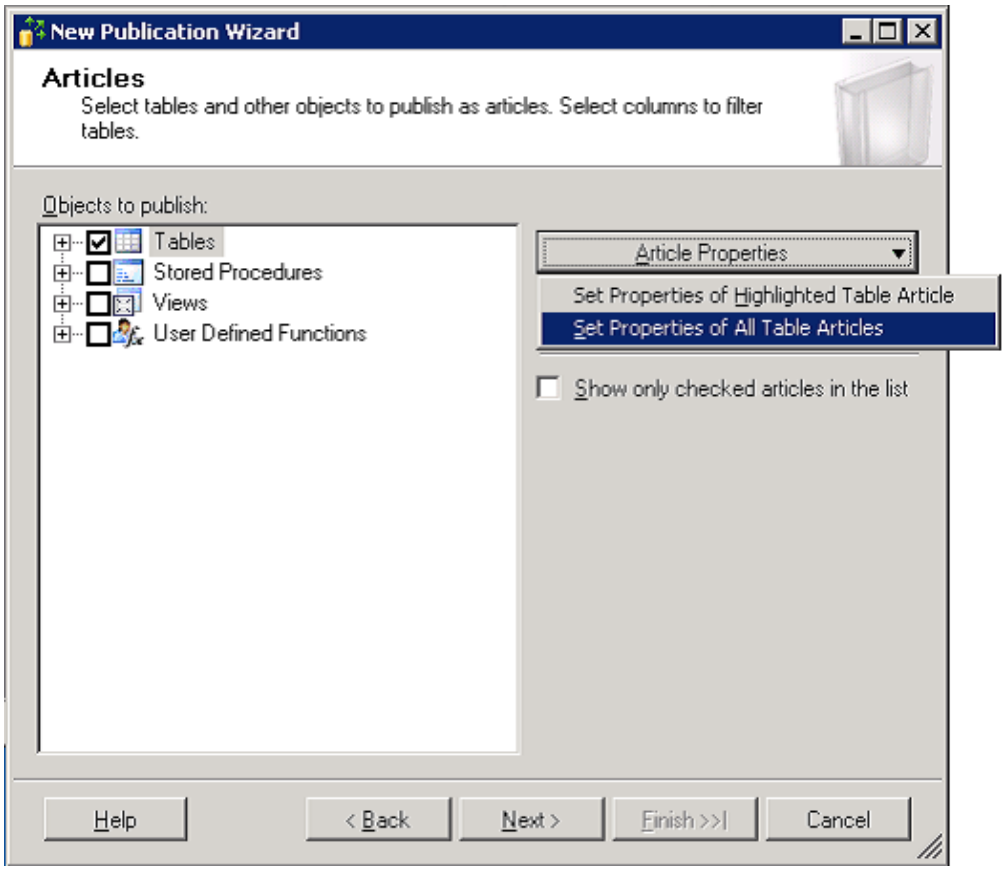
4. In the **Publication Type** pane, under **Publication Type** select **Transactional publication** and click **Next**.

5. In the **Articles** pane, select **Tables**, expand **Tables** and exclude the following entries:

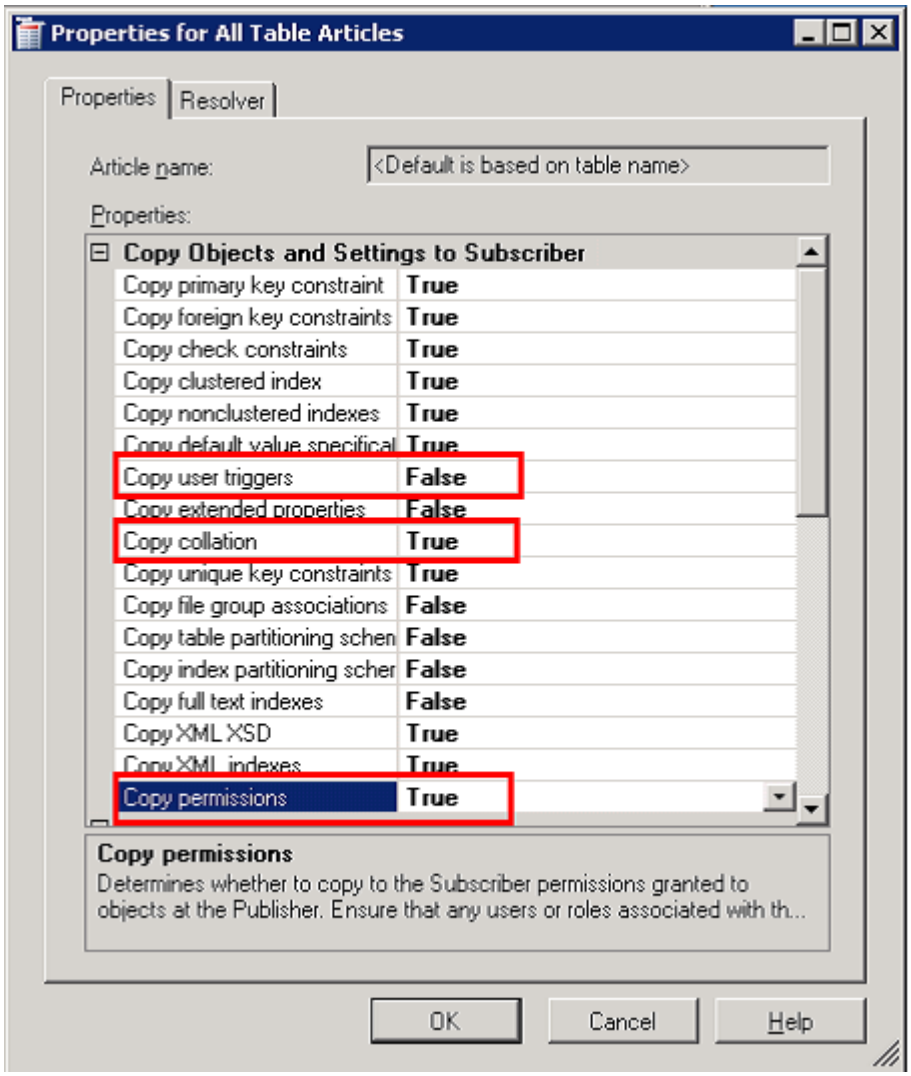
   - ci_twa_ci
   - dlgtsrv
   - ebr_fulltext
   - ebr_fulltext_adm
   - ebr_patterns
   - ebr_properties
   - ebr_synonyms
   - ebr_synonyms_adm
   - options
   - server_types
   - usp_alias
   - usp_bopsid
   - usp_config_daemon_type
   - usp_config_other_daemons
   - usp_configuration

- usp_domsrvr
- usp_interval_log
- usp_mailbox
- usp_record_lock
- usp_servers
- usp_session_ext
- usp_webeng_alias
- usp_webeng_domsrvr
- usp_webengine

6. Click **Article Properties,** select **Set Properties for All Table Articles**.

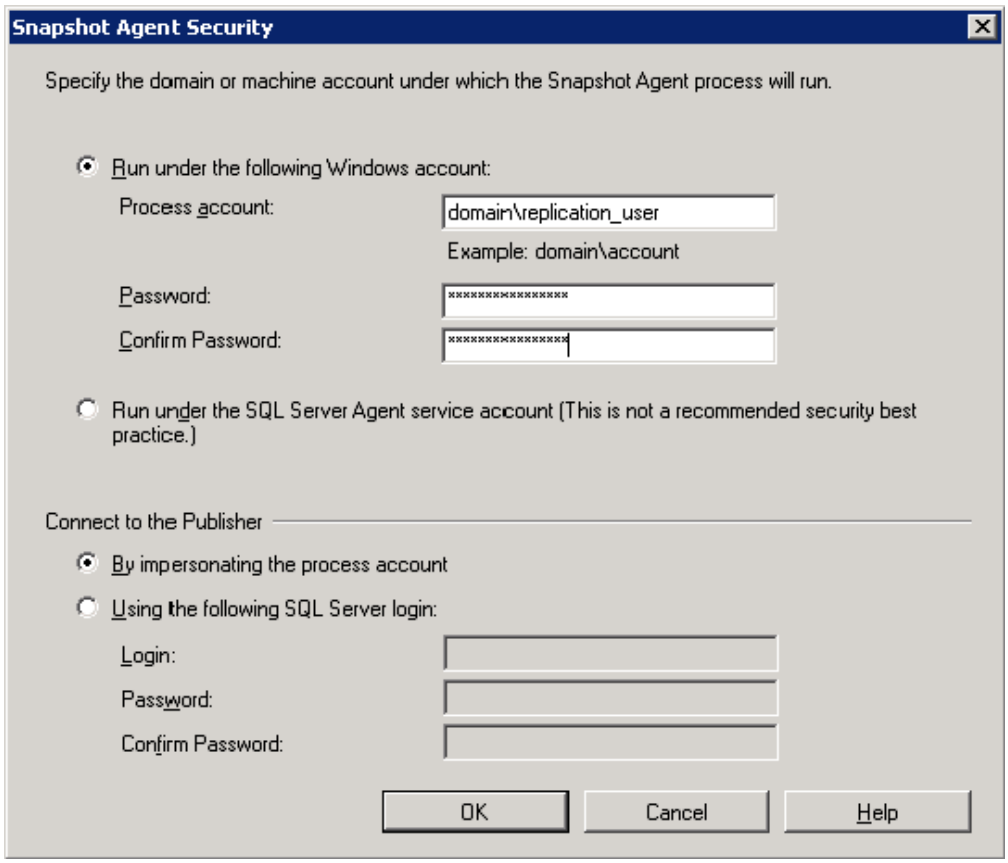


7. In the **Properties for All Table Articles** window, expand **Copy Objects and Settings to Subscriber**.



8. Perform the following steps:
    a. Set **Copy user triggers** to **False**.
    b. Set **Copy collation** to **False**.
    c. Set **Copy permissions** to **True**.
9. Click **OK** and then click **Next**.
10. In the **Filter Table Rows** ensure that you do not add any filters and click **Next**.
11. In the Snapshot Agent page, select **Create a snapshot immediately and keep the snapshot available to initialize subscriptions** and click **Next**.
12. In the **Agent Security** pane, click **Security Settings**.
    The **Snapshot Agent Security** window appears.
13. Select **Run under the following Windows account**, specify the details and click **OK.**

Note: For testing purposes, you can use a local administrator account that has access to the replication snapshot shared folder. Do not change the **Connect to the Publisher** option and retain the default value to impersonate the process account.



14. In the **Agent Security** pane, click **Next**.
15. In the **Wizard Action** pane, select **Create the Publication** and click **Next**.
16. In the Complete the Wizard pane, specify a name for the publication and click **Finish**. The publishing process begins.
17. Update the publication properties (see page).

Update the Publication Properties

Follow these steps:

1. In the Microsoft SQL Server Management Studio, connect to the production database server.
2. Expand **Replication, Local Publications**.

3. Right-click the publication that you created and select **Properties.**

> **Note:** If you change a property that requires the regeneration of the snapshot, you are prompted to regenerate the snapshot.

4. In the **Publication Properties** window, complete the following steps:

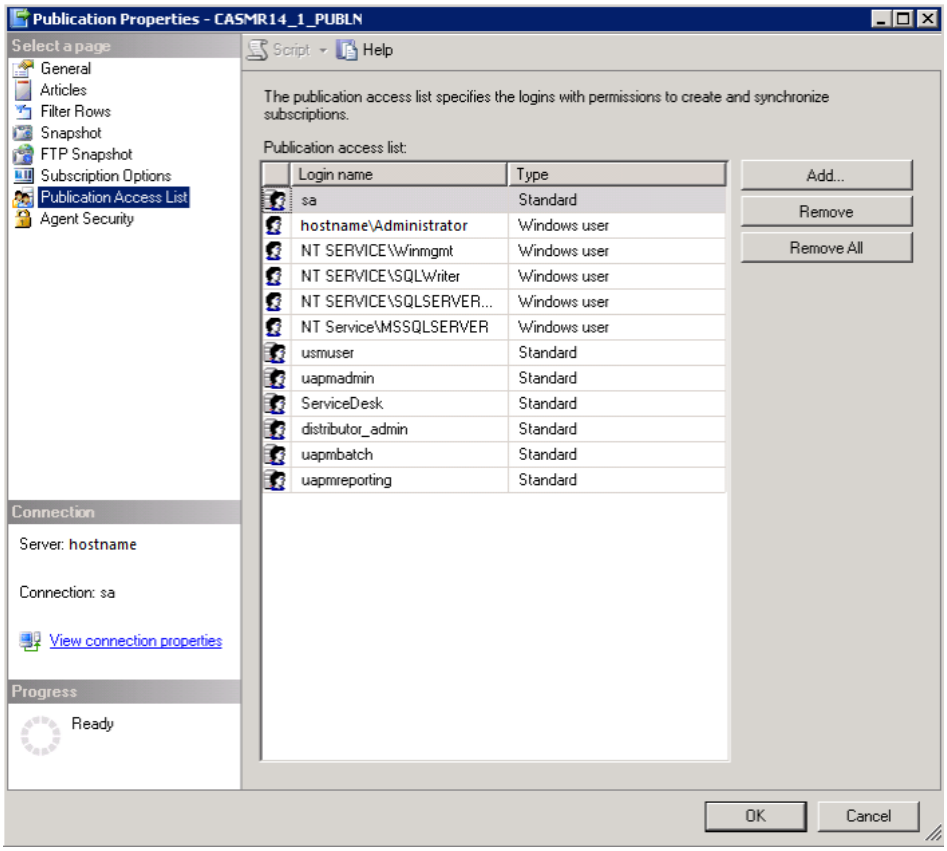
   a. In the tree on the left, click **Snapshot**.

   b. Clear the **Put files in the default folder** check box.

   c. Select the **Put files in the following folder** check box.

   d. Specify the path to the file share.

   e. In the tree on the left, click **Publication Access List**.



f. Click **Add**.

g. In the **Add Publication Access** window add *ServiceDesk, uapmadmin, uapmreporting, usmuser* (and *mdbadmin,* if available) users

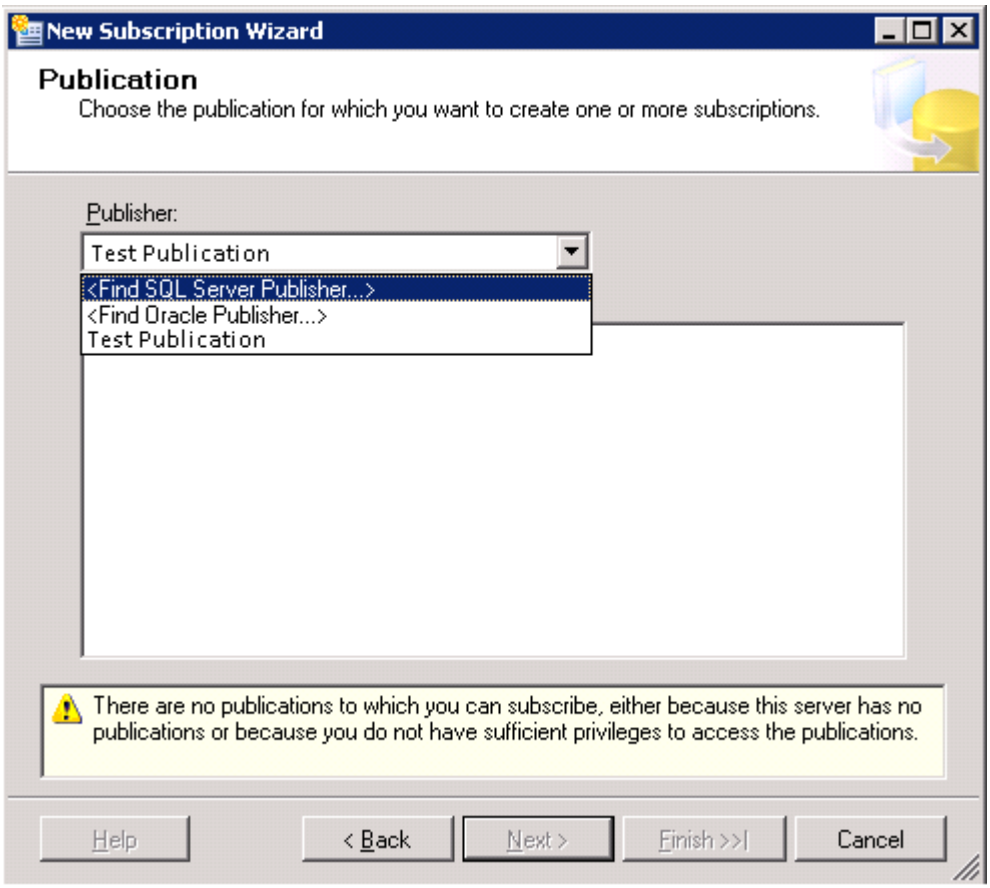
h. Click **OK** and then click **Yes.**

Configure Subscription on the Reporting Database

To replicate the database, the reporting database (subscriber) must subscribe to the specific publication of the publisher database.

Follow these steps:

1. In the Microsoft SQL Server Management Studio, connect to the reporting database server.
2. Expand the **Replication** folder, right-click **Local Subscription** and select **New Subscription.**
3. In the **New Subscription Wizard** window, click **Next**.
4. In the **Publications** pane, click **<Find SQL Server Publisher>** in the **Publisher** drop-down list.



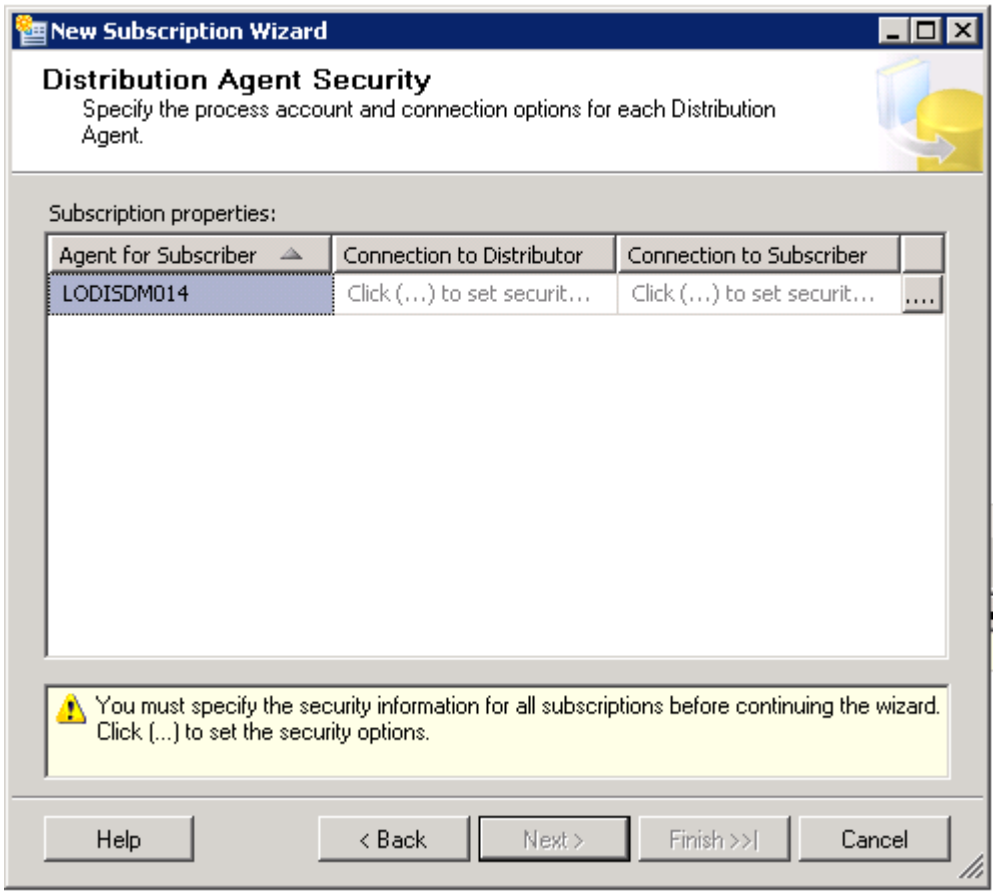
5. Specify the production database and the appropriate details and click **Connect.**
   After successful connection, the **Publication** pane displays all the available publications in the database server.

6. Select the publication that you previously configured and click **Next**.

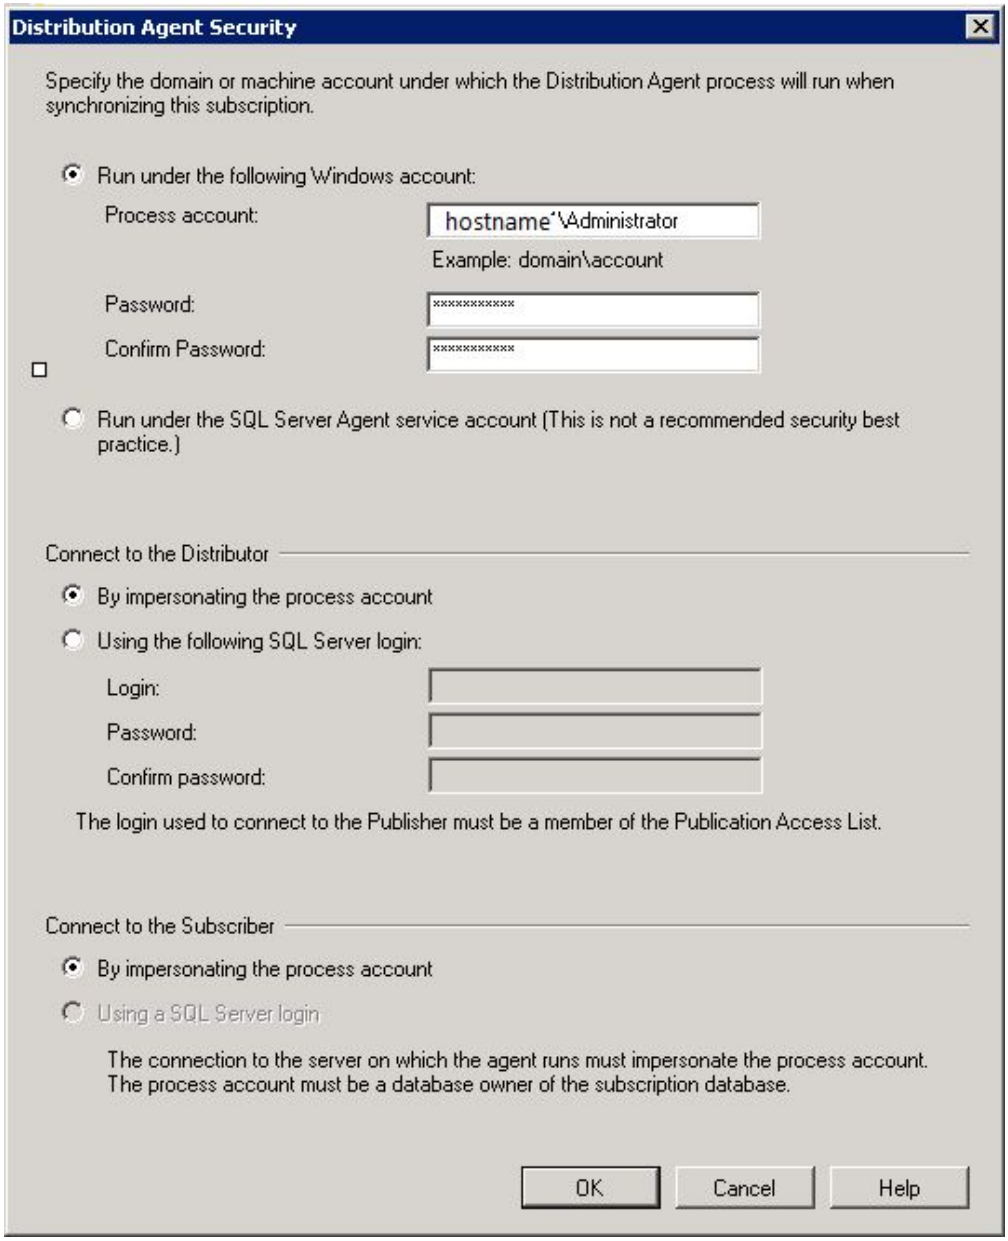
7. In the **Distribution Agent Location** pane, select **Run each agent as its Subscriber (pull subscriptions)** and click **Next**.

8. In the **Subscribers** pane, ensure that **Subscription Database** is **mdb** and click **Next.**

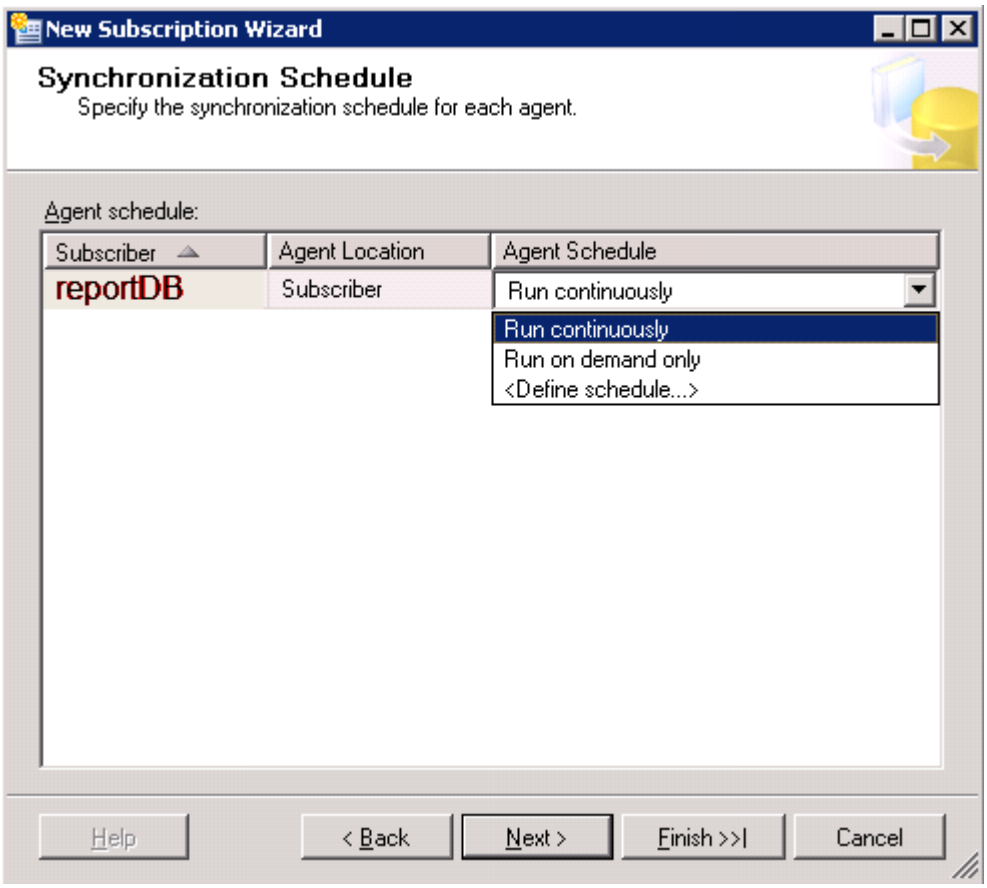
9. In the **Distribution Agent Security** pane, click the button next to **Connection to the Subscriber** .



10. Specify the security credentials for the Subscriber Agent, click **OK,** and click **Next**.



11. In the **Synchronization Schedule** pane, under **Agent Schedule** select **Run continuously**. To schedule the replication process, select **Define Schedule**.



12. In the **Initialize Subscriptions** pane, click **Next**.
13. In the **Wizard Action** pane, select **Create the subscription** and click **Next**.
14. In the **Complete the Wizard** pane, click **Finish**.
15. After the subscription creation process is complete, click **Close**.

Troubleshoot

The following topics explain how to troubleshoot issues:

- Replication Process Fails (see page 818)
- Unable to Copy Data to the Replicated Database (see page 819)

Replication Process Fails

When you run the configuration utility for the database replication, the replication process may fail for several reasons. To know why the replication process failed, you can view the *Replication.log* file available in the **Configuration Utility** folder.

For information about the error messages, refer to Microsoft SQL Server documentation for the respective error message.

After you understand the log messages, run the **DisableReplication.bat** file before you start the replication process again.

If database replication using the configuration utility fails repeatedly, perform the replication process manually. For more information see, Manual Configuration (see page 808).

Unable to Copy Data to the Replicated Database

During replication, some information may not be copied to the subscriber server. Since data is not copied to the replication database, reports are not available.

This is a known issue. See the following Microsoft SQL Server documentation for more information:

http://support.microsoft.com/en-us/kb/956032.

Configuring CA Service Desk Manager

This section contains the following articles:

How to Configure Surveys

This article contains the following topics:

Customer surveys let CA SDM administrators systematically collect and analyze customer feedback about service desk performance. You can modify surveys to suit the needs of your site.

Configure Your System for Surveys

Before you can use surveys, you need to configure your system properly, which involves two steps:

1. Install and configure the CA SDM web interface. When a user accesses the URL for a survey, the web interface formats the survey and populates the survey information.

2. Using the Options Manager, configure and install the web_cgi_url option to specify the location of the CA SDM web engine. For more information, see Install/Uninstall Options Manager Options (see page 1336).

Prepare a Survey

You prepare surveys using the Customer Survey List, which is a typical list window. For example, you can use this window to view all surveys or a subset based on search criteria that you enter; you can create new surveys; you can view details on a particular survey; and you can report on the surveys currently listed.

Each survey has the following features that you can define:

- A name that you can use for searching and reporting purposes
- An introduction that you can use to explain the purpose of the survey to customers
- An ordered list of questions for the customer to answer, each of which includes a set of possible answers
- An optional area where the user can enter free-form comments
- A completion message to display after the user submits the survey

Define Survey Notifications

You can use the Survey tab on the Update Activity Notification page to define a survey notification for an activity notification. When the selected activity notification is triggered, the contact who initiated the activity receives the survey notification. An activity log is generated both when a survey notification is sent and when one is received back from a customer.

Follow these steps:

1. On the Administration tab, browse to Notifications, Activity Notifications.
   The Activity Notification List appears.

2. Select the desired activity notification.
   The detail page displays.

3. Click the Edit button.
   The Update Activity Notification page displays.

4. Edit the fields as appropriate.

5. Select the appropriate object type from the drop-down list.

6. Click the Survey tab.
   This tab contains the following fields:

   - **Send Survey**
     This check box allows you to activate or deactivate the survey. If selected, the survey is sent to the contact when the selected activity notification is triggered.

   - **Default Survey**
     Specify a default survey using the search icon or specify your own in the text box.

   - **Notification Method**
     Choose *one* of the following notification methods:

     - Email

     - Notification

     - Pager_Email

   - **Survey Message Title**
     Enter the title for the survey.

   - **Survey Message Body**
     Enter a message for the contact. When a contact receives notification of a survey, the message body automatically includes a URL that they can access from their web browser to find and fill out the survey form.

7. Save the activity notification.
   When the selected activity notification is triggered, the contact who initiated the activity receives the survey notification.

Survey Reporting

Within CA SDM you can report on surveys from within the administration tab of the web client in all of the usual ways. For example, from the Customer Survey List window, you can choose Reports from the File menu, and then choose a Summary or Detail report. You can also choose Print Form from the various detail windows to print the form data for your surveys, questions, and answers.

You can also fashion your own reports based on the survey data maintained in the CA SDM database.

Create a Managed Survey

The Managed Survey lets the CA SDM administrator select a desired survey sample population and match it to a specific survey. The administrator can then distribute targeted requests for respondents to take the survey at a specific time. This gives the administrator the flexibility of creating open survey periods, while maintaining the ability to have activity-based and category-based surveys related to Requests, Change Orders, and Issues.

The purpose of Managed Surveys is to provide a mechanism for managing surveys. This function can be useful when for survey forms that need to be monitored from time to time (for example, surveys only used during a short period every year or surveys that have been offline too long).

Important! If you want to send the survey to a large number of contacts, set the default value of NX_SURVEY_ILIMIT in NX.env to a higher limit, such as 1073741824.

You can create a managed survey from the Service Desk node on the Administration tab.

Follow these steps:

1. Click the Administration tab.
   The Administration page appears.

2. Click Service Desk, Surveys.
   Click Managed Surveys, Managed Survey List.
   The Managed Survey List appears.

3. Click Create New.
   The Create New Managed Survey page appears.

4. Complete the fields as appropriate.
   See Managed Survey Fields (see page 823) for field descriptions.

5. Use the controls available on the tabs at the bottom of this page to configure the managed survey as appropriate.
   See Managed Survey Tabs (see page 823) for more information.

6. Click Save.
   The managed survey definition is saved and the Managed Survey Detail page appears.

The following buttons are available:

- **Event History**
  Opens the Event History window, which lists the status, time loaded, fire time, and condition for each event associated with the managed survey.

- **Attach Event**
  Opens the Attach Managed Survey Events window, which allows you to attach events with an object type of Managed Survey.

Managed Survey Fields

The following fields require explanation:

- **Name**
  Identifies the title of the managed survey.
- **Managed Survey Status**
  Select *one* of the following options:
- (Default) Survey Period Open
  - Configuration in Progress
  - Survey Cancelled
  - Survey on Hold
  - Survey Period Closed

  You can create a managed survey status from the Service Desk node on the Administration tab.
- **Active**
  Specifies whether the managed survey is active or inactive.
- **Assignee**
  Specifies the contact that is assigned as the survey owner.
- **Group**
  Specifies the group that is associated with the survey.
- **Survey**
  Allows you to search for existing surveys.

Managed Survey Tabs

The following tabs are available on the Create Managed Survey, Managed Survey Detail and Update Managed Survey pages:

- **Activities**
  Allows you to view the Managed Survey Activity Log List. To display only the log entries of interest, you can filter the list by specifying:
  - Earliest Log Date
  - Latest Log Date
  - Activity Type

- Created By

- **Objects**
  Allows you to specify assignee (managed survey owner) or associated groups as notification recipients for the managed survey.

- **Contacts**
  Allows you to specify one or more contacts as notification recipients for the managed survey.

- **Types**
  Allows you to specify one or more contact types as notification recipients for the managed survey (for example, Analyst, Customer, Manager, or Vendor).

- **Initial Message**
  Allows you to view or edit the text for the initial message title and body. Also allows you to specify the notification method for the initial message (for example, e-mail, CA SDM notification, FAXserve, or pager e-mail).

- **Reminder Message**
  Allows you to view or edit the text for the reminder message title and body. Also allows you to specify the notification method for the reminder message (for example, e-mail, CA SDM notification, FAXserve, or pager e-mail).

Create a Survey Template

You can create a survey template from the Service Desk node on the Administration tab.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Click the Administration tab.

2. Click Service Desk, Surveys, Survey Templates.
   The Customer Survey List appears.

3. Click Create New.
   The Create New Survey page appears.

4. Complete the appropriate fields.
   See Survey Template Fields (see page 825) for field definitions.

Note: The Survey Name field and the Active? dropdown are required.

5. Click Save.
   The template is saved and questions can be added.

6. Click Add Question to specify the question's sequence, comment label, status and question text. Or click Add Answer to open the Survey Answer Template Detail page.

> **Note:** If multi-tenancy is installed, the list page displays a tenant column and a tenant drop-down list in the search filter. Specifying <empty> in the search filter searches for public objects. On detail pages, select the appropriate tenant from the drop-down list. If you select <empty>, the object is public.

Survey Template Fields

The following fields require explanation:

- **Comment Label**
  Indicates the label for the comment text box.

  > **Note:** Use this field when you indicate that you want to include comments in the survey.

- **Active**
  Sets the template to active or inactive.

- **Submit Cycle**
  Indicates to send the survey every 'nth' time.

- **Survey Introduction**
  Shows the introduction text of the selected survey.

- **Survey Completion Message**
  Shows the text when the survey is completed.

- **Include Comments**
  Allows a customer to enter free-form comments by adding a text box to the end of the survey form.

- **Use Stricter Rules?**
  Prevents a user from submitting the same survey more than once.

Notifications

Contents

With CA SDM, you can automatically notify key personnel about ticket activities (researching, escalating) and events (opening a ticket, for example). You can also notify key personnel about Knowledge Report Card (KRC) and Support Automation Assistance Sessions. When a significant activity or event occurs, CA Service Desk Manager creates a notification message that does the following:

- Identifies the ticket activity or the notification event
- References the ticket
- Includes other optional information
- Can identify potential contacts

You can view a notification message for a ticket because of a system action. A system action includes opening, closing, or modifying a ticket through its history information.

Setting up automatic notifications involves the following tasks:

- Defining activity notifications that determine the types of activities that generate notifications.
- Defining object contact notifications that determine the object contacts that can be used to send notifications in an activity notification.
- Identifying the methods used to send messages.

Create Object Contact Notifications

Object contact notifications let you notify the recipients based on the current value of a field on the ticket. Instead of identifying a person to notify, as in a notification method, you identify an object. For example, you can identify the To field to ensure that notification goes to the person currently identified in the To field, even if the value has changed since the ticket was defined.

Follow these steps:

1. Select Notifications, Object Contact Notifications on the Administration tab.
   The Object Contact Notification List page opens.

2. Click Create New.
   The Create New Object Contact Notification page opens.

3. Complete the following fields:

   - **Symbol**
     Defines a unique identifier for the object contact notification.

   - **Status**
     Specifies if the object contact notification is active or inactive.

   - **Object Type**
     Displays the name of the object to which the attribute applies.

   - **Object Attribute Name**
     Provides the name of the object contact notification (in the Symbol field) in Majic, which is internal CA code. The attribute name depends on the Object Type selection:

     - If the Object Type is Issue or Workflow Task, the attribute name is assignee, requester, or group; these are the attribute names in the chg objects and they map to fields in the Change_Request tables.

     - If the Object Type is an Issue Activity log, the attribute name must start with the attribute name in the activity log object that links it to a specific instantiation of the chg object. The attribute name could be change_id.group.

   - **Description**
     Describes the object contact notification.

4. Click Save.
   The new object contact notification is displayed in the Object Contact Notification List.

Previous Assignee Notifications

You can define Previous Assignee or Group values for an activity notification that detects changes to key fields when a ticket is saved. Previous values let you notify a previous assignee when a ticket is transferred, or notify both the current and previous groups when the priority of a ticket is escalated.

The Previous value fields of a ticket are local fields that exist only in memory and not in the database. The fields are populated during the save operation of the ticket only when respective attributes are changed and cleared at the completion of the notification processing. A previous value field is associated with a particular activity type through an activity association.

You can define Previous values that detect changes to the following key fields of a ticket:

Field	Requests, Incidents, Problems	Change Orders	Issues
Status	Yes	Yes	Yes
Active	Yes	Yes	Yes

Field	Requests, Incidents, Problems	Change Orders	Issues
Assignee	Yes	Yes	Yes
Request Area/Category	Yes	Yes	Yes
Group	Yes	Yes	Yes
Impact	Yes	Yes	Yes
Priority	Yes	Yes	Yes
Urgency	Yes	No	No
Severity	Yes	No	No

There are several contacts that you can specify for each object type (request, incident, problem, change order, or issue), which notify the current and previous contacts when an activity occurs.

- **Assignee** -- Person assigned to handle the ticket.
- **Assignee Previous** -- Person previously assigned to handle the ticket.
- **Group** -- Group assigned to handle the ticket.
- **Group Previous** -- Group previously assigned to handle the ticket.

After the notification rule is saved, the Assignee Previous and Group Previous fields display on the Object Contact Notifications List page.

Example: Configure Current and Previous Values for Key Fields

The following usage example describes how an administrator configures current and previous values for key fields to help ensure that the previous support representative is notified when a request is transferred away from them.

1. **Situation --** A support representative is frustrated because a ticket was transferred away from them and they were never notified.
2. **Task --** The administrator adds the Assignee and Assignee Previous object contacts to the notification rule for the Transfer activity notification. They attach a message template and specify the current and previous assignees to notify on the request form.
3. **Action --** When the request is saved, the Assignee and Assignee Previous fields of the request are populated. When the activity occurs (ticket is transferred), the condition for the rule is evaluated.
4. **Result --** If the condition is met, a notification message that describes the ticket activity is sent to the current assignee and the previous assignee.

Notify Contacts When a Ticket is Transferred Example

You can notify both the current and previous contacts when a CA SDM ticket is transferred.

Example: Notify both the current and previous contacts when a ticket is transferred

1. On the Administration tab, browse to Notifications, Activity Notifications.
   The Activity Notifications List page appears.

2. Select the Transfer activity notification.
   The Transfer Activity Notification Detail page appears.

3. In the Object Type field, select Requests/Incidents/Problems.

4. On the Notification Rules tab, under Symbol, select the Default Transfer Notification Rule.
   The Default Transfer Notification Rule page appears.

5. On the Object Contacts tab, click Update Object Contacts.

6. Click Search.
   The Notification Rule Update Recipients page appears.

7. From the Object Contacts list, select Assignee and Assignee Previous from the list on the left, and click the contact selection button (>>).
   The selected item is added to the list on the right.

   Note: Use the CTRL or SHIFT keys plus the left mouse button to select multiple object contacts.

8. Click OK.

9. Save the notification rule.
   The Object Contacts list displays the selected object contact.

10. On the Default Transfer Notification Rule page, click Message Template. Select a template and ensure that the Auto Notification option is enabled.

11. Create a request, specify an Assignee, and click Save.

12. On the Request Detail page, select Activities, and Transfer from the File menu.

13. Specify a new Assignee, and click Save.
    The notification is sent to the current and previous assignees when the transfer activity occurs.

Configuration Item Notifications

A configuration item (CI) notification lets you define an activity notification that is associated with a specific CI that is associated with a specific CA SDM ticket. This feature lets you track information about the users, organizations, and vendors of a CI. You can specify the CI object contacts on the Notification Rules Update Recipients page, such as CI Maint Org, CI Primary Contact, and so on.

Notify the Primary Contact of a Configuration Item for an Issue Example

You can define an activity notification for a primary contact that are sent for a specific CI for a specific CA SDM ticket.

Example: Notify the primary contact of a configuration item for an issue

1. On the Administration tab, browse to Notifications, Activity Notifications.
   The Activity Notification List page appears.

2. Select the Initial Activity Notification from the list.
   The Initial Activity Notification Detail page appears.

3. Select the object type you want to use.

4. On the Notification Rules tab, select the Default Notification Rule link.
   The Default Notification Rule page appears.

5. Select the Default Message Template link and ensure that the Auto Notification option is enabled.

6. Select the Object Contacts tab, and click Update Object Contacts.
   The Object Contact Notification Search page appears.

7. Click Search. A list of object contacts appears.

8. Select CI's Primary Contact from the list on the left, and click the contact selection button (>>).
   The selected item is added to the list on the right.
   You can use the CTRL or SHIFT keys plus the left mouse button to select multiple object contacts. You can add one object for a request and multiple objects for a change order or issue.
   The object contact is in the list on the right.

9. Click OK.

10. Save the notification rule.
    The Object Contacts list displays the selected object contact.

11. Complete the following tasks:

    - On the Service Desk tab, create or update an existing CI.

    - Add the primary contact listed on the Object Contacts tab. The selected object contact appears on the Configuration Items Detail page.

    - Add the CI to the Issue.

When an activity event occurs, the rule is implemented and the condition is evaluated. If the criteria for the condition is met, a notification message that describes the ticket activity is sent to all contacts of the CI associated with this notification rule.

Notification Log Reader

The Notification Log Reader displays the notifications received for the logged-in user by date, urgency, and status. With the Notification Log Reader, you can do the following:

- Change the sort order and set menu options to have the Notification Log Reader appear automatically when new messages are received.
- Double-click a notification message to request that CA SDM display the detail page for the ticket associated with the notification.
- Monitor notification messages by entering specific selection criteria to query the database for analysis or for selection of notification messages based on data entered in the fields. For example, you can list only those notification messages that have not been cleared by changing the Message Status field to Not Cleared.
- Clear notification messages to keep your list of notifications to a manageable size. Cleared notifications are not displayed when you first access the Notification Log Reader, although you can display them, if needed.

Set Notification Log Reader Options

You can set options for the Notification Log Reader to define how you are notified when new messages are received for an issue.

Follow these steps:

1. On the ServiceDesk tab, browse to View, Log Reader.
   The Notification Log Reader page appears.
2. Use the check box to the left of each notification to set the following options. You can select items to perform operations such as Clear Selected or Delete Selected.
   - **Header**
     Displays the header of the message, which usually contains the number of the ticket and the activity type.
   - **Start Date**
     Displays the date and time the notification was sent to your Log Reader window.
   - **Status**
     Displays the status of the notification.
   - **Urgency**
     Defines the level of urgency for the notification (low, normal, high, or emergency), which indicates the relative importance of different activities. Urgency levels are predefined; however, the system administrator is responsible for setting up other aspects of notification, such as notification methods and activity associations. The system administrator also defines the method of notification used for contacts and groups for each urgency level.

- **Message Text**
  The full message text for the notification.

The Log Reader displays any changes.

3. Click Close.
   The Notification Log Reader page closes and the options are set.

Personalized Responses

You can create personalized responses and attach them to requests, issues, and change order records when adding activities to the record. For example, you can append a personalized response on the Status Change or Log Comment windows available from the Activities menu.

Create a Personalized Response

You can create a personalized response to append to requests, issues, and change order records.

Follow these steps:

1. From the Administration tab, navigate to Service Desk, Personal Responses.
   The Personal Response list page displays.

2. Click Create New.
   The Create New Personalized Response page displays.

3. Complete the fields on the page:

   - **Response Owner**
     Specifies the contact who owns the response. If this field is left blank, the response is available to all analysts.

   - **Response**
     Specifies the text delivered to all those who receive this response. This field can be up to 1000 characters long.
     You can use variables in this field, for example:

```
Ticket ref_num: @{call_req_id.ref_num}

Assignee: @{call_req_id.assignee.combo_name}

Customer: @{call_req_id.customer.combo_name}

Description: @{call_req_id.description}
```

4. Select the type of records for which you want this response available. Click Save.
   A personalized response is created.

Personalized Response Variable Substitution

Variables can be embedded in the text of a Personal Response. These variables allow information to be substituted from the corresponding Request, Change Order, Issue, Problem or Incident. The syntax of the variables is the same as is used elsewhere in the CA SDM product, such as in the Activity Notification Message Templates and the Manual Notify Activity Message Text. The information can

only be substituted from the corresponding Request, Change Order, Issue, Problem or Incident. Activity Notification Message Templates and the Manual Notify Activity Message Text allow information from the Activity Log Record to be included as well.

Check boxes for each object type (Requests, Change Orders, Issues, Incidents, and Problems) allow Responses to be filtered during selection. If the object type is not checked, the Response is not available for that object. For example, if only the Request box is checked, the Response is only presented in Activities for a Request.

A single Response can be used for all object types (Requests, Change Orders, Issues, Problems or Incidents). Because each object has different attributes, information that does not apply to the object is not substituted (for example, attempting to substitute the Request Number in a Response for an Issue).

A Response text example and the variable substitutions that occur for each object type follows:

```
This is Request # '@{call_req_id.ref_num}'
This is Change Order #' '@{change_id.chg_ref_num}'
This is Issue # '@{issue_id.ref_num}'
```

For a *Request*, the following substitution occurs:

```
This is Request # 'cr_demo:11'
This is Change Order # "
This is Issue # "
```

For a *Change Order*, the following substitution occurs:

```
This is Request # "
This is Change Order # 'chg_demo:3'
This is Issue # "
```

For an *Issue*, the following substitution occurs:

```
This is Request # "
This is Change Order # "
This is Issue # 'iss_demo:6'
```

By using the "Display this Response for" check boxes, you can create different versions of a Response with the appropriate substitution variables for the corresponding object (Requests, Change Orders, Issues, Problems or Incidents).

The format of the substitution variables for the different objects is as follows.

Object	Variable Format
Request / Incident / Problem	@{call_req_id.attr}
Change Order	@{change_id.attr}
Issue	@{issue_id.attr}

The substitution occurs when the Response is copied to the User Description field. The Response is copied after it is selected from the Personalized Response drop-down list and the drop-down list loses focus.

Internal Logs

You can define whether a particular access type is qualified to view internal logs. If allowed to view internal logs, contacts see a check box labeled Internal on each of the Log Activity windows, which they can select to mark the activity as internal. When activities are marked as internal, only contacts with an access type that is qualified to view internal logs sees the activity or is notified of it.

View the Log Reader

The Log Reader lists the notifications that are received for the logged-in user. You can filter the list by clicking Show Filter and specifying search criteria in the search fields. From the menu select View, Log Reader.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

View Notification History

You can see the notification history for the currently logged in user (from the main CA SDM page or a list page, select View, Notification History) , or for the currently open ticket record (select View, Notification History on the menu bar)

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

View Response Time Statistics

You can monitor the response time of your system to evaluate performance issues. Choose View, Response Time Statistics.

Create a Notification Method

A notification method lets you inform people when an activity that affects a ticket takes place. You can assign different notification methods for different notification levels (low, medium, high, or emergency).

Follow these steps:

1. Select Notifications, Notification Methods on the Administration tab.
   The Notification Method List page opens.

2. Click Create New.
   The Create New Notification Method page opens. Complete the following fields, as appropriate:

   - **Symbol**
     Defines a unique identifier for this record.

   - **Write to File**
     Specifies if the context information of the notification method is written to a file. If you select this option, the TEMP (Windows) or TMP (UNIX) environment variable determines the directory used for creating notification files. The environment used depends on who started the CA SDM services. On Windows, for example, configure the System Variables environment and specify TEMP if it is not already defined. If the system cannot find the environment variable, notification files are written to the root directory of the default drive.

   - **Supports SMTP**
     Specifies that SMTP addresses are supported for email recipients.

   - **Record Status**
     Specifies if the database record is active or inactive.

   - **Description**
     Gives a description of the notification method.

   - **Notification Method**
     Shows the name (including the path if it is required) of the program or executable script that runs, and any applicable switches. For example: Launchit c:\\backup\\applog.bat or pdm_mail -p.

     Note: Because the notification method runs from the CA SDM server, put the notification method script in a directory that can be accessed from the path on the server. Alternatively, specify the full path to the script. On UNIX, depending on the shell you are running, you can check the path by executing which pathname_to_script command.

     Out of the box, the following Notification Methods are provided:

     - Email
     - Notification
     - Pager_Email
     - xMatters/Email
     - xMatters/Notification

- xMatters/Pager_Email

> **Note:** CA SDM supports only one notification method at a time. If you are using Email, then you cannot use Notification at the same time. This applies to all out of the box notification methods like Email, Notification, Pager_Email, xMatters /Email, xMatters/Notification, and xMatters/Pager_Email. When xMatters integration is disabled, the Notification Method must be manually reset to either Email, Notification, or Pager_Email.

Select one of the notification method from the Low, Normal, High, or Emergency drop-down list. When xMatters is integrated, select Notification Method as **xMatters/Email**. It indicates that the notification will be sent to the xMatters agent for incidents, requests, or problems. CA SDM objects like Change Orders, Issues, or Knowledge Documents are processed using the Email notification method.

3. Click Save.
   The notification method is defined and the Notification Method Detail page appears. If there appears to be a problem with the notification methods, examine the logs. The logs are in the $NX_ROOT/log directory on UNIX or $NX_ROOT\log on Windows.

Create a Notification Rule

This article contains the following topics:

Create the notification rule to specify the contacts to be notified and under what circumstances.

> **Note:** If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

> **Note:** The "Document about to expire" activity notification is activated seven days before the actual expiration date that displays in the knowledge document.

Follow these steps:

1. Select Notifications, Notification Rules from the Administration tab.
   The Notification Rule List page opens.

2. Click Create New.
   The Create New Notification Rule page opens.

3. Complete the following fields:

- **Symbol**
  Defines a unique identifier for this notification rule. For example, enter Ticket Description Update.

- **Object Type**
  Defines the object to which the rule applies. For example, select Request/ Incident/ Problem for an activity related to a ticket.

4. Click Save & Continue.

5. Click Condition to select the macro you can use to define a condition for this rule. Do one of the following actions to define the condition:

   Note: A notification rule without a condition notifies all contacts every time the activity occurs.

   - Search for the macro from the list and select it.

   - Click Create New to create a macro.

6. Click Message Template to add a message template that you have created for this rule. Do one of the following:

   - Search for the template from the list and select it.

   - Click Create New to create a message template.

7. Choose the appropriate contacts to notify from the following tabs:

   Note: Use the Update Contacts button that appears on each tab to search for and select more contacts to notify.

   - **Object Contacts**
     Displays the available organizations, vendors, and configuration items for the selected Object type that receive notification about tickets. For example, you can select Affected End User or Affected End User's Admin Org to notify.

   - **Contacts**
     Displays the individuals who are added to the notification rule, regardless of their association with the ticket.

   - **Contact Types**
     Displays the users who are defined within the notification rule with the same classification, such as analyst or customer.

8. Click Save.
   The notification rule is created.

Example Notify the Current and Previous Assignees

You can configure previous values for an activity notification that detects changes to key fields when a ticket is saved. Using previous values, you can notify both the current and previous assignee when a ticket is transferred, and much more.

Follow these steps:

1. Open the Transfer activity notification.
   The Transfer Activity Notification Detail page opens.

2. Verify the following fields are set to the following values:

   - **Object**: Requests/Incidents/Problems.

   - **Notification Rules**: Default Transfer Notification Rule for request/incident/problem

3. Click Default Transfer Notification Rule for request/incident/problem rule.
   The Default Transfer Notification Rule for request/incident/problem Notification Rule Detail page opens.

4. Verify that the Auto Notification option is enabled on the Default Transfer message template for request/incident/problem template.

   Note: The Auto Notification check box sends the notification associated with this template automatically when the activity occurs. For example, you set up an initial notification, set up the objects to notify, and set up the message template, but you are not ready to turn on the notifications. In this case, you do not select Auto Notification. When you are ready to start automatic notifications, you select the check box. The notification becomes active and occurs as defined.

5. On the Object Contacts tab, click Update Object Contacts.
   The Object Contact Notification Search page opens.

6. Click Search.
   The Notification Recipients - Update page opens.

7. From the Object Contacts list, select Assignee and Assignee Previous and click the move button (>>).
   The selected items are added to the list on the right.

   Note: Use the CTRL or SHIFT keys plus the left mouse button to select multiple object contacts.

8. When the object contacts are in the list on the right, click OK.

9. Click Close Window.
   The Object Contacts list displays the selected object contacts.

10. Complete the following steps to test this notification:

    a. Create a request, specify an assignee, and save the request.

    b. On the Request Detail page, select Activities, Transfer. Specify a new assignee and save the request.

    The notification is sent to both the current and previous assignees when the ticket is transferred.

Example Notify the Primary Contact of a CI/Asset

You can define a notification rule for an activity notification that is sent for a specific configuration item associated with a service desk ticket. These notifications let you notify the person responsible for maintaining the configuration item when a request, problem, incident, change order, or issue is created.

Follow these steps:

1. Open the Initian activity notification.
   The Initial Activity Notification Detail page opens.

2. Verify the following fields are set to the following values:

   - **Object**: Requests/Incidents/Problems.

   - **Notification Rule**: Default initial Notification Rule for request/incident/problem

3. Click Default initial Notification Rule for request/incident/problem.
   The Default initial Notification Rule for request/incident/problem Notification Rule Detail page opens.

4. Verify that the Auto Notification option is enabled on the Default initial message template for request/incident/problem template.

   Note: The Auto Notification check box sends the notification associated with this template automatically when the activity occurs. For example, you set up an initial notification, set up the objects to notify, and set up the message template, but you are not ready to turn on the notifications. In this case, you do not select Auto Notification. When you are ready to start automatic notifications, you select the check box. The notification becomes active and occurs as defined.

5. On the Object Contacts tab, click Update Object Contacts.
   The Object Contact Notification Search page opens.

6. Click Search.
   The Notification Recipients - Update page opens.

7. Select the Primary Contact of the CI from the list on the left and click the move button {>>).
   The selected items are added to the list on the right.

   Note: Use the CTRL or SHIFT keys plus the left mouse button to select multiple object contacts.

8. When the object contacts are in the list on the right, click OK.

9. Click Close Window.
   The Object Contacts list displays the selected object contacts.

10. Complete the following steps to test this notification:

    a. On the Service Desk tab, create or update an existing CI.

    b. Add the primary contact listed on the Object Contacts tab. The selected object contact appears on the Configuration Items Detail page.

    c. Add the CI to the Issue.

    When the activity occurs, a notification message that describes the ticket activity is sent to the contact responsible for the CI.

Create Message Templates

Create a message template that contains the values to use for the notification message. When you send multiple notification messages, you can use the message templates to simplify your workload.

Follow these steps:

1. Select Notifications, Message Templates from the Administration tab.
   The Message Template List page opens.

2. Click Create New.
   The Create New Message Template page opens.

3. Complete the fields as appropriate.

   - **Symbol**
     Defines a unique identifier for this message template.

   - **Object Type**
     Specifies the object type associated with this template. For example, select Request/ Incident/ Problem for any notification related to a ticket.

- **Record Status**
  Specifies the status of the template as either active or inactive. Set the status to Active to use the message template.

- **Auto Notification**
  Specifies to send the notification associated with this template automatically, when the activity occurs. For example, you set up an initial notification, set up the objects to notify, and set up the message template, but you are not ready to turn on the notifications. In this case, you do not select Auto Notification. When you are ready to start automatic notifications, you select the check box. The notification becomes active and occurs as defined.

- **Notify Level**
  Indicates the relative importance of sending this notification. For example, select Emergency if you want to send the email notification to the contact immediately when the associated activity occurs.

- **Notification Message Title**
  Specifies the summary title of the message. You can use variables to insert the incident number in the message title. For example, @{call_req_id.type.sym} @{call_req_id. ref_num} @{type.sym}.

- **Notification Message Body**
  Specifies the content of the message. You can use variables to insert the analyst name, end-user name, and description into the message. For example,

```
@{call_req_id.type.sym} @{call_req_id.ref_num} @{type.sym}.

Assigned to: @{call_req_id.assignee.combo_name}

Customer: @{call_req_id.customer.combo_name}

Description: @{call_req_id.description}

Click on the following URL to view:

@{call_req_id.web_url}
```

  You can use the ARTIFACT keyword to specify how artifacts are handled in outbound messages, message templates, notifications, and auto-replies. The ARTIFACT keyword uses the following values:

  - **NONE** -- Specifies no validation of artifacts. This value is the same as not using the keyword.

  - **PROTECTED** -- Validates a ticket against the hash for confirmation. If confirmation fails, the artifact is considered invalid and filtering fails when filtering searching for an artifact ({{object_id}}).

  - **SECURE** -- Decrypts the ticket number. If the value is not a valid password, the artifact is considered invalid and filtering fails when filtering is searching for an artifact ({{object_id}}).

- **HTML Message**
  Specifies the HTML message that is displayed to the recipient. If the recipient receives the message on an external device, such as a cell phone or PDA, the message displays in plain text only. Click Edit HTML Message to open the HTML Editor.

- **Quick View**
  Displays the message as it appears to the recipient.

- **HTML Source**
  Displays the message in the HTML source code.

4. Click Save.
   The message template is created.

Create a Manual Notification

You can define a manual activity notification that is sent for a specific activity. An activity is an action that someone performs, such as resolving a service desk ticket or sending a managed survey. Even daily activities such as returning a call, canceling or closing a record, increasing priority, or updating status can result in a notification being sent.

Manual notifications let you do the following activities:

- Use temporary email addresses
- Add default users to manual notifications
- Show in an email notification all other recipients of the notification
- Process the outgoing email queue after a server error that leaves emails in the queue
- Notify the attached Object Contacts, Contacts, and Contact Types

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, select one of the following:
   - Incident from the Incident List page
   - Problem from the Problem List page
   - Request from the Request List page
   - Change order from the Change Order List page
   - Issue from the Issue List page

2. Select Activities, Manual Notify on the menu bar.

   The Manual Notification page appears.

3. Add the recipients of the notification in the To or Cc fields. The following fields enable you to add the recipients:

   Note: This feature will only be available if you apply a patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

   Important! You cannot add the same recipient in both To and Cc fields.

   Note: The option to add recipients in the To and Cc list can be enabled if you install the **mail_show_to_cc_list** option from the Options Manager. If you disable the option, you can add recipients in the To list only**.** This option shows all the recipients of the email notification. For manual email notification, both To and Cc list recipients are displayed and for automatic email notification, only To list recipients are displayed. Pager email notification method does not support the listing of all the recipients in To or CC list.

   - **Available Recipients:** Lists relevant contacts and Contact Objects that you can add to the Recipients list, as specified in the Manual Notify settings in Activity Notifications options. When you select a contact object name, only the contact names that are associated with the object are added to the Recipients list. After selecting the recipient(s), click **Add To Recipients** (required) or click **Add Cc Recipients** (optional). The selected recipient(s) appear (s) on the respective Selected Recipient list.

   - **Contact:** Enter characters into the contact field of the ticket. The field displays results as you type and generates a list of suggested results. After selecting the contacts, click **Add To Contact** (required) or click **Add Cc Contact** (optional). The selected contact appears on the respective Selected Recipient list.

   - **Email address:** Accepts an SMTP address for an email recipient. You can specify any valid email address including addresses that are not associated with a contact record. Separate multiple addresses with a semi-colon. This field appears when the option notification_allow_temp_address is installed using Options Manager. After selecting the email address, click **Add To Email** (required) or click **Add Cc Email** (optional). The selected email address appears on the respective Selected Recipient list.

4. Complete the following fields, as appropriate:

- **Urgency:** Specifies the relative importance of the notification (by default: low, normal, high, or emergency). The system administrator defines the Urgency levels.
- **Preferred Method:** Specifies the notification method to use, such as Email or Notification.

  Note: When you specify an email address, set the method to one that supports SMTP, otherwise, remove email addresses from the Selected Recipients list.

- **Internal:** Makes the notification visible to internal contacts only.
- **Message Title** : Specifies a title for the notification message. This title is a short description of the message, similar to an email subject line. The default title is the ticket type and number, and the words "Manual Notify" (for example, "Incident 32 Manual Notify").
- **Message Text:** Specifies the entire text of the notification. You can click Spelling to check the spelling of the message text.
- **Personalized Response:** Specifies a personalized response such as a generic or administrator signature. The response is added to the end of the message text.

  Note: The administrator must set up a personalized response before you can use this option. For more information about personalized responses, see Personalized Response (see page 2316)

5. You can send documents or URLs to the selected recipients, if you have selected the **Email** method and if you have installed the **mail_allow_attmnts** option.

   Note: This feature will only be available if you apply a patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

   Ensure that you read the following considerations before using this feature:

   - Attachment repository used for storing manual notification attachments should be configured to match the sender and receiver email server restrictions in terms of file size and extensions. There is no separate repository to store the attachments. As an Administrator, you may need to add extra validations to match Exchange limitations.
   - Mailer daemon needs to be explicitly configured to use SSL (use the options manager) if encryption is needed.
   - The SOAP web services method **notifyContact** does not support this functionality.
   - Based on the size of the attachments, emails with many attachments may slightly degrade the performance of sending emails.

- No changes are made to the mobile interface as Manual Notify is not supported from the mobile interface.
- CA SDM does not handle bounce emails and emails failed to be delivered by the mail server.
- Email attachments are not encrypted.
- CA SDM is not responsible for language differences in the email content. An email in Portuguese can be sent to the English supported device.
- CA SDM does not have the mechanism to detect if huge (number/size) emails are sent. Ensure that you check the email size at the firewall level.
- The attachments can be sent to CA SDM contacts, and to the contacts that are not created in CA SDM (using email addresses directly). CA SDM will not take responsibility of the following:
  - attachments being forwarded to other contacts.
  - attachments may contain virus or malware content in the files.
  - attachments may contain sensitive information (such as personal information)
- If an Analyst sends the same attachment as part of two different manual notify activities, then, there would be duplicate attachments created and linked to the cr object. Ensure that you check before uploading any attachment.

To upload the documents or URLs, click **Attach Documents** or **Attach URLs** from the **Attachments** tab and follow the on-screen instructions. After you upload, the URL or the document is listed on the tab.

6. Click Notify.
   The notification is sent and the activity is recorded on the Activities tab.

How to Set Up Notification for an Activity

You can define a notification that is sent for a specific activity. An activity is an action that someone performs, such as resolving a ticket, sending a managed survey, running the Knowledge Report Card. Even daily activities such as returning a call, canceling or closing a record, increasing priority, or updating status are activities that can result in a notification being sent.

Follow these steps:

1. Open the CA SDM Web UI (see page).
2. Verify the Prerequisites (see page 846).
3. If you do not want to use a predefined message template, Create a Message Template (see page 848).
4. If you do not want to use a predefined notification rule, Create a Notification Rule (see page 849).

5. If you do not want to use a predefined activity association, Create an Activity Association (see page 851).

6. If you do not want to use a predefined activity notification, Create an Activity Notification (see page 852).

Open CA SDM Web UI

Log in to the web UI from the following servers, depending on your CA SDM configuration:

- Conventional: Primary or secondary servers
- Advanced availability: Application or background servers

Verify the Prerequisites

Verify the following prerequisites, before you being the setup:

- Installed the option to add URL in the notification (see page 846).
- Verified the notification method for the recipient (see page 846).
- If you want to send a manual notification to an email address that is not associated with a contact, allow temporary email address (see page 847).

Install the Option to Add URL Hyperlinks to Notifications

The web_url field in the Change_Request and Workflow_Task tables holds a URL value that allows a user to access a particular change order or workflow task through the web interface. When used in email notifications, a user can click the URL and can go to the web interface without any further querying.

Before you can implement the URL hyperlinks in notifications, configure the system as follows:

1. Install and configure the CA SDM web interface.

2. Using the Options Manager, configure and install the web_cgi_url option to specify the location of the CA SDM web engine. For example, http://hostname/scripts/pdmcgi.exe. For advanced availability, the host name should point to the application server or the load balancer.

Verify the Notification Method for the Recipient

Ensure that the contact to whom you want to send the notification, is assigned to that particular notification method.

Follow these steps:

1. Select Security and Role Management, Contacts on the Administration tab.
   The Contact Search page opens.

2. Search for the contact using the filter and select the contact that you want to notify from the search result.
   The contact detail page opens.

3. Select Notification on the Contact Details tab.

4. Verify the notification method. Based on your notification priority, choose the required option. For example, you want to send an email notification for any emergency notification. Select the Email option in the Emergency field.

5. To change the notification method, click Edit, change the option, and click Save.
   The notification method for the contact is verified.

Allow Temporary Email Addresses

A temporary email address is an address that is not associated with a contact in the system. Temporary email addresses are useful in circumstances such as the following one:

- An end user is out of the office or is having difficulty accessing their standard email account.
- The analyst wants to use email to track interactions with the user.
- The analyst sends a manual notification to a *temporary* email address for the user.
- The analyst can view the activity log, which is updated with the manual notification.

Recipients cannot reply to temporary addresses when their email address is not associated with a contact record or does not have permission to update the ticket.

Note: Temporary email addresses are always SMTP email addresses, and are supported only when the Preferred Method supports SMTP. For information about how to set up temporary email addresses, see the *Online Help*.

Follow these steps:

1. Select Options Manager, Notifications on the Administration tab.
   The Option List page opens.

2. Click notification_allow_temp_address.
   The notification_allow_temp_address Options Detail page opens.

3. Click Edit.

4. Click Install.
   The notification_allow_temp_address Options Detail page opens.

5. Click Close Window.

6. Restart the CA SDM servers. See How to Restart the CA SDM Servers (see page 913).
   Temporary email addresses are now allowed for manual notifications.

Create Message Templates

Create a message template that contains the values to use for the notification message. When you send multiple notification messages, you can use the message templates to simplify your workload.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Notifications, Message Templates from the Administration tab.
   The Message Template List page opens.

2. Click Create New.
   The Create New Message Template page opens.

3. Complete the fields as appropriate.

   - **Symbol**
     Defines a unique identifier for this message template.

   - **Object Type**
     Specifies the object type associated with this template. For example, select Request/ Incident/ Problem for any notification related to a ticket.

   - **Record Status**
     Specifies the status of the template as either active or inactive. Set the status to Active to use the message template.

   - **Auto Notification**
     Specifies to send the notification associated with this template automatically, when the activity occurs. For example, you set up an initial notification, set up the objects to notify, and set up the message template, but you are not ready to turn on the notifications. In this case, you do not select Auto Notification. When you are ready to start automatic notifications, you select the check box. The notification becomes active and occurs as defined.

   - **Notify Level**
     Indicates the relative importance of sending this notification. For example, select Emergency if you want to send the email notification to the contact immediately when the associated activity occurs.

   - **Notification Message Title**
     Specifies the summary title of the message. You can use variables to insert the incident number in the message title. For example, @{call_req_id.type.sym} @{call_req_id. ref_num} @{type.sym}.

- **Notification Message Body**
  Specifies the content of the message. You can use variables to insert the analyst name, end-user name, and description into the message. For example,

```
@{call_req_id.type.sym} @{call_req_id.ref_num} @{type.sym}.

Assigned to: @{call_req_id.assignee.combo_name}

Customer: @{call_req_id.customer.combo_name}

Description: @{call_req_id.description}

Click on the following URL to view:

@{call_req_id.web_url}
```

  You can use the ARTIFACT keyword to specify how artifacts are handled in outbound messages, message templates, notifications, and auto-replies. The ARTIFACT keyword uses the following values:

  - **NONE** -- Specifies no validation of artifacts. This value is the same as not using the keyword.
  - **PROTECTED** -- Validates a ticket against the hash for confirmation. If confirmation fails, the artifact is considered invalid and filtering fails when filtering searching for an artifact ({{object_id}}).
  - **SECURE** -- Decrypts the ticket number. If the value is not a valid password, the artifact is considered invalid and filtering fails when filtering is searching for an artifact ({{object_id}}).

- **HTML Message**
  Specifies the HTML message that is displayed to the recipient. If the recipient receives the message on an external device, such as a cell phone or PDA, the message displays in plain text only. Click Edit HTML Message to open the HTML Editor.
- **Quick View**
  Displays the message as it appears to the recipient.
- **HTML Source**
  Displays the message in the HTML source code.

4. Click Save.
   The message template is created.

Create a Notification Rule

Create the notification rule to specify the contacts to be notified and under what circumstances.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Note: The "Document about to expire" activity notification is activated seven days before the actual expiration date that displays in the knowledge document.

Follow these steps:

1. Select Notifications, Notification Rules from the Administration tab.
   The Notification Rule List page opens.

2. Click Create New.
   The Create New Notification Rule page opens.

3. Complete the following fields:

   - **Symbol**
     Defines a unique identifier for this notification rule. For example, enter Ticket Description Update.

   - **Object Type**
     Defines the object to which the rule applies. For example, select Request/ Incident/ Problem for an activity related to a ticket.

4. Click Save & Continue.

5. Click Condition to select the macro you can use to define a condition for this rule. Do one of the following actions to define the condition:

   Note: A notification rule without a condition notifies all contacts every time the activity occurs.

   - Search for the macro from the list and select it.

   - Click Create New to create a macro.

6. Click Message Template to add a message template that you have created for this rule. Do one of the following:

   - Search for the template from the list and select it.

   - Click Create New to create a message template.

7. Choose the appropriate contacts to notify from the following tabs:

   Note: Use the Update Contacts button that appears on each tab to search for and select more contacts to notify.

- **Object Contacts**
  Displays the available organizations, vendors, and configuration items for the selected Object type that receive notification about tickets. For example, you can select Affected End User or Affected End User's Admin Org to notify.

- **Contacts**
  Displays the individuals who are added to the notification rule, regardless of their association with the ticket.

- **Contact Types**
  Displays the users who are defined within the notification rule with the same classification, such as analyst or customer.

8. Click Save.
   The notification rule is created.

Create an Activity Association

Associate an activity with the object attribute to track the changes to the related object attribute. For example, associate Field Update activity with the object attribute of the Description field of an incident record. This enables you to send a notification whenever the description of the incident is updated. An object attribute can have only one activity notification.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Notifications, Activity Associations on the Administration tab.
   The Activity Association List page opens.

2. Click Create New.
   The Create New Activity Association Type page opens.

3. Complete the following fields:

   - **Symbol**
     Defines a unique identifier for this association.

   - **Code**
     Defines an internal code for the activity association.

   - **Object Type**
     Specifies the name of the object to which the attribute applies. For example, select Request/ Incident/ Problem.

- **Object Type Attribute**
  Defines the object attribute to which the activity type is associated. For example, enter the object attribute of the Description field of an incident record.

- **Activity Type**
  Indicates the type of activity. For example, select Field Update to check when the selected object attribute is updated.

- **Log Me**
  Determines if this activity association creates a log entry in the Audit Log.

4. Click Save.
   The Activity Association Type Detail page opens.

5. Click Close window.
   The activity association is created.

Create an Activity Notification

Associate the activity with a notification. When the activity takes place, the associated notification is sent to the selected contacts.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants. You cannot maintain different Manual Notify activity notifications per tenant, or copy a Manual Notify activity notification.

Follow these steps:

1. Select Notifications, Activity Notifications from the Administration tab.
   The Activity Notification List page opens.

2. Click Create New.
   The Create New Activity Notification page opens.

3. Complete the following fields:

   - **Symbol**
     Defines a unique identifier for this activity notification.

   - **Code**
     Defines an internal code for the activity notification.

   - **Activity Valid for**
     Specifies the object to which this activity applies.

4. Click Save & Continue.
   The Update Activity Notification page opens.

5. Complete the following fields:

   - **Internal**
     Specifies if the activity notification is available only to internal employees or visible to end users.

   - **Record Status**
     Defines if the activity notification is active or inactive. Set the status to active to use the activity association.

   - **Related Ticket Activity**
     Specifies if the activity log on a ticket is propagated to all related tickets. The activity log propagation is only valid for related incidents, problems, and change orders. If you use multi-tenancy, perform the following actions:

     - Specify the appropriate tenant type from the Related Ticket Activity drop-down list.

     - Enter the name of the tenant in the tenant field, or click the search icon to search for a tenant.

   - **Object Type**
     Specifies the name of the object to which the activity applies.

6. Select the Notification Rules tab and click Update Notification Rules. Do one of the following actions:

   - Enter the search criteria, click Search, and select the notification rule from the search result.

   - Click Create New to create a notification rule.

7. (If you want to send a survey to the recipient of the notification) Select the Survey tab and define a survey notification (see page 854). Surveys let you collect and analyze the customer feedback. An activity log is generated when a survey notification is sent and when one is received back from a customer.

   Note: The Survey tab applies to all object types except Knowledge Documents, Knowledge Document Comments, and Knowledge Report Card. When specified from the Object Type list, the Emails tab appears instead of the Survey tab on the Update Activity Notification page. From the Emails tab, you can search for one or more email messages to associate with this notification or define a new one.

8. (If you want to trigger an event after the notification is sent) Select the Events tab. Events are procedures that an issue management system follows after a certain amount of time has elapsed. When the activity notification is triggered, the selected events occur. For example, update the status of the incident to Close. Search for the event and click Update Events button to add the event to an activity notification.

9. Click Save.
   The Activity Notification Detail page opens.

10. Click Close Window.
    The activity notification is created. If an error occurs on the outgoing mail server, email notifications are not sent and queue in the $NX_ROOT/site/mail_queue directory. When the mail server becomes active again, after an interval it processes and sends email. You can set the email retry interval variable (see page 854) to recycle the email that was queued when the mail server was busy.
    Notification email messages that the outgoing mail server fails to send are resubmitted until you do one of the following actions:

    - Stop the Mail Daemon (pdm_mail_nxd) that handles outbound email notifications.
    - Manually delete the messages from the $NX_ROOT/site/mail_queue directory.

Define Survey Notifications

Complete the following fields, as appropriate:

- **Send Survey**
  Indicates whether to activate or deactivate the survey. If selected, the survey is sent to the contact when the selected activity notification is triggered.
- **Default Survey**
  Specify a default survey using the search icon or specify your own in the text box.
- **Survey Message Title**
  Enter the title for the survey.
- **Survey Message Body**
  Enter a message for the contact. When a contact receives notification of a survey, the message includes a URL that they can access from their web browser to find and fill out the survey form.

Set the Email Retry Interval Variable

You can define the time interval (in seconds) to retry failed attempts to send outgoing email to the mail server.

Note: CA SDM does not retry sending messages that the outgoing mail server accepts, but cannot be delivered. For these messages, the outgoing mail server retry capabilities and policies, if any, are in effect.

Retries are on a per-message basis. If the mail server is unavailable for a period, each message is retried when its own timer expires, rather than all the messages being sent at once. However, if you restart the outgoing mail daemon, all unsent messages attempt to be sent at that time, and if they all fail to be sent, their retry timers are all reset at the same time.

The setting (NX_EMAIL_RETRY_INTERVAL) in the NX.env file controls the retry interval. You can change the default retry interval setting on one or more servers.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server.
2. Navigate to the $NX_ROOT directory
3. Use a text editor such as WordPad to open the NX.env file.
4. Modify the value of to the NX_EMAIL_RETRY_INTERVAL interval you want as follows:

   ```
   NX_EMAIL_RETRY_INTERVAL=number_of_seconds
   ```

   - **NX_EMAIL_RETRY_INTERVAL**
     Defines the time interval (in seconds) to retry failed email attempts.
   - ***number_of_seconds***
     Specifies the number of seconds for each email retry interval. The default time is 600 seconds (10 minutes). The minimum value that you can use is 20 seconds. If you set a value that is less than the minimum of 20 seconds or more than 2000000 seconds, the default value of 10 minutes is used.
5. Save and close the file.
   Restart the CA SDM servers. For more information about how to start the CA SDM server, depending on your CA SDM configuration, see How to Restart the CA SDM Servers (see page 913) .
   The change takes effect.

Service Management Overview

This article contains the following topics:

Service Management Processes and Best Practices

Implementing standardized processes and best practices directly impacts the effectiveness, productivity, and cost of the Service Support environment. CA provides a library of recommended processes and best practices for Service Management that aligns with industry standards and recognized best-practice frameworks including ITIL, CobIT, BS15000, and more. The processes described for CA SDM include the following:

- Incident Management
- Problem Management
- Change Management

- Request Management
- Configuration Management
- Release Management
- Knowledge Management
- Support Automation

Note: Information about the Best Practices library is available online. You can learn about the Service Management Best Practices of CA, including white papers and other collateral at . The strategic process expert partners of CA can help personalize the best-practice library for your organization.

ITIL Configuration

Information Technology Infrastructure Library (ITIL) is a collection of best practices in computer data center management. In addition to defining recommended processes, a major benefit of the ITIL framework is its precise definitions of commonly used data center terminology. Often in the IT world, the same word is used to mean different things; or different people use a particular word with a meaning that is individually nuanced. ITIL helps to avoid this problem.

The following ticket types are available:

- Request
- Change Order
- Issue
- Incident
- Problem

Important! CA SDM only supports an ITIL interface. The ITIL interface supports data objects that were not used in previous non-ITIL versions of the product, for example, problem and incident tickets.

ITIL does the following:

- Produces an ITIL interface for your CA SDM installation.
- Allows your CA SDM database, forms, and fields to differ from a standard installation, and to conform to ITIL conventions instead.

Important! When upgrading your existing system, clear the "Load default data" check box to retain the database tables and data; otherwise, all existing data is lost.

ITIL Service Disciplines

ITIL describes best practices for several disciplines. The Service Support and Service Delivery disciplines combine to provide the Service Management capability of an organization. Complex interrelationships among all ten of the Service Management disciplines interact to help ensure that IT infrastructure delivers a high level of service to businesses.

Service Support includes the following disciplines:

- Incident Management
- Problem Management
- Change Management
- Release Management
- Configuration Management

CA SDM specifically addresses Incident, Problem, Change, and Configuration Management.

Service Delivery includes the following disciplines:

- Service Management
- Availability Management
- Capacity Management
- Financial Management for IT Services
- IT Service Continuity Management

CA SDM specifically addresses Service Management.

Configure the CA SDM Components

This article contains the following topics:

Components in CA SDM

CA SDM components include CMDB, Visualizer, Web Screen Painter, and Support Automation.

Configuration Management Database (CMDB)
CMDB consolidates and reconciles disparate sources of IT-related data in the context of business services. It lets you view the configuration item (CI) information such as resource attributes, relationships, and dependencies. You can use CMDB to display the relationships associated with a contemplated change, and thereby to understand the impact associated with such a change from a business service perspective (impact analysis). CMDB is installed automatically when you install CA SDM.

Visualizer
Visualizer provides a graphical depiction of a CI and its related CIs including the types of the relationships. You can double-click a CI in the Visualizer to follow relationship trails and understand the impact that one CI has on the other CIs. You can configure Visualizer on the Primary Server or a Secondary Server when you install CA SDM on that server. However, if you want to configure Visualizer after installing CA SDM, you launch CA SDM and then use the Configuration Wizard Visualizer.

Web Screen Painter
You can use Web Screen Painter to modify the database schema of CA SDM to meet your needs. Web Screen Painter also allows you to test your schema changes on your own web forms before updating the physical DBMS schema or affecting other users. In the conventional configuration, you can install Web Screen Painter on the Primary Server or any Secondary Server. However, in the advanced availability configuration, you must install Web Screen Painter only on the Background Server. If you install it on a standby server or an application server, you get an error message upon launching it.

Support Automation

Support Automation is a set of tools, processes, and technology. It enables the automated diagnosis, repair, and prevention of computer problems with minimal interaction required by the end user. Support Automation helps IT Analysts access end-user computers remotely and fix issues. You can configure Support Automation when you install CA SDM.

Configure the CA SDM Components

CA SDM is used to configure the primary and secondary servers as well as the database and web interface.

To install and configure CA SDM and its components on SQL server, enable TCP/IP on a system.

CA SDM Release 12.9 does not provide tools.jar and javac for AIX. Install tools.jar on AIX before you run the product configuration. Configuring REST Web Services and Support Automation requires the tools.jar file. To use the REST sample files, install javac on AIX. You can download the Java SDK for AIX from the IBM website in the IBM Developer kits section for Linux. Download the 32-bit binaries of Java SE and install JDK 1.6 SR10 on the AIX computer at any location. Copy tools.jar from the installed JDK location to <Shared Component>\JRE\1.6.0_10\lib and copy javac to \JRE\1.6.0_10\bin. You can also find the JRE location in the NX_JRE_INSTALL_DIR variable.

Note: If Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) coexist on the network, verify that appropriate tools and mechanisms to support these technologies are in place before you start the server configuration.

Follow these steps:

1. Select Start, Programs, CA, Service Desk, Configuration.
   The Configuration Wizard appears.

2. Complete the required fields. For information about the fields that appear in the wizard, see Server Configuration Utility (see page 869).

3. To complete the configuration, follow the on-screen prompts.

The default value for the TCP service number is displayed the first time that you configure the product. To determine the TCP service number on your installation, open a telnet session from your Windows workstation to the server:

- If your network is using NIS, enter the following command:

  ```
  ypcat services | grep slump.
  ```

  The output includes a line similar to the following line:

  ```
  slump nnnn/tcp   #This is required for slump to work!
  ```

- If your network is not using NIS, enter the following command:

  ```
  grep slump /etc/services.
  ```

  The output includes a line similar to the following line:

  ```
  #slump nnnn/tcp
  ```

  Enter the number *nnnn* in the TCP Service Number field.

Note: If configuration fails during the Validate Extension Tables step, database connectivity can be an issue. Run the configuration again, and verify that you provided the correct database connectivity information.

Product Configuration

After you install CA SDM and any additional products you select, complete the following steps:

- Configure the CA SDM components (servers, the database, the web interface).
- Configure the web interface if the web server and primary server are on different computers.
- Configure Support Automation.
- Implement Knowledge Document Life Cycle Reports for Automated Policies.
- Configure CA Business Intelligence.
- Implement multi-tenancy

For configuring servers for advanced availability configuration, see the scenario How to Configure Servers for Advanced Availability (see page 508).

Set Up the CMDB Audit Log

The object and trigger definitions, attributes, and HTML forms that are used by CMDB audit has changed. Set the CMDB Release 12.9 audit log by performing the following steps:

Follow these steps:

1. Remove the *cmdb_write_audit_log_site* trigger if you have created site/mods/*extension*.mod (*extension* specifies the extension name).
   In this release of the product, auditing is automatically created and enabled.
2. Add 'UI_INFO("AUDIT_LOG")' to each attribute that you want to log.
3. To migrate your existing HTML forms, use the new CA SDM templates.

CMDB Visualizer Configuration on AIX

Valid on IBM AIX

CA SDM installs CMDB Visualizer by default on all operating environments. You can configure the CMDB Visualizer, if necessary. IBM AIX requires additional security policy files.

Follow these steps:

1. Verify that CMDB Visualizer is configured.
2. Download unrestricted policy files (version 1.4.2 or later) from the Unrestricted JCE policy files page at the IBM website.

   Note: Register on the IBM website to download the policy files.
3. Replace the local_policy.jar and US_export_policy.jar files in your Shared Components JRE directory (default location: /opt/CA/SC/JRE/1.6.0_10/lib/security) with the policy files that you downloaded from the IBM website.

4. Stop and start Visualizer using the following commands:

```
pdm_tomcat_nxd -c STOP -t VIZ
pdm_tomcat_nxd -c START -t VIZ
```

   CMDB Visualizer is configured on IBM AIX.

Modify Third-Party Scripts for CMDB Compatibility

For scripts in the current product release, the ext_asset attribute is renamed to ID. To CMDB extension tables, modify the third-party scripts that use CA SDM web services. Perform the following steps:

Follow these steps:

1. Open the third-party script that you want to modify.

2. Replace all SQL references of ext_asset with ID.
   The script is compatible with the current product release.

How to Switch the Target Server for CMDB Reports

To create CMDB reports, a CA Cohesion ACM system exports CI data to a CMDB server. To export CI data, switch the target CMDB server by completing the following steps:

1. Use a CMDB server as the target for exporting CI data, and run CMDB Reports.

2. Restart the CA Cohesion ACM Server service.

3. Switch to a different target CMDB server for exporting CI data, and run CMDB Reports.

4. (Optional) Repeat Steps 2 and 3.

Configure Single Point of Entry

CA SDM and CA Service Management are integrated, single point of entry can permit Single Sign-On (SSO) to CA Service Catalog. To configure Single Point of Entry, follow these steps:

Follow these steps:

1. Install the catalog_server General option.

2. Restart CA SDM.

3. Navigate to the CA SDM Employee Self-Service page.

4. Click Browse Catalog Services.
   The CA Service Management logon page appears.

When CA EEM is configured for both CA SDM and CA Service Management, Single Point of Entry can permit single sign-on to CA Service Catalog. When single sign-on is configured, the CA Service Management logon page is not displayed.

Note: Single sign-on is not available if you enter CA SDM Employee Self-Service as a guest.

Follow these steps:

1. Verify that CA EEM Security options eiam_hostname and use_eiam_authentication are installed.
2. Set up your users in CA EEM and verify that these users are also CA Service Management users.
3. Click the Administration tab.
4. Open the Security and Role management folder.
5. Click Access Types.
6. Select the Employee role.
7. Verify that the validation type under the Web Authentication tab is set to CA EEM-Use CA Embedded Entitlements Manager.
8. Log in as the defined CA EEM user and navigate to the Employee Self-Service page.
9. Click Browse Catalog Services.
   The CA Service Management main page appears.

How to Modify the System Environment

CA SDM uses environment variables that are specified in the environment template file (NX.env.tpl) to determine certain behaviors. You can use environment variables to modify some system behaviors. You typically use the Options Manager to control system behavior, but at times CA Technical Support instructs you to modify a particular environment variable directly.

Consider the following when editing the environment template file:

- Environment variables set in this file can be overridden by setting the environment variable in the process space in which a process runs. Although convenient in some limited cases, this setup is not wanted. Preceding a variable setting with an at symbol (@) prevents variables in the process space overriding the variable. Unless there is a specific reason for allowing an override, the @ symbol always precedes the variable name in the template file.
- The comment characters for this file are pound (#) and exclamation point (!). The exclamation point character is also used to disable an option.

Important! Modify the template file (NX.env.tpl) and allow the configuration process to apply the changes to the environment file. Never modify the environment file (NX.env) directly.

Follow these steps:

1. Back up the environment template file (.tpl) that corresponds to your system environment:
   - UNIX -- $NX_ROOT/pdmconf/NX.env.tpl.
   - Windows -- installation-directory\pdmconf\NX.env_nt.tpl.
2. Edit the environment template file on the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: One of the standby servers

   Note: You can view and modify this file using any text editor (Windows users use WordPad).
3. Make the changes as instructed by your support technician, and save the changes.
4. To apply the changes you made to the environment template file to the actual environment file, run the configuration utility on the primary or standby server installation.
5. Depending on your CA SDM configuration, complete one of the following actions:
   - Conventional: For the changes that are made to the environment file to take effect, restart the primary server.
   - Advanced availability: Restart all the CA SDM servers (see page 866).

   Note: To avoid shutting down your system, your support technician can instruct you to restart only certain processes rather than recycling your entire CA SDM server.

Options Manager Usage

The CA SDM web client lets you use the Options Manager from the Administrative tab to do the following actions:

- Obtain a list of all the available options.
- View a summary of each option such as the application with which it is associated, a brief description, and its status.

- View the details of any specific option.
  When you view the detailed information for any option, you can get a comprehensive description of its functionality from the *Online Help*. The *Online Help* description includes any special actions that you are required to take when changing the option. For example, after installing or uninstalling some options, ensure that you restart the CA SDM server for the option to take effect. The *Online Help* description also indicates it.

- Review the status of all options at the summary level.

- Uninstall any of the available options (applicable only on the background server).
  Many of the options are preconfigured and installed during the CA SDM installation. Using the Options Manager to install or uninstall options can alter some or all of the default settings.

- Install any defined option (applicable only on the background server).

How to Move the Authentication Module to an External Server

This article contains the following topics:

The authentication module in CA SDM is a singleton daemon that is responsible for the user authentication. The authentication module runs on the primary server for the conventional configuration and on the background server for the advanced availability configuration. You can move the authentication module to an external server for the following scenarios:

- **Conventional configuration:**

  - The primary server is on UNIX or a Linux platform and you require a Windows authentication, you move the authentication module to a Windows secondary server.

  - The primary server is on a Solaris platform and you require the CA EEM authentication, you move the authentication module to the secondary server as CA SDM does not support the CA EEM integration on Solaris.

- **Advanced availability configuration:**

  - The background server is on UNIX or a Linux platform and you require a Windows authentication, you move the authentication module to a Windows application server.

- The background server is on a Solaris platform and you require the CA EEM integration, you move authentication module to an application server as CA SDM does not support the EEM integration on Solaris.

The following diagram illustrates how to move the authentication module:

Note: The selected external server must have CA SDM installed. If you move the authentication module to an external server such as an application server, it becomes a single point of failure. If the application server is down, users cannot log in.

Verify the Prerequisites

The analysis of the CA SDM server platforms helps you to decide how to move the authentication module to an external server.

Follow these steps:

- Identify the operating system of the following server, which is based on the configuration type:
  - **Conventional:** Primary server.
  - **Advanced Availability**: Application server.
- Identify the type of required authentication from the following models:
  - Windows authentication for the CA SDM implementation on UNIX or Linux.
  - CA EEM authentication for the CA SDM implementation on Solaris.
- Make sure that CA SDM is installed on the selected external server.

Configure CA SDM for Using External Authentication

To redirect the authentication requests to an external server, specify the hostname of the target server where the authentication module is present. The process of configuring CA SDM for moving the authentication module is different for the conventional and advanced availability configuration of CA SDM.

Conventional Configuration

Follow these steps:

1. Log in to the primary server as an administrator.
2. From the command prompt, change the directory to samples\pdmconf under NX_ROOT and run pdm_perlpdm_edit.pl.
3. From the pdm_edit.pl top menu select U, and press Enter.
   The User Validation server submenu appears.

4. Enter E to specify the hostname of the external server, and press Enter.
5. Enter primary for the primary server or the hostname of the secondary server, and press Enter.

You have configured the redirection of authentication requests to an external server.

Advanced Availability Configuration

Follow these steps:

1. Log in to the background server web interface as an administrator.
2. Select the Administration tab.
3. Expand Options Manager, Security.
4. Click the bopauth_nxd_host entry in the Option List.
   The bopauth_nxd_host Options Details page is displayed.
5. Click Edit.
6. Select the hostname of the target server from the Option Value drop-down list.
7. Click Save.

Note: By default, the authentication module runs on the background server.

You have configured the redirection of authentication requests to an external server.

How to Restart the CA SDM Servers

Depending on your CA SDM configuration, perform the following processes:

- Restart the CA SDM servers in conventional configuration.
- Restart the CA SDM servers in advanced availability configuration.

Restart the CA SDM Servers in Conventional Configuration

For the conventional configuration, you restart the servers in the following order:

Note: To restart a server click Start, Settings, Control Panel, Administrative Tools, Services. Right-click the CA SDM Server and select Start.

1. Restart the secondary server.

2. Restart the primary server.

Restart the CA SDM Servers in Advanced Availability Configuration

For the advanced availability configuration, we recommend that you restart the CA SDM servers in the following order:

Note: To restart a server click Start, Settings, Control Panel, Administrative Tools, Services. Right-click the CA SDM Server and select Start.

1. Restart all Standby Servers.
2. Promote the Standby Server as the New Background Server (see page 867).
3. Start the Old Background Server.
   When you start the background server, it becomes a standby server.
4. Choose the Less Active Application Server (see page 868).
5. Restart the Less Active Application Server.
6. Stop the Other Application Server (see page 868).
7. Start the Application Server.
8. Perform the steps 6 and 7 for the other application servers.

Promote the Standby Server as the New Background Server

Before you stop the background server, promote the standby server (that you have upgraded) as the new background server. If Support Automation is installed with CA SDM, notify the active Support Automation users about the background server shutdown.

Follow these steps:

1. Execute the following command on the background server to notify all active users using Support Automation to save their work:

   ```
   sa_server_notifier [-h] | [-q seconds] | [-c]
   ```

   - **-h**
     Displays the help page.
   - **-q seconds**
     This option notifies a local server (background) to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. This option cannot be used for a standby server or application server.

- **-c**
  This option cancels a previously sent quiesce request.

A pop-up message is displayed to all the active users using Support Automation. This message notifies the users about the server shutdown and the time that is left for the shutdown. The users must save their work and logout within that scheduled time.

2. Execute the following command on the standby server that you wish to promote as the new background server:

```
pdm_server_control  -b
```

- **-b**
  Notifies a local standby server to become the background server. The standby server must already be running. If the server is not running, it is started but no failover is performed; to start a failover, run the command again.

The background server shuts down automatically and the standby server is promoted as the new background server. This change does not affect the end-user sessions. The in-progress updates (if any) are stored and delayed, until the new background server comes online.

Choose the Less Active Application Server

You choose an application server with the least user activity. Run the following command on each application server to choose the one with no or minimal active sessions:

```
pdm_webstat
```

Note: This command does not capture the SOAP or REST Web Service sessions.

Stop the Other Application Server

You inform all the active users on an application server to move to the less active application server before you stop it. Ensure that you have restarted the less active application server before moving all the users to it.

Follow these steps:

1. (Recommended) Inform all active Support Automation analysts on the application server which you want to stop, to create a ticket in CA SDM with their session information. This process ensures that the session information is not lost. For example, the Support Automation analyst is in a session with a customer to resolve a hardware issue. In such a case, the Support Automation analyst can create an issue in CA SDM with the session information before the application server shuts down.

2. Send a notification (for example, an email notification) to all the active users on the application server to move to the less active application server that you just restarted. This notification can include the details of the updated application server.

3. Execute the following command on the application server:

   ```
   pdm_server_control [-h] -q interval -s server_name
   ```

   - **-h**
     Displays the help page.

   - **-q interval -s server_name**
     Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

   A pop-up message is displayed to all the active users on the application server to notify them about the server shutdown and the time left for the shutdown. The users must save their work and logout within that time. The application server stops after the specified time. The users log on to the other application server to resume their work. The Support Automation analyst can refer to the ticket and resume their work.
   The application server is stopped successfully.

Verify the Authentication

Verify the authentication with a user ID that has a corresponding contact record in Windows or CA EEM, based on the authentication type. A successful login indicates that you have successfully moved the authentication module.

Follow these steps:

1. Launch the browser and enter the CA SDM URL.

2. Log in to CA SDM with a user name having a corresponding contact record in Windows or CA EEM, based on the authentication type.

If the module has been moved successfully, the Service Desk Home Page opens.

Server Configuration Utility

The CA Service Desk Manager Server Configuration utility (pdm_configure) initializes and configures the CA Service Desk Manager server, database, and web environment. Configuration runs automatically during CA Service Desk Manager installation. The system administrator also can run Configuration on demand. The system administrator can configure the Administrative Client on Linux.

Follow these steps

- Select Server Configuration (see page 870)
- General Settings (see page 870)
- System Accounts (see page 871)
- Load Default Data (see page 872)
- Select Database (see page 872)
  - MS SQL Database Configuration (see page 873)

Select Server Configuration

You can select the CA Service Desk Manager installation configuration type and the type of database to configure.

Select Server Configuration

Specifies the configuration type for your CA Service Desk Manager installation. The options in the subsequent screens automatically updates to correspond to the configuration type you select. You can select the Advanced Availability option or Conventional option.

General Settings

Configure the General Settings page with the following options:

- **Configuration Type**
  The server type to configure.
  - Advanced Availability: If you are executing the Server Configuration utility for the first time, background server is automatically selected. Configure the background server and then add the application or stand-by servers to support advanced availability and failover.
  - Conventional: If you are executing the Server Configuration for the first time, primary server is automatically selected. After the primary server is configured, you can add secondary servers to manage high traffic volume and improve performance.
    For example, you can add more Object Managers and web engines to another server. There can be zero or more secondary servers in a CA Service Desk Manager enterprise system.
- **Slump Host Name**
  Available only for the Advanced Availability configuration. Slump host name specifies the system on which the server is installed.
- **Server Id**
  Available only for the Advanced Availability configuration. This field is automatically populated.
- **Primary Server Node**
  Available only for the Conventional configuration.
  Specifies the host name of the primary server. This field is case-sensitive. The Primary Server Node value is the same for both primary and secondary servers in the CA Service Desk Manager installation.

- **Object Manager Display Name**
  Specifies the server connecting to the server object managers (domsrvr). All object managers that start on this computer use this name for display purposes only. You can change this value when the object manager is started.

- **Object Manager Name**
  Specifies the names or aliases of the object managers to which you want to establish a connection. You can enter a single name or a list of names. The default of ANY connects to any running object manager, and is acceptable in most situations.

  Important! Verify the names of the object manager or group of object managers with your system administrator.

- **Local Host Name**
  Specifies the name of the server. This field is case-sensitive.

  - Conventional: You can enter the value only for secondary servers. This field is case-sensitive.
  - Advanced Availability: The value is automatically populated from your background server configuration details.

- **Configure /etc/services (UNIX only)**
  Adds the new socket ports to the /etc/services file. Valid only if you are the root user.

- **Slump Socket Port**
  Specifies the name of the main communications socket port. CA Service Desk Manager uses this port for all servers that are configured in your environment. The default value is 2100. The primary server always opens a listen port on the slump socket port. Every daemon (service) that communicates across the slump port connects to the primary server using this port.

- **Proctor Socket Port**
  Available only for the Conventional configuration. Applies only to systems that use secondary servers (proctors). Each secondary server listens on this port for messages from the primary server. The secondary servers open this port only when they cannot connect to the slump port on the primary server. For example, the port opens when the primary server is not running.
  Default: 2300

System Accounts

Configure the System Accounts page with the following options:

- **Privileged User Name**
  Identifies an operating system user ID with administration privileges. On Windows, if the name you specify does not exist, the system creates a local use with domain rights to different places, depending on how your local computer is defined:

  - If the local computer is not defined as a primary or backup domain controller, the privilegeduser is added to the local computer as a local user.

- If the local computer is defined as a primary domain controller, the privilegeduser is added as a domain user.
- If the local computer is defined as a backup domain controller, the privilegeduser is added to the primary domain controller as a domain user.

Important! If you have modified the user and domain user rights, contact the system administrator to set up the privileged user.

- **Privileged User Password (Windows)**
  Specifies a password for the privileged user account. If the privileged user name exists on the local computer, and the local computer is not defined as a primary or backup domain controller, the local user is checked. If the local computer is defined as a primary domain controller or a backup domain controller, the domain user is checked.
- **Privileged User Password (Linux)**
  Specifies a privileged user password for integrations with AMS and Workflow.
- **Restricted User Name (Windows only)**
  Specifies an operating system user ID that is used on behalf of clients as they access functions. The user name is restricted because it has limited user rights. The default is rhd. The rhd user is added in the same manner as the privileged user.
- **Restricted User Password (Windows only)**
  Specifies a required password for the restricted user name is added. The configuration stores the value.
- **Default User Name (UNIX)**
  Appears only for client installations. The default user name can be the privileged user, but it is typically a separate user ID for client users.

Load Default Data

Load default data is available only for the Advanced Availability configuration.

- **Load default data**
  Specifies whether to load the CA Service Desk Manager default system data into the database. If you have modified any system default values, selecting this option replaces the data values.

Note: You can select the option only during the background server configuration.

Select Database

Specifies the type of database to configure for your CA Service Desk Manager installation. The available options on the left automatically update to correspond the database type you select. For example, if the Database Type is SQL, the options update with MS SQL Database Config.

- Advanced Availability: The database type that you select must match the background server database.
- Conventional: The database type that you select must match the primary server database.

MS SQL Database Configuration

If you are using MS SQL Database, specify the following details:

- **Load Default Data**
  Applicable only for Conventional configuration.
  Load Default Data whether to load the CA Service Desk Manager default system data into the database. If you have modified any system default values, selecting this option replaces the data values.

- **Database Server Node**
  The name of the MS SQL instance that CA Service Desk Manager uses for configuration. The service instance is in the format hostname\instance_name. If the default instance is used, you only have to specify the hostname.

  - Advanced Availability: The database server node must match the background server database node.
  - Conventional: The database server node must match the primary server database node.

- **Database Name**
  Indicates the name of the database.

  - Advanced Availability: The database name must match the background server database.
  - Conventional: The database name must match the primary server database.

- **Database Admin User**

  Specifies the admin user who has permission to create user and schema.

- **Database Admin Password**

  Specifies the database password of user specified by database admin user.

- **Database Userid**
  The database user ID and password. The SQL user ID is added while creating the database.

  Note: The special at-sign character (@) cannot be used in database IDs or passwords.

- **Database Password**
  The password for the SQL database.

- **SQL Listening Port (Optional)**
  (Optional). The listening port of the defined SQL server instance.
  Default: 1433

Oracle Database Configuration

If you using the Oracle database, specify the following details:

CA Service Desk Manager requires a Net Service Name specifying the Oracle database where the MDB resides. CA Service Desk Manager also requires a system identifier (SID) for the database. CA Service Desk Manager requires the Net Service name and SID information to access the database with both Oracle client technology and JDBC technology. For information about Service Names and SIDs, refer to Oracle documentation.

- **Load Default Data**
  Applicable only for Conventional configuration and indicates the CA Service Desk Manager default system data into the database. If you have modified any system default values, selecting this option replaces the data values.

- **Remote Database**
  To indicate whether the Oracle MDB is on a remote server (selected) or the local server. If the Oracle server is local, the MDB is created during the configuration. If it is remote, the MDB must already be configured with the remote installer.

  Note: For Advanced Availability configuration, we recommend that you configure the Oracle MDB on a remote server.

- **Create Tablespaces**
  Specifies whether to create tablespaces for the MDB database or use existing tablespaces.

  - If this check box is selected, the script creates tablespaces with the default names MDB_DATA and MDB_INDEX.

    Note: The Data Tablespace Name and Index Tablespace Name fields are disabled.

  - If this check box is not selected, provide names of the existing tablespaces in the Data Tablespace Name and Index Tablespace Name.

    Important! To use the existing tablespaces, configure the database to use at least 500 MB of tablespace, and an index tablespace of at least 150 MB.

- **Net Service Name**
  Identifies the Net Service Name of the Oracle database where the MDB resides. If the database is remote, provide the Net Service Name that is defined within the Oracle client on the local computer.

- **mdbadmin User Password**
  Specifies the password of the mdbadmin user for accessing the mdb.

- **DBA User Name**
  Identifies the name of an Oracle user with DBA access.

- **DBA Password**
  Identifies the password for the DBA user.

  Note: The special at-sign character (@) cannot be used in database IDs or passwords.

- **Data Tablespace Name**
  Specifies the name for the MDB data tablespace you want to create. Used only if the Oracle server is on the local computer.

- **Index Tablespace Name**
  Specifies the name for the MDB index tablespace you want to create. Used only if the Oracle server is on the local computer.

- **Tablespace Path in DB Server**
  Specifies the directory path to the physical tablespace location.

- **Oracle Home Path**
  Specifies the Oracle Home path.

- **JDBC Connectivity**
  Specifies whether to use JDBC Connectivity. Several components of CA Service Desk Manager use JDBC technology to access the database and require specific information about the Oracle server.

  - **Database Host Name**
    Identifies the name of the computer where the Oracle server is installed.

  - **SID**
    Specifies the system identifier (SID) for the database as defined on the Oracle server computer. The SID value must be the SID for the MDB, and is not the same as the Net Service Name.

  - **Listener Port**
    Specifies the listener port for the database.

Important! For Windows installation, configure the Oracle MDB to use UTF-8 as the database character encoding to support multilingual search.

Web Interface

Configure the Web Interface with the following options:

- **Web Host**
  Specifies the system that hosts the web server. This value is used to build URLs for the system. By default, the web host is your local system.

- Advanced Availability: You can configure web services only on application server.
- Conventional: Available only if you are on a primary server, and defaults to the primary server name. You can change this value if your default web server is on another computer. For example, if you move your web server to a secondary server, you can change this value to the name of your secondary server. This value is used to build URLs for the system.

- **Config Type**
  Specifies the web server for your installation:

  Note: The Tomcat port is always used to access upload, the Asset Maintenance System, and pdmgraph, regardless of this setting.
  Note: Select the Manual option only when using an alternate http or servlet server.

  - On Windows, you can select Tomcat or IIS.
  - On UNIX, you can select Tomcat or Apache.

- **Web Site**
  NT only. Identifies the web site for the CA Service Desk Manager Server. The names appearing identify the available web sites. The IIS port is used to specify the port that is associated with the site.

  Note: You can install any mail system client on your server that complies with Microsoft MAPI 1.0 standard.

- **Tomcat Port**
  Specifies the Tomcat port number. Defaults to 8080, but you can set this port value. This value appears in the URL that is constructed to access the web site, for example, http://bobcat:8080/CAisd/UploadServlet.

- **Tomcat Shutdown Port**
  Specifies the socket port for Tomcat to monitor for shutdown requests.

- **Apache Config File (UNIX)**
  Specifies the complete path to the Apache configuration file. An include file is added to this configuration file when integrating with an existing Apache installation.

- **IIS/Apache Port**
  Specifies the IIS or Apache server port number. If you configure with IIS or Apache, and are not using port 80, enter an alternate port number. If you are using port 80, leave this field blank.

- Deploy SOAP Web Services
  - Advanced Availability: Applicable only for the application server. Enabling this option notifies the active users on the application server about the server shutdown details. For example, during rolling maintenance of the application server, a form is displayed to the active users stating that the application server shuts down within a specified time.

- Conventional: This check box is only available if you are configuring a secondary server. This option lets you deploy the web services on the secondary server. By default, web services are installed on the primary server.

REST Web Services

Configure the REST Web Services page with the following options:

- **REST Tomcat Port**
  Specifies the REST Tomcat Port.
  Default: 8050

- **Tomcat Shutdown Port**
  Specifies the REST Tomcat Shutdown Port.
  Default: 8055

Note: For Advanced Availability configuration, this option is available only for application servers.

Federated Search

Configure the Federated Search Tomcat with the following options:

- **Configure Federated Search**
  Specifies the option to select Federated Search. The Tomcat options are available only after selecting this option.

- **Tomcat Port**
  Specifies the Federated Search Tomcat Port.
  Default: 8040

- **Tomcat Shutdown Port**
  Specifies the Federated Search Tomcat Shutdown Port.
  Default: 8045

Visualizer

Configure the Visualizer page with the following options:

- Service Desk Manager Web Services
  - **Web Host**
    Displays the web host address.
  - **Web Host Port**
    Displays the Visualizer web host port.
- Visualizer Tomcat

- **Tomcat Port**
  Specifies the Visualizer Tomcat Port.
  Default: 9080

- **Tomcat Shutdown Port**
  Specifies the Visualizer Tomcat Shutdown Port.
  Default: 9085

Note: For Advanced Availability configuration, this option is available only for application servers.

Support Automation

On the Support Automation page, select the appropriate Configuration Type:

- **None**
  Configures CA Service Desk Manager without Support Automation functionality.

Important! If you want to configure Support Automation in a multi-tenancy environment, we recommend that you separately migrate the CA Support Automation r6.0 SR1 eFix5 divisions to Release 12.9 tenants before enabling Support Automation on a CA Service Desk Manager server.

- **Main Server**
  Configures the Support Automation server in main server (standalone) mode.
  Note: If you select the Main Server option, and are planning to configure one or more socket proxy servers, set the Socket Server host name and external port to the socket proxy host. For multiple socket proxies, you set the Socket Server to the host and external port of the load balancer server.

Note: For Advanced Availability, the main server resides on background and stand-by servers.

  - HTTP
    - **Host Name or IP** -- Specifies the address of your server.
    - **External Port** -- Specifies the external port of your server.
      Default: 8070
  - Socket Server
    - **Host Name or IP** -- Specifies the address of your socket server.

- **External Port** -- Specifies the external port of your socket server.
  Default: 10443
- **Internal Port** -- Specifies the internal port of your socket server.
  Default: 7005
- **Bind to IP** -- Specifies the IP where you want to bind the server.

- **Socket Proxy Server**
  Configures the Support Automation server in socket proxy mode. Use a Socket Proxy Server to off-load some of the CPU-intensive operations of Support Automation, such as encryption/decryption from the main server.
  Advanced Availability: This option is available only for the application server.
  Conventional: This option is available only for the secondary server.
  - Socket Configuration
    - **Main Server Host Name or IP** -- Specifies the address of the main server.
    - **Main Server Internal Port** -- Specifies the internal port of the main server.
      Default: 7005
    - **Main Server HTTP Port** -- Specifies the HTTP port of the main server. This field is available only for conventional configuration.
    - **External Port** -- Specifies the external port of the server.
      Default: 10444
    - **Bind to IP** -- Specifies the IP where you want to bind the server.

- **Message Routing Server**
  Configures the Support Automation server in message routing server mode. Use Message Routing Servers (MRS) to manage multiple Remote Control sessions that are based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions.
  Advanced Availability: This option is available only for the application server.
  Conventional: This option is available only for the secondary server.
  - Socket Configuration
    - **External Port** -- Specifies the external port of the socket.
      Default: 10444
    - **Bind to IP** -- Specifies the IP where you want to bind the server.

- Tomcat Configuration
  1. **Tomcat Port**
     - Specifies the Support Automation Tomcat port.
       Default: 8070
  2. **Tomcat Shutdown Port**

- Specifies the Support Automation Tomcat Shutdown port.
  Default: 8075

> **Note:** When you change the main server Tomcat port, also change the port references in the server.properties file with tomcat server.xml.

Configuration Options

Configure the Config Options page with the following options:

- **Server Configuration**
  Select the configuration that you want to apply for this server from the drop-down list. Select Default to apply default CA Service Desk Manager configurations.

- Windows

  - **Start service when completed**
    Select this check box for the server to start when the configuration is complete.

    > **Note:** The UNIX users must be at the root user level for these options to be enabled.

  - **Start service when completed**
    Select this check box if you want the server to start when the configuration is complete.

  - **Put CA Service Desk Manager links in /usr/bin**
    This option only works if you are at root. Selecting this option puts important CA Service Desk Manager links into /usr/bin.

  - **Start Event converter daemons**
    Select this option to enable the event converter daemons. This option allows you to create the CA Service Desk Manager tickets from either CA NSM World View or CA NSM Event Monitor.

Character Encoding (UNIX/Linux)

The ICU converter provides the character encoding mapping that CA Service Desk Manager uses when transcoding character data between Unicode and the operating system character encoding.

> **Note:** This configuration page is only available on UNIX and Linux systems.

Configure the Character Encoding page with the following options:

- **Use detected converter**
  Auto-detection has determined the converter available for your UNIX/Linux system. Leave selected if you want to use this converter.

- **Specify a converter**
  The ICU converter name field provides feedback of the converter CA Service Desk Manager has determined best matches the operating environment. The converter also provides a means of overriding the auto-detected converter by specifying a converter name. The converter names are not case-sensitive.
  You can find a list of ICU converter names and aliases that are grouped by industry standards using the ICU Converter Explorer tool at the following web site:
  http://ibm.com/software/globalization/icu/demo/converters
  Give special attention to two converter names, if these converters appear as auto-detected:

  - **US-ASCII**
    Appears when the following conditions occur:

    - The auto-detection could not determine a matching converter and defaulted to US-ASCII. In this case, the ICU Converter Explorer or an equivalent tool must be used to determine a converter best matching the character encoding of the operating system locale. Enter its name into the ICU converter name field.

    - The character set of the operating system locale only supports a limited 7-bit character encoding such as C, POSIX, US-ASCII, ISO646-US. In this case, we recommend that you select a different operating system locale which utilizes a character set encoding that supports a wider selection of characters. See your operating system documentation for details for changing the locale environment for the user or shell that is used to invoke the CA Service Desk Manager configuration program. A matching locale environment must be used for all subsequent accounts that are used to launch and operate CA Service Desk Manager.

  - **UTF-8**
    Specifies to encode Unicode as UTF-8.

    Important! CA Service Desk Manager must run on an UTF-8 locale on UNIX platforms.

- **Default HTTP character set**
  Specifies the character set that is used on web pages that are sent from CA Service Desk Manager web servers. This value is specified in the web page HTTP character set declaration as the charset parameter in the HTTP Content-Type header, and is described in RFC 2616 Hypertext Transfer Protocol - HTTP/1.1.
  The configuration application attempts to determine whether this value is an alias of the ICU Unicode converter that is specified in ICU Unicode converter name. If it is not, you can override the value.

Configure the CA SDM Environment

This section contains the following topics:

How to Configure the Employee and Guest Interface

This article contains the following topics:

You can use CA SDM to configure separate interfaces for employees and guests. You configure these separate interfaces through the Options Manager in the Administration tab. The following values control these interfaces:

- **employee_intf_incident_support**

  Displays the following values:

  - Request only
  - Incident only
  - Both Incident and Request

- **guest_intf_incident_support**

  Displays the following values:

  - Request only
  - Incident only
  - Both Incident and Request

Important! For a new installation, ITIL is configured by default value set to *Incident only*. If you are migrating from a previous non-ITIL configuration, though the options are installed, the values are set to *Request only*.

Configure the Employee Interface

You can configure the employee interface to display incidents, requests, or both.

Follow these steps:

1. Click the Administration tab.
   The Administration console appears.

2. Click Options Manager, Request Mgr.
   The Option List appears.

3. Click employee_intf_incident_support.
   The Options Detail page appears.

4. Change the Option Value field to one of the following values:

   - **Incident Only**
     (ITIL Default) Displays only Incident ticket types on the employee interface.

   - **Request Only**
     Displays only Request ticket types on the employee interface.

   - **Both Incident and Request**
     Displays both Incident and Request ticket types on the employee interface.

   Click Save.

5. Click Refresh to confirm your selections.
   The Options Detail is updated.

6. Close the Options Detail.

Configure the Guest Interface

You can configure the guest interface to display incidents, requests, or both.

Follow these steps:

1. Click the Administration tab.

2. Click Options Manager, Request Mgr.

3. Click guest_intf_incident_support.

4. Change the Option Value field to one of the following values:

   - **Incident Only**
     (Default) Displays only Incident ticket types on the guest interface.

   - **Request Only**
     Displays only Request ticket types on the guest interface.

   - **Both Incident and Request**
     Displays both Incident and Request ticket types on the guest interface.

   Click Save.

5. Click Refresh to confirm your selections.
   The Options Detail is updated.

6. Close the Options Detail.

How to Configure the Web Interface

This article contains the following topics:

When you install CA SDM, the *web interface* (commonly referred to as the *browser interface*) is automatically installed.

Select the web server depending on the CA SDM configuration. Consider the following use cases:

- Conventional: No additional action is required when the web server and the primary server are on the same computer. If they are installed on a different computer, install and configure both primary and secondaryserver.

- Advanced Availability: No additional action is required when the web server and the background server are on the same computer. But if they are on a different computer, install and configure both background and application server. The web interface for end usersis never hostedfrom the background server. The web interface must be hosted only on the application servers.

Select the computer on which the web server resides depending on your CA SDM configuration:

- Conventional: Secondary server. Install this server after you install the primary server.

- Advanced Availability: Application server. Install this server after you install the background server.

Important! By default, Tomcat is the default web server. If you want to use IIS as your web server, manually configure the product and select IIS. For information, see the *Server Configuration Online Help*.

To configure the web interface, complete the following steps:

1. (Required) Enable the web engine on the secondary server on Windows or UNIX.

2. (Required) Configure the web interface (see page 887).
   You can then start the web interface (see page 887).

Add Web Engines or Web Directors

Web engines connect to an object manager for processing all requests to CA SDM objects. Web directors are optional, and are used when two or more web engines are installed on a single server. You can configure web directors on any server. Depending on the CA SDM configuration, CA SDM installs a default web engine on the following servers:

- Conventional: Primary server.
- Advanced Availability: All servers.

Follow these steps:

1. Select Systems, Configurations on the Administration tab.
   The Configurations List page opens.
2. Select the configuration to which you want to add the web engine or web director.
   The Configuration Detail page opens.

   Note: If you are changing the configuration for the first time, then create a configuration first. When you want to make a configuration change, always create or copy an existing one. This process allows you to revert to the previous configuration, if needed.

3. Select the Web Engines/Web Directors tab.
   The Web Engine/Web Directors Listpageopensdisplays the web engines and web directors that are configured for the server.
   - Conventional: A web engine exists by default on the primary server. You can add web directors to any server.
   - Advanced availability: A web engine exists by default on all servers. You can add more web directors on any CA SDM server.
4. Click Add Web Engine/Web Director.
   The Create New Web Engine/Web Director page opens.
5. Complete the following fields:

   Important! Enter only English characters for all the input fields for any localized language.

- **Host Name**
  Specifies the host name for the web engine or web director. You can click Search to look up for the servers.
  For an advanced availability configuration type, the host name is read-only and is automatically populated based on the host name you specified while creating the configuration.

- **Type**
  Specifies if you are configuring a webengineorwebdirector. Based on the option that is selected, the relevant fields are automatically populated.

  - Select Web Engine if you want to configure a web engine.
  - Select Web Director if you want to configureawebdirector.

  Note: Ensure that you have selected the appropriate option. You cannot edit the process type after you have saved the configuration.

- **Web Director**
  Specifiesthewebdirector that is assigned to the web engine. You can click Search to look up for the web directors added to the server.

  Note: When implementing any web engine load-balancing scheme, SSL-Login, or both, at least two web engines must be assigned to the same web director.

- **CGI Name**
  Specifies the unique CGI name for the web engine. It is the name of an actual CGI executable when IIS or Apache is used as the HTTP server; it is a servlet parameter when Tomcat is used as the HTTP server.
  Examples: (web engines) pdmweb1, pdmweb2, (web directors) pdmweb_d1, and pdmweb_d2.
  Default: pdmweb.exe (The CGI name must be unique).

- **CGI Port Number**
  Specifies the port on which CA SDM web clients can connect. The CGI port number is the same port on which the tomcat server is running.
  Default: 8080

- **Protocol**
  Specifies the protocol for accessing the web engine.

  - Select HTTPS if the web engine is configured to handle all CA SDM web-client user authentication requests.
  - Select HTTP if the web engine is configured to handle all web client non-user authentication requests (afteruserisauthenticatedthrough the secure login web engine).

- **Record Status**
  Specifies whether the web engineorwebdirector is active or inactive.

Note: Before setting the record status of a web director to inactive, remove the link between the web director and the associated web engines.

- **Object Manager**
  Specifies the object manager that you want to assign to the web engine.

  - **Default**
    Specifies that the default object manager is assigned to the web engine.

  - **ANY**
    Specifies that the web engine can connect to any available object manager with more willingness value. Willingness value is the availability of the server to accept new clients. A willingness value of zero means that the web engine does not accept any sessions.

  - **Choose**
    Allows you to specify an object manager for the web engine. Selecting this option provides you the option to add multiple object managers or aliases to the configuration.

Click Save.

The web engineorwebdirectorthatyouadded appears in the Web Engines/Web Directors List.

Configure the Web Interface

If the default web interface configuration specified does not meet the CA SDM installation requirements, modify the *web.cfg* file. The *web.cfg* is located in the *installation-directory* \bopcfg\www. Edit the file using a text editor, such as Notepad or WordPad.

Each entry in the file consists of a single line containing a property name, optionally followed by a value. Lines beginning with a pound sign (#) are treated as comments and are ignored.

Start the Web Interface

Verify that the Daemon Server services and the database server are started before starting the web interface. If the secondary server is configured, the Remote Daemon Proctor service must be started before starting the primary server service. To start the services on Windows and Linux OS, perform the following steps:

- (Windows): Select Start, Control Panel, Administrative Tools, Services). Right-click the CA SDM Remote Proctor and select Start.

- (Linux): Run the *pdm_init* command to start the primary server and *pdm_proctor_init* to start the secondary server.

Verify that the services are started and then start the web interface. You can also start the web interfacefroman internal web site. If you are on the primary or secondary server system and are using the Internet Information Services (IIS), perform the following steps:

- Select Start, All Programs, CA, Service Desk Manager, Service Desk Manager Web Client.

- On a system that is not a primary or a secondary server, open a web browser and enter the following URL address:

```
http://servername:8080/CAisd/pdmweb.exe
```

  In this URL, *servername* is the name of the computer that is hosting the CA SDM web server.

- On a System that is not a primary or secondary server with IIS as the web server, open a web browser and enter the following URL address:

```
http://servername/CAisd/pdmweb.exe
```

- To start the web interface from an internal website, add */pdmweb.exe* to the URL for your web pages. Use the following sample HTML code as a guide:

```
A HREF=http://<server-name>:<port-no>/CAisd/pdmweb.exe
```

  In this URL, *server-name* identifies your computer and *port-no* is the port on which your web server is listening.

  Note: If the Internet Explorer browser security is set to high, a warning message appears after starting the web interface. To avoid this message, add the website to your trusted sites or lower your security settings. In advance availability, the default web interface is readily available with the default installation and configuration.

Record Locking Behavior in the Web Interface

Editing a database record using the web interface, the user is given an exclusive lock of two minutes. You can change the default time by using the ExclLockSeconds property in the web.cfg file.

The following conditions apply when a database record is updated:

- If a user *can* edit and submit changes within an allotted time, the changes are included the database.
  When the database record is locked, other users (both web and non-web users) can view the record, but cannot edit the record. If they try to edit the record when it is locked, an error message appears.

- If a user *cannot* edit and submit changes within an allotted time, the record lock automatically drops and other users can edit the record.
  When the user submits the updates, time stamps are checked to ensure that nobody else has changed the record:

  - If the record has not been changed since the exclusive lock was dropped, the user updates are saved to the database.

  - If another user has edited the record after the lock expires, the user receives an error response and the changes are not saved. The user must restart the edit process and must reapply the changes.

Enabling the CAPA Help

CA Productivity Accelerator (CAPA) provides context-sensitive in-application performance support for the CA SDM analyst web forms. The CAPA player package directly integrates with the Context Help menus of CA SDM analyst web pages. The integration of CAPA Help content with CA SDM is achieved through the help menu scripts. These scripts launch the CAPA recorded Help content from the CA SDM Help menu drop-downs and right-click context help.

Note: This section does not include information about the CAPA recording tool, obtaining and configuring the CAPA Help content, and installing the Smart Help.

CA SDM provides a unique identifier to recognize each web form uniquely. If an identification element is present in the top frame of the CA SDM, the CAPA recording tool recognizes the web application form. Once the top frame is recognized, all sub frames are considered to be part of this application. The sub frames that are loaded from a different domain must also be identified. Otherwise, these sub frames are not considered a part of CA SDM. To enable CAPA help, prepare the help content and configure the options to launch the CAPA help.

Note: To modify the HTML files, use the invoke methods from the ias_helper.js files for the CAPA recorder to recognize the html forms.

CAPA Help is not supported on the CA SDM Employee, Customer, or PDA interfaces.

Follow these steps:

1. Open the capa.properties file from the following CA SDM directory:

   ```
   %NX_ROOT/bopcfg/www/wwwroot
   ```

2. Change the following values in the file:

   - **Enable_Alerts** = 0. This option verifies and displays the javascript alert messages in a browser console when the CA SDM web page loads.

3. Save the file.

4. Go to the web.cfg file in the CA SDM directory, add DebugScript=1, and restart the web engine.
   The recorded content is prepared, published, and deployed on the CAPA server.

5. Open the capa.properties file and change the following values:

   - **Enable_For_Recording** = 0

   - **Show_Learn_Links** = 1. This value displays the CAPA Help option in the CA SDM Help Menu and in the right-click Help context menu.

- **Server_Name** = name of the server where CAPA published content is deployed.
- **Server_Port =** CAPA server port where the CAPA published content is deployed. For example, the TOMCAT port.
- **Virtual_Dir** = virtual directory where the CAPA published content is deployed on the CAPA server.
- **Namespace** = application context namespace. For example, app.SDM.Project123;en.
- **Enable_Alerts** = 0

6. Save the file.
   You are ready to launch the CAPA Help from the CA SDM analyst web forms.

How to Configure Integrated Windows Authentication for CA SDM

As a system administrator, you can authenticate CA SDM users through an existing external authentication method. The following scenario describes configuring Integrated Windows Authentication (IWA) to authenticate CA SDM users through Microsoft Active Directory (AD). Configure CA SDM access types like administrators to use IWA. The users of the selected access types are directly authenticated through Active Directory.

Follow these steps:

1. Verify the Prerequisites (see page 890)
2. Configure Internet Information Services (IIS) for IWA. (see page 891)
3. Configure CA SDM for IWA. (see page 891)
4. Test IWA (see page 892)

Verify the Prerequisites

Verify the following requirements before you configure the external authentication for CA SDM:

- You have configured servers for CA SDM.
- You have installed IIS 7.0 on the following server depending on your configuration:
  - Conventional configuration: primary server.
  - Advanced Availability: application server.
- You have configured CA SDM to use IIS 7.0.
- You have the list of access types for which the external authentication is required. For example, CMDB Administrator, Employee, and CMDB User.

Configure IIS for IWA

You configure the IIS server to enable IWA. The configuration changes the authentication mode of IIS from Anonymous to Windows Authentication. After the configuration, the server starts redirecting authentication requests to the external source.

Follow these steps:

1. Log in as administrator to the following server depending on your configuration:
   - Conventional: Primary or secondary server.
   - Advanced Availability: Background server.
2. Open the Administrative Tools, Internet Information Services Manager.
3. Expand the Server Name node, where Server Name is the name of the CA SDM server.
4. Expand Sites, Default Web Site, CAisd node.
   The CAisd Home page opens.
5. Double-click the Authentication icon.
   The Authentication Settings page opens.
6. Disable the Anonymous Authentication by clicking the existing Status value.
7. Enable the Windows Authentication by clicking the existing Status value.
8. Restart IIS to apply the changes.

You have configured IIS for IWA.

Configure CA SDM for IWA

You configure the IWA for each of the selected access types. After an access type is configured for the external authentication, CA SDM externally authenticates the contacts of that access type.

Follow these steps:

1. Log in to CA SDM as a system administrator.
2. Select the Administration tab, Security and Role Management, Access Types.
   The Access Type List page opens.
3. Click the access type for which the external authentication is required.
   The Update Access Type form opens.
4. Select the Web Authentication tab and select the Allow External Authentication check box.
5. Select an appropriate value from the Validation Type drop-down list. The following values require description:

- **No Access**
  Specifies that the selected access type is not allowed to access.

- **Open**
  Specifies that the access is open to all.

- **OS**
  Specifies that the CA SDM server operating system credentials are required to access CA SDM. If you have configured EEM, the login request would be redirected to the EEM server.

- **PIN**
  Specifies that the value of selected CA SDM contact record field is required for the authentication. For example, if you select Pin as Validation Type and select Contact_Number from the PIN Field drop-down, the contact number of the user is required for authentication.

Note: The Validation Type is not used for the IWA validation, but it is used when the user logs in through the CA SDM login form. The CA SDM Login page appears only when the user clicks the Logout link or when the credentials do not match with IIS credentials.

6. Click Save.
   To configure the external authentication for other access types, repeat steps 1 through 6.

Test IWA

You test the IWA with a user id having the corresponding contact record in CA SDM. A successful login indicates that you have configured the IWA successfully.

Follow these steps:

1. Log in to the following server depending on your configuration, with a user id having the corresponding contact record in CA SDM:

   - Conventional: Primary or secondary server.

   - Advanced Availability: Application server.

Note: If the LDAP options have been installed in the Options Manager, you can also create new contact in CA SDM from any Active Directory contact.

2. Launch the browser and enter the CA SDM URL.
   The Service Desk Home page opens.

Search Engine Configuration

This article contains the following topics:

The EBR Search Engine installs with CA SDM by default.

Note: For more information about the search engine options, see the *Online Help*.

Knowledge Reindex Utility

The Knowledge reindex utility, pdm_k_reindex.exe, is located under the Knowledge Management installation directory.

Note: Reindexing the documents in the knowledge base can be a time-consuming operation based on your database size. It is recommended that you run the Knowledge Reindex utility after all the changes have been added. For advanced availability configuration, you cannot execute the knowledge reindex utility during the failover process.

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use pdm_task to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

Follow these steps:

1. Open the command prompt.
2. To run the knowledge reindex, enter the following command:

For example:

```
pdm_k_reindex
```

The following options are available with this command.

- **-D**
  Defines the debug mode, such as printing to the command window.
- **-v**
  Defines the verbose mode, such as printing to the stdlog file.
- **-i**
  Does not create table indexes in the reindex table after reindexing.

Note: Parameters with a dash as a prefix, such as " - D", must precede other parameters that do not have this prefix.

The other option is as follow:

- ***File*:reindex.txt**
  Documents are reindexed to the specified file.

- **+i**
  Creates the indexes of the reindexed table only, which is the search table after reindexing. The old indexes are dropped before reindexing.

- **+t**
  Switches the names of search and reindex tables only.

Note: A “+” prefix denotes only this parameter applies.

- **sdtout**
  Defines the frequency of statistic appearing in the command window. By default the knowledge reindex utility provides statistics into the command window for every 1000 documents processed. However, sometimes statistics are required to be provided more often. Use the following parameter:

  ```
  pdm_k_reindex -i sdtout:10
  ```

  In this case, statistics display in the command window for every ten documents.

The documents are reindexed in the knowledge base.

New Tags to Configure a Domserver for the Crawler Surface

You must have a dedicated server for the Crawler Surface depending on your CA SDM configuration and data size for indexing. The dedicated server minimizes the impact on the production environment:

- Conventional: Primary or secondary server

- Advanced Availability: Application server
  Note: For more information on how to configure CA SDM server, see Server Configuration Utility (see page 869).

The following two new tags are introduced in the crawler_surface_config.xml file to take care of the indexing:

- A new tag has been introduced in crawler_surface_config.xml file root\general_configuration\sdm_domsrvr_name to let the customer mention the name of a dedicated domserver instance for the Crawler Surface.
  Default: domsrvr
  This value is a default domserver (object manager) instance name.

- Another new tag has been introduced in the crawler_surface_config.xml file *sharepoint_properties_file* at the *root\general_configuration*.
  Default: sharepoint
  This value is the name of *sharepoint.properties* file available by default at NX_ROOT\CATALINA_BASE_FS\lib.

How to Enable Auto-Failover

Server health monitoring observes how a server reacts to the operating load and tracks its responsiveness to the client requests. The purpose of this monitoring is to prevent server failures by ensuring that the server always retains sufficient capacity to conduct the required tasks. Most of the standard health monitoring tools support remote server monitoring through the HTTP and HTTPS protocols.

CA SDM automatic failover feature exposes the following HTTP-based standard interfaces:

- Health Monitoring Interface: HTTP(S) interface to monitor the background server health. It also makes reliable failover decisions to initiate the failover on a chosen standby server in case of any disruptions to the background server's availability or ability to conduct required tasks.

- Failover Initiating Interface: HTTP(S) interface to promote the chosen standby server as the new background server without causing any service disruption.

Follow these steps:

1. Install Apache Tomcat on the background and all standby servers.

   Note: Ensure that Tomcat is using JRE 1.7 and ensure that the Tomcat is not using the port number that is configured for the CA SDM components.

2. (Optional) Configure SSL on the Tomcat servers that you have installed. For more information about configuring SSL, see How to Configure SSL Authentication (see page 935).

3. Log in to the background server.

4. Deploy the health servlet. Complete the following steps:

   a. Copy the HealthServlet.war file from the $NX_ROOT/samples/HealthServlet folder to the *TOMCAT_HOME*/webapps folder.

   b. Restart Tomcat.

The HealthServlet.war file is deployed in the webapps folder. To confirm the deployment, verify that the HealthServlet folder is created in the same webapps folder.
After the successful deployment, the health servlet is ready to perform the health checks. It includes checking the status of the SLUMP and health of the CA SDM processes that are defined in the health.xml file. Find the health.xml file in the following location:

```
TOMCAT_HOME/webapps/HealthServlet/WEB-INF/classes
```

5. (Optional) Customize the health.xml based on your organization needs. For example, you want to monitor the webengine process. Add the process in the health.xml file with the correct tagname, as defined in CA SDM. Complete the following steps to find the tagname:

    a. Open the pdm_startup.i and pdm_startup files from the $NX_ROOT/pdmconf directory.

    b. Look for the process that you want to monitor in both the files.

    c. Find the corresponding tagname by matching the variables in both the files.
    For example, webengine process is defined in the pdm_startup.i file as follows:

    ```
    #define WEBENGINE(_TAG,_HOST,_SLUMP_NAME,_DOMSRVR, _CFG, _WEBDIRECTOR,
    _RPC_NAME)
    ```

    The webengine process is defined in the pdm_startup file as follows:

    ```
    WEBENGINE(webengine, $NX_LOCAL_HOST, web:local, domsrvr, $NX_ROOT/bopcfg
    /www/web.cfg, "", "rpc_srvr:%h")
    ```

    From the example, we can find out that the tagname for webengine process is webengine.

    Important! For creating a new process, the existing process is commented out in the pdm_startup file and new entries are added. Ensure that you look for the tagname in the new process entries.

    Important! If you modify health.xml, ensure that the XML does not have any errors and that you restart Tomcat to reflect the changes that are made to the XML.

6. Perform steps 4 and 5 for all standby servers.

7. Configure the chosen third-party tool to monitor the health of the background server at regular intervals. To monitor the health, use the following HTTP URL:

    ```
    http(s)://Background_server_name:port_number/HealthServlet/GetHealth
    ```

8. Configure the chosen third-party tool to initiate a failover logic when the background server health degrades. We recommend that you to configure the failover logic so as to promote the standby server as the new background server. Use the following failover servlet in the failover logic:

   Important! We recommended you to configure the failover servlet on SSL with the access privileges given only to predefined users. Follow this recommendation for configuring third-party tools to initiate failover.

   ```
   http(s)://Standby_server_name:port_number/HealthServlet/FailoverServlet
   ```

   You have enabled auto-failover.

9. After the successful configuration, the third-party tool starts monitoring the background server health using the health servlet URL.

   - Each server type has its own set of processes. If the SLUMP and all the CA SDM processes are working properly, the third-party tool receives an HTTP 200 response from the background server with a predefined payload:

     ```
     AA-Server-Status: All OK!

     AA-Server-Role: BG
     ```

   - If a SLUMP or any of the CA SDM processes (listed in health.xml) stop working and cannot resume, the third-party tool receives an HTTP 503 response from the background server with a predefined payload as:

     ```
     AA-Server-Status: NOT OK!

     AA-Server-Role: BG
     ```

10. If the HTTP 503 response is received, the third-party tool automatically initiates the failover logic.

Screen Reader Usage

You can modify system behavior for optimal use with a screen reader for visually impaired users.

To enable screen reader usage:

1. Enable screen reader usage on the main menu from View, Preferences, and select the Using Screen Reader option.

   Important! You must log off and log back on for this change to take effect.

2. From the Help menu, select Screen Reader Usage for an overview of using CA SDM with a screen reader.

Deploy the Health Servlet on the Application Server

Server health monitoring prevents server failures and downtimes by ensuring that the server always retains sufficient capacity to conduct the required tasks.

Note: Ensure that your health servlet is installed on a separate instance of Tomcat server than CA SDM.

To deploy health servlet on the CA SDM Application Server, complete the following:

Follow these steps:

1. Install Apache Tomcat on the CA SDM Application Servers.

   Note: Ensure that Tomcat is using JRE 1.7 and ensure that the Tomcat is not using the port number that is configured for the CA SDM components.

2. (Optional) Configure SSL on the Tomcat servers that you have installed.
   For more information about configuring SSL, see How to Configure SSL Authentication (see page 935).

3. Log in to the application server and deploy the health servlet by completing the following steps:

   a. Copy the HealthServlet.war file from the $NX_ROOT\samples\HealthServlet\HealthServlet.WAR to the *Apache Tomcat Webapps directory (TOMCAT_HOME*/webapps).

   b. Restart Tomcat.

      The HealthServlet.war file is deployed in the webapps folder. To confirm the deployment, verify that the HealthServlet folder is created in the same webapps folder. After the successful deployment, the health servlet is ready to perform the health checks. It includes checking the status of the SLUMP and health of the CA SDM processes that are defined in the health.xml file. Find the health.xml file in the following location:

      `TOMCAT_HOME/webapps/HealthServlet/WEB-INF/classes`

4. (Optional) Customize the health.xml based on your organization needs. For example, you want to monitor the webengine process. Add the process in the health.xml file with the correct tag name, as defined in CA SDM. Complete the following steps to find the tag name:

a. Open the pdm_startup.i and pdm_startup files from the $NX_ROOT/pdmconf directory.

b. Look for the process that you want to monitor in both the files.

c. Find the corresponding tag name by matching the variables in both the files.
For example, webengine process is defined in the **pdm_startup.i** file as follows:

```
#define WEBENGINE(_TAG,_HOST,_SLUMP_NAME,_DOMSRVR, _CFG, _WEBDIRECTOR,
_RPC_NAME)
```

d. The webengine process is defined in the **pdm_startup** file as follows:

```
WEBENGINE(webengine, $NX_LOCAL_HOST, web:local, domsrvr, $NX_ROOT/bopcfg
/www/web.cfg, "", "rpc_srvr:%h")
```

Important!: For creating a new process, the existing process is commented out in the pdm_startup file and new entries are added. Ensure that you look for the tag name in the new process entries.

Important!: If you modify health.xml, ensure that the XML does not have any errors and that you restart Tomcat to reflect the changes that are made to the XML.

5. Configure the chosen third-party tool to monitor the health of the application server at regular intervals. To monitor the health of the server, use the following HTTP URL:

   ```
   http(s)://application_server_name:port_number/HealthServlet/GetHealth
   ```

6. After the successful configuration, the third-party tool starts monitoring the CA SDM application server health using the health servlet URL.
   For more information on how to deploy health servlet on the background and standby servers, see How to Enable Auto-Failover (see page 895).

7. Each server type has its own set of processes. If the SLUMP and all the CA SDM processes are working properly, the third-party tool will receive an HTTP 200 response from the Application server with a predefined payload, as follows:

   ```
   AA-Server-Status: All OK!
   AA-Server-Role: AP
   ```

   If a SLUMP or any of the CA SDM process (listed in health.xml) stops working and cannot resume, the third-party tool receives an HTTP 503 response from the application server with a predefined payload, as follows:

   ```
   AA-Server-Status: NOT OK!
   AA-Server-Role: AP
   ```

   You have successfully deployed the health servlet for the CA SDM Application Server.

Managing Servers

This article contains the following topics:

The CA SDM installation consists of one or more server components that an administrator can manage. The number of servers depends on the CA SDM configuration:

- Conventional: One primary server and one or more secondary servers.
- Advanced Availability: One background server, one or more standby servers, and one or more application servers.

After you install CA SDM, configure each computer that runs the CA SDM components. You can run the server configuration as part of the installation process, or you can run it later. The CA SDM services must be restarted after you change the server configuration.

How to Change a Server Configuration

As an administrator, you can configure the servers for CA SDM installation. The number and type of servers depend on the CA SDM configuration. The initial configuration occurs as part of the CA SDM installation process.

Note: A change in the system environment can require changes to the server configuration. For example, the database management system or integration changes with a web server (EEM server or Tomcat)

Follow these steps:

1. Log in to the server you want to configure again.
2. From the Windows Start menu, select Programs, CA, CA SDM, Configuration.
   The CA SDM Configuration utility opens.

3. Complete the utility fields, and click Next.
   The right panel changes to show the appropriate fields for the link that is highlighted in the navigation pane on the left.

4. Continue following the on-screen instructions and click Finish.
   The server configuration is changed.

How to Configure TCP/IP

You can change the default TCP Internet Protocol (TCP/IP) setting on one or more servers. This setting cannot be forced on the client if it is not supported on the server.

The TCP/IP setting is controlled by using the NX.env file, which is found in the $NX_ROOT directory. Use a text editor such as WordPad for editing this file. The following option controls the TCP/IP setting:

```
NX_PROTOCOL_ONLY=mode
```

where *mode* can be one of the following values:

- **IPv4**
  In IPv4 mode, the system opens up sockets for slump processes that listen to IPv4 traffic.

- **IPv6**
  In IPv6 mode, the system opens up sockets for slump processes that listen to IPv6 traffic.

- **Mixed**
  In mixed mode, the system opens up sockets for slump processes that listen to both IPv4 and IPv6 traffic. Depending upon your CA SDM configuration, you can configure mixed mode in the following circumstances:

  - Conventional: The Secondary servers that use a different Internet Protocol from the primary server or each other.

  - Advanced Availability: The Application servers that use a different Internet Protocol from the background server or each other.

Note: If IPv4 and IPv6 hosts coexist on the network, ensure that the appropriate transition strategies, tools, and mechanisms to support these technologies are in place before you change the server configuration.

Example

```
NX_PROTOCOL_ONLY=ipv4
```

Activity Log Security

The Activity Log security option prevents end users from updating fields on an activity log. You can select the internal option to prevent a customer from seeing the log.

Activity Log security affects activity logs from the following ticket types:

- Request
- Change order
- Issue
- Incident
- Problem

Enable Activity Log Security

You can enable Activity Log Security from the Options Manager in the Administration tab.

Follow these steps:

1. Click the Administration tab.
2. Click Options Manager, Request-Change-Issue.
3. Click activity_log_security.
4. Click Edit, and select one of the following Option Values:

   - **Editable**
     (Default) Allows all fields on the activity log to be editable through the web interface or web services.
   - **Write Protected**
     Displays the activity log as read-only. If you select the internal option, only internal users can edit the log which cannot be viewed by the customer.

   Note: If the security option is enabled and you try to edit the log using the web interface or external web services, an error message displays that the activity log is read-only

   Click Save.

5. Click Refresh to confirm your selections. Close Window.
   Activity log security is enabled.

Important! The activity_log_security option cannot be uninstalled. You can only change the value of the option to Editable or Write Protected in Options Manager, Request-Change-Issue.

Impact on Web Screen Painter

The Activity Log Security feature, $NX_ACTIVITY_LOG_ SECURITY, includes the following attributes (time_spent, time_stamp, and description) for the alg, chgalg, issalg objects in majic.

Example: $NX_ACTIVITY_LOG_SECURITY for Object alg in cm.maj

In this example, for object alg in cm.maj, $NX_ACTIVITY_LOG_SECURITY appears on the three attributes:

```
time_spent DURATION $NX_ACTIVITY_LOG_SECURITY {ON_POST_VAL update_cr_timespent
( call_req_id ) 50 ;
 } ;
time_stamp DATE $NX_ACTIVITY_LOG_SECURITYÂ Â Â { ON_NEW DEFAULT NOW ; } ;
descriptionÂ Â Â Â  STRING Â Â Â $NX_ACTIVITY_LOG_SECURITY;
```

In Web Screen Painter, *Updatable only for new record* field is disabled when the value of the keyword evaluates to WRITE_NEW.

Improve Performance With Browser Caching

The CA SDM web interface uses many JavaScript, style sheets, and image files, which can be fairly large and can affect performance.

To improve performance of the web interface, set up your HTTP server so that the user browser caches these files and loads only once a day.

The web interface performance improves.

Note: The default installation automatically configures caching for Apache and IIS; however, you can configure it manually.

Configure the Microsoft Internet Information Server

You can configure Microsoft Internet Information Server (IIS) to notify the browser that files loaded from the CA SDM directory expire one day after loading. The browser queries the server for these files only once a day, regardless of how many times they are used.

Follow these steps:

1. Launch the Internet Services Manager application (for Windows 2000 and XP, select Programs, Administrative Tools, Internet Services Manager).

2. Navigate to the CA SDM file folder, which is typically CAisd:

    a. Click the plus sign that is adjacent to the server running the CA SDM web interface.

    b. Click the plus sign that is adjacent to Default Web Site.

    c. Scroll down to CAisd.

3. Right-click the CAisd folder, and select Properties.
   The Properties page appears.

4. Click the HTTP Headers tab.

5. Select the Enable Content Expiration check box.

6. Select the Expire After option, enter 1 into the text field, and select a day from the drop-down list.

7. Click OK.
   The properties are saved and the changes take effect immediately.

Configure Apache

You can configure Apache to notify the browser that files loaded from the CA SDM directory expire one day after loading. This configuration means that the browser queries the server about these files only once per day, regardless of how many times they are used.

You configure Apache by updating a text configuration file. The default installation modifies your active configuration file in the apache conf directory (typically httpd.conf) to contain the statement:

```
Include installation-directory/bopcfg/www/CAisd_apache.conf
```

Installation-directory must be replaced with a full path. On Windows, this path is typically c:\Program Files\CA\CA SDM. On UNIX, replace *installation-directory* with the value of $NX_ROOT.

The file CAisd_apache.conf, which is referenced by the Include statement, contains the following text. Again, *installation-directory* is replaced with the full path as it was in the Include statement.

```
<IfModule mod_alias.c>
    Alias /CAisd installation-directory/bopcfg/www/wwwroot/
    <IfModule mod_expires.c>
           <Directory installation-directory/bopcfg/www/wwwroot>
              ExpiresActive   On
              ExpiresDefault  "access plus 1 day"
           </Directory>
    </IfModule>
</IfModule>
```

To configure Apache manually for browser caching of the CA SDM files, include statements similar to those in CAisd_apache.conf in your Apache configuration file. You can either add them directly to the file, or add an Include statement referencing a separate file, like the default installation.

Changes to Apache configuration files take effect only after you recycle Apache.

Clear the Cache

If you change a JavaScript, image, style sheet, HTML, or help file loaded by the HTTP server itself, you must instruct the users to clear their browser cache.

Note: For changes to HTMPL files to take effect, you must either recycle the web engine or use the pdm_webcache utility. In a development environment, you can avoid this task by specifying the configuration file property SuppressHtmplCache.

To clear the browser cache for Internet Explorer, perform the following:

Follow these steps:

1. Select Tools, Internet Options.
   An Internet Options dialog appears.

2. Click Delete Files.
   A confirmation window appears.

3. Click OK.
   The browser cache is cleared

To clear the browser cache for Firefox, perform the following:

1. Select Tools, Clear Private Area.

2. Click the Clear Private Data Now button.
   The browser cache is cleared.

Add a CA SDM Server

If you want to install a new server in your CA SDM deployment, you must first add the corresponding server record before you configure it.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server
2. Select System, Servers from the Administration tab.
3. Click Create New to add a server record for the following server, depending on CA SDM configuration:
   - Conventional: Secondary server
   - Advanced availability: Application or standby server

4. Complete the fields as appropriate for the server.

5. Click Save to add the server detail.

Create Server Fields

The following fields appear when you create or update a server:

- **Host Name**
  Specifies the local host name of the server. The local host name is stored in the usp_servers table in local_host column.

  Important! Ensure that host name is entered as case-sensitive in the usp_servers table.

- **Attachment Servlet Path**
  You must specify the fully qualified domain name of a server using this field:
  http://<host>:<port>/CAisd/UploadServlet
  Where <host> is the fully qualified domain name of a server.
  We recommend that you configure this field.

- **Time Zone**
  Specifies the time zone where the server is located. This time zone value is used to trigger events in the application. This value is used only if the Use End User Time Zone option is not selected, or if no time zone is specified for the service type.

- **Record Status**
  Indicates the state of the server. Active status indicates that the server is a part of the CA SDM deployment.

  Important! If you have inactivated any server, it is recommended not to start CA SDM services on that server. This action may result in unexpected behaviour.

- **Server Type**
  Specifies the type of server that you want to configure. Following server types can be selected, depending on your CA SDM configuration:

  - Advanced Availability: Application or standby server
  - Conventional: Secondary server

- **Configured**
  Available only for advanced availability configuration. This field indicates the state of the configured server. The default value of this field is No. The value is updated to Yes after you successfully run pdm_configure on that server. If you edit any of the automatically entered field values of a server record, the Configured field turns to No.

How to Start the CA SDM Servers

This article contains the following topics:

Depending on your CA SDM configuration, complete the following actions:

- Start the CA SDM servers in conventional configuration (see page)
- Start the CA SDM servers in advanced availability configuration (see page).

The following table describes the processes that start automatically after you start the CA SDM servers:

Note: In this table, the Notification Manager process applies only to the Windows environment and the Default DB process applies only to the UNIX environment.

Process	Description
Daemon Agent (pdm_proctor_nxd)	The daemon agent responsible for starting the managed daemons
Daemon Monitor (pdm_d_mgr)	Monitors daemon processes
BOP Virtual DB (bpvirtdb_srvr)	BOP virtual database server
Data Dictionary (ddictbuild)	Rebuilds data dictionary each time the system is started -- this runs and then goes away
KPI Daemon (kpi_daemon)	Manages the collection, organization, and storage of KPI data.
Oracle agent (orcl_agent)	Agent for Oracle database -- many instances, depending upon load
Oracle DB (orcl_prov_nxd)	Oracle database provider
SQL agent (sql_agent) (runs only if you are using MS SQL)	Agent for SQL Server database -- many instances, depending upon load
SQL DB (sql_prov_nxd) (runs only if you are using MS SQL)	Microsoft SQL Server database provider
Event Manager (ehm_nxd)	Event manager
Message Dispatcher (sslump_nxd)	Dispatches messages
Notification Manager (bpnotify_nxd)	Manages notifications
Object Engine (domsrvr)	CA SDM Object Manager

Process	Description
Report Manager (pcrpt_nxd)	PC reporting
Software Version Control (pdm_ver_nxd)	Manages versions of specified system components
Method Engine (spel_srvr)	Spell code interpretation server
Text API (pdm_text_nxd)	Text API daemon for email and CA NSM interfaces
Timed Events/Notifications (animator_nxd)	Timed events and notifications
User Validation (boplgin)	User account validation
User Authentication (bopauth)	User account authentication
Web Engine (webengine)	Runs the engine for the web client
Archive Purge Daemon (arcpur_srvr)	Manages the background Archive and Purge processing
BU Daemon (bu_daemon)	Handles FAQ Rating calculation for Knowledge Documents
DB Monitor (dbmonitor_nxd)	Monitors CA common tables for changes
EBR Daemon (bpebr_nxd)	Handles knowledge search requests
EBR Idx Daemon (bpeid_nxd)	Handles EBR keyword indexing/re-indexing
KRC Daemon (krc_daemon)	Manages statistical calculations and notifications for the Knowledge Report Card
KT Daemon (kt_daemon)	Manages Knowledge Documents (KD approval process, permissions, notifications, and so on)
LDAP virtdb (ldap_virtdb)	Agent for communication with LDAP Servers
Mail Daemon (pdm_mail_nxd)	Handles outbound email notifications
Mail Eater (pdm_maileater_nxd)	Handles inbound email notifications
MDB Registration Server (mdb_registration_nxd)	Agent for handling MDB registration requests
PDM RPC (PDM_RPC)	Manages the Web Services requests
Repository Daemon (rep_daemon)	Handles attachment repositories
Spell checker (lexagent_nxd)	Handles spell checking requests
Time-to-Violation (ttv_nxd)	SLA Violation forecaster
tomcat controller (pdm_tomcat_nxd)	Manages Tomcat services

Start the CA SDM Servers in Conventional Configuration

Start the servers in the following order:

1. Start the secondary server (see page 909).
2. Start the primary server (see page 909).

Start the Secondary Server

If your installation includes one or more secondary servers, you must start the secondary servers prior to starting the primary server.

Follow these steps:

- (Windows) Select Services from the Control Panel, select the CA SDM Remote Proctor service and click Start.
- (UNIX) Use pdm_init from the command line.

Start the Primary Server

Every CA SDM installation has one primary server that handles basic product functionality.

Important! If your installation includes one or more secondary servers, you must start the secondary servers (see page 909) before starting the primary server.

Follow these steps:

- (Windows) Select Control Panel, CA SDM Server service and click Start. You can start the service manually each time you need it, or you can configure it to start automatically like any other Windows service.
- (UNIX) Use pdm_init from the command line.

Start the CA SDM Servers in Advanced Availability Configuration

Start the servers in the following order:

Note: (Windows) Select Control Panel, CA SDM Server service and click Start. You can start the service manually each time you need it, or you can configure it to start automatically like any other Windows service. (UNIX) Use pdm_init from the command line.

1. Start the background server.
2. Start the standby and application servers (in any order).

How to Stop the CA SDM Servers

This article contains the following topics:

Depending on your CA SDM configuration, do one of the following actions:

- Stop the CA SDM servers in conventional configuration (see page).
- Stop the CA SDM servers in advanced availability configuration (see page).

Stop the CA SDM Servers in Conventional Configuration

You stop the following servers:

- Stop the primary server (see page 910).
- Stop the secondary server (see page 910).

(Conventional Configuration) Stop the Primary Server

You can stop the primary server in the Windows or UNIX environment.

(Windows), follow these steps:

1. Select Services from the Control Panel.
2. Select the CA Service Desk Manager Server service and click Stop.
   The primary server is stopped. The processes or daemons on the secondary servers are also stopped.

(UNIX), follow these steps:

- Enter the following command in the command prompt:

  ```
  pdm_halt
  ```

  The primary server is stopped. The processes or daemons on the secondary servers are also stopped.

(Conventional Configuration) Stop the Secondary Server

You can stop the secondary server in the Windows or UNIX environment.

(Windows), follow these steps:

1. Select Services from the Control Panel.
2. Select the CA Service Desk Manager Remote Proctor service and click Stop.
   The secondary server is stopped.

(UNIX), follow these steps:

- Enter the following command in the command prompt:

```
pdm_halt
```

The secondary server is stopped.

Stop the CA SDM Servers in Advanced Availability Configuration

You stop the following servers:

- Stop the standby server (see page 911).
- Stop the background server (see page 911).
- Stop the application server (see page 912).

(Advanced Availability Configuration) Stop the Standby Server

You can stop the standby server in the Windows or UNIX environment.

(Windows), follow these steps:

1. Select Services from the Control Panel.
2. Select the CA Service Desk Manager Server service and click Stop.
   The standby server is stopped.

(UNIX), follow these steps:

- Enter the following command in the command prompt:

```
pdm_halt
```

The standby server is stopped.

(Advanced Availability Configuration) Stop the Background Server

Before you stop the background server, promote the standby server (that you have upgraded) as the new background server. If Support Automation is installed with CA SDM, notify the active Support Automation users about the background server shutdown.

Follow these steps:

1. Execute the following command on the background server to notify all active users using Support Automation to save their work:

   ```
   sa_server_notifier [-h] | [-q seconds] | [-c]
   ```

   - **-h**
     Displays the help page.

- **-q seconds**
  This option notifies a local server (background) to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. This option cannot be used for a standby server or application server.

- **-c**
  This option cancels a previously sent quiesce request.

A pop-up message is displayed to all the active users using Support Automation. This message notifies the users about the server shutdown and the time that is left for the shutdown. The users must save their work and logout within that scheduled time.

2. Execute the following command on the standby server that you wish to promote as the new background server:

```
pdm_server_control  -b
```

- **-b**
  Notifies a local standby server to become the background server. The standby server must already be running. If the server is not running, it is started but no failover is performed; to start a failover, run the command again.

The background server shuts down automatically and the standby server is promoted as the new background server. This change does not affect the end-user sessions. The in-progress updates (if any) are stored and delayed, until the new background server comes online.

(Advanced Availability Configuration) Stop the Application Server

Before you stop an application server, notify all active users to move to another application server.

Follow these steps:

1. Send a notification to all the active users on the application server for stopping servers. This notification can include the details of other application servers.

2. Execute the following command on the application server that you want to stop:

```
pdm_server_control -q interval -s server_name
```

- **-q interval -s server_name**
  Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

A pop-up message is displayed to all the active users on the application server. This message notifies the users about the server shutdown and the time left for the shutdown. The users must save their work and logout within that time. The application server stops after the specified time. The users log on to the other application server to resume their work. (Recommended) The active Support Automation analysts can create a ticket related to their session to save their work. They can log in to the other application server and refer to this ticket to resume their work.

How to Restart the CA SDM Servers

This article contains the following topics:

Depending on your CA SDM configuration,

- Restart the CA SDM servers in conventional configuration (see page).
- Restart the CA SDM servers in advanced availability configuration (see page).

Restart the CA SDM Servers in Conventional Configuration

For the conventional configuration, you restart the servers in the following order:

Note: To restart a server click Start, Settings, Control Panel, Administrative Tools, Services. Right-click the CA SDM Server and select Start.

1. Restart the secondary server.
2. Restart the primary server.

Restart the CA SDM Servers in Advanced Availability Configuration

For the advanced availability configuration, we recommend that you restart the CA SDM servers in the following order:

Note: To restart a server click Start, Settings, Control Panel, Administrative Tools, Services. Right-click the CA SDM Server and select Start.

1. Restart all Standby Servers.
2. Promote the Standby Server as the New Background Server (see page 867).
3. Start the Old Background Server.
   When you start the background server, it becomes a standby server.
4. Choose the Less Active Application Server (see page 868).
5. Restart the Less Active Application Server.

6. Stop the Other Application Server (see page 868).
7. Start the Application Server.
8. Perform the steps 6 and 7 for the other application servers.

Promote the Standby Server as the New Background Server

Before you stop the background server, promote the standby server (that you have upgraded) as the new background server. If Support Automation is installed with CA SDM, notify the active Support Automation users about the background server shutdown.

Follow these steps:

1. Execute the following command on the background server to notify all active users using Support Automation to save their work:

   ```
   sa_server_notifier [-h] | [-q seconds] | [-c]
   ```

   - **-h**
     Displays the help page.
   - **-q seconds**
     This option notifies a local server (background) to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. This option cannot be used for a standby server or application server.
   - **-c**
     This option cancels a previously sent quiesce request.

   A pop-up message is displayed to all the active users using Support Automation. This message notifies the users about the server shutdown and the time that is left for the shutdown. The users must save their work and logout within that scheduled time.

2. Execute the following command on the standby server that you wish to promote as the new background server:

   ```
   pdm_server_control  -b
   ```

   - **-b**
     Notifies a local standby server to become the background server. The standby server must already be running. If the server is not running, it is started but no failover is performed; to start a failover, run the command again.

   The background server shuts down automatically and the standby server is promoted as the new background server. This change does not affect the end-user sessions. The in-progress updates (if any) are stored and delayed, until the new background server comes online.

Choose the Less Active Application Server

You choose an application server with the least user activity. Run the following command on each application server to choose the one with no or minimal active sessions.

```
pdm_webstat
```

Note: This command does not capture the SOAP or REST Web Service sessions.

Stop the Other Application Server

You inform all the active users on an application server to move to the less active application server before you stop it. Ensure that you have restarted the less active application server before moving all the users to it.

Follow these steps:

1. (Recommended) Inform all active Support Automation analysts on the application server which you want to stop, to create a ticket in CA SDM with their session information. This process ensures that the session information is not lost. For example, the Support Automation analyst is in a session with a customer to resolve a hardware issue. In such a case, the Support Automation analyst can create an issue in CA SDM with the session information before the application server shuts down.

2. Send a notification (for example, an email notification) to all the active users on the application server to move to the less active application server that you just restarted. This notification can include the details of the updated application server.

3. Execute the following command on the application server:

   ```
   pdm_server_control [-h] -q interval -s server_name
   ```

   - **-h**
     Displays the help page.

   - **-q interval -s server_name**
     Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

   A pop-up message is displayed to all the active users on the application server to notify them about the server shutdown and the time left for the shutdown. The users must save their work and logout within that time. The application server stops after the specified time. The users log on to the other application server to resume their work. The Support Automation analyst can refer to the ticket and resume their work.
   The application server is stopped successfully.

How to Configure Processes for CA SDM Servers

As an administrator, you can add or modify processes and daemons to enhance the performance of the CA SDM servers. You can configure object managers, web engines, web directors, and other processes for the CA SDM servers in your environment. You can add the processes across several servers to increase volume, performance, and enhance security.

Follow these steps:

1. Add a Server (see page)
2. Create a Process Configuration (see page 917)
3. Add CA SDM Server Processes (see page 919)
4. Configure the Server (see page 930)
5. Verify the Configuration (see page 930)

Add a Server

If you want to install a new server in your CA SDM deployment, you must first add the corresponding server record before you configure it.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server
2. Select System, Servers from the Administration tab.
3. Click Create New to add a server record for the following server, depending on CA SDM configuration:
   - Conventional: Secondary server
   - Advanced availability: Application or standby server
4. Complete the server fields (see page) as appropriate.
5. Click Save to add the server detail.

Server Fields

The following fields appear when you create or update a server:

- **Host Name**
  Specifies the local host name of the server. The local host name is stored in the usp_servers table in local_host column.

  Important! Ensure that host name is entered as case-sensitive in the usp_servers table.

- **Attachment Servlet Path**
  You must specify the fully qualified domain name of a server using this field:
  http://<host>:<port>/CAisd/Upload/Servlet
  Where <host> is the fully qualified domain name of a server.
  We recommend that you configure this field.

- **Time Zone**
  Specifies the time zone where the server is located. This time zone value is used to trigger events in the application. This value is used only if the Use End User Time Zone option is not selected, or if no time zone is specified for the service type.

- **Record Status**
  Indicates the state of the server. Active status indicates that the server is a part of the CA SDM deployment.

  Important! If you have inactivated any server, it is recommended not to start CA SDM services on that server. This action may result in unexpected behaviour.

- **Server Type**
  Specifies the type of server that you want to configure. Following server types can be selected, depending on your CA SDM configuration:

  - Advanced Availability: Application or standby server
  - Conventional: Secondary server

- **Configured**
  Available only for advanced availability configuration. This field indicates the state of the configured server. The default value of this field is No. The value is updated to Yes after you successfully run pdm_configure on that server. If you edit any of the automatically entered field values of a server record, the Configured field turns to No.

Create a Process Configuration

Important! (Recommended) Ensure that both background server and all other standby servers have similar configuration. The standby server becomes the new background after fail over and function likes the old background server.

You can create a process configuration for your CA SDM installation, or can modify an existing configuration to suit your requirement.

Consider the following points while creating or modifying a process configuration:

- If you want to modify a process configuration, we recommend you to create a new one or copy the existing configuration and then modify it. This process allows you to revert to the previous configuration, if necessary.

- In conventional configuration, you create configuration only for a primary server and not for secondary servers. All secondary server configuration details must be included within the configuration created for the primary server. For example, to add a webengine with the secondary server hostname details, open the configuration for the primary server and add the necessary details.

- For an advanced availability configuration type, you can create configurations only for the specific server. Make sure that you create the same configuration for the background server and standby server.

Follow these steps:

1. Select Systems, Configurations on the Administration tab.

2. Click Create New to add a server configuration.

3. Complete the following fields and click Save:

> **Important!** Enter only English characters for all the input fields for any localized language.

- **Configuration Name**
  Specifies the name that you want to assign to the configuration you create.

- **Advanced Availability**
  Indicates whether the configuration is created for conventional configuration or for the advanced availability configuration type. Select Yes if the configuration is valid for advanced availability configuration type.

> **Note:** Configurations that are created for one configuration type (advanced availability or conventional) cannot be implemented for the other configuration type.

Host Name
Specifies the host name for the configuration. The host name is taken from the servers records configured under the Servers page. You can click the Search button to look up for the servers added to your CA SDM installation.

- **Record Status**
  Specifies if the server configuration record is active.

- **Current Configuration**
  Indicates that the configuration is applied on the selected CA SDM server. This field is read-only and is updated based on the configuration you select while executing server configuration utility (pdm_configure).

The configuration is saved. New tabs are enabled on the page to add object managers, web engines, web directors, and other processes.

Note: The host name and the advanced availability fields become read-only once you have saved the configuration.

Click Edit in List on the Configuration List page to modify the record status of a process configuration.

Note: You cannot modify the record status if the current configuration of a selected server is in use.

Add CA SDM Server Processes

You can configure object managers, web engines, web directors, and other processes for the CA SDM servers in your environment. We recommend that you become familiar with the following information before configuring the CA SDM processes:

Important: Reconfigure the specific server by running the pdm_configure utility on the server after adding the CA SDM processes.

- **Object Manager**
  Object managers manage all the CA SDM objects. Each object manager has an associated name, which it uses to communicate with other objects. Enterprise systems with multiprocessor servers can add object managers to spread out the processing load. Depending on your configuration type, CA SDM installs a default object manager on the following servers:
  - Conventional: Primary server
  - Advanced Availability: All servers

  Note: You cannot modify the default object manager, but can add extra object managers to any server.

- **Web Engines**
  Web engines help prepare web pages for the web client. All systems have one or more web engines. Each web engine connects to an object manager for processing all requests to CA SDM objects. Each web engine can run and be accessed directly. In direct access, every web browser enters the specific CGI interface for a specific web engine. With this approach, all clients can connect to one web engine and can overburden the web engine, while the other web engines go unused. To handle such heavy traffic, you can assign two or more web engines to a single web

director. All requests that go to web engines are directed to the web director. The web director then redirects the client to the most available web engine.
Depending on your configuration type, CA SDM installs a default web engine on the following servers:

- Conventional: Primary server
- Advanced Availability: All servers

- **Web Directors**
  Web directors are optional, and are used when two or more web engines are installed on a single server. Web Director receives connection requests from users, selects a web engine to handle the request, and redirects the request to that web engine. This process is transparent to the end user who always accesses CA SDM with the same URL, regardless of the number of web engines configured. Web directors can be used for the following purposes:

  - To configure CA SDM for efficient use of secure sockets (SSL).
    The HTTPS protocol allows web transactions to be encrypted, providing maximum security for sensitive data, especially passwords. However, pages using SSL are ineligible for browser caching, which can have a negative impact on the performance.
  - To direct logins to a specific web engine (or web engines).
    After a user is authenticated, Web Director can move the session to a different web engine, which can be on a different HTTP server. This setup lets you configure SSL for a web engine, providing protection for your passwords while using HTTP protocol for transactions.
  - To have multiple Web Directors, each handling a different group of web engines.
    This setup can be useful in geographically dispersed organizations that want to locate groups of web engines physically closer to their end users.

- **Aliases**
  Aliases are easily identifiable names you can create for object manager Slump names. You can create aliases for a specific object manager or a group of object managers. These aliases can be used in place of an object manager name while configuring CA SDM processes. Aliases are optional in CA SDM.

- **Knowledge Daemons**

  Applicable only to a conventional configuration type. Knowledge daemons provide the knowledge base for CA SDM (knowledge documents, approval process, permissions, notifications, and so on). CA SDM configures the knowledge daemon by default on the primary server. You can move the daemon to a secondary server by changing the host name.

- **Login User Authentication**

  Applicable only to a conventional configuration type. CA SDM configures the login user authentication daemon by default on the primary server. You can move the daemon to a secondary server by changing the host name.

- **LDAP Virtual DB**

Applicable only to a conventional configuration type. CA SDM configures the LDAP virtual database daemon by default on the primary server. You can move the daemon to a secondary server by changing the host name.

- **Repository Daemons**

  Applicable only to a conventional configuration type. The Repository daemon enables you to locate the attachment records saved in the repository directory. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the Visualizer (see page 869) options. .

- **Visualizer**

  Applicable only to a conventional configuration type. You can configure visualizer on a CA SDM server to use web services. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*.

- **REST Web Services for Tomcat Server**

  Applicable only to a conventional configuration type. REST Web Services enables you to configure the web UI for CA SDM to be able to communicate with external world. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*.

- **Support Automation**

  Applicable only to a conventional configuration type. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*. You can only add one support automation process for each secondary server. You can configure the following support automation servers:

  - **SA Main Server**
    Specifies the server on which support automation is installed. You can add the SA main server only to a secondary server.

  - **SA Dedicated Object Manager Server**
    The server on which the object manager for the support automation configuration resides. You can configure the dedicated object manager server on a secondary server.

    Note: You can add a dedicated object manager server only if the SA Main Server is configured.

  - **SA Message Routing Server**
    You can configure the message routing server on a secondary server to manage multiple Remote Control sessions and help improve the performance during assistance sessions.

- **SA Socket Proxy Server**
  You can configure the socket proxy server on a secondary server to take load off the main server during CPU-intensive operations of Support Automation, such as encryption /decryption.

- **UNI Converter**
  You can add UNI Converter to any one of the servers running on the UNIX platform. You can add the UNI converter to the following servers:

  - Conventional: Primary server, secondary server
  - Advanced Availability: Application server

- **TNG Converter**
  You can add a TNG converter to any one of the servers running on the Windows platform. You can add the TNG converter to the following servers:

  - Conventional: Primary server, secondary server
  - Advanced Availability: Application server

  Note: If the Daemon Manager manages the TNG converter, it starts and stops with the other daemons. If you need the TNG converter to catch events after the CA SDM daemons are shut down, start and stop the TNG converter as a service.

Add Object Managers

Adding object managers to CA SDM servers improves the overall system performance. CA SDM installs a default object manager on all servers. You cannot modify the default object manager, but you can add more object managers on any CA SDM server to increase the server performance. Depending on your configuration type, CA SDM installs a default object manager on the following servers:

- Conventional: Primary server.
- Advanced Availability: All servers.

Note: You cannot modify the default object manager, but can add additional object managers to any server.

Follow these steps:

1. Select **Systems**, **Configurations** under the **Administration** tab.
   The **Configurations List** page opens.
2. Select the configuration to which you want to add the object manager.
   The **Configuration Detail** page opens.

3. Select the **Object Managers** tab.
   The **Object Manager List** page opens displaying the object managers that are configured for the server. The default object manager (if any) is also displayed in the list.

4. Click **Add Object Manager**.
   The **Create New Object Manager** page opens.

5. Complete the following fields and click **Save**.

> **Important!** Enter only English characters for all the input fields for any localized language.

Host Name

Specifies the host name to which you want to add the object manager. You can click the Search button to look up for the servers added to your CA SDM installation.

For an advanced availability configuration type, the host name is read-only and is automatically populated based on the host name you specified while creating the configuration.

- **Display Name**
  Specifies a display name for the object manager. The display name appears on the clients to indicate which object manager it is connected to.

- **Object Manager Group**
  Specifies the group name to which the object manager is added.

  > **Important!** Enter only English characters for the object group name for any localized language.

- You can group object managers so that the groups can be assigned to provide service to specific groups of web engines. Users that require this feature often have web engines that are geographically separated from the primary server and want to collocate an object manager and the webengine. The users group the object managers that are assigned to the local webengines, and then assign the webengines to this group of object managers.

- **Accept Mask**
  Specifies the mask for the object manager. The Accept mask feature tells the object manager from which clients it accepts connections.
  For example, a web engine attempts to connect to an object manager with names such as web:seattle:1 (http://webseattle:1/), web:seattle:2 (http://webseattle:2/) or web:texas:1 (http://webtexas:1/). You can specify an Accept mask like web:seattle.* (http://webseattle.%2A/) to accept all seattle connections and reject others. You also specify a mask like web:.* to accept connections from web engines and reject connections from clients.

- **Record Status**
  Specifies whether the object manager is active or inactive.

  Note: Before setting the record status of an object manager to inactive, you must remove the link between the object manager and associated web engines.

The object manager that you added appears in the **Object Managers** list.

Add Web Engines or Web Directors

Web directors are optional, and are used when two or more web engines are installed on a single server. The Web Director receives connection requests from users and selects a web engine to handle the request. The request is then redirected to that web engine.

Web engines connect to an object manager for processing all requests to CA SDM objects. Web directors are optional, and are used when two or more web engines are installed on a single server. You can configure web directors on any server. Depending on the CA SDM configuration, CA SDM installs a default web engine on the following servers:

- Conventional: Primary server.
- Advanced Availability: All servers.

Follow these steps:

1. Select **Systems**, **Configurations** on the **Administration** tab.
   The **Configurations List** page opens.
2. Select the configuration to which you want to add the web engine or web director.
   The **Configuration Detail** page opens.

   Note: If you are changing the configuration for the first time, then create a configuration first. When you want to make a configuration change, always create or copy an existing one. This process allows you to revert to the previous configuration, if needed.

3. Select the **Web Engines/Web Directors** tab.
   The **Web Engine/Web Directors List** page opens displays the web engines and web directors that are configured for the server.
   - Conventional: A web engine exists by default on the primary server. You can add web directors to any server.
   - Advanced availability: A web engine exists by default on all servers. You can add more web directors on any CA SDM server.

4. Click **Add Web Engine/Web Director**.
   The **Create New Web Engine/Web Director** page opens.

5. Complete the following fields and click **Save**.

> **Important!** Enter only English characters for all the input fields for any localized language.

- **Host Name**
  Specifies the host name for the web engine or web director. You can click Search to look up for the servers.
  For an advanced availability configuration type, the host name is read-only and is automatically populated based on the host name you specified while creating the configuration.

- **Type**
  Specifies if you are configuring a web engine or web director. Based on the option that is selected, the relevant fields are automatically populated.

  - Select Web Engine if you want to configure a web engine.
  - Select Web Director if you want to configure a web director.

> **Note:** Ensure that you have selected the appropriate option. You cannot edit the process type after you have saved the configuration.

- **Web Director**
  Specifies the web director that is assigned to the web engine. You can click Search to look up for the web directors added to the server.

> **Note:** When implementing any web engine load-balancing scheme, SSL-Login, or both, at least two web engines must be assigned to the same web director.

- **CGI Name**
  Specifies the unique CGI name for the web engine. It is the name of an actual CGI executable when IIS or Apache is used as the HTTP server; it is a servlet parameter when Tomcat is used as the HTTP server.
  Examples: (web engines) pdmweb1, pdmweb2, (web directors) pdmweb_d1, and pdmweb_d2.
  Default: pdmweb.exe (The CGI name must be unique).

- **CGI Port Number**
  Specifies the port on which CA SDM web clients can connect. The CGI port number is the same port on which the tomcat server is running.
  Default: 8080

- **Protocol**
  Specifies the protocol for accessing the web engine.
  - Select HTTPS if the web engine is configured to handle all CA SDM web-client user authentication requests.
  - Select HTTP if the web engine is configured to handle all web client non-user authentication requests (after user is authenticated through the secure login web engine).
- **Record Status**
  Specifies whether the web engine or web director is active or inactive.

  Note: Before setting the record status of a web director to inactive, remove the link between the web director and the associated web engines.
- **Object Manager**
  Specifies the object manager that you want to assign to the web engine.
  - **Default**
    Specifies that the default object manager is assigned to the web engine.
  - **ANY**
    Specifies that the web engine can connect to any available object manager with more willingness value. Willingness value is the availability of the server to accept new clients. A willingness value of zero means that the web engine does not accept any sessions.
  - **Choose**
    Allows you to specify an object manager for the web engine. Selecting this option provides you the option to add multiple object managers or aliases to the configuration.

The web engine or web director that you added appears in the Web Engines/Web Directors List.

Add Aliases

Clients and other daemons can be connected to a specific Object Server using aliases. Aliases are easily identifiable names you can create for object manager Slump names. You can create aliases for a specific object manager or a group of object managers. These aliases can be used in place of an object manager name while configuring the CA SDM processes. Aliases are optional in CA SDM. Before you create aliases, perform the following activities:

- Define object managers and add some to groups.
  For example, domsrvr:group1:11, domsrvr:seattle:12, domsrvr:seattle:13, domsrvr:Tacoma:11.
- Enter a regular expression that matches a group of object managers.
  For example, you want the Java clients that are located in Washington to connect to object managers located in Seattle. You connect them to /domsrvr:seattle.*. Or, you can define an alias named SEATTLE and can assign it the value /domsrvr:seattle.*.
- Define web engines and assign aliases to the web engines.

Important! If you have created aliases for an object manager group, ensure that you modify the respective aliases after modifying the object manager group.

Follow these steps:

1. Select **Systems**, **Configurations** under the **Administration** tab.
2. Select the configuration to which you want to add the alias.
3. Select the **Aliases** tab.
4. Click **Add Alias**.
5. Complete the following fields and click Save:

Important! Enter only English characters for all the input fields for any localized language.

- **Name:** Specifies the name for the alias you created.
- **Definition:** Specifies the regular expression that is associated with the alias. The following format is used for an alias definition:

```
domsrvr:[[set the product group or family]:][<host_id><id>][.*]
```

Default: /domsrvr:.*

- **Record Status:** Specifies whether the alias is active or inactive.

The alias that you added appears in the Aliases List.

Add Additional Processes

CA SDM enables you to configure support automation servers, visualizer, LDAP, KT, TNG/UNI, BopLogin repository daemons, and REST web services process to a server. For more information about the processes, see System Configurations (see page 942).

Follow these steps:

1. Select **Systems**, **Configurations** on the **Administration** tab.
2. Select the configuration to which you want to add the additional processes.
3. Select the **Additional Processes** tab.
   The **Additional Process List** displays the list of processes that are configured for the server along with the default processes, if any.

4. Click **Add Process**.

5. Complete the following fields as appropriate and click **Save**:

> **Important!** Enter only English characters for all the input fields for any localized language.

- **Process**
  Indicates the CA SDM server process that you want to add.

- **Repository Daemon**
  Specifies the repository daemon that is configured for the server. Repository daemons support attachment repositories. CA SDM configures a repository daemon by default on the primary server. You can move the daemon to a secondary server by changing the host name.

- **SA Main Server**

  Applicable only to a conventional configuration type.

  Specifies the SA main server that is configured for the server. You can only configure one SA Main server.

- **SA Dedicated Object Server**
  Specifies the dedicated object manager for the support automation configuration. You can specify only one Dedicated Object Server either on primary or secondary server.

> **Note:** You can add a dedicated object manager server only if the SA Main Server is configured.

- **SA Message Routing Server**
  Specifies the message routing server that is configured for the server. You can configure the message routing server on a secondary server to manage multiple Remote Control sessions and help improve the performance during assistance sessions.

  Applicable only to a conventional configuration type.

- **SA Socket Proxy Server**

  Applicable only to a conventional configuration type.

  Specifies the socket proxy server that is configured for the server. You can configure the socket proxy server on a secondary server to take load off the main server during CPU-intensive operations such as encryption/decryption.

- **REST Web Services for Tomcat Server**

  Applicable only to a conventional configuration type.

Specifies the REST Web Services configures for the server. REST Web Services enables you to configure the web UI for CA SDM to be able to communicate with external world. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*.

- **TNG Converter**

  You can add a TNG converter to any one of the servers running on the Windows platform. You can add the TNG converter to the following servers:

- **Conventional:** Primary server, secondary server.

- **Advanced Availability:** Application server.

  Note: If the Daemon Manager manages the TNG converter, it is started and stopped with the other daemons. If you want the TNG converter to catch events after the CA SDM daemons are shut down, start and stop the TNG converter service.

- **UNI Converter**
  Specifies the UNI converter that is configured to respond to UNIX events. These events can be filtered and configured to create tickets and trigger other work in the Service Desk. You can add UNI Converter to any one of the servers running on the UNIX platform. You can add the UNI converter to the following servers:
  Conventional: Primary server, secondary server.
  Advanced Availability: Application server.

- **Visualizer Tomcat Server**

  Applicable only to a conventional configuration type. Specifies the visualizer that is configured for the server.

  You can configure visualizer on a CA SDM server to use web services. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*.

  Note: You can configure only one Visualizer Tomcat Server on a Secondary Server.

- **Hostname**
  Specifies the server that hosts the process you added. You can click the Search button to look up for the servers.

- **Record Status**
  Specifies whether the process you added is active or inactive.

The process that you added are displayed in the Additional Process List page.

Configure the Server

Use the Server Configuration utility (pdm_configure) to initialize and configure the CA Service Desk Manager server, database, and web environment. For more information, see Server Configuration Utility (see page 869)

Verify the Configuration

1. After the configuration is completed and the services are properly started, execute the pdm_status or task manager command to verify that the new daemons added.

2. Verify that the current configuration is updated with the configuration you selected during pdm_configure.

How to Perform Rolling Maintenance on CA SDM Servers

Important! Migration from an advanced availability environment is not possible using rolling maintenance. You must shutdown the CA SDM services in all the application and standby servers before starting the migration activity. For more information, see How to Upgrade CA SDM (see page 399).

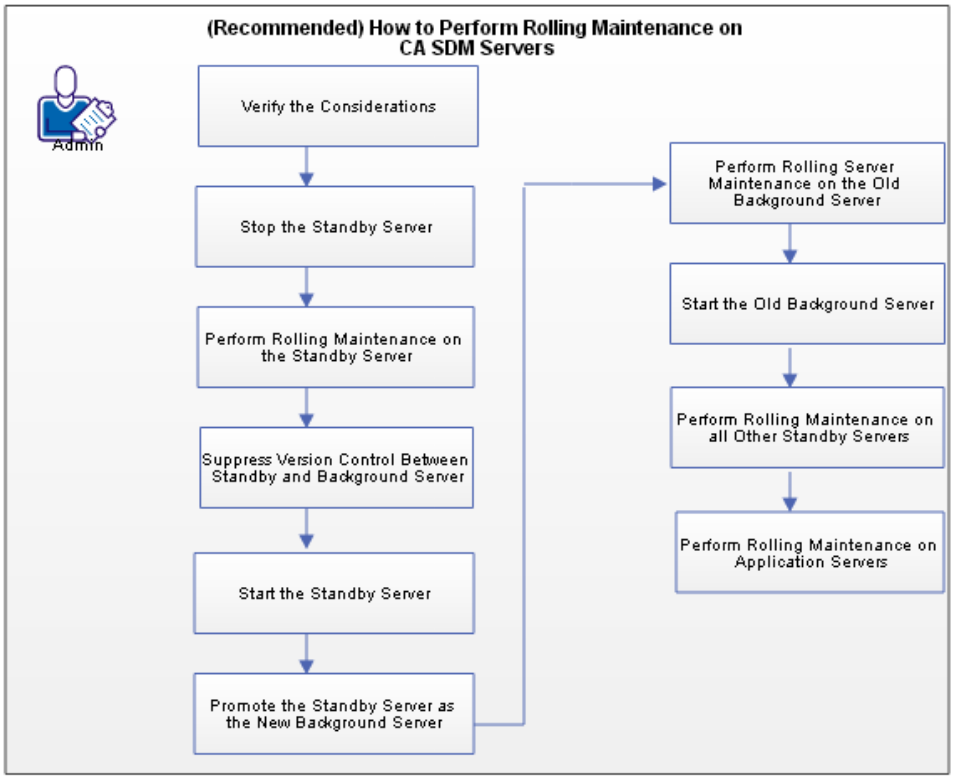
This article contains the following topics:

As a system administrator, you perform the rolling server maintenance on the CA SDM servers. This maintenance can be performed to apply patches or to perform a general maintenance on the servers. We recommend you to perform the maintenance on all the servers in a specific order. This process ensures all the servers are updated with the similar changes causing minimal or no disruption to end users. For any server-specific changes, you do not need to update all the other servers.

Important! Before applying a common MDB patch or an OS or security patch, shut down all the CA SDM servers. In such cases, the user task is disrupted with no access to CA SDM until all servers are up and running. We recommend the system administrator to plan the patch application accordingly.

The following diagram shows the recommended process to perform a rolling maintenance on the CA SDM servers:

Note: Depending upon your organization standards, the rolling maintenance process in your organization may differ from the recommended process.



Follow these steps:

1. Verify the Considerations (see page 932).
2. Stop the Standby Server (that you wish to promote as the new background).
3. Perform Rolling Maintenance on the Standby Server.
4. Suppress Version Control between the Standby and Background Server (see page 932).
5. Start the Standby Server.
6. Promote the Standby Server as the New Background Server (see page 867).
7. Perform Rolling Maintenance on the Old Background Server.
8. Start the Old Background Server.
   When you start the background server, it becomes a standby server.
9. Perform Rolling Maintenance on all Standby Servers.

Note: Stop the standby server, perform a rolling maintenance, and start the server.

10. Perform Rolling Maintenance on Application Servers (see page 933).

Verify the Considerations

During a failover of the background server to the standby server, consider the following points:

- The new users cannot log in.
- For the users that are already connected, some actions do not work during the failover. The users must try the actions after the failover. The following actions do not work:
  - Creating the tickets with attachments
  - Downloading the attachments
  - Searching Knowledge documents
  - Indexing the new knowledge documents
  - Inbound email
  - The SLA events that are not triggered until the failover has completed

Important! If you have configured your third-party tool to enable the auto-failover of the CA SDM servers, you must disable it before starting the rolling maintenance.

Suppress Version Control between the Standby and Background Server

CA SDM version control helps you to manage the system modifications across all CA SDM servers. Ensure that you suppress the version control on the standby server before starting it. This process ensures, that the standby server is not upgraded to the system modifications of the background server. To suppress the version control, run the following command on the standby server that you just upgraded:

```
pdm_server_control  -v
```

Promote the Standby Server as the New Background Server

Before you stop the background server, promote the standby server (that you have upgraded) as the new background server. If Support Automation is installed with CA SDM, notify the active Support Automation users about the background server shutdown.

Follow these steps:

1. Execute the following command on the background server to notify all active users using Support Automation to save their work:

   ```
   sa_server_notifier [-h] | [-q seconds] | [-c]
   ```

   - **-h**
     Displays the help page.

   - **-q seconds**
     This option notifies a local server (background) to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. This option cannot be used for a standby server or application server.

   - **-c**
     This option cancels a previously sent quiesce request.

   A pop-up message is displayed to all the active users using Support Automation. This message notifies the users about the server shutdown and the time that is left for the shutdown. The users must save their work and logout within that scheduled time.

2. Execute the following command on the standby server that you wish to promote as the new background server:

   ```
   pdm_server_control  -b
   ```

   - **-b**
     Notifies a local standby server to become the background server. The standby server must already be running. If the server is not running, it is started but no failover is performed; to start a failover, run the command again.

   The background server shuts down automatically and the standby server is promoted as the new background server. This change does not affect the end-user sessions. The in-progress updates (if any) are stored and delayed, until the new background server comes online.

Perform Rolling Maintenance on Application Servers

As a best practice, you can first perform the rolling maintenance on an application server that has the minimal or no users connected to it. Then, inform all users active on other application servers to log in to the updated server. Finally, you can perform the maintenance on the other application servers. This process ensures that the users are not moved between application servers multiple times.

Follow these steps:

1. Choose the less active application server (see page 868).

2. Stop the less active application server, perform the rolling maintenance, and start it.
   The application server is updated with all the changes.

3. Stop the other application server (see page 868).

4. Perform the rolling maintenance on the application server and start it.
   The application server is updated with all the changes.

5. Perform steps 3 and 4 for the other application servers.
   All the application servers are updated with all the changes.

Choose the Less Active Application Server

You choose an application server with the least user activity. Run the following command on each application server to choose the one with no or minimal active sessions.

```
pdm_webstat
```

Note: This command does not capture the SOAP or REST Web Service sessions.

Stop the Other Application Server

You inform all the active users on an application server to move to the less active application server before you stop it. Ensure that you have restarted the less active application server before moving all the users to it.

Follow these steps:

1. (Recommended) Inform all active Support Automation analysts on the application server which you want to stop, to create a ticket in CA SDM with their session information. This process ensures that the session information is not lost. For example, the Support Automation analyst is in a session with a customer to resolve a hardware issue. In such a case, the Support Automation analyst can create an issue in CA SDM with the session information before the application server shuts down.

2. Send a notification (for example, an email notification) to all the active users on the application server to move to the less active application server that you just restarted. This notification can include the details of the updated application server.

3. Execute the following command on the application server:

   ```
   pdm_server_control [-h] -q interval -s server_name
   ```

   - **-h**
     Displays the help page.

   - **-q interval -s server_name**
     Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

   A pop-up message is displayed to all the active users on the application server to notify them about the server shutdown and the time left for the shutdown. The users must save their work and logout within that time. The application server stops after the specified time. The users log on to the other application server to resume their work. The Support Automation analyst can refer to the ticket and resume their work.
   The application server is stopped successfully.

How to Configure SSL Authentication

As a system administrator, you can configure the web director to direct login requests to a specific web engine using the Secure Socket Layer (SSL) protocol. Configuring the SSL authentication provides enhanced login security while allowing users to access a higher performance connection.

Follow these steps:

1. Verify the Prerequisites (Setting up SSL) (see page 935)
2. Set the Web Engine Capability by Web Director Parameters (see page 935)
3. Choose the SSL Login Environment (see page 935)
4. Set Up SSL Login Environment (see page 937)

Verify the Prerequisites

Verify the following prerequisites before you begin the SSL configuration:

- Installed and configured CA SDM on the server where you want to implement SSL.
- Configured and assigned at least two web engines configured and assigned to a web director. For more information about how to configure web engines and web directors, see the How to Configure Processes for CA SDM Servers (see page 915).

Set the Web Engine Capability by Web Director Parameters

After you configure the web engine to use a web director, the web engine can handle the web client requests. The web engine can service login requests (redirect nonlogins elsewhere) or nonlogin requests (redirect logins elsewhere) or both (‘general purpose’ web engine). The WebDirector parameter found in the <Host_Name>-web[#].cfg file determines how webengine can service login requests.

The following table shows the relationship between the web engine role and web director parameter setting:

Web Engine Capability	‘<Host_Name>-web[#].cfg’ ‘webdirector’ Parameter Settings
Service login requests	‘UseDirector AfterLogin’; ‘Willingness 0’
Service non-login activity	‘UseDirector BeforeLogin’; ‘Willingness [1 thru 10]’
General purpose	‘UseDirector Yes’; Willingness [1-10]’

Choose the SSL Login Environment

You can use the web director for a targeted SSL login in a mixed SSL/non-SSL web environment to redirect every web-login request to the specific SSL web engines. All other requests can be redirected to and serviced by the non-SSL web engines.

Choose from the following SSL Login environment:

Non-SSL Environment with Basic Load-Balancing

You can use web director in a non-SSL environment with basic load-balancing. Web director balances load across all web engines according to each web engine willingness value. Each web engine can service login requests and nonlogin requests. The HTTP protocol is used for communication between the web client and the web server.

For each web engine under web director control, set the web director parameters in the web engine '<*Host_Name*>-web[*#*].cfg' as follows:

- UseDirector: Yes
- WebDirectorSlumpName: (do not change this value)
- WillingnessValue: [1 through 10]
- RedirectingURL: (the preappended protocol value can be either missing or 'http')

Global SSL Environment with Basic Load-Balancing

You can use web director in a global SSL environment with basic load-balancing. Web director balances load across all web engines according to each web engine willingness value. Each web engine can service login and nonlogin requests. The HTTPS protocol must be used for all communications between web clients and the web server.

For each web engine under web director control, set the web director parameters in the web engine '<*Host_Name*>-web[*#*].cfg' as follows:

- UseDirector: Yes
- WebDirectorSlumpName: (do not change this value)
- WillingnessValue: [1 through 10]
- RedirectingURL: (the preappended protocol value must be 'https')

Targeted Login in a Non-SSL Environment with Optional Load-Balancing

You can use web director for a targeted login in a non-SSL environment with optional load-balancing. The login-only web engine services only the login requests. The remaining web engines under web director control, service all other requests. This configuration puts the entire burden of servicing login requests on the specified login-only web engines. The HTTP protocol is used for communications between the web client and the web server.

For the login-only web engines, set the web director parameters in the web engine '<*Host_Name*>-web[*#*].cfg' as follows:

- UseDirector: AfterLogin
- WebDirectorSlumpName: (do not change this value)
- WillingnessValue: 0

- RedirectingURL: (the preappended protocol value can either be missing or ‘http’)

For the nonlogin web engines, set the web director parameters in the web engine ‘<*Host_Name*>-web [#].cfg’ as follows:

- UseDirector: Before Login
- WebDirectorSlumpName: (do not change this value)
- WillingnessValue: [1 through 10]
- RedirectingURL: (the preappended protocol value can be either missing or ‘http’)

Targeted SSL Login in a Mixed Environment with Optional Load-Balancing

You can use web director for a targeted SSL login in a mixed SSL/non-SSL web environment with optional load-balancing. Every web-login request is redirected and serviced by the SSL web engines, while other requests being serviced by the non-SSL web engines. The HTTPS protocol must be used for all communications between the web client and the SSL web engines.

Set Up SSL Login Environment

Setting up SSL allows web transactions to be encrypted, providing maximum security for sensitive data, especially passwords. Depending on your configuration type, you can implement an SSL login environment on the configured CA SDM servers.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Advanced Availability: Application server
   - Conventional: Primary or secondary server
2. Verify that the server has successfully imported an SSL certificate.
3. Create a copy (including subdirectories) of the directory ‘$NX_ROOT/bopcfg/www/wwwroot’, and assign it the following name:
   ‘$NX_ROOT/bopcfg/www/wwwrootsec’
4. Add a new virtual directory for the web server named CAisdsec.
5. Point this virtual directory to the following physical directory:
   ‘$NX_ROOT/bopcfg/www/wwwrootsec’
6. Verify that the virtual directory permissions for CAisdsec match the CAisd virtual directory permissions for the script execution. Enforce SSL for the CAisdsec virtual directory.

   Note: In this example, CAisdsec is user-defined and can be renamed.

7. Save the changes.

> **Note:** Webdirectors do not use a '<Host_Name>-web[#].cfg' file. However, web engines require a unique '<Host_Name>-web[#].cfg' file. Sample web.cfg files are automatically generated while running the configuration. You can import the modifications in the original web.cfg to the new web configuration files by specifying the original web.cfg as the template file you want to use.

8. Copy and save the following files, because a backup of these files is useful whenever you decide to restore the original environment:
   - $NX_ROOT/pdmconf/pdm_startup.tpl
   - $NX_ROOT/pdmconf/pdm_startup
   - $NX_ROOT/bopcfg/www/web.cfg file
   - Any existing primary-web[#].cfg files
   - $NX_ROOT/bopcfg/www/CATALINA_BASE/webapps/CAisd/WEB-INF/web.xml and web.xml.tpl
   - For a secondary server configuration, save backup copies of any existing $NX_ROOT/bopcfg/www/web.cfg or <Secondary_Server_Host_Name>-web[#].cfg files and $NX_ROOT/bopcfg/www/CATALINA_BASE/webapps/CAisd/WEB-INF/web.xml*
9. For each web engine assigned to a webdirector, ensure that the parameters (<Host_Name>-web[#].cfg 'webdirector') of the web engine are set correctly by examining the file in a text editor. If necessary, modify the 'webdirector' parameter values to reflect the web engine role you want. Then copy them to the directory: $NX_ROOT/bopcfg/www.
10. Move all $NX_ROOT/samples/pdmconf/primary-web[#].cfg files to the $NX_ROOT/bopcfg/www directory.
    For the secondary server configuration, Move all $NX_ROOT/samples/pdmconf/' secondary_server_name-web[#].cfg' from the primary server to the secondary server $NX_ROOT/bopcfg/www directory
11. For the servlet server like Tomcat, CA SDM creates web.xml files that can replace the web.xml file on each server hosting a webengine. These files are name primary-web.xml. Rename the files and copy them to the directory: $NX_ROOT/bopcfg/www/CATALINA_BASE/webapps/CAisd/WEB-INF directory.
    For the HTTP server like IIS or Apache, create copies of 'pdmweb.exe' in the $NX_ROOT/bopcfg/www/wwwroot directory, a 'pdmweb[#].exe' for each web engine, and a 'pdmweb_d[#].exe' for each webdirector that has been configured. Verify that the 'pdmweb[#].exe' and 'pdmweb_d[#].exe' are named according to the correct CGI I/F values (for example: 'pdmweb1.exe', 'pdmweb2.exe', pdmweb_d1.exe', and so on).
12. If you are using IIS and want to add Server Extensions for each CGI interface, you can take the file primary-site.dat file and copy it to your $NX_ROOT/bopcfg/www directory as site.dat. When the system is reconfigured these sites is added to IIS.

13. Reconfigure the primary server without reinitializing the database and start services.

14. After reconfiguring verify that the current settings are valid. Start the CA SDM daemons. Verify that there are no errors in the stdlog files. Use pdm_status to view the daemons and their status. Use http://localhost:8080/CAisd/pdmweb.exe to access the system.

15. For Knowledge Management to CA SDM integration, if SSL has been enforced for CA SDM, the CA SDM URL protocol value must be changed.

    a. From the Knowledge Management Tool Settings Manager, General, Integration, change the CA SDM URL protocol value from http to https.

    b. Save and exit.

16. Open a web browser to the CA SDM login page and verify that a user can log in and that the expected redirect/login behavior is observed.

Implement SSL Login Environment

To implement the SSL login you have set up, make changes to the web director parameter values.

Follow these steps:

1. For Secure Login Web engines, edit the <Host_Name>-web[#].cfg as follows:

    a. Change the CAisd parameter value from /CAisd to /CAisdsec.

    b. Change the UseDirector parameter value from Yes to AfterLogin if the web director uses pass through an authentication.

    c. Change the Willingness parameter value from 5 to 0.

    d. Verify that the RedirectingURL value protocol is listed as https.

    e. Change the Redirecting URL <cgi directory> value from CAisd to CAisdsec.

    f. Save the changes.

2. For non-secure web engines handling all other activity, edit the <Host_Name>-web[#].cfg files as follows:

    a. Verify that the CAisd parameter value is /CAisd.

    b. Change the UseDirector parameter value from Yes to BeforeLogin.

    c. Maintain the Willingness value of 5 or set it to any integer value from 1 to 10, depending on the particular loading weight desired.

    d. Verify that the RedirectingURL value protocol is listed as http.

    e. Verify that the RedirectingURL <cgi directory> value is CAisd.

f. Save the changes.
After the configuration, restart Service Desk. After the service restarts, test the login by accessing the non-ssl web engine using HTTP. Verify if it automatically redirects you to the HTTPS secure webengine for the login. Once you are logged in, it automatically redirects you back to the non-ssl HTTP webengine for the normal Service Desk activity.

Verify SSL Login Environment

You can verify the SSL login environment for web engines.

Follow these steps:

- The secure-login web engines must reside in the physical directory that is mapped to the SSL-enforced virtual directory (CAisdsec in this example).
For secure-login web engines, create instances of pdmweb.exe in the $NX_ROOT/bopcfg/www/wwwrootsec directory with the name of pdmweb[#].exe. The executable name must match the CGI I/F value for each secure-login web engine.
Example: If you have assigned the CGI I/F value of the secure-login web engine to pdmweb2, create a physical copy of pdmweb.exe, and rename it pdmweb2.exe.

- The non-secure web engines and web directors must reside in the physical directory that is mapped to the non-SSL virtual directory CAisd.
For non-secure web engines and web directors, create instances of pdmweb.exe in the $NX_ROOT/bopcfg/www/wwwroot directory. A copy of pdmweb.exe must exist for each non-secure web engine and webdirector configured. Rename the copies so that the new names of the executables match the CGI I/F values that have been defined for the web engines and web directors.
Example: If you have assigned the CGI I/F value of pdmweb3 to the non-secure web engine and the value of pdmweb_d1 to the web director, then create two copies of pdmweb.exe. Rename the first copy to pdmweb3.exe, and then rename the second copy to pdmweb_d1.exe.

Set Up SSL Login for Tomcat Server

Configure SSL on Tomcat Servers in your CA SDM environment.

Follow these steps:

1. To create a key store on each CA SDM server that requires an SSL certificate, perform the following steps:

> **Note:** A keystore is a store or storage unit for certificates, in which the certificates are imported to, and then Tomcat points to use that keystore and certificates for SSL.

a. Create a directory under the C: drive (or the local drive you want) with the name, certificates.

b. Using the command line, navigate to the JRE bin directory (for the JRE installed with Service Desk - usually /SC/JRE)

c. Run the command "keytool -genkey -alias tomcat -keyalg RSA -keystore c:/certificates /keystore.jks".

d. Fill in the fields as appropriate (make sure to note what you filled in each filed as you may need this information later).
A keystore.jks file is created in the C:\certificates\ directory.

2. Generate the Certificate Request for each server. Perform the following steps to generate the certificate request:

a. Using the command line, navigate to the JRE bin directory (for the JRE installed with Service Desk - usually /SC/JRE)

b. Run the command "keytool -certreq -alias tomcat -keystore c:/certificates/keystore.jks -file servername-certreq.csr"
A .csr file is created in the c:/certificates directory on each server where you generated the certificate request.

c. Send the .csr files to the vendor of your choice who will then generate the appropriate certificates you need based on the certificate request, for each server.

Note: The certificate you receive from each is different. Some vendors will send you multiple certificated possibly including a root certificate, an intermediate certificate, and a certificate of authority. Each vendor has different instructions on which certificates they provide need to be imported into the keystore. So the key here is to ask the specific vendor that you used to generate the certificates for you, for specific instructions on how to import their certificates into a tomcat keystore.

Once you received the specific instructions from the vendor, you can follow those to import the appropriate certificates into the keystore on each server. Once that is complete, you can now configure Tomcat on the Service Desk side of things to point it to that keystore where the certificates have been imported.

3. Open the \bopcfg\www\CATALINA_BASE\conf\server.xml file using a text editor and locate the following:

```
<-- <Connector port="8443" maxHttpHeaderSize="8192"
maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
enableLookups="false" disableUploadTimeout="true"
acceptCount="100" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS"
keystoreFile="C:\Documents and Settings\user\.keystore"
keystorePass="password"/> -->
```

4. Change the code to the following:

```
<Connector port="8443" maxHttpHeaderSize="8192"
maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
enableLookups="false" disableUploadTimeout="true"
```

```
acceptCount="100" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS"
keystoreFile="C:\certs\keystore.jks"
keystorePass="password"/>
```

Note: Be sure to remove the <-- and --> tags that currently comment out the HTTPS /SSL connector for Tomcat, and set the appropriate path and password for your keystore that you generated in the beginning.

5. Save the server.xml file.

6. Restart Tomcat by using the following commands:

```
pdm_tomcat_nxd  - c stop
pdm_tomcat_nxd  - c start
```

Note: We recommend you to restart all the CA SDM servers to ensure that the Tomcat is restarted.

7. Test your tomcat SSL connection by opening a browser and navigating to the Service Desk URL, using the HTTPS protocol, and the tomcat port. For example, use the following URL:

```
https://servername:8080/CAisd/pdmweb.exe
```

The Service Desk Login Screen should open. You have successfully configured SSL on Tomcat.

System Configurations

Contents

To enhance the performance of CA SDM Servers, add or modify the processes and daemons. Configure object managers, web engines, web directors, and other processes for the CA SDM servers in your environment. You can add the processes across several servers to increase volume, performance, and enhance security.

Additional Processes

Depending on your configuration type, you can configure the following extra processes for the CA SDM servers:

Processes	Configuration details
Knowledge Daemons Login User Authentication LDAP Virtual DB	Applicable only to the conventional configuration. CA SDM configures these daemons by default on the primary server. You cannot delete the daemons but can move the daemons to a secondary server by changing the host name.
Repository daemons REST Web Services for Tomcat Server Visualizer	Applicable only to the conventional configuration. Using the CA SDM web UI, you can add these processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*.
SA Main Server SA Dedicated Object Server SA Message Routing Server SA Socket Proxy Server	Applicable only to the conventional configuration. Using the CA SDM web UI, you can add the processes only for secondary servers. After you have added the process through the web UI, enable the specific option during the CA SDM configuration. For more information about enabling the processes, see the *Server Configuration Online Help*. You can only add one support automation process for each secondary server.
TNG converter UNI Converter	Depending on the operating system, you can add the processes to the following servers: Conventional: Primary server, secondary server. Advanced Availability: Application server.

Current Locks

Current Locks let you view and release locks on any object. During normal operations, the system locks objects while users work with data. If there is a system failure, you can free objects for future updates. Because the initial locks default to 5 (five) minutes, you unlock the objects when another user needs the same data.

View Current Object Locks

You can view a snapshot of currently locked objects.

Follow these steps:

1. On the Administration tab, select System, Current Locks.
   The Current Locks page lists the following information about object locks:

   - **Lock**
     Process that requested the lock.
   - **Name**
     The lock name. If the lock is related to a ticket, the lock name can reflect the ticket number.
   - **Table Name**
     Location of the locked object.
   - **Object Name**
     The Majic object.
   - **Lock Owner**
     The table user.
   - **Locked Since**
     Date and time of the object lock.
   - **Process**
     Process that initiated the lock.

2. Refresh the browser.
   The Current Locks page shows the most recent object locks.

Unlock Objects

You can review and release object locks to allow other users to access the object.

Follow these steps:

1. On the Administration tab, select System, Current Locks.

   The Current Locks page shows a list of object locks.

2. Refresh the browser.

The Current Locks page shows the most recent object locks.

3. Right click the row.

   A Delete Lock menu appears.

4. Click Delete Lock.

   A confirmation message appears.

5. Click OK.

   The Current Locks page updates and a message notifies you that the object is free.

Managing Your Database

This article contains the following topics:

You can run utilities to manage your database while CA SDM is shut down. If you are running database management utilities and using a database other than the CA SDM default repository, the database environment variables must be set.

Note: For information about setting environment variables, see the database documentation you are using.

Database Backup

You can back up the contents of a single database table, multiple database tables, or your entire CA SDM database, using the database backup utility, pdm_backup. The output of the backup utility is an ASCII file that the pdm_restore utility can use.

As part of its processing, pdm_backup first shuts down the daemons (UNIX) or services (Windows). pdm_backup stops CA SDM and then writes one or more tables from a CA SDM database to an ASCII file. You can use this output file as the input file to pdm_restore. In addition to the contents of the database, pdm_backup backs up application configuration files.

If you have operating environment-specific backup tools, we recommend that you use them instead of pdm_backup. Because pdm_backup is a generic tool, it can be slow on some operating environment combinations.

Note: As part of its processing, pdm_backup first shuts down the daemons (UNIX) or services (Windows).

Syntax

This command has the following format:

```
pdm_backup [-d] [-g] [-v] -f filename [ALL | table1...tableN]
```

-d

Specifies to back up the database data only.

-g

Specifies that only non-database data be backed up. This means only windows (forms) and other non-database data is backed up.

-v

Specifies verbose mode, which writes comments about command progress to stdout.

-f *filename*

Specifies an output file.

ALL|table1...tableN

Specifies ALL files or the table or tables to write. If more than one table is specified, separate each with spaces.

- You can find table names in the CA SDM database schema file, ddict.sch, located in $NX_ROOT /site (UNIX) or *installation-directory*\site (Windows). $NX_ROOT or *installation-directory* is the directory where you installed CA SDM.
- If no table is specified, the entire CA SDM database is written, including window groups and menu registration files.

Restrictions

pdm_backup cannot be run while CA SDM is active.

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use *pdm_task* to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

Database Restore

The database restore utility, pdm_restore, loads an output file from pdm_backup to the CA SDM database. The pdm_restore utility first shuts down the daemons (UNIX) or services (Windows). Then it restores, clears, and replaces all existing database records. Use the formatted ASCII file created by pdm_backup as input for the pdm_restore utility.

You can also use the pdm_restore and pdm_userload utilities to gain access to the CA SDM application in case of a catastrophic database corruption. If your database is damaged to the point where you cannot gain any access to the application and if all other measures have failed, rerun configuration and reinitialize the database to rebuild your database and populate reference data and system tables.

This procedure initializes your database in the same way that you did during the original installation. You can now access CA SDM. The pdm_restore utility can be used to restore the last backed up copy of your database.

For more information, see pdm_restore--Restore a Database (see page 947).

pdm_restore--Restore a Database

pdm_restore stops CA SDM and then deletes all records from a CA SDM database and replaces them with records from a file you specify with the -f option. The data from the input file is the only data that will be in the CA SDM database after running pdm_restore.

The input file must be created using pdm_extract or pdm_backup, or otherwise formatted for pdm_restore. pdm_backup can back up non-database data, and pdm_restore can restore this data also. pdm_backup and pdm_restore are not recommended when other backup and restoration tools are available.

Note: As part of its processing, pdm_restore first shuts down the daemons (UNIX) or services (Windows).

Syntax

This command has the following format:

```
pdm_restore [-d] [-g] [-n] [-w] [-v]  -f filename
```

Restrictions

pdm_restore can be run only on a CA SDM server. Only the privileged user or root can run pdm_restore. The following restrictions are applicable if you are using the advanced availability configuration:

- If you are restoring the database, run the pdm_restore command only on the background server.
- Ensure that you have stopped all servers (application, background, and standby) before you run the pdm_restore command.

Important! Use pdm_restore only with a full database backup created by pdm_backup, because your current database is deleted and replaced by the backup file. Do not run pdm_restore when users are logged in to CA SDM.

-d
Specifies that only database data is restored.

-g
Specifies that only non-database data be restored. Only windows (forms) and other non-database data are restored.

-n
Specifies that NX.env is restored if restoring non-database data. By default, NX.env is not restored. We recommend that the NX.env file not be restored unless the restore is to the same server the backup came from. Restoring an incorrect NX.env can affect unintended databases.

-w
Specifies that web.cfg is restored if restoring non-database data. By default, web.cfg is not restored.

-v
Specifies verbose mode.

-f *filename*

Specifies an input file that contains a full backup created by pdm_backup.

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use *pdm_task* to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

Database Table Replacement

This article contains the following topics:

The pdm_replace utility is a quick and easy way to replace the entire contents of a CA SDM database table with new information. This utility can be useful for massive revisions of look-up tables.

Note: pdm_replace takes the same input file format as pdm_userload. You can create an input file for pdm_replace using pdm_extract; however, you cannot use the output of pdm_backup as input to pdm_replace.

Note: For more information, see pdm_replace--Replace a Database Table (see page 949) and How to Create and Use an Input File (see page 965).

pdm_replace--Replace a Database Table

pdm_replace deletes a table in a CA SDM database and replaces it with a table from a temporary file you specify with the -f option; the data from the input file is the only data that is in that table after running pdm_replace. Back up your table before running pdm_replace.

Note: As part of its processing, pdm_replace first shuts down the daemons (UNIX) or services (Windows).

pdm_replace accepts a text file as input, which is the same file format used by pdm_userload. You can create an input file for pdm_replace using pdm_extract; however, you cannot use the output of pdm_backup as input to pdm_replace.

Important! Be sure to name your input file with a name different from the table name you are attempting to replace. For example, if you are replacing a table named ca_contacts and you name the input file ca_contacts.dat, after you execute the pdm_replace command to point to the input file (ca_contacts.dat), it deletes the file after execution because it has the same name as the table.

Restrictions

- pdm_replace can be run only on the following servers, depending on your CA SDM configuration:
  - Conventional: Primary server

- Advanced availability: Background server

  Important! Ensure that you have stopped all application and standby servers before running this command on the background server.

- Only the privileged user or root can run pdm_replace.
- Do not run pdm_replace when users are logged in to CA SDM.

Syntax

This command has the following format:

```
pdm_replace [-v] -f filename
```

-v

Specifies verbose mode.

-f *filename*

Specifies an ASCII file with the following format:

```
TABLE table_name
fieldname1fieldname2 . . . . fieldnameN
{ "value11", "value12", . . . "value1N" }
{ "value21", "value22", . . . "value2N" }
.
.
.
{ "valueN1", "valueN2", . . . "valueNN" }
```

This format is the same file format used by pdm_userload. You can create an input file for pdm_replace using pdm_extract; however, you cannot use the output of pdm_backup as input to pdm_replace.

Data Extraction

The pdm_extract utility extracts data from the CA SDM database and produces output in various formats. You can further process this data or enter it into other applications, such as a spreadsheet or another database.

With the pdm_extract utility, you can do the following:

- Dump the entire CA SDM database
- Dump one or more database tables
- Extract specific information from the database and produce output in one of the following three formats:

- Output compatible with pdm_userload
- Comma-separated value (CSV) output
- Informal report-style output

For more information, see pdm_extract--Extract Data from Database (see page 951).

pdm_extract--Extract Data from Database

The pdm_extract command extracts data from specified CA SDM database tables or the entire CA SDM database, and outputs it as ASCII-formatted text.

Syntax

This command has the following format:

```
pdm_extract [-c|-e|-r] [-d] [-h] [-u] [-v] [-C] --B] [-f formatstring| ALL | table1 .
. . TableN]
```

-c

Produces comma-separated value (CSV) output, such as:

```
"field1","field2","field3"
```

The -c, -e, and -r output format options are mutually exclusive.

-e

Produces comma-separated value (CSV) output with embedded double quotes escaped by another double quote. For example:

```
"Text with a "quoted string" in it"
```

The -c, -e, and -r output format options are mutually exclusive.

-r

Produces left-justified output in the formats if the column labels are not supplied in the input file:

```
"label":"value"
```

or

```
"value"
```

This option is intended for use with line printers, for example:

```
Field_Name: Field Value
```

The -c, -e, and -r output format options are mutually exclusive.

-d

Uses the date format found in the file $NX_ROOT/fig/english/cfg/dataent.fmt (UNIX) or *installation-directory*\fig\english\cfg\dataent.fmt (Windows), which you can edit to suit your requirements.

-h

Displays help and usage information.

-u

Produces output without headers.

-v

Specifies verbose mode, which writes comments about command progress to stdout.

-C
Changes encoding from UTF-8 to another charset. The default output is UTF-8.
Example: To convert the output to JIS, you would run "-C iso-2022-jp"
Example: To encode to the operating system's native charset, use "DEFAULT" or "NATIVE".

-B
Suppresses the Byte Order Mark if the variable NX_ADD_UTF8_BYTE_ORDER_MARK is set.
The NX_ADD_UTF8_BYTE_ORDER_MARK option is a signature into a file. It allows editors that support UTF-8 to maintain the UTF-8 integrity of the file.
Note: This is only needed for non-ASCII data. If this is not installed, the default behavior omits the Byte Order Mark (BOM). If installed, set it to "1" or "Yes".

-f *formatstring*

Extracts specific records and fields according to *formatstring*, which is an SQL subset statement.

For a date after a period, use the following syntax:

pdm_extract -v -f "select id, ref_num from Call_Req where open_date >= DATE '2005-02-24'" > daterange1.txt

For a date range, use the following syntax:

pdm_extract -v -f "select id, ref_num from Call_Req where open_date >= DATE '2004-01-20' and open_date < DATE '2004-02-25'" > daterange2.txt

Note: Use single quotes around the date in the YYYY-MM-DD format.

The syntax for DATE is as follows:

```
DATE 'yyyy-mm-dd'
```

yyyy = integer representing year (between 1970 and 2038)

mm = integer representing month

dd = integer representing day

Examples:

```
DATE '2005-01-18'
DATE '1999-12-25'
```

The syntax for TIMESTAMP is:

```
TIMESTAMP 'yyyy-mm-dd hh.mm.ss[.nnnnnn][[+|-][hh.mm]]
```

yyyy = integer representing year (between 1970 and 2038)

mm = integer representing month

dd = integer representing day

hh = integer representing hour

mm = integer representing minutes

ss = integer representing seconds

nnnn = optional integer representing fractions of sec.

[+|-][hh.mm] = optional time zone interval.

Examples:

```
TIMESTAMP '1998-04-28 12:00:00.000000'
TIMESTAMP '2004-10-17 18:30:45'
TIMESTAMP '2005-03-21 12:00:12+08:00'
TIMESTAMP '1999-05-10 09:12:23.005-03:30'
```

Note: The -d option is not needed, as it only affects the format of the output.

A command usage example follows:

```
pdm_extract -f "select * from Call_Req where open_date > TIMESTAMP '2004-01-12 12:00:
00'"
```

In this example, all columns are being extracted from the Call_Req table where the open_date is after midnight 1/12/2004.

ALL

Extracts output from all tables in the database.

```
table1. . . tableN
```

Extracts output from the specified tables. Table names must be separated by spaces.

The default format, if none is specified, is an ASCII file compatible with pdm_userload.

Data Selection for Extraction

To select the data for extraction, the data extractor uses an integral SQL subset with the following rules:

- The following SQL functions are specifically supported in the subset:
  - IS NULL, IS NOT NULL, LIKE
  - SELECT statements and WHERE clauses
- The following SQL functionality is not supported in the subset:
  - Joins
  - Embedded tabs and new-line characters
  - Clauses other than SELECT, FROM, and WHERE
  - Asterisks (*) in SELECT statements
  - Nested SELECTs
  - Aggregate functions
- All SQL reserved words must be in uppercase characters
- Every token in a WHERE clause must be surrounded by white space
- All date/time specifications must be in one of three formats:
  - Elapsed seconds from 12:00:00 a.m. 1/1/1970 Greenwich Mean Time (GMT):

    ```
    start_date< or >174182431500
    ```

  - SQL DATE format:

    ```
    start_date< or >DATE '2001-11-28'
    ```

  - SQL TIMESTAMP format:

    ```
    start_date< or >TIMESTAMP '2001-07-04 15:45:00'
    ```

Note: TIMESTAMP format uses GMT. You can adjust time zones by adding or subtracting the appropriate number of hours, such as: 2001-03-23 14:00:00+02:00 or 2001-06-06 04:45:00-09:00.

Use the Data Extractor on UNIX

Before you use the CA SDM data extractor on UNIX, you must do the following:

1. Set the value of the $NX_ROOT environment variable to the full path name of the CA SDM installation directory that you defined during installation.
2. Append $NX_ROOT/bin to your PATH environment variable.
3. Set umask to 000.

Data Dereferencing

This article contains the following topics:

The pdm_deref utility is a dereferencing tool that converts data from various sources into a format suitable for loading into the CA SDM database. Dereferencing extracts internal IDs for cross-referenced fields. The utility can also be used to calculate down time and SLA down time values.

The pdm_deref utility converts data into one of the following formats:

- Output compatible with pdm_userload, suitable for loading into the CA SDM database
- Comma-separated value (CSV) output
- Informal report-style output

Note: For more information, see pdm_deref--Dereference ASCII Data (see page 955).

pdm_deref--Dereference ASCII Data

pdm_deref processes ASCII-formatted input to exchange data found in one database table for data found in another database table. It can be used to create files compatible with pdm_userload from a non-CA SDM database or spreadsheet. It can also be used to create reports or output files for a non-CA SDM database or spreadsheet.

Important! Do not use pdm_deref if you are unfamiliar with SQL. The directories "export" and "import" in $NX_ROOT/samples (UNIX) or installation-directory\samples (Windows) contain a standard set of specfiles for viewing.

Syntax

This command has the following format:

```
name pdm_deref  - s specfile [-c|-e|-r] [-d] [-h] [-n] [-u] [-v] <filename>
```

-s specfile

(Required) Specifies a file that defines which data is exchanged and the conditions under which it changes.

Specfile contains a list of SQL commands in the following format (note that "att" means attribute and "atts" means attributes):

```
Deref
{
input = <list of "from" atts from input file>
output = <list of "to" atts for output file>
rule = "SELECT <atts used to fill output atts> \
  FROM <table name>  \
  WHERE <att from table name to match input 1> =?\
  AND <att from table name to match input 2> = ? \
  OR <att from table name to match input 3> =?"
}
```

-c

Produces comma-separated value (CSV) output, such as:

```
"field1","field2","field3"
```

The -c, -e, and -r output format options are mutually exclusive.

-e

Produces comma-separated value (CSV) output with embedded double quotes escaped by another double quote. For example:

```
"Text with a "quoted string" in it".
```

The -c, -e, and -r output format options are mutually exclusive.

-r

Produces left-justified output in the formats if the column labels are not supplied in the input file:

```
"label":"value"
```

or

```
"value"
```

This option is intended for use with line printers, for example:

```
Field_Name: Field Value
```

The -c, -e, and -r output format options are mutually exclusive.

-d

Produces diagnostic information.

-h

Displays help and usage information.

-n

Specifies that you do not want to treat 0 valued foreign keys as NULL. This argument should be used only under special circumstances when recovering a damaged database.

-u

Produces output without headers.

-v

Specifies verbose mode.

filename

(Optional) Specifies the ASCII-formatted input file to be processed. If omitted, stdin is used.

Restriction -- **Valid on UNIX only**

Before using pdm_deref on UNIX, the $NX_ROOT environment variable must be set to the path of the CA SDM installation directory, and the PATH environment variable must include $NX_ROOT/bin.

Example: Using pdm_deref to Set Up Data for Input

This example shows how you can use pdm_deref to set up data for input.

Given the following data in the ca_location table:

```
id    location_name_name
86873FA40BA4234A8CF7A418D7C8B2DB    "Boulder NCC"
```

the following statement in the specfile:

```
Deref
{
input = place
output = location_uuid
rule = "SELECT id FROM ca_location WHERE location_name=?"
}
```

would change the following input:

```
last_name, first_name, place
{"Potts", "Elmore", "Boulder NCC"}
```

to the following output, which can be loaded into the ca.contact table with pdm_userload:

```
last_name, first_name, location_uuid
{"Potts", "Elmore", "86873FA40BA4234A8CF7A418D7C8B2DB"}
```

Example: Using pdm_deref to Set Up Data for Output

This example shows how you can use pdm_deref to set up data for output.

Given the following data in the ca_contact table:

```
id  last_name first_name
"69499D5A2424884887E62EC9823F5E47"    "Potts"    "Elmore"
```

the following statement in the specfile:

```
Deref
{
input = primary_contact_uuid
output = firstname, lastname
rule = "SELECT first_name, last_name FROM ca_contact
WHERE id=?"
}
```

would change the following input:

```
location_name, primary_contact_uuid
{"Boulder NCC", "69499D5A2424884887E62EC9823F5E47"}
```

to the following output, which can be printed or sent to a spreadsheet:

```
location_name, firstname, lastname
{"Boulder NCC", "Elmore", "Potts"}
```

Use the Dbadmin Mode

The dbadmin mode is a utility starts or triggers the data manipulation layer of the CA SDM system without starting the object layer. The utility provides the ability to lock the entire database to perform low-level data maintenance and data integrity.

For example, use pdm_extract, pdm_load, pdm_deref, and pdm_replace for performing batch data updates on the system. By using the dbadmin command, the administrator is essentially placing a database lock on the entire system. The backup (pdm_backup) and restore (pdm_restore) utilities, both automatically place the system in dbadmin mode to guarantee a consistent backup and restore.

The dbadmin mode is also useful to configure the system without starting the object layer until the data is modified. For example, an attribute “required” in majic on an existing system can confuse the animator if an update to an object that has the required attribute null. You can put the system into dbadmin mode and update the objects using pdm_load, and then start the system as usual.

Follow these steps:

1. Halt CA SDM either from Windows Service Manager or by running pdm_halt from the command line.

   Note: It is a good practice to send an announcement to alert users and to check for logged in users before halting the system.

2. From the command line, enter the following command using the same case as shown:

   ```
   pdm_d_mgr  - s DBADMIN
   ```

   Note: There is no return message, but a pause occurs before the command prompt returns. If there is no pause, check your spelling to verify that you entered data correctly.

3. Run pdm_status to verify that the system is in dbadmin mode.

   Note: When the system is in dbadmin mode, the system returns the following status, which indicates that it is safe to work on the system:

   ```
   C:\>pdm_status
   The Daemons are not running.
   ```

4. When all work is complete, run pdm_halt to shut down dbadmin mode.

5. Restart the system by following your usual procedures.

How to Use pdm_deref Example

The following example shows how to use the pdm_deref utility in a CA SDM ticket tracking system.

Assume that an existing ticket tracking system that you implemented on a spreadsheet has columns labeled Trouble Description, Technician First and Last Name, and Entry Date. These columns correspond to the description, assignee, and open_date fields in the CA SDM Change_Request table. The Trouble Description field contains the same data type as the description field. But the assignee field is a numeric field, and the Technicianfield on the spreadsheet is in a “last name, first name” format.

Follow these steps:

1. Load the technicians’ names into the Contact table.
2. Prepare a pdm_deref input file with the existing information.
3. Build a specifications file to map the new contact names to assignee values.
4. Prepare a pdm_userload input file to be used to update the Change_Request table.

This process is described in more detail in the following steps:

1. Prepare a pdm_userload input file, location.dat, for the Location table as follows:

```
TABLE ca_location
location_name address_2 address_2
{"Boulder NCC - NQ", "716 Main
    Street","Boulder, CO 84302"}
{"Colorado Springs NCC", "2765 Spring Street",
    "Colorado Springs, CO 84303"}
{"Denver NCC", "3765 Stoneridge Way", "Denver,
    CO 80254"}
```

2. Load the data as follows:

```
pdm_load -f location.dat
```

3. Prepare an input file, contact.dat, with the original information as follows:

```
TABLE ca_contact
last_name first_name middle_name location pri_phone_number
{"Harrison", "Frank," "Harold", "NCC - HQ", "303-555-2333"}
{"Hertzog", "William", "I.", "Colorado Springs NCC", "303-966-1987"}
{"Lyman", "Jeanie", "L.", "Denver NCC", "303-966-5301"}
```

4. Prepare a dereferencing tool specifications file, contact.spec as follows:

```
Deref
{
input = c_location
output = location_uuid
rule = "SELECT id FROM ca_location WHERE location_name=?"
}
```

Important! Do not place a blank space in front of the SELECT keyword. Deref uses the new contacts' first and last names to obtain the appropriate numeric ID fields for loading the Change_Request table. In addition, the "hooks" represented by question marks (?), correspond to the specified input fields. You must have the same number of hooks as input fields, and they must be in the same order.

5. Run pdm_deref as follows:

```
pdm_deref -s contact.spec < contact.dat > contact.out
```

The output file, contact.out, looks like the following:

```
TABLE ca_contact
last_name first_name middle_name location.uuid pri_phone_number
{"Harrison", "Frank", "Harold", "69499D5A2424884887E62EC9823F5E47", "303-555-
2333"}
{"Hertzog", "William", "I.", "86873FA40BA4234A8CF7A418D7C8B2DB", "303-966-1987"}
{"Lyman", "Jeanie", "L.", "58AA42789957734E8BEE146D07F7AD49", "303-966-5301"}
```

6. Load the contact.out file into the CA SDM database as follows:

```
pdm_load -i -f contact.out
```

Note: You must use the pdm_load command to use the - i option.

7. (UNIX only, optional) Write a script, Convert_Ticket, as shown in the following:

```
#!/bin/sh
pdm_load -i $1
cat $2 | pdm_deref -s $3 | pdm_load -i
```

You can run this script, as shown by the following:

```
Convert Ticket location.dat contact.dat contact.spec
```

In this example, pdm_load with the -i flag is used to speed the process. If you are making these updates on a regular basis, you can drop the -i flag so that pdm_load checks for duplicate records.

The following are additional examples of dereferencing tool specification files:

```
Deref
{
    input = first_name, last_name, middle_name
    output = assignee
    rule = " SELECT id from ca_contact \
           WHERE first_name=? \
           AND last_name=? \
           AND middle_name=? "
```

```
}
```

This rule converts three fields labeled first_name, last_name, and middle_name to the appropriate contact UUID. If all three input fields are not present, the rule is not applied. No match produces an error message and processing continues. For multiple matches, the first value is used; an error message is produced, and processing continues.

Database Loader

This article contains the following topic:

The database loader utility, pdm_userload, adds, updates, and deletes CA SDM database records. You create a formatted ASCII input file for the pdm_userload utility and select the tables to load and the optional fields to add.

Important! The pdm_userload utility accesses the CA SDM database and does not directly interact with application software processes. The inventory items added to the database with pdm_userload do not update the helper/selection lists until the application has been halted and restarted.

Although the pdm_userload utility can run with the application active, system performance is degraded. For best results, ensure that the background server is running but that no users are using the client interface before you run pdm_userload.

For more information, see pdm_userload--Add, Update, and Delete Database Records (see page 962).

Note: To add records with cross-referenced fields, use the pdm_deref utility pdm_deref--Dereference ASCII Data (see page 955).

pdm_userload--Add, Update, and Delete Database Records

The pdm_userload utility updates a CA SDM database using an input file you specify.

Important! You should always backup your database before you perform a pdm_userload.

Whenever you upload tickets (such as issues or requests), your ticket number should include a unique prefix or suffix in its string. CA SDM views this number as a string of characters not as a sequential number, and does not guarantee that it assigns a unique number to the uploaded tickets. As long as you assign a unique prefix or suffix using awk or another text processor, however, you can upload tickets without CA SDM writing over previously assigned numbers.

Syntax

This command has the following format:

```
pdm_userload [-a] [-c] [-h] [-r] [-v] [-u] [-m]  - f filename
```

Input File Format

The input file entries follow this format:

```
TABLE table_name
fieldname1fieldname2 . . . . fieldnameN
{ "value11", "value12", . . . "value1N" }
{ "value21", "value22", . . . "value2N" }
.
.
.
{ "valueN1", "valueN2", . . . "valueNN" }
```

table_name is the name of the table to be loaded, as listed in the CA SDM database schema file, which is located in $NX_ROOT/site/sch/schema.sch (UNIX) or *installation-directory*\site\sch\schema.sch (Windows), where $NX_ROOT or *installation-directory* is the directory where you installed CA SDM.

-f filename

Specifies an input ASCII file.

-a

Updates all existing records, regardless of whether more than one existing record matches a single input record. Without this option, input records that match more than one existing record are rejected.

Important! Use this option carefully.

-c

Checks the input file against the database and reports on the updates that would be made, but does not make the updates.

-r

Removes database records that match input records. The -a option can be used with the -r option.

Note: Make a backup copy of the database before running pdm_userload with this option. old database records are removed, you must restore the CA SDM database with this backup copy if you wish to recover any deleted records.

-v

Specifies verbose mode.

-u

Updates existing records, but does not insert new records into the database.

-m

Mass update. Specify when you are using pdm_userload to add or delete a large number of records. This option suppresses all client notifications of updates and sends a cache refresh message for a table when pdm_userload finishes processing the table.

-x
Uses locale sensitive numeric input formats.

-t
Specifies the name or UUID of tenant to associate all loaded data with the specified tenant. This argument is valid only when multi-tenancy is installed.

Pdm_userload supports new arguments on the TABLE statement, "Truncate" and "NoNewID". These arguments are specified in an optional parenthesized option after the table name. For example:

```
TABLE Call_Req (TRUNCATE, NONEWID)
```

- **Truncate**
  Causes pdm_userload to issue a database-specific TRUNCATE command for the table prior to loading any data. In addition, it forces pdm_userload logic to use insert-only logic regardless of command-line arguments, as all records are new.

- **NoNewID**
  Causes pdm_userload to use the id value from its input control file for new rows in the table, rather than generating a new ID for inserted data.

Restrictions

You can run pdm_userload while CA SDM is active, but performance can become very slow. It is best to run pdm_userload when no one is using CA SDM.

Drop and Restore Constraints

Some of the mdb tables that start with ca_ (such as ca_contact_) have referential constraints that may impact mass loading of data using pdm_load, pdm_userload, and pdm_restore tools. If mass loading these tables is required, you may need to drop the referential constraints prior to mass loading of the data.

Two SQL scripts are provided for each DBMS type to drop and restore constraints. Prior to mass loading of data affecting ca_* tables, run the Drop version of the script. After the data load has completed, run the Add version of the script.

For SQL Server the scripts are located in *installation-directory*\samples\views\SQLServer directory. Run the following command to drop constraints:

```
osql -E -e < SQLDropConstraints.sql'
```

Run the following command to add back constraints:

```
osql -E -e < SQLAddConstraints.sql
```

For Oracle, the scripts are located in *installation-directory*\samples\views\Oracle directory.

Run the following command to drop constraints:

```
sqlplus mdbadmin/ <password> < OracleDropConstraints.sql
```

Run the following command to add back constraints:

```
sqlplus mdbadmin/ <password> < OracleAddConstraints.sql
```

How to Create and Use an Input File

You can use an input file and the pdm_userload utility to populate database tables.

The input file format is as follows:

- Surround field values with double quotes (“value”) and separate values with a comma and a space (“value1”, “value2”).
- Precede double quotes with a backslash (\) to embed them in text strings. To set a date/time field to the current date and time, use @NOW@ for the input value.
- Surround each record with curly braces separated by spaces, as follows:

  ```
  ( { record field values } )
  ```

- If properly delimited, input records can span more than one line in the input file as long as individual fields stay on one line. For a multi-line field such as comments, values can include a new line character (\n) to force a new line when the database field is displayed.
- Explicit new line characters are needed only for special formatting. Ordinary running text is automatically displayed with appropriate line breaks, as shown by the following example:

  ```
  "Record status is \"COMPLETE\""
  ```

To create an input file for the pdm_userload utility, perform the following steps:

Follow these steps:

1. Determine which table you want to load, and the fields you want to populate in that table. You must populate the Name or Symbol key field for each record that you load.
2. Make a copy of the appropriate *filename*.dat file for the table that you are loading.

3. Edit your newly created copy of the *filename*.dat file, as follows:

    a. Add an entry for each record to be loaded.

    b. From under the TABLE line (see the following example), remove fields that you do not want to populate.

    ```
    TABLE table_name
    fieldname1 fieldname4 . . . fieldnameN
    ```

4. Save your file and exit from the editor.

5. Run the pdm_userload utility and specify the file, as shown by the following example. In this example, the input file name is myData.dat:

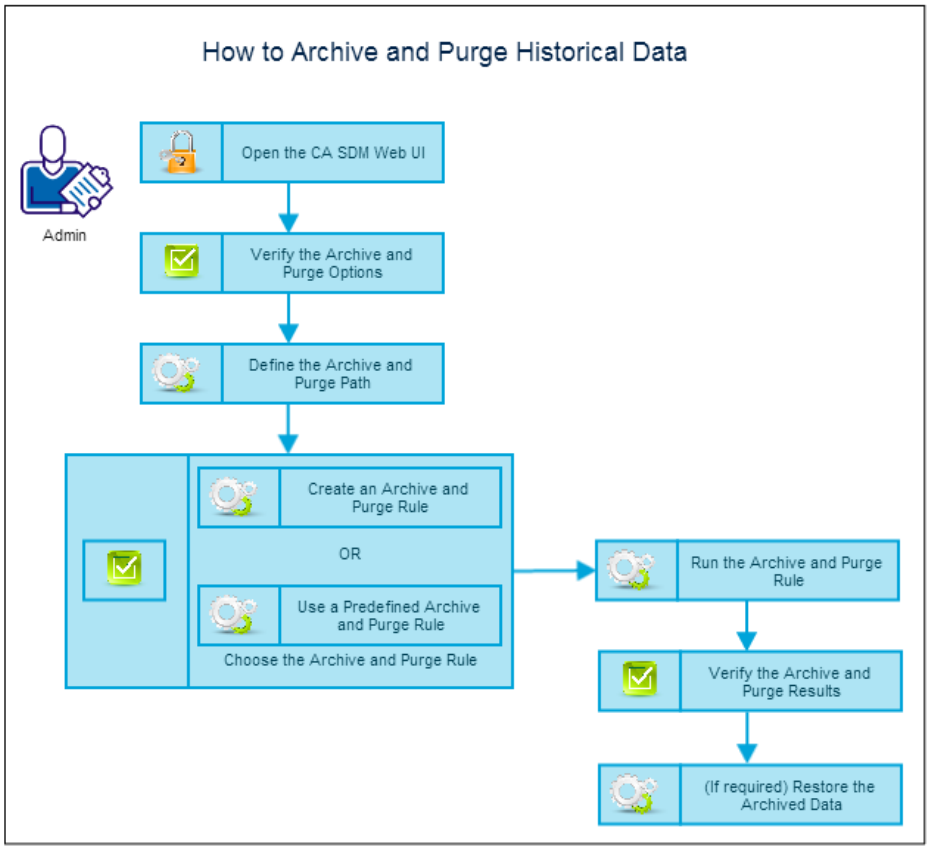
    ```
    pdm_userload -f myData.dat
    ```

    The database table is populated.

How to Archive and Purge Historical Data

Periodically remove the historical records from the system to keep the database at a manageable size for optimum performance. You create rules or activate the predefined rules to archive the historical records and purge them from the database.

The following diagram shows how to archive and purge the historical data:



Follow these steps:

- Open CA SDM Web UI (see page 967)
  - Verify the Archive and Purge Options (see page 968)
  - Define the Archive and Purge Path (see page 968)
- Choose the Archive and Purge Rule (see page 969)
  - Create an Archive and Purge Rule (see page 969)
    - Archive and Purge Rule Fields (see page 971)
  - Use a Predefined Rule (see page 972)
- Verify the Archive and Purge Results (see page 973)
  - View the Archive and Purge History (see page 973)
  - View the Archive and Purge Log File (see page 973)
- (If necessary) Restore the Archived Data (see page 973)

Open CA SDM Web UI

Log in to the web UI from the following servers, depending on your CA SDM configuration:

- Conventional: Primary or secondary servers
- Advanced availability: Application or background servers

Verify the Archive and Purge Options

Before you set up the archive and purge rule, verify the archive and purge options that you may require to install or uninstall, depending on your organization needs. For example, the default_schedule option specifies the default schedule (workshift entry) used by the archive and purge rules. If the option value is set to an invalid workshift entry name or empty string, the rule does not execute the rule with the schedule value. The option value field sets the NX_DEFAULT_SCHEDULE variable, which is located in the NX.env file.

Select Options Manager, Archive and Purge on the Administration tab. Install or uninstall the option that you require.

Define the Archive and Purge Path

You can define the location where you want to store the archived data. This path can be the root directory of a remote server or a UNC path. Depending on your CA SDM configuration, the following servers must run on Windows to access the UNC path:

- Conventional: Primary server
- Advanced Availability: Background server

Follow these steps:

1. Log in to web UI from the following CA SDM servers, depending on your CA SDM configuration:
   - Conventional: Primary or secondary servers
   - Advanced Availability: Application or background servers
2. To archive and purge attachments, complete the following steps:
   a. Select Attachments Library, Repositories on the Administration tab.
   The Repositories page opens.
   b. Right-click on a repository (such as Service Desk) and click Edit.
   The repository details page opens.
   c. Edit the following fields:
      - **Archive Type**
        Specifies the archive and purge action to be taken on the contents of the repository. Following values are valid:
        None: No archive and purge process is performed.
        Archive and Purge:The historic records are written to the file specified in the archive field and purged from the database.
        Purge Only:The historic records are purged from the database, but are not written to the archive file.
      - **Archive Path**
        Specifies the directory path or the UNC path to which files in the repository are moved during the archive process.

- **UNC Credentials**
  Specifies the credentials to access the UNC path. Click UNC Credentials to open the Credentials Search page.

  - If you have already created the credentials to access the specified UNC path, search using the fields and select the credentials.

  - If you want to create the credentials, click Create New. For more information about creating credentials, see the Create UNC Credentials (see page 1096) topic.

d. Click Save.

3. If you want to archive and purge data other than attachments, complete the following steps:

   a. Select Archive and Purge, Archive and Purge Settings on the Administration tab.

   b. Enter the path where you want to store the archived and purged data as the Archive Purge Rule Path.

   c. If you are using a UNC path to store the archived data, click UNC Credentials.
   The Credentials Search page opens.

      - If you have already created the credentials to access the specified UNC path, search using the fields and select the UNC credentials.

      - If you want to create the credentials, click Create New. For more information about creating credentials, see the Create UNC Credentials (see page 1096) topic.

   d. Click Save.

The archive and purge path is defined.

Choose the Archive and Purge Rule

You are required to select the appropriate archive and purge rule. Consider the following possibilities:

- Create an archive and purge rule (see page 969). For example, you create an archive and purge rule for Knowledge Management forums.

- Use a predefined archive and purge rule (see page 972). For example, you use the predefined rules for archiving and purging KPI data.

Create an Archive and Purge Rule

Before you can perform an archive or purge, you create a rule. The rule defines what you want to archive and when.

Example: You create an archive and purge rule to remove deleted forums from the database.

Follow these steps:

1. Select Archive and Purge, Archive and Purge Rules on the Administration tab.
   The Archive and Purge Rule List page opens.

2. Click Create New.
   The Create New Archive and Purge Rule page opens.

3. Complete the archive and purge rule fields (see page 971), as appropriate.

   - Select knowledge document as the Config. Object Name.
   - Add KS_TYPE=20 as the Additional Query.

4. Click Save.
   The new rule is displayed on the Archive and Purge Rule List page.

Example: You create an optional configuration rule inside the arcpur_cfg.xml and itil_arcpur_cfg.xml files to archive and purge the KPI_Ticket_Data node.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:

   - Conventional: Primary server
   - Advanced availability: Background server

2. Find the following files in the $NX_ROOT/site/cfg/ directory:

   - arcpur_cfg.xml
   - itil_arcpur_cfg.xml

3. Edit the files to define the end_time (last_mod_dt) in KPI_Ticket_Data node. It specifies the criteria to select the records for archive and purge.

4. Link the records in the KPI_Ticket_Data table to the records in the Ticket table (such as cr, chg, or iss). This ensures that all ticket-related records in the KPI_Ticket_Data table are archived and purged.

5. KPI_Ticket_Data node does not have a SREL relationship with any Ticket node and it relies on two fields, obj_name, and obj_id, to link with a ticket. The obj_name value can be cr, chg, or iss and the obj_id value is the ticket id. Define a main_obj for each ticket object.
   The following is a sample main_object definition for the ticket object, cr:

```
<!-- KPI Ticket Data -->
<main_obj>
<name>KPI Ticket Data</name>
<internal_name>KPI Ticket Data</internal_name>
<factory>ktd</factory>
<default_query>obj_name='cr'</default_query>
<date_field>end_time</date_field>
<ref_by value="obj_id">cr.id</ref_by>
</main_obj>
```

Note: The configuration rule can only select records for cr. The ref_by tag can match the value of obj_id in KPI Ticket Data to the value of id in cr. If a match is found, it means that a KPI Ticket Data record is referenced by a cr record, so the KPI Ticket Data record is not archived and purged.

6. After adding the configuration rules for all ticket objects, depending on your CA SDM configuration, perform the following steps:

   - Restart the CA SDM servers for conventional (see page).
   - Restart the CA SDM servers for advanced availability (see page 866).

   These configuration rules become selectable configuration object names in the Archive and Purge Rule Detail form.

Archive and Purge Rule Fields

You can use the following fields to define or edit rule definitions.

- **Rule Name**
  Specifies a unique identifier for the rule.
- **Status**
  Indicates whether this rule is active. The inactive rule runs only once, even if it is scheduled for a recurrent process.
- **Schedule**
  Specifies a workshift during which the rule should be in effect.
- **Recurrence Interval**
  Specifies how often this rule will run.
- **Archive File Name**
  Specifies the name of the file where you want to store the historic records. Enter the file name that you have mentioned while defining the archive and purge path. For more information, see the Define the Archive and Purge Path (see page 968) topic.
- **Operation Type**
  Specifies one of the following types of operation that the rule must execute:
  - **Archive/Purge**
    Archives the historic records to a file and purges the archived records from the database.
  - **Purge Only**
    Purges historic records from the database, but they are not written to the archive file.
  - **Archive Only (Test Run)**
    Writes historic records to the archive file without purging them from the database. Use this option to test a newly created or edited archive and purge rule.

- **Config. Object Name**
  Specifies the name of the database object this rule can archive and purge. The Object Name field is automatically populated according to your selection in the Config. Object Name field.

- **Days Inactive**
  Specifies the number of days a record is inactive to be eligible for the archive and purge from the database.

- **Additional Query**
  Archives and purges specific inactive records among the existing inactive records. Use this field when you want to create different rules for archiving and purging the subsets of expired records for the same object. Use the same syntax as you use for stored queries.
  The following query archives and purges only assigned inactive request records with a priority of 1:

  ```
  priority = 1 AND (assignee IS NOT NULL OR group IS NOT NULL) and active = 0
  ```

  The following query format archives and purges records that are based on time-span:

  ```
  close_date < EndAtTime(\'LAST_YEAR\')
  ```

Use a Predefined Rule

You can use the predefined rules in CA SDM to archive and purge historical data. These predefined rules are set to Inactive, by default. Set it active to use the rule.

Example: Use the predefined rule to archive and purge the KPI data.

Follow these steps:

1. Select Archive and Purge, Archive and Purge Rules on the Administration tab.
2. Search for any of the following predefined rules for KPI data:
   - KPI Ticket Data
   - KPI Data (System)
   - KPI Data (Stored Query)
   - KPI Data (SQL)
3. Select the rule from the search result.
4. Click **Edit** to modify the archive and purge rule fields (see page 971).

Important! Ensure that you select the **Active** option from the **Status** field.

5. Click Save.
   The predefined rule is ready for use.

Verify the Archive and Purge Results

You check the results of the archive and purge rule that you have scheduled. Do one or both of the following actions:

- View the Archive and Purge History (see page 973).
- View the Archive and Purge Log File (see page 973)

View the Archive and Purge History

You can view the history for each archive and purge rule. For example, view the objects that are purged by a rule.

Follow these steps:

1. Select Archive and Purge, Archive and Purge History on the Administration tab.
   The Archive and Purge History List page opens.
   Note: To display the Additional Search Arguments field, click the spigot icon. This field is intended only for expert users who understand SQL and Majic and can use it to specify search arguments that are not available in the standard search filter fields. To specify an additional search argument, enter a SQL WHERE clause in this field.

2. Click Show Filter and specify the filter criteria. For example, enter the earliest start date to show only entries from the specified time frame.

The list of matching rules are displayed.

- Click the rule name for which you want to review the rule configuration.
  The Archive and Purge Rule Detail page opens.

View the Archive and Purge Log File

You can check the arcpur.log file from the $NX_ROOT/log/ directory to find the errors that have occurred while executing the scheduled archive and purge rule.

Note: The size limitation for arcpur.log files is defined in $NX_ROOT/NX.env as

```
# The size limit for the Archive and Purge log file and data file.
@NX_ARCPUR_FILESIZE=2000000000
```

Archive and purge creates arcpur.log.0, arcpur.log.1 though arcpur.log.9 after reaching the file limit for each log files.

(If necessary) Restore the Archived Data

You can restore the archived data when you need them in the database again.

Follow these steps:

1. Start the daemons in dbadmin mode. Dbadmin mode allows limited access, so you can safely run pdm_load to restore the archived data. Run the pdm_d_mgr -s DBADMIN command on the following servers, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced Availability: Background server
2. Go to the root directory or the UNC location where you have stored the archived data.
3. Locate the archived data file (.dat file).
4. Copy the file to the following servers, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced Availability: Background server
5. Run pdm_load against the data file. For example:

   ```
   pdm_load -a -f 2004611T1726_Call_Request.dat
   ```

6. If there is a problem with the pdm_load command, complete the following steps:
   a. Check the command line and $NX_ROOT/log/arcpur.log for errors.
   b. Restart the CA SDM servers (see page 866).
7. To prevent the record from being archived and purged at the next cycle, complete the following steps:
   a. Update the record to make it active again.
   b. Inactivate the associated archive and purge rule.

Setting Up Multi-Tenancy

This article contains the following topics:

Manage Multi-Tenancy

This article contains the following topics:

How to Initialize a New Tenant

As the service provider, you may want to build a standard set of data for a new tenant, such as categories, data partitions, ticket templates, and so on. This task can be done by using pdm_extract or pdm_tenant_extract to build a pdm_userload input file containing the data you want.

If necessary, you can edit this file with any text editor. It can then be loaded into the database using pdm_userload with the -t argument to set the tenant column to the new tenant.

The following process describes how to initialize a new tenant:

1. Create the tenant in the ca_tenant table. Use the online Create Tenant (see page) page.

2. Load the standard data as previously described.
   Use pdm_userload -t to set the tenant.

3. Create contact records for the new tenant.
   Load outside data or use pdm_userload -t.

How to Convert an Existing Tenant Implementation to the Tenant Object

You may have used data partitions and another CA SDM object to achieve some of the functionality now provided by multi-tenancy. If you want to convert an implementation to multi-tenancy, the first step is to map the data in the previously-used object to the new tenant object. The previously-used object is called the *pre-tenant* object. For most sites with these requirements, the org (organization) object is the pre-tenant object, but the following approach can be used for any pre-tenant object.

1. If the pre-tenant object is not org, verify that its Majic object definition specifies TENANT_REQUIRED.

2. Verify the attribute mappings from the pre-tenant object to the new tenant object in the buildtenant.xml file in the following location:
   $NX_ROOT/samples/multi_tenancy

Note: You must copy buildtenant.xml to the $NX_ROOT/site/cfg directory. In addition, buildtenant.xsd must be in the same directory as buildtenant.xml, or you will receive an error. When you install the product, buildtenant.xsd is located in $NX_ROOT/site/cfg, so you do not have to copy this file.

The default settings are based on org. If the pre-tenant object is not org, you must edit the file.

3. Run pdm_buildtenant -f (see page 983).
   A new tenant is created for each pre-tenant object, and sets the tenant attribute in the pre-tenant object to reference the new tenant.

4. Log in to CA SDM, and review both the tenant object and the pre-tenant object.

> **Note:** In some situations, you want to map multiple pre-tenant objects to a single tenant object. To do this, manually update the pre-tenant objects affected, and then delete or inactivate the unused tenants.

How to Populate the Tenant Attributes in Your Tables

To populate the tenant attribute in all or a subset of a table, use the *pdm_settenant* utility. This utility uses a configuration file to select the objects to be tenanted and to specify where to obtain the tenant for the objects. You can specify an explicit tenant, or specify that the tenant should be derived from an SREL reference in the object to be tenanted.

To populate the tenant attributes in your tables using pdm_settenant, complete the following steps:

1. Create or edit a configuration file.
   The configuration file selects the rows that will have their tenant attribute set and specifies a source for the tenant attribute's value. The product provides a sample settenant.xml file in the following location:
   $NX_ROOT/samples/multi_tenancy

> **Note:** You can modify the sample settenant.xml file, or create a file and copy it to the $NX_ROOT/site/cfg directory. In addition, settenant.xsd must be in the same directory as settenant.xml, or you will receive an error. When you install the product, settenant.xsd is located in $NX_ROOT/site/cfg, so you do not have to copy this file.

2. Run pdm_settenant -f [configuration file] -r (see page 985)
   The pdm_settenant utility reads its configuration file and processes each rule it defines in sequence.
   We recommend that you use this utility first to populate the tenant attribute in the cnt (contact) object, and then use the cnt object as a source for populating tenant into other objects.
   After the cnt object is properly tenanted, it can be used as a base for setting tenant in other tables by completing the following steps:

   a. Specify a TenantRule with type="SREL" in the configuration file for an attribute referencing the cnt object to set tenant in other tables.

b. (Optional) Specify a TenantRule with type="Name" < tenantname > to set tenant explicitly in some of the tables.

3. Run pdm_settenant with a new configuration file.

4. Rerun pdm_settenant as required.
   After you have populated the tenant column in an object, you can use SRELs to that object as the basis of an SREL TenantRule for setting tenant in other objects.

Example: SREL Type Syntax

SREL type syntaxt checks for cnt objects that do not have a tenant value specified and uses the tenant value from the linked organization object:

```
<Object name="cnt">
<TenantRule type="SREL">organization</TenantRule>
<Where>tenant is null</Where>
</Object>
```

Example: Name Type Syntax

Name type syntax checks for org objects that do not have a tenant value specified and sets their tenant field to the name of an actual Tenant object:

```
<Object name="org">
<TenantRule type="Name">Tenant A</TenantRule>
<Where>tenant is null</Where>
</Object>
```

Tenant Hierarchies

A *tenant hierarchy* is a structured tenant group that is system-created or modified when you assign a *parent tenant* to a tenant. The tenant becomes a *subtenant* of the parent and higher tenants (if any) in that hierarchy.

Note: The service provider can create multiple unrelated hierarchies, or none. Even in a system with tenant hierarchies, you can define standalone tenants.

A subtenant typically represents a subdivision within its *supertenants*. A subtenant can have its own business rules and data, and supertenant data is "pushed" to the subtenant automatically on a read-only basis.

CA SDM supports a tenant hierarchy of unlimited depth. However, the *service provider* can specify a limit on the total number of tenants and the depth of tenant hierarchies (default is four levels). The service provider also determines whether individual tenants can have subtenants.

Note: The service provider can participate in tenant hierarchies, but this is not required. The service provider cannot have a parent tenant.

Create a Subtenant

Subtenancy allows you to build and modify tenant hierarchies for organizational and data-sharing purposes. To place a tenant into a tenant hierarchy, you assign it a parent tenant.

Follow these steps:

1. On the Administration tab, select Security and Role Management, Tenants.

   Note: The Security and Role Management, Tenants option is available only when multi-tenancy is enabled.

2. Click an existing tenant to Edit, or click Create New.
   Enter any required data or changes.

3. Select a Parent Tenant.

   Note: The Parent Tenant drop-down only displays tenants that are allowed to have subtenants.

4. Click Save.
   The tenant is a subtenant of the parent tenant.

   Note: When a tenant is a subtenant, it belongs to the Subtenant group of the parent tenant, as do the subtenants (if any) of that subtenant, and so on. The parent tenant joins the Supertenant group of the subtenant, as do the supertenants (if any) of that supertenant, and so on. Each joins the Related Tenants group of the other.

System-Maintained Tenant Groups

CA SDM generates and maintains three tenant groups automatically for each tenant in a tenant hierarchy (*tenant* is the tenant name):

- *tenant*_subtenants (tenant, its child tenants, and their lower subtenants)
- *tenant*_supertenants (tenant, its parent tenant and its higher supertenants)
- *tenant*_relatedtenants (entire single hierarchy)

System-maintained tenant groups can be used like user-defined tenant groups. However, only their names and descriptions can be modified.

Tenant Data Assignments

CA SDM displays the tenant in the same format in both the View and Edit versions of a detail page for an existing object, because the tenant for an existing object cannot be changed from the web interface.

When you edit a tenanted object, drop-down lists on the edit page are automatically restricted to values that are public, owned by the same tenant as the base object or any tenants above it in the tenant hierarchy, or owned by the service provider (if the drop-down list applies to a SERVICE_PROVIDER_ELIGIBLE attribute).

There are no changes on the detail page for lookup fields associated with a tenanted object. If a user with access to multiple tenants clicks a lookup link to a tenanted table, the web engine automatically restricts the lookup to values appropriate for the attribute, and displays a banner message on the pop-up search or list page.

Note: Tenant restrictions are not displayed in the search filter, and they cannot be changed by the user.

Tenant becomes a selector (either a lookup or a drop-down list) when you ask to create a tenant-required object.

If the tenant field is empty, you can specify a tenant value directly by filling in the field, or indirectly by specifying a value for a tenant-implying attribute (such as Affected End User). The interface displays the following suffixes:

- **(T)**
  Indicates an attribute that is tenant-implying; that is a lookup to a tenant-required table.
- **(TO)**
  Indicates an attribute that is optionally tenant implying that is, a lookup to a tenant-optional table.

web.cfg properties control the text of these indicators.

Except for the tenant attribute itself, tenant-implying attributes are always shown as lookups, even if created with a dtlDropdown macro.

CA SDM automatically sets the tenant when you look up or autofill a tenanted value into any tenant-implying field (except that filling a SERVICE_PROVIDER_ELIGIBLE field with a reference to a service provider object does not set the tenant). After the tenant is set, lookups for tenant-implying fields are restricted in the same way as existing tenanted objects.

Note: Until you save the object, the tenant field remains editable, and you can change the tenant by directly updating it. When you change the tenant, CA SDM automatically clears any tenant-implying fields containing references to objects belonging to the previous tenant.

CA SDM typically initializes the Tenant selector to empty. You can change this behavior in several ways:

- Open the Create New page from a page such as the Quick Profile, which pre-populates a tenant-implying field
- Set the Retain Tenant user preference
  This is a new user preference that initializes the tenant for new objects to the same tenant as the last detail page viewed or updated, or in the last list page search filter restriction.
- Open the page with a URL that explicitly specifies a tenant
  This is not provided in any predefined URL, but is available to allow sites to create menu items or buttons that specify a tenant.

Note: If you create configuration items from another CA Technologies product (such as CA APM) or the command-line interface, then the object is Public.

Create a Tenanted Object

The service provider can add tenant-specific data to objects such as issues, requests, change orders, and so on. You can add a tenant to a ticket (such as an incident) that is created from a Scoreboard tab.

Follow these steps:

1. Click File, New Incident.
2. Complete any of the following steps:
   a. Select the tenant from the Tenant drop-down.
   b. Click Affected End User (or any other tenant-implying field).
      The Contact Search page appears. Search for a user; you can filter the search by tenant.
   c. Enter a name into the Affected End User field.
      The tenant data completes automatically.
3. Continue to create the incident.

Activity Notifications

Activity Notifications control both the contents of notifications and which contacts receive notifications for various events in the history of a ticket.

In a multi-tenancy environment, the notification rule is a tenant-optional object. Public notification rules apply to all tickets; tenanted rules apply only to tickets with the same tenant as the rule, or to tenants in its subtenant hierarchy. The tenanting restriction is applied in addition to any condition specified with the rule itself.

Default Notification Rules are stored as public objects. If multi-tenancy is installed, you must create a copy of the Notification Rule for each of the tenants, otherwise the Update Contacts option is restricted.

Repositories

The repository (doc_rep) object is tenant-optional. Tenants can define their own repositories, and it is possible to define public repositories for objects such as attachments to public knowledge documents. Each tenant can have its own default repository, and you can specify a default public repository.

All attachments are either public or associated with a single tenant. If a tenant does not have its own default repository, the public repository is displayed as the default for its tenanted objects.

How to Export and Import Tenant Data

This article contains the following topics:

The service provider can extract tenant data from an existing multi-tenancy implementation and import it into a new system.

Note: Depending on the volume of your data, the extraction process can take several hours. You may have to perform the extract and import in multiple phases, as follows:

- **Initial**
  Extracts a base line and creates a control file used in subsequent phases .
- **Update**
  Uses the control file to extract only data that has changed since the previous run.
- **Final**
  Performs the same steps as Update, except that it also extracts animations. Animations are omitted from both the Initial and Update phases.

To extract data from one database and import it into another, complete the following steps:

1. Run an initial phase of pdm_tenant_extract (see page 989) to extract base-line data. This builds the control file used by subsequent phases.

2. Prepare a new, clean MDB for the extracted data.

   Important! The output from the initial phase *must* be loaded into a database that has never been used for the product or for any other product. Each table loaded from initial phase data is truncated prior to the load, which could cause loss of data if the database is already in use.

3. To avoid duplicate privileged contacts appearing on the new system, you must inactivate the privileged contacts. Log onto CA SDM and change the Status of these contacts to "inactive" before loading the extracted data.

4. To avoid referential problems during the data load, run the appropriate drop constraints script:

   - (Oracle) Run $NX_ROOT/samples/views/Oracle/OracleDropConstraints.sql
   - (SQL Server) Run $NX_ROOT/samples/views/SQLServer/SQLDropConstraints.sql

5. Use pdm_userload (see page 990) to load the data from the initial phase into the clean MDB prepared in steps 2 and 3.

6. Run an update or final phase of pdm_tenant_extract to extract additional data created or modified since the previous phase. Pdm_tenant_extract uses the control file created in step 1 to determine the data already processed by the previous phase.

7. Use pdm_userload to load the data extracted in step 5 into the same MDB containing data loaded from the previous phases.

   Note: For more information about this utility, see pdm_userload (see page 990).

8. Repeat steps 5 and 6 as required until all data has been imported into the new database. The last run should be the final phase.

9. To protect the integrity of the new database, restore the constraints dropped in step 3 by running the appropriate add constraints script:

   - (Oracle) Run $NX_ROOT/samples/views/Oracle/OracleAddConstraints.sql
   - (SQL Server) Run $NX_ROOT/samples/views/SQLServer/SQLAddConstraints.sql

10. Use pdm_tenant_delete (see page 987) to delete the extracted data from the original database.

11. Ensure that all repositories associated with extracted tenants are copied to the target settings.

How to Handle Attachments and Repositories

Attachments are stored in repositories. You must copy all repositories that are associated with extracted tenants to the target system, including public repositories. This process is primarily a manual operation, with the following steps:

1. Redefine location-specific information for all repositories, after completion of the initial load of the data into the target system. This task includes changing the following values:
   - Server Name
   - Upload Path
   - Servlet Path
   - Archive Path
2. Manually create all required directories and folders.
3. Copy all attachment files from the previous location to the new repository location after (or during) the load of the data from the Final phase.

After you complete these steps, all references for attachments in the target system should be successful. However, copies of the attachments remain on the source system. Use the pdm_clean_attachments.pl utility (see page 985) to clean these redundant attachments.

Utilities Used for Multi-Tenancy

This article contains the following topics:

This section describes utilities that are used to manage a multi-tenancy environment.

Note: Required parameters are enclosed within "{ }", while optional parameters are in "[ ]".

pdm_buildtenant -- Creating Tenants from Another Object

The *pdm_buildtenant* utility is used to create tenants from another object. You may have used data partitions and another CA SDM object to achieve some of the functionality now provided by multi-tenancy. If you want to convert an implementation to multi-tenancy, the first step is to use pdm_buildtenant to map the data in the previously-used object to the new tenant object.

Important! Before you run pdm_buildtenant, you *must* configure the service provider.

In this section, the object used to hold tenant-like information is named the pre-tenant object. For most sites with these requirements, the org (organization) object is the pre-tenant object, but the following approach can be used for any pre-tenant object.

The pdm_buildtenant utility builds the tenant objects from pre-tenant objects. This application creates a tenant for each pre-tenant object, and sets the tenant attribute in the pre-tenant object to reference the new tenant. This utility has the following syntax:

```
pdm_buildtenant [-h] | [-f [configuration_file]
```

- **-f configuration_file**
  (Optional) Specifies the location of a configuration file specifying the rules for creating tenants from the pre-tenant object. If this argument is not included, pdm_buildtenant uses the configuration file from the $NX_ROOT/site/cfg directory. This file assumes the pre-tenant object is org; if this is not the case, you *must* edit the configuration file before using pdm_buildtenant.

  Note: You *must* copy buildtenant.xml to the $NX_ROOT/site/cfg directory. In addition, buildtenant.xsd must be in the same directory as buildtenant.xml, or you receive an error. When you install the product, buildtenant.xsd is located in $NX_ROOT/site/cfg, so you do not have to copy this file.

- **-h**
  Displays usage information for pdm_buildtenant.

The following is the format of the configuration file:

```
<?xml version="1.0" encoding="utf-8" ?>
<BuildTenant>
   <Object from="MajicObjectName">
    <Attribute from="sourceAttribute1" to="tenantAttribute1" />
    <Attribute from="sourceAttribute2" to="tenantAttribute2" />
   </Object>
</BuildTenant>
```

The *from* attribute of the Object tag identifies the pre-tenant object. Each Attribute tag identifies an attribute to be copied from the pre-tenant object to an attribute of the new tenant.

Important! For UNIX implementations of multi-tenancy, you *must* run pdm_task to export LIBPATH before executing the pdm_settenant and pdm_buildtenant utilities. If you do not run pdm_task before executing these utilities, you receive system errors. Use ../pdm_task to run the command.

pdm_clean_attachments -- Delete Redundent Attachments After Importing Tenant Data

After importing tenant data, you should delete redundant attachments. This utility has the following syntax:

```
pdm_perl pdm_clean_attachments.pl [-h] | [-n repository_name] | [-S|-K]
```

- **-h**
  Specifies to display command line help.
- **-n *repository_name***
  Specifies the name of the repository to process. If not specified, all repositories are processed.
- **-S**
  Specifies that only CA SDM repositories are processed.
- **-K**
  Specifies that only Knowledge Management and Embedded Images repositories are processed.

Note: Running the pdm_clean_attachments.pl command without any arguments processes all repositories.

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use *pdm_task* to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

pdm_settenant -- Assigning Tenants to Objects

After you define tenants, you must use the *pdm_settenant* utility to set the tenant column in other objects. This utility has the following syntax:

```
pdm_settentant [-h] | {-f [configuration_file] | -r} [-d domsrvr]
```

- **-d domsrvr**
  (Optional) Specifies a domsrvr to use. If this argument is not specified, pdm_settenant uses the default domsrvr.
- **-f *configuration_file***
  (Optional) Specifies the location of a configuration file specifying the data that will be updated and the rules for updating the file. If this argument is not specified, pdm_settenant uses the configuration file from the $NX_ROOT/site/cfg directory (after the configuration file is copied to the $NX_ROOT/site/cfg folder).
  Note: You can modify the sample settenant.xml file, or create a file and copy it to the $NX_ROOT /site/cfg directory. In addition, settenant.xsd must be in the same directory as settenant.xml, or you will receive an error. When you install the product, settenant.xsd is located in $NX_ROOT/site /cfg, so you do not have to copy this file.

The following sample XML code describes the format of this file:

```
<?xml version="1.0" encoding="utf-8" ?>
<SetTenant>
   <Object name="MajicObjectName">
    <TenantRule type="SREL">MajicColumName</TenantRule>
    <Where>tenant is null</Where>
   </Object>
   <Object name="MajicObjectName">
   <TenantRule type="Name">TenantName</TenantRule>
   <Where>tenant is null</Where>
   </Object>
</SetTenant>
```

Each Object tag specifies a CA SDM object to be tenanted. The TenantRule tag specifies how pdm_settenant should determine the tenant, and the Where tag selects the objects to be tenanted. There are two types of TenantRule tags:

- type="Name"
  Specifies an explicit tenant by name.

- type="SREL"
  Specifies an SREL attribute in the object. Pdm_settenant copies the tenant of the object referenced by the SREL.

- **-h**
  Displays usage information for pdm_settenant.

- **-r**
  Outputs a report displaying the total number of rows in each tenant-required table, and how many have a null tenant column.

Note: If both the -f and -r arguments are specified, pdm_settenant outputs a report after completing its update. If you only specify the -r argument, pdm_settenant outputs a report, but does not update any data.

Running pdm_settenant without any arguments displays usage information. To run pdm_settenant using the default configuration file, specify the -f option without the configuration_file argument. The pdm_settenant utility reads its configuration file and processes each rule it defines in sequence. It writes output to the pdm_settenant.log file in the $NX_ROOT/log directory.

You can run pdm_settenant as many times as needed. The first pass may take a significant time (possibly several hours at a large site). Subsequent passes run faster, as they only need to process rows that have not been updated. This prepares the database prior to installing the multi-tenancy option.

Important! On UNIX implementations of multi-tenancy, you must run pdm_task to export LIBPATH before executing the pdm_settenant and pdm_buildtenant utilities. If you do not run pdm_task before executing these utilities, you will receive system errors. Use .. /pdm_task to run the command.

Assign Tenants to Objects Considerations

After you define tenants, you can use the pdm_settenant (assign tenants to objects) utility to set the tenant column in other objects. When you change the tenant for an object, you must consider whether to change the tenancy on related tenanted objects in order to maintain data integrity. Failure to keep these objects synchronized can cause data to appear missing from CIs, relationships, MDRs, versioning, and so on. The following CA CMDB objects are tenanted:

- nr -- CI definitions
- nr_com -- Log entries associated with a CI
- bmhier -- Relationships associated with CIs
- mdr_idmap -- MDR provider definitions
- ci_mdr_idmap -- CI/MDR federated mappings

For each CI, do the following to synchronize data when you use pdm_settenant to change tenancy:

- Specify nr for the CI object name.
- Change the log entries associated with the CI in nr_com so that you can view the log entries for the new tenant.

Example: XML to Change the Tenant and Log

The following XML changes the tenant for a CI named CITest to T2 and also changes the corresponding log entries in nr_com:

```
<TenantRule type="Name">T2</TenantRule>
<Where>name = 'CITest'</Where>
</Object>
<Object name="nr_com">
<TenantRule type="Name">T2</TenantRule>
<Where>asset_id.name = 'CITest'</Where>
\</Object>
```

pdm_tenant_delete -- Deleting Tenant Data from a Database

The *pdm_tenant_delete* utility removes all data for a specified tenant from the database.

Important! The referential constraints on the ca_ tables must be dropped before running pdm_tenant_delete and restored afterwards.

This utility has the following syntax:

```
pdm_tenant_delete -h|-t tenant_name [-C|-R] [-Q]
```

- **-h**
  Displays the usage information for pdm_tenant_delete.

- **-t *tenant_name***
  Specifies the name of the tenant of the data to be deleted.

  Note: The tenant must be marked inactive before you can use this utility to delete the data.

- **-C**
  Specifies that all contacts for a tenant will be marked inactive. Since contacts can be shared between products, default logic should not mass delete or mass inactivate contacts unless explicitly requested.

  Note: This option is ignored if the -R option is specified.

- **-R**
  Specifies that all rows in all tenanted tables marked CA_COMMON in ddict.sch will be deleted, including the tenant object itself.

  Important! These tables are shared between multiple products, so use this option with caution.

- **-Q**
  Specifies quick query processing to execute database queries as fast as possible. If this argument is not specified, the utility uses background query processing so that queries run only when the system is otherwise idle. This argument improves running time at the expense of a greater impact on an active system.

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use *pdm_task* to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

pdm_tenant_extract -- Extracting Tenant Data

The *pdm_tenant_extract* utility extracts all data for a specified tenant from the database. It extracts the data in pdm_userload format so that it can easily be loaded into another database. This utility has the following syntax:

```
pdm_tenant_extract -h | -c control_file [-d domsrvr] [-g yes|no] [-o output_file]    -
p phase  [[-t tenant_name]...] [-Q] [table1 [table2...]]
```

- **-h**
  Displays the usage information for pdm_tenant_extract.

- **-c *control_file***
  Specifies the location of the control file for this tenant extract. For the Initial phase, the file is created in the specified location (and must not already exist). The file must exist for the Update and Final phases.

- **-d domsrvr**
  (Optional) Specifies a domsrvr to use.

- **-g yes|no**
  (Optional) Specifies whether or not public data is included in the output file. If this argument is not specified, public data from all tables is included.

- **-o *output_file***
  (Optional) Specifies the location of the output file. If this argument is not specified, output is directed to stdout.

- **-p *phase***
  Specifies the phase of the extract. Use one of the following values:
  I -- Initial
  U -- Update
  F -- Final

- **-t *tenant_name***
  Specifies the name of a tenant to be extracted. This argument is required for the Initial phase and can be repeated for multiple tenants. It is not valid on the Update and Final phase.

- **-Q**
  Specifies quick query processing to execute database queries as fast as possible. If this argument is not specified, the utility uses background query processing so that queries run only when the system is otherwise idle

- ***table1 [table2...]***
  (Optional) Specifies the tables to extract. If omitted, all tables are extracted.

Important! The output from the initial phase must be loaded into a database that has never been used for CA SDM or for any other product. Each table loaded from initial phase data is truncated prior to the load, which could cause loss of data if the database is already in use.

Note: To avoid referential problems during the data load, run the appropriate drop constraints script ($NX_ROOT/samples/views/Oracle/OracleDropConstraints.sql or $NX_ROOT/samples/views/SQLServer/SQLDropConstraints.sql). After the loads complete, re-apply the constraints with the appropriate xxxAddConstraints.sql script found in the same directory.

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use *pdm_task* to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

pdm_userload -- Load Tenant Data

The *pdm_userload* utility is used to load data into a CA SDM database. This utility is available even if multi-tenancy is not installed. Multi-tenancy adds support for one additional argument (-t) that specifies the name of a tenant whose id must be inserted into the tenant column of all rows inserted or updated into a tenanted table. `The specified tenant must already be in the database.

When extracting data, complete the following steps to avoid errors in stdlog:

1. Before you start loading data, shut down CA SDM and restart the product in DBADMIN mode as follows:
   - **Windows**
     Run pdm_d_mgr -s DBADMIN
   - **UNIX**
     Run pdm_init -s DBADMIN
2. After the data loads, shut down CA SDM using the pdm_halt command.
3. Restart CA SDM in normal mode.

How to Implement Multi-Tenancy

This scenario describes how an administrator, as the CA SDM privileged user, implements multi-tenancy for the first-time. From start to finish, the CA SDM implementation changes as follows:

1. A single client uses a single implementation.
2. Multiple independent clients (tenants) and their users *share* a single implementation. Each tenant experiences the implementation as solely for its own use.

As the administrator, you use the CA SDM Administration interface to perform these steps:

1. Step 1: Install and enable multi-tenancy in setup mode (see page).
2. Step 2: Create the service provider tenant (see page).
3. Step 3: Create additional tenants (see page).
4. Step 4: Assign tenant access for a role (see page).
5. Step 5: Create subtenants (see page).
6. Step 6: Create tenant groups (see page).
7. Step 7: Change multi-tenancy to on mode (see page) and restart services.
8. Step 8: Review the implementation and correct (see page) any problems.

Step 1: Install and Enable Multi-Tenancy

You activate multi-tenancy by installing a multi-tenancy option in the product, and then enabling the setup mode. The setup mode specifies that multi-tenancy features are in effect for administrators. This mode lets you can view and edit tenant-related objects and attributes. However, the product does not enforce tenancy restrictions, and nonadministrator users see no changes. This mode lets you prepare multi-tenancy by performing tasks such as defining tenants or assigning tenants to roles without impacting normal use of the product.

Important! When multi-tenancy is in setup mode, web interface changes are active for service provider administrators. This behavior lets you view and edit tenancy-related objects and data on the web interface. However, tenancy restrictions are not enforced, and users other than service provider administrators do not see any product interface changes. Therefore, you can continue to use the product while implementing multi-tenancy.

Follow these steps:

1. Log in to CA SDM as an administrator and click the Administration tab.
2. In the tree on the left, click Options Manager, Multi-Tenancy.
   The Option List page appears.
3. Click multi_tenancy.
   The multi_tenancy Options Detail page appears.
4. Click Edit.
   The Update Options page appears.
5. Select setup from the Option Value drop-down list.
6. Click Install.
   The multi_tenancy option is installed.

7. Click Refresh.
   The page displays your changes.

8. Close the window.
   The Option List page reappears.

9. Restart services.
   Multi-tenancy is ready for you to implement in setup mode.

Step 2: Create the Service Provider Tenant

You use the product to create the service provider tenant. When you create the first tenant, the following occurs:

1. The first tenant always becomes the service provider.

   Important! You cannot change this designation -- on the Create Tenant page, the Service Provider check box and Record Status field are read-only.

2. The product associates the privileged user (typically ServiceDesk on Windows, or srvcdesk on Linux/UNIX) to the service provider tenant. The product sets all system contacts (such as System_AHD_Generated) to belong to the new service provider tenant.
   Note: Windows provides an Administrator system user. The privileged user must assign a tenant to the Administrator user manually.

Follow these steps:

1. Select Security and Role Management, Tenants on the Administration tab.

   Note: The Security and Role Management, Tenants option is available only when multi-tenancy is installed and in either setup or on mode.

2. Click Create New.
   The Create New Tenant page appears.

3. Complete the following fields:

   - **Name**
     Displays the tenant name.

   - **Service Provider**
     Identifies that this tenant is the service provider.

   - **Tenant Number**
     (Information Only) Displays the tenant number. CA SDM does not use this option.

- **Record Status**
  Sets the tenant to Active or Inactive.

- **Parent Tenant**
  Specifies another tenant above this tenant, making this tenant a subtenant in a tenant hierarchy.

- **Subtenants Allowed**
  Allows this tenant to have subtenants. The tenant cannot modify the setting.

- **Tenant Depth**
  (Information Only) Indicates the tenant depth of this tenant.

- **Supertenant Group**
  (Information Only) Identifies the system-maintained tenant group that contains this tenant and all tenants above it in the tenant hierarchy.

- **Subtenant Group**
  (Information Only) Identifies the system-maintained tenant group that contains this tenant and all tenants below it in the tenant hierarchy.

- **Foreign Key Group**
  (Information Only) Identifies the system-maintained tenant group that contains tenants that can be referenced from an SREL in data that belongs to this tenant. The foreign key group is the same as the supertenant group.

- **Related Tenant Group**
  (Information Only) Identifies the system-maintained tenant group consisting of both the supertenant and subtenant groups for this tenant.

- **Terms of Usage**
  Specifies the Terms of Usage statement for the tenant. For more information about creating a terms of usage statement, see Setting Up Terms of Usage (see page 1000).

- **Logo**
  Specifies the URL for the tenant logo file, which can be any web image type.

- **Location**
  Displays the Location lookup page, which lets you specify a location.

- **Contact**
  Displays the Contact lookup page, which lets you specify a contact.

Note: If no contact is associated with the respective tenant, the Email Address and Pager Email Address fields are inactive.

4. Click Save.
   The product creates the service provider tenant.

5. Close the window.

6. Right-click the Tenant list and click Refresh.
   The Tenant List is updated and displays the service provider tenant.

7. Log out of CA SDM.

Step 3: Create Tenants

You use the product to create additional tenants. You can create as many tenants as required to manage multiple separate enterprises that provide support to clients.

Follow these steps:

1. Log in to the Administrator interface as a member of the service provider. An easy way to do this login is to log in as the privileged user (for example, ServiceDesk). This user automatically belongs to the service provider tenant.

2. Select Security and Role Management, Tenants on the Administration tab.

   Note: The Security and Role Management, Tenants option is available only when multi-tenancy is installed and in either setup or on mode.

3. Click Create New.
   The Create New Tenant page appears.

4. Complete the fields in this page. Some of the fields are self-explanatory. Following fields require explanation:

   - **Service Provider**
     Identifies whether a tenant is the service provider. The first created tenant is always the service provider, afterward, this check box is read-only.

   - **Tenant Number**
     (Information Only) Displays the tenant number. CA SDM does not use this option.

   - **Subtenants Allowed**
     Allows this tenant to have subtenants. The tenant cannot modify the setting.

   - **Tenant Depth**
     (Information Only) Indicates the tenant depth of this tenant.

   - **Supertenant Group**
     (Information Only) Identifies the system-maintained tenant group that contains this tenant and all tenants above it in the tenant hierarchy.

   - **Subtenant Group**
     (Information Only) Identifies the system-maintained tenant group that contains this tenant and all tenants below it in the tenant hierarchy.

- **Foreign Key Group**
  (Information Only) Identifies the system-maintained tenant group that contains tenants that can be referenced from an SREL in data that belongs to this tenant. The foreign key group is the same as the supertenant group.

- **Related Tenant Group**
  (Information Only) Identifies the system-maintained tenant group consisting of both the supertenant and subtenant groups for this tenant.

- **Terms of Usage**
  Specifies the Terms of Usage statement for the tenant. For more information about creating a terms of usage statement, see Setting Up Terms of Usage (see page 1000).

- **Logo**
  Specifies the URL for the tenant logo file, which can be any web image type.

> **Note:** If no contact is associated with the respective tenant, the Email Address and Pager Email Address fields are inactive.

5. Click Save and close the window.
   The product creates the tenant.

6. (Optional) Click Tenant Groups to add this tenant to a new group or to an existing one.

Step 4: Assign Tenant Access for a Role

The role of a CA SDM user governs both access authorization and the user interface. The roles available to users depend on their access type. Multi-tenancy lets you control the tenant or tenant group that a user can access within the role. When multi-tenancy is installed, the Role Detail page includes additional options that let you assign or edit tenant access.

> **Note:** You can grant tenant users access to data other than their own. Non-service provider tenant analysts only have access to their own tenant and subtenants. However, you can you update their function access to include the tenant of the analyst. For example, you can define a role to set separate read and write access to certain tenant groups for users within that role.

Follow these steps:

1. Navigate to Security and Role Management, Role Management, Role List.
   The Role List appears.

2. Click the role for which you want to assign tenant access.
   The Role Detail page appears and provides Tenant Access and Tenant Write Access drop-down lists on its Authorization tab. Tenant Access is view-only, and Tenant Write Access allows create and update also.

3. Click Edit.
   The Update Role page appears.

4. Select options for Tenant Access and Tenant Write Access:

   - **Same As Tenant Access**
     Sets the access to be the same as the Tenant Access setting. This value is the default for the Tenant Write Access drop-down list and is only available for the Tenant Write Access option.

   - **All Tenants**
     Removes tenant restrictions. A user in a role with this access can do the following:

     - View any object in the database (read access).

     - Create and update (write access) any tenanted object in the database.

     When a user with All Tenants access creates an object, the user must select the tenant of the new object.

   - **Single Tenant**
     Sets tenant access for a role to a named tenant. When you select this option, another field appears that lets you select a specific tenant. A user in this role can access only those objects associated with the named tenant.

   - **Tenant Group**
     Sets tenant access for a role to a user-defined or system-maintained tenant group. After you select this option, another field appears that lets you select a specific tenant group. A user in this role can access only those objects associated with one of the tenants in this group. When a user with tenant group access creates an object, the user must select the tenant for the new object.

   - **Contact's Tenant**
     Sets tenant access for the role to the tenant of the contact using it. A user in this role can access only those objects associated with their own tenant.

   - **Contact's Tenant Group**
     Sets role access for an analyst role to the tenant group that the analyst works with, as specified on the contact record for the analyst. If the user with the role is not an analyst, this selection has the same effect as Contact's Tenant. This option is only available for analysts.

   - **Contact's Subtenant Group**
     Sets tenant access for the role to the subtenant group of the contact using it. A user in this role can access only those objects associated with their own subtenant group.

   - **Contact's Supertenant Group**
     Sets tenant access for the role to the supertenant group of the contact using it. A user in this role can access only those objects associated with their own supertenant group.

   - **Contact's Related Tenant Group**
     Sets tenant access for the role to the Related Tenants Group of the contact using it. A user in this role can access only those objects associated with their own related-tenant group.

- **Update Public**
  Controls whether a service provider user in the role has the authorization to create or update public data. All users can view public data, regardless of access rights for the current role. Tenant users (users belonging to a tenant other than the service provider) cannot update public data, regardless of their role.

- **Click Save**
  Tenant access is assigned for the role. When a user queries the database, the product restricts the results to objects belonging to tenants associated with the role of the user.

Step 5: Create Subtenants

Subtenancy lets you define and modify tenant hierarchies for organizational and data-sharing purposes. To place a tenant into a tenant hierarchy, you assign the tenant a parent tenant.

Follow these steps:

1. On the Administration tab, select Security and Role Management, Tenants.
   The Tenant List appears.

   Note: The Security and Role Management, Tenants option is available only when multi-tenancy is enabled.

2. Click an existing tenant to Edit, or click Create New.
   The Tenant Detail page appears, which lets you enter any required data or changes.

3. Select a Parent Tenant.

   Note: The Parent Tenant drop-down list only displays tenants that are allowed to have subtenants.

4. Click Save.
   The tenant is a subtenant of the parent tenant.
   Note: When a tenant is a subtenant, it belongs to the subtenant group of the parent tenant. The parent tenant joins the supertenant group of the subtenant. Each tenant joins the Related Tenants group of the other.

Step 6: Create Tenant Groups

A tenant group is a collection of tenants that share access to CA SDM objects. Tenant groups let you classify, manage, and control access to tenants. You can assign a role to a tenant or tenant group. When multi-tenancy is active, the product associates each role with: all tenants (public), a single tenant, or a single tenant group. Use tenant groups whenever a role needs access to more than one tenant. For example, you can assign analysts to a tenant group containing tenants belonging to a particular geographic location.

The product generates and maintains three tenant groups automatically for each tenant in a tenant hierarchy (*tenant* is the tenant name):

- *tenant*_subtenants (tenant, its child tenants, and their lower subtenants)
- *tenant*_supertenants (tenant, its parent tenant and its higher supertenants)
- *tenant*_relatedtenants (entire single hierarchy)

You use the system-maintained tenant groups like user-defined tenant groups. However, you can only change the system-maintained tenant group names and descriptions.

Example: Role A Needs Access to Tenant A, Tenant B, and Tenant J

Instead of assigning the role to each tenant separately, you can do the following:

1. Create a tenant group, and add Tenant A, Tenant B, and Tenant J to the group.
2. Assign Role A to this tenant group.
   Users (contacts) assigned to Role A can access the tenant group, which is comprised of Tenants A, B, and J.

Follow these steps:

1. Log in as the service provider, click the Administration tab, and select Security and Role Management.
2. Click Tenant Groups.

   Note: The Security and Role Management, Tenant Groups option is available only when multi-tenancy is installed (either on or setup).

3. Click Create New.
   The Create New Tenant Group page appears.
4. Complete the tenant group fields and click Save.
   The tenant group is created.
5. Close the window.
   The Tenant Group List appears.

6. Right-click the Tenant List and select Refresh.
   The Tenant Group List is updated.

7. Click Update Tenants on the Tenant Group Detail page and add tenant members to the group.

8. (Optional) Repeat Steps 3 through 6 for each tenant group you want to create.

Step 7: Change Multi-Tenancy to On Mode

You change changing the Multi-Tenancy option to on mode to make the multi-tenancy implementation function fully. Each tenant then views the implementation as solely for its own use. Each tenant cannot update or view the data of another tenant.

Follow these steps:

1. Log in to CA SDM as an administrator, and click the Administration tab.

2. In the tree on the left, click Options Manager, Multi-Tenancy.
   The Option List page appears.

3. Click multi_tenancy.
   The multi_tenancy Options Detail page appears.

4. Click Edit.
   The Update Options page appears.

5. Select setup from the Option Value drop-down list.

6. Click Edit.
   The Update Options page appears.

7. Select on (the default) from the following values in the Option Value drop-down list:

   - **on**
     (Default) Disallows a check-in to a tenant-required table when the tenant is null and an SREL to a table with a tenant is not available.

   - **on (warn)**
     Writes an error to the log but allows the check-in to proceed when a tenant-required object with a null tenant is created or updated.

   - **on (allow)**
     Writes a warning to the log but allows the check-in to proceed when a tenant-required object with a null tenant is created or updated.

8. Click Save, and then Refresh.
   The page displays your changes.

9. Close the window.
   The Option List page reappears.

10. Restart services.
    Multi-tenancy is fully functional.

Step 8: Review the Implementation and Correct

Review the multi-tenancy implementation and correct any problems.

Follow these steps:

1. Log in to CA SDM using the privileged username (typically ServiceDesk).

2. Click the Administration tab and browse to the Tenant List.
   The Provider shows as Yes for the privileged user in the Tenant Name.

3. Verify that your multi-tenancy restrictions are enforced by browsing to a Contact List.
   If tenant-required tables incorrectly include untenanted data in a multi-tenancy system, the following message appears in the Contact List:

   ```
   AHD05358 There were nn untenanted active Contact objects at CA Service Desk Manager startup.
   ```

   Important! If untenanted data is in the database, you can set the multi-tenancy option mode to on (warn) or on (allow). These modes let you update tenant-required tables with a null tenant. This method prevents data loss when a service level agreement (SLA) or attached event executes for a ticket that does not include a tenant.

4. (Optional) Disable multi-tenancy if problems occur and complete the following steps:

   a. Restore the Domain_Constraint and usp_role tables.

   b. Set the Multi-Tenancy option to the setup mode.

   c. Recycle the system.

   The site can resume previous operations while you correct whatever issues required the reversion.

Setting Up Terms of Usage

Contents

For each tenant, you can configure a terms of usage statement which presents the end user with an initial statement when they log in to CA SDM. The terms of usage statement reminds the end user about the proper use of the product that they must agree to before they can continue to log in to CA SDM. A log is generated after the user Accepts or Rejects the statement.

In CA SDM, you can configure a terms of usage statement from the Security and Role Management node on the Administration tab. You can set the Service Provider tenant or subtenants to display the same or different terms of usage statements. You select the terms of usage statement in the Terms of Usage field on the Tenant detail form.

Note: You must enable multi-tenancy and configure one or more tenants before you can associate a terms of usage statement with a tenant.

Create a Terms of Usage Statement

End users are presented with a terms of usage statement when they log in to CA SDM that they must agree to before they can continue to log in. You can create a terms of usage statement and select it to display for a tenant or an analyst.

Follow these steps:

1. Select Security and Role Management, Terms of Usage on the Administration tab.

   The Terms of Usage List page appears.

2. Click Create New.

   The Create New Terms of Usage page appears.

3. Complete the following fields and click Save:

   Name

   Displays the name of the terms of usage statement.

   Status

   Sets the terms of usage statement as active or inactive.

   Description

   Displays a description of the terms of usage statement.

   Text
   Specifies the text of the terms of usage statement. Click the Edit Terms of Usage button to edit the text in an HTML editor.

   The Terms of Usage statement is saved. You can now associate the terms of usage with your tenants.

Update Terms of Usage Statement of a Tenant

You can configure a tenant to display a terms of usage statement upon login. The end user must accept the terms of usage statement before they can continue to log in.

Follow these steps:

1. Select Security and Role Management, Tenants on the Administration tab.

   The Tenant List page appears.

2. Select the Tenant link you want to update.

   The Tenant Detail page appears.

3. Click Edit.

   The Update Tenant page appears.

4. Select the terms of usage statement from the Terms of Usage drop-down and click Save.

   Note: If you select <empty> in the Terms of Usage drop-down, CA SDM displays the terms of usage statement for the tenants parent, grandparent, and so on until a terms of usage statement is found. If a terms of usage statement is not found at any level, CA SDM proceeds with the login. If you create a terms of usage statement without text, CA SDM does not display a terms of usage statement and lets the end user log in to CA SDM.

   The tenant is updated.

Setting Up Security

This article contains the following topics:

Before you allow people to use CA SDM, it is important that you set up security to determine the following:

- Which users can access the system

- What level or levels of access users can have
- How users are authenticated when they log in

CA EEM User Base Configurations

CA EEM is a central repository of user information (identities). CA EEM defines user authentication and access to other applications. If you have several CA Technologies products installed, some of them can use CA EEM to store identities and access policies. CA SDM only uses CA EEM for authentication. CA EEM is not a CA SDM configuration option and must be installed separately.

The CA EEM repository of user records is *either* of the following sources:

- An external LDAP directory
- Its own internal tables in the MDB

CA EEM has an LDAP interface for use when it is configured to use the MDB.

Note: The MDB tables used by CA EEM are different from the ones used by CA SDM.

If your organization uses a directory server, such as Active Directory or eTrust Directory, consider configuring CA EEM to use the directory for its user base. This configuration makes the users in your directory accessible by any other application that uses CA EEM. Because CA EEM centralizes access management, it is typically installed on a single server.

CA SDM

CA SDM stores contact information in MDB tables. These tables have no relationship to CA EEM. CA SDM does not use CA EEM for access or identity management. CA SDM manages its own access and security with Access Types and Data Partitions.

CA SDM uses CA EEM only for authentication. If you want to use CA EEM to authenticate users in CA SDM, install CA EEM. If you integrate CA SDM with CA EEM, it replaces the CA SDM operating system authentication with CA EEM authentication.

Note: To integrate CA EEM and CA SDM, you must set the *eiam_hostname*, *use_eiam_artifact*, and *use_eiam_authentication* options in Options Manager, Security.

To summarize:

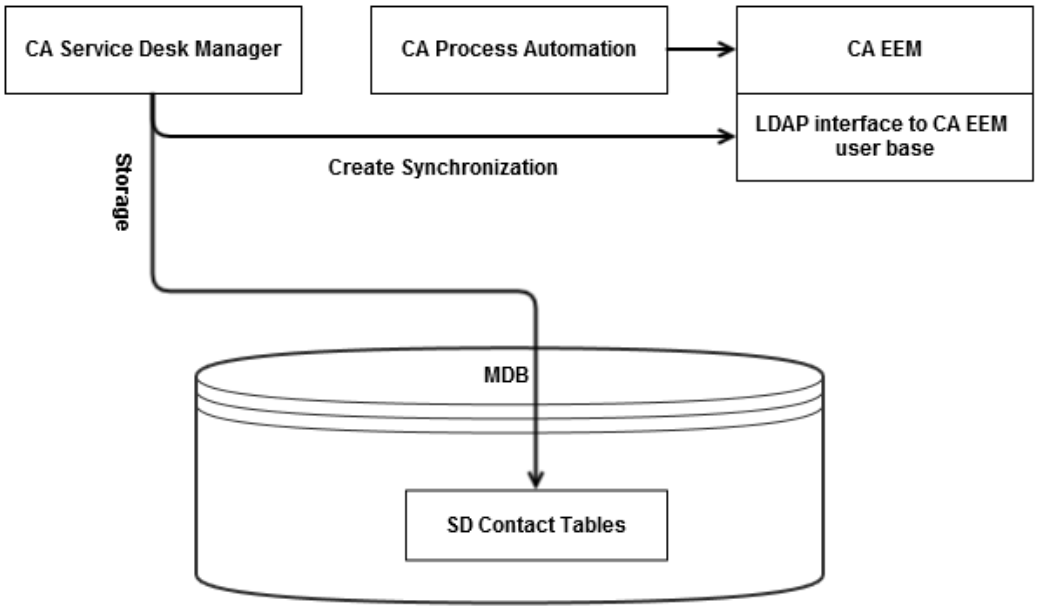
- The CA SDM user base is separate from that of CA EEM.
- CA SDM uses the MDB to store Contact information. CA SDM also features an LDAP integration, which allows it to create new Contacts from an LDAP server and synchronize existing contacts with the directory.

- CA EEM is CA's solution to centralized user management. If you have several CA products installed, they all may be using CA EEM to store identities and access policies.
- CA EEM may be configured to either point to an external (LDAP) directory or use the MDB to store user information. CA EEM itself has an LDAP interface for use when it is configured to use the MDB.

Note: The tables used by CA EEM in the MDB are different from the ones used by CA SDM.

CA EEM as LDAP Configuration

When CA EEM is configured to use MDB rather than an external directory to store user information, CA EEM exposes the user directory using an LDAP interface. If your site does not use an external LDAP server, you can still get the advantages of external LDAP configuration by configuring CA SDM to use CA EEM as an LDAP source. This configuration can be useful if your site does not use an LDAP server but you want to consolidate user management in CA EEM. Other CA products also use CA EEM, which can greatly simplify user management.



Note: This configuration is applicable only when CA EEM is configured to use the MDB. If CA EEM is configured to an external LDAP server, configure CA SDM to point to the same LDAP server, *not* CA EEM. For more information, see How to integrate CA SDM with LDAP (see page 1207).

Configure the CA EEM r8.4 SP4 CR05 User Store

You can configure CA EEM r8.4 SP4 CR05 to store user records in an external LDAP directory or in its own internal MDB tables. When CA EEM uses an external LDAP directory, it is a read-only interface; you cannot add or modify users through the CA EEM interface.

Follow these steps:

1. Click Start, Programs, CA, Embedded Entitlements Manager, EEM UI.
   The CA EEM user interface appears.
2. Click the Configure tab.
3. Click the EEM Server sub-tab.
4. On the left-hand pane, click the Global Users / Global Groups link.
5. On the right-hand pane, select one of the following options:
   - Store in internal datastore
   - Reference from an external directory
   - Reference from CA SiteMinder

   Note: If you select the Reference from an external directory option, you are prompted for the LDAP server details.
6. Click Save.
   The user store configuration for CA EEM is complete.

Configure the CA EEM r12 CR02 User Store

You can configure CA EEM r12 CR02 to store user records in an external LDAP directory or in its own internal MDB tables. When CA EEM uses an external LDAP directory, it is a read-only interface; you cannot add or modify users through the CA EEM interface.

Follow these steps:

1. Click Start, Programs, CA, Embedded Entitlements Manager, Admin UI.
   The CA EEM user interface appears.
2. Click the Configure Tab.
3. Click on User Store subtab.
4. On the left-hand pane, click the User Store link.
5. On the right-hand pane, select one of the following options:

- Store in internal user store
- Reference from an external LDAP Directory.
- Reference from CA SiteMinder

Note: If you select the Reference from an external directory option, you are prompted for the LDAP server details.

6. Click Save.
The user store configuration for CA EEM is complete.

Add Users and Groups

If CA EEM is configured to reference an external directory, you cannot add users using the CA EEM user interface. CA EEM is a read-only interface to the LDAP server. You must use whatever interface is provided with your particular LDAP server product to update user records.

Follow these steps:

1. Click Start, Programs, CA, Embedded Entitlements Manager, Admin UI/EEM UI.
2. Log in using the CA EEM administrator user name and password. These are specified during the CA EEM installation. CA EEM must be installed separately and is not a configuration option for CA SDM.
3. Click the Manage Identities tab.
4. On the left-hand pane, click the Users tab to search for and update existing user records.

Note: To manage the CA EEM groups, click the Groups tab.

5. Click the icon to the left of the Users folder.
The form for creating a user record appears.
6. Complete the form and click Save.
The new CA EEM user record is saved in the MDB.

Note: The steps to edit an existing user record and maintain group records are similar to these steps.

Security Considerations

When you first install CA SDM, the system is set up to allow maximum access to any contact that does not have an explicit access type that is defined in the contact record. Perform the following steps before using the application:

1. Review the predefined access types to determine a reasonable default for your system. Administrator is set as the default access type, which is not a good choice for most sites. For example, some sites offer read-only CA access to most members of the IT organization. If you set CMDB User as the default access type, you do not have to set the access type of new users unless they need additional privileges. Similarly, if most users require the privilege to write configuration information, you can select CMDB Analyst as the default access type.

2. Assign the access types of remaining contacts explicitly.
   For example, if you select CMDB User as the default access type, modify the contact records for your analyst contacts to assign an access type of analyst.

CA EEM Authentication for CA Process Automation

CA SDM and CA Process Automation communicate using a web services exchange over HTTP. Although every measure is made to pass minimal amounts of sensitive information between the products, a malicious entity can access user names, passwords, and proprietary information. You can take deliberate steps to secure server communication.

For CA Process Automation authentication, consider the following recommendations:

- As an option, you can configure CA Process Automation to use CA EEM as an authentication server. CA Process Automation implements default groups and policies within CA EEM. You can modify the default groups and policies to meet the needs of your organization.

- Using CA EEM eliminates the need to pass plain text user names and passwords for authentication purposes. If you are using multi-tenancy, CA EEM is required for enabling multi-tenancy within CA Process Automation.

  Note: To achieve authentication security in this integration, it is not necessary to have CA SDM configured to use CA EEM. However, CA EEM is required for CA Process Automation multi-tenancy implementation.

- Configure CA Process Automation to communicate using secure communications over HTTPS. HTTPS URLs use SSL/TLS to eliminate plain text exchanges while protecting proprietary and other sensitive data from accidental or malicious disclosure.

User Authentication

This article contains the following topics:

CA SDM provides a user authentication solution that you can modify as part of the access type. The same authentication is used by all CA SDM interfaces and by other CA products.

Authentication is flexible, allowing you to take advantage of external authentication mechanisms, such as Windows, HTTPD user validation or LDAP authentication. You can also select from a variety of internal authentication options, including operating system password, PIN, guest user access, or no access at all.

How CA SDM Authenticates Users

CA SDM authenticates users based on the user ID defined in their contact record. The product also does the following when a user requests access to the system:

1. If an external user ID is available (from HTTPD or Windows validation), CA SDM looks up the contact by login ID. If the contact is found and has an access type that permits external authentication, the user is allowed into the product.

2. If there was no successful external authentication, CA SDM prompts the user for a user ID and password. The product looks up a contact record for the user ID, obtains the access type, and then authenticates the user as specified by the access type.

Many installations find the predefined access types define authentication that is reasonable for that type of user; however, in some cases you may need to modify the authentication information for a predefined access type or define a new access type to handle a different authentication method for some of your users. You should review the authentication settings for the predefined access types to determine if they meet your needs, or if you need to modify them, or define additional types.

External Authentication

CA SDM permits users to access the system without supplying a user ID if all of the following conditions are met:

- External authentication is set for the user.
- The user's externally authenticated user ID is associated with a contact in your contact table.
- The contact record has an access type whose authentication definition permits external authentication.

External authentication does not permit users to access the system in the following cases:

- A user attempts access through a non-secure server.
- A user attempts access but is assigned to an access type that does not allow external authentication.

None of the predefined access types use external authentication. If you want to use external authentication for users, consider modifying the employee, analyst, and administrator access types to set external authentication. Your individual site requirements and different types of users determine whether to allow external authentication. When external authentication is used, the server configuration controls the access to files and directories. When you define authentication for an access type, you can decide the usage as follows:

- Do not use any external authentication that is already implemented, such as the user login on Windows or validation by the HTTPD server.
- Use the authentication that is implemented and allow or deny access based on it.

Note: If external authentication is not allowed, the user is authenticated based on the validation type that you specify.

Following are some examples of external authentication:

- If a user who has administrator access logs into a Windows computer, the user can perform administrative tasks without re-entering any login information.
- If a user who has HTTPD server validation, the user can access the web interface without re-entering any login information. Because the administrator access type specifies the analyst web user type, the appropriate web interface for the analyst is presented automatically.

Validation Types

Validation types authenticate users only under the following circumstances:

- The user access type does not permit external authentication.
- The user access type permits external authentication, but the user has not been validated externally (for example, the user has attempted access through a nonsecure server).

CA SDM provides you with the following validation options:

- **No Access** -- Users of this type have no access unless external authentication is allowed and is valid.
- **Open** -- Users of this type have access, with no additional authentication required.
  - **OS** -- Users of this type enter their operating system password for access. The operating system used for validation is the one running User Validation Host. This option is the default validation type for the administrator, analyst, and employee access types.
  - **PIN** -- Users of this type gain access by entering the correct value for the PIN field in their contact record as their password. You define the PIN field by entering the field attribute name when you select PIN as the validation type. PIN is the default validation type for the customer access type, which uses the value in the customer ID (contact_num) field as the PIN.

Logged In User Counts and Session Counts

The following KPIs count the number of unique licensed users that are logged in to the system (for example, CA SDM Web UI, SOAP Web Services, REST Web Services, and so on), regardless of how many sessions each user has opened:

Note: For a licensed user, ensure that the Licensed? check box is selected from the Access type page of the contact (navigate to Security and Role Management, Access Type on the Administration tab and search for the contact).

- webConcurrentLicenseCt
- webConcurrentSOAPLicenseCt
- webConcurrentRESTLicenseCt
- webConcurrentTotalLicenseCt

The following KPIs count the numbers of unique unlicensed users that are logged in to the system, regardless of how many sessions each user has opened:

- webConcurrentNonLicenseCt
- webConcurrentSOAPNonLicenseCt
- webConcurrentRESTNonLicenseCt
- webConcurrentTotalNonLicenseCt

The following KPIs count the number of unique sessions that started during the interval:

- webSessionCt
- webSOAPSessionCt
- webRESTSessionCt

For more information about the KPI description, see the KPI detail page (navigate to Service Desk, KPIs on the Administration tab and search for the KPI). For more information about how these KPIs count from different session types, see the How KPIs Count from Different Session Types (see page 1010) topic.

How KPIs Count from Different Session Types

There are different session types that are defined in the system. The following table shows how KPIs count these sessions:

Note: All predefined KPIs are installed as Inactive. For a KPI to begin functioning in your system, it must be set to Active. Navigate to Service Desk, KPIs on the Administration tab and search for the inactive KPI. Open the KPI and click Activate.

Important! Multiple versions of a KPI with the same name cannot be active at the same time.

Session Type	Session Type Description	Counted by KPIs
Web Client	Web browser session	webSessionCt webConcurrentLicenseCt webConcurrentNonLicenseCt webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Java Client	Java client session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Web Services	SOAP Web services session	webSOAPSessionCt webConcurrentSOAPLicenseCt webConcurrentSOAPNonLicenseCt
Utility	Server utility session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Portal	Portal session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Knowledge Chat	Knowledge Chat session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Mail Server	Mail Server session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Custom Application	Custom Application session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
PDA Client	PDA Client session	webSessionCt webConcurrentLicenseCt webConcurrentNonLicenseCt webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
REST Client	REST Web Services Session	webRESTSessionCt webConcurrentRESTLicenseCt webConcurrentRESTNonLicenseCt webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt

Example: KPIs calculating user counts

One licensed (that have the Licensed? check box selected) and two unlicensed end users are logged into the web self-service interface and reviewing some announcements.

At the same time five licensed analysts (that have the Licensed? check box selected) are logged into the analyst interface and working on incidents. One of the analysts also logs in to the SOAP Web Services interface.

- The webConcurrentLicenseCt KPI shows a count of six, meaning that six licenses are currently being used, irrespective of the number of interfaces each user is using.
- The webConcurrentNonLicenseCt KPI shows the count of two, which means that two unlicensed users are logged on to the system, irrespective of the number of interfaces each user is using.
- The webSessionCt KPI shows a count of eight, meaning that eight total users are logged in to the CA SDM Web UI.
- The webSOAPSessionCt KPI shows a count of one, meaning that one user is logged in to the SOAP Web Services interface.

(Applicable for advanced availability configuration only) Example: KPIs calculating user counts from different nodes

A licensed analyst logs in to the analyst interface from the background server and works on incidents. The same analyst logs in to the analyst interface from the application server. The webConcurrentLicenseCt KPI shows a count of one, meaning that one license is currently being used, irrespective of the number of nodes or servers the user has logged in from.

Establishing Support Structure

This article contains the following topics:

Setting Up Your CA SDM System

This section contains the following topics:

Shared Codes

This article contains the following topics:

In CA SDM, different types of tickets share certain underlying codes, such as priority, severity, impact, and urgency codes. Requests and change orders share some codes, and all types of tickets share other codes.

Consider the following information about shared codes:

- By default, numeric values rank them.
- You can modify the codes.
- You cannot add or delete shared codes.
- You can use impact, priority, severity, and urgency codes.

Based on your service desk model, set up the following codes:

Shared Codes	Description
Priority	Must be set up for all service desk models.
Severity	Must be set up for internal and combined service desk models.
Impact	Must be set up for internal and combined service desk models.
Urgency	Must be set up for internal and combined service desk models.

Priority Codes

Priority codesindicate a ranking order by which the service desk should respond to tickets (that is, they specify the level of attention a ticket should receive). Priority codes are referenced in requests, change orders, and issues; therefore, they apply to all service desk models.

You can use priorities to escalate tickets manually or automatically by monitoring events. In many service desk installations, priority codes are used on the scoreboard to provide analysts with a real-time status of their requests and change orders.

You can assign a service type to a priority code, which is then automatically assigned to tickets when the priority code is specified. This lets you associate a specific level of service to a ticket based on the assigned priority. For example, the system-defined service type, 4-hour resolution, is automatically associated with priority 1. Tickets that are assigned a priority of 1, therefore, are automatically assigned this service type, including all the service type events that are associated with the 4-hour resolution service type.

Severity Codes

Severity codesidentify the extent of the damage to equipment affected by a request. Severity codes are referenced in requests only; therefore, they apply only to internal and combined service desk models.

Note: Severity is often used as a synonym for priority. Some sites use priority only, ignoring severity altogether. If you want to distinguish between how serious a problem is on a technical level (severity) and how quickly you want it handled (priority), you can use severity and priority codes.

Impact Code values helps to calculate the Incident Priority.

Impact Codes

Impact codesmeasure the significance of a ticket on the functioning of the system. For example, if a change order could affect the functioning of the entire system, it would be assigned a high impact. Impact codes are referenced in requests and change orders only; therefore, they apply only to internal and combined service desk models.

Note: Impact and urgency codes (see page 1014) are similar, but they have distinct purposes.

Urgency Codes

Urgency codesmeasure the significance of the request for users of the system (that is, they indicate the importance of the request to the overall production environment). For example, if a request could jeopardize the mission of the enterprise, the Urgency code can be a value of 5-Immediate. Urgency codes are referenced in requests only; therefore, they apply only to internal and combined service desk models.

Urgency and impact codes serve distinct purposes, but are often confused because they coincide. For example, a request to report a fire in a critical data center can have a 3-Single Group Impact and 5-Immediate Urgency. These codes apply because the fire impacts more than one group but not necessarily the entire organization. Because the data center is critical for operations, the urgency requires immediate attention.

Status Codes

This article contains the following topics:

Status codes are used to track the status of an item. Separate status codes track requests, change orders, issues, and workflow tasks. In each case, there are predefined status codes that you can use if they suit your needs. Otherwise, you can modify the predefined status codes or define new ones that are specific to your site. Depending on your service desk model, you set up the following codes:

Status Codes	Description
Request/ Incident/ Problem	Must be set up for internal and combined service desk models.
Change Order	Must be set up for internal and combined service desk models.
Issue	Must be set up for external and combined service desk models.
Task	Must be set up for all service desk models.

Status codes let analysts sort and select information based on the status so that they can carefully track their progress. How carefully you define the status codes determines how accurate the analysts can be in describing the actual status of an item.

You can mark any status code as active or inactive. When you mark a status code as inactive, it is no longer available for analysts to use, but it remains available for future use (that is, it is not deleted from the database). If you decide later to use the status code, you need only to go back to it and mark it as active.

Note: The same area definitions are available for request, incident, and problem tickets. On the Administration tab, these areas are referred to as request/incident/problem areas. For brevity, they are referred to here simply as request areas.

Request Status Codes

The following table describes the predefined status codes for request tickets.

Request Status Code	Description
Acknowledged	The receipt of a request has been acknowledged.
Closed	A request has been completely resolved.
Closed -- Unresolved	A request has been closed but still must be resolved.
Fix in Progress	A request is pending a fix.
Hold	The service type events for the request are on hold.
Open	A request has been defined and is being used to monitor and manage its completion.
Problem Closed	A problem request is completely closed.
Problem Fixed	A problem request is fixed, but not closed.
Problem Open	A request has been identified as a problem.
Researching	A request is open pending additional research and analysis.
Work in Progress	Work is being done to fix a request.

If your site uses other terminology for identifying the request status, you should define status codes that suit your needs and ignore the predefined status codes, or change the definitions to match your use. For example, you may want to define additional request status codes, such as the following codes:

Request Status Code	Description
Duplicate	Requests that have been opened but may be a duplicate of an existing request for another user.
Emergency	Critical requests that must be addressed immediately.
Report	Requests that are resolved and closed, but should be reported on at a management level.
Test	Requests that are resolved, but should be tested for one week before closing.

Problem Status Codes

The following table describes the predefined status codes for problem tickets.

Problem Status Code	Description
Acknowledged	The receipt of a problem has been acknowledged.
Closed	A problem has been completely resolved.
Closed -- Unresolved	A problem has been closed but still must be resolved.
Fix in Progress	A problem is pending a fix.
Hold	The service type events for the problem are on hold.

Problem Status Code	Description
Open	A problem has been defined and is being used to monitor and manage its completion.
Problem Closed	A problem is completely closed.
Problem Fixed	A problem is fixed, but not closed.
Problem Open	A request has been identified as a problem.
Researching	A problem is open pending additional research and analysis.
Work in Progress	Work is being done to fix a problem.

If your site uses other terminology for identifying the problem status, you should define status codes that suit your needs and ignore the predefined status codes, or change the definitions to match your use. For example, you may want to define additional problem status codes, such as the following codes:

Problem Status Code	Description
Duplicate	Problems that have been opened but may be a duplicate of an existing problem for another user.
Emergency	Critical problems that must be addressed immediately.
Report	Problems that are resolved and closed, but should be reported on at a management level.
Test	Problems that are resolved, but should be tested for one week before closing.

Incident Status Codes

The following table describes the predefined status codes for incident tickets.

Request Status Code	Description
Acknowledged	The receipt of an incident has been acknowledged.
Closed	An incident has been completely resolved.
Closed -- Unresolved	An incident has been closed but still must be resolved.
Fix in Progress	An incident is pending a fix.
Hold	The service type events for the incident are on hold.
Open	An incident has been defined and is being used to monitor and manage its completion.
Incident Closed	An incident is completely closed.
Incident Fixed	An incident is fixed, but not closed.
Incident Open	An incident has been identified as a problem.
Researching	An incident is open pending additional research and analysis.
Work in Progress	Work is being done to fix an incident.

If your site uses other terminology for identifying the incident status, you should define status codes that suit your needs and ignore the predefined status codes, or change the definitions to match your use. For example, you may want to define additional incident status codes, such as the following codes:

Request Status Code	Description
Duplicate	Incidents that have been opened but may be a duplicate of an existing request for another user.
Emergency	Critical incidents that must be addressed immediately.
Report	Incidents that are resolved and closed, but should be reported on at a management level.
Test	Incidents that are resolved, but should be tested for one week before closing.

Change Order Status Codes

The following table describes the predefined status codes for change order tickets.

Change Order Status Code	Description
Approval in Progress	A change order is open, pending approval.
Approved	A change order has been approved.
Cancelled	A change order has been cancelled.
Closed	A change order has been completed.
Hold	The service type events for the change order are on hold.
Implementation in Progress	A change order is being implemented.
Open	A service order has been defined in a change order and the change order is being used to monitor and manage its completion.
Rejected	A change order has been rejected.
Resolved	A change order has been resolved.
RFC	A request for change has been submitted.
Suspended	Stops workflow tasks on a change order.
Verification in Progress	A change order is being verified.
Backed Out	Implemented change order was backed out.
Implemented	Change was implemented.

If your site uses other terminology for identifying the status of a change order, you should define status codes that suit your needs and ignore the predefined status codes, or change the definitions to match your use. For example, you may want to define additional change order status codes, such as those listed in the following table:

Change Order Status Code	Description
Duplicate	Change orders that have been opened but may be a duplicate of an existing change order for another user.
Emergency	Critical change orders that must be addressed immediately.
Report	Change orders that are completed and closed, but should be reported on at a management level.

Closure Codes

Use closure codes to define the final outcome of change orders, such as successful or unsuccessful. Set closure codes manually or as part of the Update Status activity on a change order when the status is closed, finished or resolved.

Issue Status Codes

The following table describes the predefined status codes for issue tickets.

Issue Status Code	Description
Approval in Progress	An issue is open, pending approval.
Cancelled	An issue has been cancelled.
Closed	An issue has been completed.
Hold	The service type events for the issue are on hold.
Implementation in Progress	An issue is being implemented.
Open	An issue has been defined and open so that it can be monitored and managed until it is resolved.
Suspended	Stops workflow tasks on an issue.
Transaction in Progress	A transaction with a customer concerning this issue is in progress.
Verification in Progress	An issue is being verified.

If your site uses other terminology for identifying the status of an issue, you should define status codes that suit your needs and ignore the predefined status codes, or change the definitions to match your use. For example, you may want to define additional issue status codes, such as the following:

Issue Status Code	Description
Duplicate	Issues that have been opened but may be a duplicate of an existing issue for another user.
Emergency	Critical issues that must be addressed immediately.

Issue Status Code	Description
Report	Issues that are completed and closed, but should be reported on at a management level.

Task Status Codes

Task status codes describe the different possible states of a workflow task. Each task in an issue or change order or request/ incident/ problem workflow has its own status, separate from the ticket status. Workflow tasks allow analysts to keep track of how long it takes to complete individual tasks within a ticket.

The following table describes the predefined status codes for workflow tasks.

Task Status Code	Description
Approve	Task approved.
Cancelled	Task is cancelled and no further updates are possible.
Complete	Task is complete.
Pending	Task is started.
Reject	Task is rejected.
Reopen	Task has been re-opened.
Reopen - Wait	A prior task was reopened.
Skip	Skip task.
Wait	Task has not started.

If your site uses other terminology for identifying the status of a workflow task, you should define status codes that suit your needs and ignore the predefined status codes, or change the definitions to match your use.

For each task status code, you can assign a type of behavior that occurs when the task reaches this state, which provides much more information about the progress toward completing the task. You can also use the accumulate function to track time and cost involved in completing the ticket.

Task Types

Task types help determine the behavior of specific workflow tasks and task status codes. To produce defining characteristics for each type of task, you can identify the task status codes or specific states that can be used.

Because change orders, issues, and request/ incident/ problem use workflow tasks, set up task types for all service desk models. The task status codes identify the behaviors associated with each task. For example, you can set the Approval task type to allow Approve, Reject, Pending, and Wait as available states. When the Approval task type enters the Pending state, you can send notification to a specific manager, analyst, and so forth.

You can mark any task type as active or inactive. When you mark a task type as inactive, it is no longer available for analysts to use, but it remains available for future use (it is not deleted from the database). If you decide later to use the task type, mark it as active again.

Note: You can view the predefined task types in the Task Type List page of the administrative function of the web interface.

Example: Task Status Codes

The following table contains some example status codes:

Task Status Code	Description
Approval	Approve or reject ticket
Group End Task	End of group tasks
Group Start Task	Start of group tasks
Start Approval	Approval to start the ticket

In this example, the Group Start Task and Group End Task types define a group of tasks in an issue or change category that must be completed. Tasks in the group can be executed in any order. After the Group Start Task is in the Pending state (started), all tasks in the group are also placed in this state.

Define Code for Application Data Components

You can define codes for your application data components. To create a code, select Service Desk, Application Data, Codes, <code_that_you_want_to_create> from the Administration tab.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants. If you are the Service Provider, select the appropriate tenant from the dropdown menu. The public (shared) option creates the object for all tenants.

Code	Description
Attribute Alias	CA SDM includes an ODBC driver that allows an external application, such as Web Intelligence, to submit SQL SELECT queries directly to the CA SDM object manager (domsrvr). The driver depicts CA SDM Majic object names and attributes as tables and columns of a virtual database. In addition, the driver allows an unlimited number of attribute alias columns to be added to each object. Each attribute alias defines a pseudo-column corresponding to a column of a joined table. For example, the attribute alias assignee_organization_name corresponds to the Majic dotted join assignee.organization. name.

Code	Description
	Attribute alias codes provide a flattened view of the database. They allow you to include columns from related tables. By convention, an attribute alias name is the same as the Majic join name, with the dots replaced by underscores. For example, if a Call Request report needs to show the assignee's organization name, and this column was not provided out of the box, you could define an alias called assignee_organization_name that equates to assignee.organization.name. To create this code, the object name is the majic object name associated with the attribute alias. For more information about objects, see the Technical Reference (see page 3821) topic.
Auto Close Settings (https://wiki.ca.com/display/CASM/.Define+Auto+Close+Settings+v14.1)	You can use a configurable setting to allow automatic closure of CA SDM tickets. When a ticket is set to a Resolved status, the ticket is automatically closed in the number of business hours specified. The Auto Close activity notification sent to the end user displays the number of business hours before the ticket is closed. You can configure business hours for each tenant. If the status is changed before the configurable number of hours ends, the ticket closure is canceled. As a system administrator, you can perform the following actions: ▪ Define an Auto Close ticket setting to control the number of business hours, for the end user, before the ticket is automatically closed. ▪ Set up an Auto Close activity notification to notify the appropriate contacts when automatic closure is scheduled for a ticket. When an analyst changes the status of a ticket to a Resolved status, the ticket is automatically closed in the number of business hours specified. After the ticket is closed, an activity log is added to the ticket. The Auto Close activity notification sent to the end user displays the number of business hours before the ticket is closed. The number of hours is configurable and tenant-specific. If the status of a ticket is changed before the configurable number of hours ends or expires, the automatic ticket closure is canceled. For each ticket type and tenant, you can define a different number of business hours. If business hours are not defined for a particular tenant, the public setting is used instead. If you use multi-tenancy, consider the following: ▪ The system uses the default public Auto Close setting when a tenant-specific Auto Close setting is not found. ▪ There is one Auto-Close setting for each tenant.
Contact Type	Contact type codes are classifications for the people associated with your network, such as vendors, analysts, or customers. Contact type codes let you sort and select information based on the kind of person involved with a ticket. For example, you can report on how many tickets were created by an outside vendor contact. You can also use contact types to restrict certain functions to certain types of users. For example, only users with the contact type of analyst can resolve tickets.
Cost Centers	A cost center is a group or unit that uses purchased assets. Cost center codes are used to roll up groups of purchased assets for budgeting and reporting purposes. A cost center could be an internal department, a subsidiary, or any group that needs to have its assets tracked separately.

Code	Description
Countries	You can associate country codes with your organization's location codes, as part of the address information.
Departments	You can define department codes to reflect the departments within your organization. Departments can then be associated with records such as contacts and groups.
End User Roles	End user role codes categorize the various people who contact the service desk. For example, a user might be an existing customer, a potential customer, or a sales manager.
iCalender Event Templates	iCalendar event templates control the information that is exported to iCalendar format. The following predefined templates are installed with CA SDM: ▪ Change Schedule ▪ KnowledgeScheduleCreation ▪ KnowledgeScheduleExpired ▪ KnowledgeScheduleReview ▪ KnowledgeScheduleStart **Note:** You can edit the predefined iCalendar event template codes, but you cannot delete or create them. **Important!** The SchedExpMaximum variable in web.cfg controls the maximum events allowed for an export. Increasing the default (1000) could cause system instability. If you attempt to export more than the value specified in SchedExpMaximum, a message appears refusing your exporting request. You can set a display alarm (such as 1 Day before or 1 Hour before) for each event that creates a calendar.
Impact	Impact codes indicate how much a ticket affects work being performed. You can use impact codes to select and sort records, and organize them for reports. The predefined impact codes are: ▪ 1-Entire organization ▪ 2-Multiple Groups ▪ 3-Single Group ▪ 4-Small Group ▪ 5-One person ▪ None = No Impact is assigned You can change the symbols for impact codes. For example, your site might decide not to use numbers at all and assign codes of low, medium, high, and so on. **Note:** You can edit the predefined impact codes, but you cannot delete or create them.

Code	Description
Location	Location codes precisely identify a physical place. You can use location codes to identify where inventory components reside, such as contacts and resources like printers. Location codes can identify any type of place, for example, a city, building, or a specific floor of a building. You can configure automatic ticket assignment for the location, based on request areas, change categories, issue categories, and groups. For example, to auto assign issue tickets in a certain category to analysts associated with this location, click the Update Issue Categories button on the Auto Assignment tab and select the category from the list. For more information about configuring Auto Assignment, see Auto Assignment (https://wiki.ca.com/display/CASM/.Auto+Assignment+v14.1).
Organization	Organization codes can define the companies, divisions, or departments in your enterprise. You can use organization codes to indicate the working and reporting relationships of your service desk users. This information is defined on a user's contact records and displayed on their tickets. Organizations can also be assigned to the resources in an asset class, or the issues assigned to a specific ticket area or category.
Outage Type	Outage types represent a single general type of outage for an incident that a user reports, or to specify other types of outages such as a scheduled or test outage. When a user reports an outage incident, you can specify an outage type on the ticket to help categorize and track the incident. For example, you can use an outage type of Facilities on a ticket to indicate that an outage that affected the end-user facilities.
Position	Position codes can indicate the job title of a person who opens a ticket.
Priority	Priority codes indicate the amount of attention a ticket should receive. Priority codes are used when defining automatic notification and external processing for specific types of situations. They are also used as a label in the scoreboard to prioritize tickets. You can modify a priority code's symbol. For example, your site might decide not to use numbers at all and assign priority codes of low, medium, high, and so on. You can modify a priority code's associated service type. For example, you could change the service type for priority code 1 from the default value of 04hr resolution to a custom service type of 02hr resolution.
Product	Product codes identify the products supported by your service desk.
Reason	Reason codes define the purposes for opening tickets. For example, a reason for opening an issue might be an inquiry, a complaint, or a suggestion.
Reporting Methods	Reporting method codes define the ways a ticket can be reported to the service desk. For example, a customer might create an issue over the phone or via e-mail.
Resolution	Incident management focuses on getting the end user up and running as fast as possible. Analysts can indicate what they did to resolve an incident by using a resolution code. Resolution codes specify the category code of the ticket resolution, for example, an Applied Patch resolution code indicates that the ticket was addressed by applying a patch or fix to the software.
Resolution Method	Resolution methods define the ways the service desk can resolve tickets. For example, an analyst can resolve an incident or request through a chat session or an on-site visit.
Root Cause	

Code	Description
	Root cause codes identify the source of a problem reported in your service desk. Root cause codes comprise a set of nodes, which are separated by periods to indicate where the root cause fits into a hierarchy of root causes. For example, the root cause name Network. Cable.Install indicates the Install root cause as part of the Cable root cause, which in turn is part of the Network root cause. By default, the Root Cause Selection window displays as a hierarchical selection list. If you want to display the Root Cause Selection window as a normal list, you can install the no_hier_list option through the Options Manager.
Severity	Severity codes indicate the effect a ticket has on people. For example, a printer problem might affect a larger number of people than the failure of user system or computer. Severity codes are used to select and sort tickets and organize them for reports.
State /Province	State/province codes identify the states and provinces where tickets might originate in your service desk.
Symptom	Symptom codes represent a single general symptom for an incident that a user reports. When a user reports an incident, you can specify a symptom code on the ticket to help categorize and track the incident. For example, you can use a symptom code of Slow Response on a ticket for an application that is not running as fast as a user expects.
Timer	Timers act as a stopwatch with various thresholds that give the analyst indications of elapsed time. You can define the amount of time the timer remains at each threshold, and have the timer change color, beep, or display a reminder as it reaches each threshold. A service desk analyst cannot control the stopwatch; only the administrator can control it. Requests are the only type of ticket that uses timers; therefore, set up timers for internal and combined service desk models. For more information, see Timer Setup (see page 1026).
Time Zone	You can set up specific time zones for servers, service types, contacts, and locations in your CA SDM system. You can set up local service types that apply to a specific time zone and global service types that apply across the entire enterprise. This setup eliminates the need for the administrator to know the time zone of a server and manually adjust the work shift times to fit different time zones. For more information, see Time Zone Setup (see page 1026).
Urgency	Urgency codes indicate the importance of the user tasks affected by a ticket. You assign urgency codes to tickets based on how it affects user tasks. Urgency codes can be used to select and sort information and to organize it for reports.
Web Macro	CA SDM includes a number of predefined macros. Most of these macros insert JavaScript text to create an element on a web form. Use Web Screen Painter to create and modify forms using these macros.
Workshift	Workshift codes specify the dates, days, and times when the monitoring of an event is in effect. You can add new workshifts or update existing workshifts. Workshifts often coincide with the times your service desk is operating. By defining workshifts, you can set up events and monitor them precisely. For more information, see Workshift Setup (see page 1028).
Timespan	Timespan codes allow you to define time spans that can be applied to stored queries. You can create time spans that control the start time, end time, and trigger time of stored queries.
Site	

Code	Description
	Site codes represent general groupings, such as cities or regions. Sites can include several locations, which are physical places like buildings or floors. Site records are referenced in location records. You should create site records before location records so the sites are available when you define the locations.

Timer Setup

The following threshold values are predefined for the timer:

Threshold Duration	Color
00:00:00	Green
00:01:00	Yellow
00:05:00	Red

The predefined values start the timer at green. After one minute, the timer changes to yellow. After five minutes, the timer changes to red. The elapsed time is displayed when the analyst views the request in detail and is reset each time a new request is selected. You can add steps to this process or change existing steps.

You can mark any timer as active or inactive. When you mark a timer as inactive, it is no longer part of the process, but it remains available for future use (that is, it is not deleted from the database). If you decide later to use the timer, back to it and mark it as active.

Timer codes control the reminders to analysts that they have been working on a request longer than the recommended amount of time. This way of reminding analysts has the recommended amount of time defined as a threshold, such as 5 minutes. The timer then uses various methods to indicate that the threshold has been reached. These methods include sounding beeps, changing the background color of the Timer field on the Request Detail window, or displaying messages telling the analyst to resolve the request as quickly as possible.

The Timer field that tracks the time spent on a request is reset each time the request is opened, and service desk analysts cannot control it or change it.

Time Zone Setup

Contents

Timezone codes are specified for users in their contact record. A timezone code displays the local time for users, regardless of their locations around the world, in the Time field on the Quick Profile, thus allowing you to see if it is currently during business hours for them.

You can add new timezone codes, and modify the predefined ones. Timezone codes indicate the time difference difference between a particular time zone and Greenwich Mean Time (GMT). You can also specify when to start and end Daylight Savings Time, if applicable.

Service Type Event Triggers

Service types define the events that are triggered after a specified delay time.

Example: Event Triggers by Work Shift Schedule

In this example, a work shift schedule associated with the service type constrains the actual time an event is triggered, as follows:

- Work shift is 8:00 a.m. to 5:00 p.m.
- Event delay is three hours
- Current server time is 3:00 p.m.

The event is triggered tomorrow at 9:00 a.m. server time because of the following:

- According to the current server time, two hours remain in the work shift for today (Current time is 3:00 p.m. Work shift ends at 5:00 p.m.)
- The event delay is three hours. Two hours of this delay are spent in the current day's work shift (3:00 p.m. to 5:00 p.m.). One additional delay hour is carried over to the next day's work shift (8:00 a.m. to 9:00 a.m.)

Consequently, the event begins at 9:00 a.m. the following day.

Time Zone Event Triggers

A time zone associated with the service type can constrain event trigger times.

Example: Event Triggers by Time Zone

In this example, a time zone associated with the service type constrains the actual time an event is triggered as follows:

- Work shift is 8:00 a.m. to 5:00 p.m.
- Event delay is three hours
- Current server time is 3:00 p.m.
- Current time in time zone is 12 noon

The event is triggered today at 6:00 p.m. server time because of the following:

- According to the current server time, two hours remain in the work shift for today (Current time is 3:00 p.m. Work shift ends at 5:00 p.m.).
- According to the current time zone time, five hours are left in the work shift for today (Current time is 12 noon Work shift ends at 5:00 p.m.).
- The event delay is three hours (12 noon to 3:00 p.m. time zone time. 3:00 p.m. to 6:00 p.m. server time).

Consequently, the event begins at 6:00 p.m. server time or 3:00 p.m. time zone time.

Time Zone Rules

You can specify a time zone for a server, for a location, and for a service type. You can also tell CA SDM to use the time zone of the Affected End User of a ticket. CA SDM uses the following rules to determine which time zone triggers an event:

- **Affected End User time zone** -- CA SDM uses this rule when the following conditions exist:
  - The Use End User Time Zone option is selected.
  - A time zone is specified for the affected end user of the ticket.
- **Affected End User location time zone** -- CA SDM uses this rule when the following conditions exist:
  - The Use End User Time Zone option is selected.
  - No time zone is specified for the affected end user of the ticket.
  - A time zone is specified for the affected end-user location.
- **Service type time zone** -- CA SDM uses this rule when the following conditions exist:
  - A time zone is specified for the service type.
  - The Use End User Time Zone option is not selected.
- **Server time zone** -- CA SDM uses this rule when the following conditions exist:
  - A time zone is specified for the server.
  - The Use End User Time Zone option is not selected.
  - No time zone is specified for the service type.
- **No time zone support** -- CA SDM uses this rule when the following conditions exist:
  - No time zone is specified for the service type.
  - The Use End User Time Zone option is not selected.
  - No server records exist.

Workshift Setup

Contents

You can create new workshift codes.

Follow these steps:

1. Select Service Desk, Application Data, Codes, Workshifts on the Administration tab.
   The Workshift List page appears.

2. Click Create New.
   The Create New Workshift page appears.

3. Complete the fields as appropriate. The following tabs are available on the Create Workshift, Workshift Detail, and Update Workshift pages:

   - **Schedule**
     Specifies the days, date, and time of the workshift. You can specify days, or dates, or both days and dates. Specifying a time is optional. Use the following syntax:

     ```
     day_range date_range [{time}]
     ```

     - **day_range**
       Specifies a day or range of days in the following format:

       ```
       week_day | week_day - week_day
       ```

       Valid week_day values are Sun, Mon, Tue, Wed, Thu, Fri, and Sat.

     - **date_range**
       Specifies a date or range of dates in the following format:

       ```
       date | date - date
       ```

       Enter date as mm/dd/yy, where mm is the month, dd is the day, and yy is the year.

     - **{time}**
       Specifies a time or range of times in the following format:

       ```
       {hh:mm[:ss] [am or pm]} | {hh:mm[:ss] [am or pm]} - {hh:mm[:ss] [am or pm]}
       ```

       Time values must be enclosed in braces. Enter time in hours, minutes, and optionally seconds, where hh represents hours, mm represents minutes, and ss represents seconds. You may optionally specify am to identify a time from midnight to noon; this is the default and need only be specified for clarity. You must specify pm to set a time interval from noon to midnight. You may also omit am and pm and specify hours from noon to midnight in 24-hour format, for example 13:30. If am and pm are used, hour values greater than 12 are invalid.

       Note: If the server and clients are in different time zones, events take place according to the time zone of the server.

     Examples:

     ```
     Mon - Fri {8:00 am - 5:00 pm}
     ```

```
Sun {9:00 - 12:00 2:00 pm - 4:00 pm}

Sat 12/24/08 - 1/1/05 {8:00 - 12:00 14:00 - 4:00 pm}

7/4/09
```

Note: Sat 12/24/08 - 1/1/09 indicates every day from December 24, 2008 through January 1, 2009. It does not mean just Saturdays within the specified date range. 7 /4/09 means no work hours on July 4, 2009.

- **Auto Assignment**
  Allows you to configure automatic ticket assignment for the workshift, based on request areas, change categories, and issue categories. These fields are optional. Editable. For more information about configuring Auto Assignment, see the Auto Assignment (see page 1132) topic.

You can click the More icon to display the Additional Search Arguments field. This field is intended only for expert users who understand SQL and Majic. You can enter a SQL WHERE clause in this field to specify an additional search argument.

4. (Optional) Perform the following steps to configure automatic assignment of request, incident, or problem tickets for this workshift:

   a. Click Update Request Areas.
   The Request/Incident/Problem Area Search page appears.

   b. (Optional) Complete the filter fields to display only the area records of interest and click Search.
   The Request/Incident/Problem Area Update page appears.

   c. Select the areas you want to assign to this workshift from the Request Areas Available list. To select multiple areas, hold down the CTRL key while clicking the left mouse button, or hold down the Shift key to select a range of areas.

   d. Click the double right-arrow button.
   The selected areas move to the Request Areas Assigned list.

   e. Click OK.
   The Workshift Detail page displays the selected request areas on the Auto Assignment tab.

5. (Optional) Perform the following steps to configure automatic assignment of change orders for this workshift:

   a. Click Update Change Categories.
   The Change Category Search page appears.

b. (Optional) Complete the filter fields to display only the category records of interest and click Search.
The Change Categories Assigned Update page appears.

c. Select the categories you want to assign to this workshift from the Change Categories Available list. To select multiple categories, hold down the CTRL key while clicking the left mouse button, or hold down the Shift key to select a range of categories.

d. Click double right-arrow button.
The selected categories move to the Change Categories Assigned list.

e. Click OK.
The Workshift Detail page displays the selected change categories on the Auto Assignment tab.

6. (Optional) Perform the following steps to configure automatic assignment of issue tickets for this workshift:

a. Click Update Issue Categories.
The Issue Category Search page appears.

b. (Optional) Complete the filter fields to display only the category records of interest and click Search.

c. The Issue Categories Assigned Update page appears.

d. Select the categories you want to assign to this workshift from the Issue Categories Available list. To select multiple categories, hold down the CTRL key while clicking the left mouse button, or hold down the Shift key to select a range of categories.

e. Click double right-arrow button.
The selected categories move to the Issue Categories Assigned list.

f. Click OK.
The Workshift Detail page displays the selected issue categories on the Auto Assignment tab.

7. Click Save.
The new code definition is saved.

Create Personal Responses

You can create personalized responses and attach them to requests, issues, and change order records when adding activities to the record. For example, you can append a personalized response on the Status Change or Log Comment windows available from the Activities menu.

Follow these steps:

1. From the Administration tab, navigate to Service Desk, Personal Responses.
The Personal Response list page appears.

2. Click Create New.
   The Create New Personalized Response page appears.

3. Fill in the fields on this page including:

   - **Response Owner**
     The contact who owns the response. If this field is left blank, the response is available to all analysts.

   - **Response**
     The text delivered to all those who receive this response. This field can be up to 1000 characters long.
     You can use variables in this field, for example:
     Ticket ref_num: @{call_req_id.ref_num}
     Assignee: @{call_req_id.assignee.combo_name}
     Customer: @{call_req_id.customer.combo_name}
     Description: @{call_req_id.description}

4. Select the type of records for which you want this response available. By default, all record types are selected.

5. Click Save.

Edit a Sequence Number Format

Contents

Sequence Numbers

Sequence numbers define the format for your ticket numbering scheme. You can modify the predefined sequence number formats, but you cannot create new ones.

Note: CA SDM treats the number format as a character string, not as a sequence of numbers. Therefore, when you load tickets into CA SDM from another system, assign a unique prefix or suffix so that existing tickets are not inadvertently overwritten.

When a ticket is opened, it is automatically assigned the next available sequential number. For example, if the last request opened is 5, the next one is assigned the number 6.

Important! After you install a new version of CA SDM, the internal record ID for all tickets is reset to 1. To help ensure that duplicate record IDs are not created, do not create tickets before restoring any backed-up data.

You can configure how requests, change orders, and issues are numbered by including a unique prefix or suffix in the numbering scheme for each one. For example, if you want to track requests by month, you can add a month identifier as a prefix or suffix to the request numbering scheme.

Because you define a separate numbering scheme for each type of ticket, set up numbering schemes for all service desk models. You can control the format of the numbering of requests, change orders, and issues by changing the Sequence Number settings. By default, new tickets are numbered using consecutive integers. Because the number field of a ticket is actually a string field and not numeric, you assign additional string values to use as prefixes or suffixes when the ticket number is generated for a new ticket. For example, you can specify r:, c:, and i: for prefixes for requests, change orders, and incidents. This setup lets users easily differentiate between the various ticket types and prevents confusion.

Incidents and problems share numbering schemes with requests, because incidents and problems are internally different types of requests.

Edit a Sequence Number Format

You can edit an existing sequence number format, but you cannot create new ones.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants. A tenant dropdown appears in the search filter. If you select <empty> in this dropdown, the search is public. A tenant column also appears on the list page.

Follow these steps:

1. Select Service Desk, Sequence Numbers on the Administration tab.
   The Sequence Number Control List page appears.

2. Select the symbol for the sequence number format to edit.
   The Sequence Number Control Detail page appears.

3. Click Edit.
   The Update Sequence Number Control page appears.

4. Edit the fields as needed:

   - **Symbol**
     The name identifying the sequence number format.

   - **Prefix**
     The character string that forms the first part of the ticket number.

   - **Code**
     The internal code name for the number format. Cannot be changed.

   - **Suffix**
     The character string that forms the last part of the ticket number.

5. Click Save.
   The format definition is saved and the Sequence Number Format Detail page appears.

Define Closure Codes

You use closure codes to indicate the final outcome of a change order. You set the field manually or when updating status activity on a change order. CA SDM provides the following default closure codes:

- **Successful**
  Indicates the change order was successful.
- **Unsuccessful**
  Indicates the change order was unsuccessful.
- **Successful with Errors**
  Indicates the change order was successful, but directly or indirectly caused errors.

You can define closure codes to use in managing change orders.

Follow these steps:

1. On the Administration tab, select Service Desk, Change Orders, Closure Code.
   The Closure Code List appears.
2. Click Create New.
   The Create New Closure Code page appears.
3. Complete the required fields.
4. Save and close the window.

Define Change Type Codes

Change type codes identify how change orders fit within the operating practices of the organization. Predefined codes are provided for the following ITIL change types:

- **Standard** -- A change to a service infrastructure that is pre-authorized by change management and has an accepted and established procedure to provide a specific change requirement
- **Normal** -- A change that is raised by request from the initiator (an individual or group) that requires the change
- **Emergency** -- A change that is accelerated outside of normal processing, which sometimes adds a higher risk or impact than if handled normally

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Service Desk, Change Orders, Change Type on the Administration tab.
   The Change Type List appears.

2. Click Create New.
   The Create New Change Type page appears.

3. Complete the required fields:

   - **Symbol**
     Defines an identifier for the change type code. This identifier appears in the Type field on a ticket.

   - **Status**
     Specifies whether this database record is active or inactive. Select a value from the drop-down list.

4. Click Save.
   The change type record is saved and the Change Type Detail page appears.

Define Change Order Status Transition

Change order status transitions control the movement of a change order ticket from one discrete state to another (for example, from Open to Closed). With transitions, you can define a subset of the full status list and determine the next status of the ticket as it continues through its lifecycle. You can use the predefined transitions (listed on the Change Order Transitions List page), modify the transitions, or create transitions.

Note: You can specify how strictly the system enforces Status policies by configuring the Status Policy Violations option in Options Manager (General Options). This option only applies to automated system processes, such as integrations and macros.

You can define a subset of the full status list and determine the next status of the ticket as it continues through its lifecycle.

Note: Because status transitions can be shared between integrations such as CA Workflow and Events and Macros, do not inactivate predefined status transitions unless explicitly requested.

Follow these steps:

1. On the Administration tab, select Service Desk, Change Orders.
   The Change Order Transition List page appears.

2. Complete the fields as appropriate. The following fields require explanation:

- **From Status**
  Defines the current status of the ticket, for example, Open.

- **To Status**
  Specifies a valid next status of the ticket, for example, Assigned.

- **Default Transition**
  Specifies the default status transition. CA SDM uses the default transition when a user clicks the default transition button on the ticket detail page, or when a user (including a web services user) updates the status to a <d> value. You can only configure one default transition for each status (or one for each tenant in a multi-tenanted system).

- **Must Comment**
  Indicates that a comment for the transition must be supplied. Specifying this option indicates that an analyst must supply an activity log comment when changing the status on a request.

- **Condition**
  Specifies the condition by which the transition is allowed. For example, when the condition "nonprty 1&2 assigned req" is associated with the Request Transition of Acknowledged to Hold, the condition verifies if the transition to move the status from Acknowledged to Hold is allowed.

- **Condition Error Message**
  Specifies the message returned to the user if the transition is rejected.

- **Description**
  Specifies the message returned to the user if the transition is rejected.

The transition is defined.

3. Click Save, Close Window.
   The new transition appears in the Change Order Transition List when you refresh the page.

Update Initial Status Transitions

You can update the list of statuses that are valid at initial creation of the ticket.

Follow these steps:

1. On the Transitions List page, click the Initial Transitions button.
   The Initial Transitions page appears and displays all available status codes and descriptions.

2. Fill in the following check boxes as appropriate:

   - **Allowed**
     Specifies a valid transition for the status list. Use this option to restrict status workflows.

   - **Default**
     Specifies the default status transition. CA SDM applies the default transition when a user clicks the default transition button on the ticket detail page, or when a user (including a web services user) updates the status to a <d> value. There is only one default transition for each status (or one for each tenant in a multi-tenanted system).

- **Must Comment**
  Specifies that an activity log comment for the transition is required when changing the status on a ticket. An error message appears on the ticket form when the analyst attempts to close the ticket without adding a comment.

3. (Optional) Select a status code in the Name column to update its details.

4. Click Save.
   The updated status transition appears on the Transitions list.

Define Workflow Task Status Code

Workflow task status codes can be attached to change orders, issues or requests/ incidents/ problems. For example, this code can indicate how close the change order is to being completed. Each workflow task has its own status, which remains separate from the status for the entire change order. Workflow task status codes allow you to locate, categorize, and track change orders based on their workflow status.

Follow these steps:

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

1. On the Administration tab, browse to Service Desk and select any of the following:

   - Change Orders
   - Issues
   - Requests/ Incidents/ Problems

2. Select Workflow Task Status Codes.
   The Task Status Code List appears.

3. Click Create New.
   The Create New Task Status page appears.

4. Complete the fields as appropriate.

   Symbol - Defines an identifier for the task status code. This identifier appears in the Status field next to the tasks listed on the Workflow Tasks notebook page of the issue or change order. This is a required field.

   Code - Displays the internal code for the task status. This is a required field.

   Record Status - Identifies whether the database record is active or inactive. This is a required field. Select a value from the drop-down list.

Allow Task Update - When checked, indicates that an analyst can change the status of the task. This allows a qualified person to override a status that is entered by default, such as Pending.

Task Completed - When checked, indicates that the task is complete when it reaches this status. This option cannot be selected if Allow Task Update is selected.

Allow Accumulate - When checked, includes tasks with this status in calculations of estimated cost and duration for the original issue or change order. If not selected, tasks with this status are not included in estimates made by choosing the Accumulate feature on the Issue Detail or Change Order Detail window.

Continue to Next Tasks - When checked, changes the status of the next task to Pending when the current task reaches this status. This option can only be selected if Task Completed is selected.

Stop Service Type Events - When checked, automatically delays service type events when a task is changed to this status. For example, the predefined Hold status has this option checked, so that when you change the status of a task to Hold, all service type events are stopped.

Cannot Update Message - Displays the contents of this field if Allow Task Update is not selected and someone tries to change a task with this status.

Last Modified Date - Displays when the record was last modified, in the time zone of the server. This field is read-only, and is filled automatically each time the record is updated.

Last Modified By - Displays the name of the contact who last updated this record. This field is read-only, and is filled automatically each time the record is updated.

5. Click Save.
   The task status code definition is saved.

Define Change Status Codes

Change order status codes indicate how close a change order is to being completed. The status code appears in the Status field on a change order. Once change orders are assigned status codes, you can locate, categorize, and track them based on their condition.

Follow these steps:

1. On the Administration tab, select Service Desk, Change Orders, Status.
   The Change Order Status List appears.

2. Click Create New.
   The Create New Change Order Status page appears.

3. Complete the fields as appropriate. The following fields require explanation:

   - **Make Change Order Active**
     Activates an inactive change order, request, or issue when assigned to a ticket.

- **Stop Service Type Events and Targets**
  Automatically delays service type and events and targets for a ticket. For example, the predefined Hold status has this option checked, so when you change the status of a ticket to Hold, all service type events and targets are stopped.

- **Make Change Order Resolved**
  Indicates that a change order is resolved.

4. (Optional) Use the controls available on the tabs at the bottom of the page to configure the following:

   - **Change Order Transitions**
     Controls how users select available statuses on the ticket form. With transition controls, you can control how a ticket transitions through different statuses by limiting the status list. You can use predefined transitions, modify the transitions, or create transitions.

   - **Change Order Dependent Attribute Controls**
     Controls how attributes are designated as required (must supply) or locked (cannot update) depending on ticket status. With dependent attribute controls, you can determine which fields are shown, or required for the status. You can use predefined attributes, modify the attributes, or create dependent attributes.

5. Click Save.
   The status record is saved and the Change Order Status Detail page appears.

Risk Level

Risk levels determine the amount of risk involved in a change order. Risk levels are calculated after submitting risk surveys for a change order.

- **Level**
  Specifies the name of the risk level.

- **Value**
  Specifies the value of the risk level.

- **Description**
  Specifies the description of the risk level.

- **Status**
  Specifies if the risk level is active or inactive.

Define Issue Status

Issue status codes indicate how close an issue is to being completed. The status code appears in the Status field on an issue. Once issues are assigned to status codes, you can locate, categorize, and track them based on their condition.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration tab, browse to Service Desk, Issues, Status.
   The Issue Status List displays.

2. Click Create New.
   The Create New Issue Status page displays.

3. Complete the fields as appropriate.

   Record Status -- Shows whether this database record is active or inactive. This is a required field. Select a value from the drop-down list.

   Code -- Identifies the internal code for the status. This is a required field.

   Make Issue Active -- When checked, activates an inactive change order, request, or issue when you assign this status to the ticket.

   Stop Service Type Events -- When checked, automatically delays service type events when a ticket is changed to this status. For example, the predefined Hold status has this option checked, so that when you change the status of a ticket to Hold, all service type events are stopped.

   Make Issue Resolved -- When checked, indicates that an issue is resolved when it reaches this status.

4. Click Save.
   The Issue Status Detail page displays.

5. Click Close Window.
   The new status appears in the Issue Status List when you redisplay the list.

Define a Priority Calculation

This article contains the following topics:

Priority calculation is a predefined set of values that automatically set Priority, Urgency, and Impact values on problems and incident tickets.

Note: If you migrated from a previous release, the priority calculation values must be enabled after the migration. For more information about enabling priority calculation, see the Configure Ticket Management After Upgrade (see page 1040) topic.

You can define a priority calculation to handle, incidents, problems, or both. However because two priority calculations cannot handle the same ticket type, you can review and update existing priority calculations before you create ones. For example, if you want to add a priority calculation to manage problem tickets, first clear the Problem field on the active priority calculation. Then, create a priority calculation to manage problem tickets.

If multi-tenancy is installed, you can use one public priority calculation that applies to all tenants or several tenant-specific priority calculations.

Follow these steps:

1. On the Administration tab, select Service Desk, Request/Incidents/Problems, Priority Calculation.
   The Priority Calculation List page appears.

2. Click Create New.
   The Create Priority Calculation page appears.

3. Complete the following fields as appropriate:

   - **Name**
     Identifies the priority calculation.

   - **Status**
     Specifies the ticket status for this priority calculation.

   - **Incidents**
     Specifies whether this priority calculation applies to incident ticket types.

   - **Problems**
     Specifies whether this priority calculation applies to problem ticket types.

   - **Spelling**
     Verifies the spelling of text in the Description field.

   - **Description**
     Specifies the purpose of the priority calculation.

4. Complete the priority calculation by setting the Priority value based on Impact and Urgency. For example, if the Urgency is 5-Immediate and the Impact affects the 1-Entire Organization, you can select the Priority value of 1 from the drop-down list.

5. Set the following Priority Calculation Options as appropriate:

   - **Impact Default**
     Specifies the initial Impact (see page 3757) value to display when the user creates a ticket.

   - **Override Impact**
     Works with the Impact Increment field. Specifies whether the user can override the ticket Impact value with the Impact level specified in the attached Affected Service.

- **Impact Increment**
  Works with the Override Impact field. Increments the Impact by the specified amount when the user overrides the Impact value. When the ticket uses a blackout window, the Impact value increments only when the open date is within the blackout window time frame. The Impact value can only raise to a maximum of 1-High. For example, if you set the value to 2 and the default Impact is 3-Medium, the user can only override the Impact on a ticket to 1-High.

- **Urgency Default**
  Specifies the Urgency (see page 3807) value to display when the user creates a ticket.

- **Override Urgency**
  Specifies whether the user can override the ticket Urgency value with the Area Urgency level specified in Incident or Problem area.

- **Urgency Increment**
  Works with the Override Urgency field. Increments the Urgency level by the specified amount when the affected end user sets the Escalate Urgency flag.

- **Capture Reason**
  Specifies whether the user is required to enter the reason for changing the Urgency or Impact values. If the user changes the Urgency or Impact values, the Escalate Detail page appears while saving the ticket. The user is required to describe the reason for changing the Urgency or Impact values.

- **Enable for Templates**
  Specifies whether to use the priority calculation for tickets that use templates.

6. Click Reset Matrix if necessary to restore the settings to the defaults.
   The default values reset.

7. Click Save.
   The Update Priority Detail page appears. On the next new or updated ticket or Knowledge Document, the fields update according to the values in the active priority calculation. If no priority calculation is active for a ticket type, the system clears the Priority, Urgency, and Impact fields.

Priority Calculation Search Fields

The following fields are available to search for active and inactive priority calculations:

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The Public Data option specifies whether to include public and tenant priority calculations, exclude public priority calculations, or only show public priority calculations.

- **Name**
  Identifies the priority calculation.

- **Description**
  Specifies the purpose of the priority calculation.

- **Incident**
  Specifies whether to search for priority calculations that manage incidents.

- **Problem**
  Specifies whether to search for priority calculations that manage problems.

- **Status**
  Specifies whether the priority calculation is active or inactive.

Note: You can click the More icon to display the Additional Search Arguments field. This field is intended only for expert users who understand SQL and Majic and can use it to specify search arguments that are not available in the standard search filter fields. You can enter a SQL WHERE clause in this field to specify an additional search argument.

Use Ticket Templates to Calculate Priority Values

If you want ticket templates to calculate priority, you configure the priority calculation with the *Enable for Templates* option. If you enable this option the Urgency and Impact values come from the template, but the priority field comes from priority calculation record. The priority value displays as read-only.

If you do not enable this option, the Urgency, Impact and Priority fields come from the template. You can edit the priority field and no priority calculation is done for the ticket until it is saved.

To use ticket templates to calculate priority values

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Priority Calculation.
   The Priority Calculation List appears.

2. Select the priority calculation that you want to use for calculating priority with templates. You can also create a priority calculation to use ticket templates to calculate priority values.

3. Select *Enable for Templates* from the Priority Calculation Options list.

4. Click Save.
   The option is enabled.

Manage Request/Incident/Problem Status

This topic contains the following information:

- Define Dependent Attribute Controls (see page 1046)

Define a Request/Incident/Problem Status

Request/incident/problem status codes indicate how close a ticket is to resolution. Status codes allow you to track the progress of tickets, and categorize and locate tickets based on their condition. As a system administrator, you can use predefined status codes, modify the predefined status codes, or create new status codes.

You can mark any request/incident/problem status as active or inactive. When you mark a status code as inactive, it is no longer available for analysts to use, but it remains available in the database for future use. If you decide to use the request/incident/problem status in the future, you can go back and mark it as active.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration Tab, select Service Desk, Requests/Incidents/Problems, Status.
   The Request/Incident/Problem Status List page appears.

2. Click Create New.
   The Create New Request/Incident/Problem Status page appears.

3. Complete the request/incident/problem status fields (see page 1044) as appropriate.

4. Click Save.
   The Request/Incident/Problem Status Detail page appears.

5. Click Close Window.
   The new request/incident/problem status appears in the Request/Incident/Problem Status List when you redisplay the list.

Request/Incident/Problem Status Fields

The following fields are required to create or update the request/incident/problem status:

- **Symbol** -- Defines a unique identifier for the record. This identifier appears in the Status field on a ticket.

- **Record Status** -- Shows whether the database record is active or inactive.

- **Code** -- Defines the internal code for the status.

- **Make Active** -- If checked, specifies that an inactive change order, request, or issue is active when you assign this status to it.

- **Stop Service Type Events and Targets** -- If checked, specifies that service type events are delayed automatically when a ticket is changed to this status. For example, the Hold status that is predefined for requests, issues, and change orders has this option checked. When you change the status of a ticket to Hold, all service type events are stopped.

- **Make Resolved** -- If checked, causes the request, change order, or issue to have the Resolve Date /Time automatically set when it is changed to this status.

- **Description** -- Gives a detailed description of the record.

- **Status valid for** -- Defines what ticket types the record is valid for. The default is checked for all ticket types (Requests, Incidents, and Problems).

Note: If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Update a Request/Incident/Problem Status

As a system administrator, you can modify the predefined status codes or status codes you have created. Request/incident/problem status codes indicate how close a ticket is to being resolved. Status codes let you carefully track the progress of tickets, categorize and locate tickets based on their condition.

You can mark any request/incident/problem status as active or inactive. When you mark a status code as inactive, it is no longer available for analysts to use, but it remains available in the database for future use. If you decide to use the request/incident/problem status in the future, you can go back and mark it as active.

Follow these steps:

1. On the Administration Tab, browse to Service Desk, Requests/Incidents/Problems, Status.
   The Request/Incident/Problem Status List appears.

2. Select the request/incident/problem status.
   The Request/Incident/Problem Status Detail page appears.

3. Click Edit.
   The Update Request/Incident/Problem Status page appears.

4. Update one or more of the fields as needed.

5. (Optional) Use the controls available on the tabs at the bottom of the page to configure the following:

- **Request/Incident/Problem Transitions**
  Controls how users select available statuses on the ticket form. With transition controls, you can control how a ticket transitions through different statuses by limiting the status list. You can use predefined transitions, modify the transitions, or create transitions.

- **Request/Incident/Problem Dependent Attribute Controls**
  Controls how attributes are designated as required (must supply) or locked (cannot update) depending on ticket status. With dependent attribute controls, you can determine which fields are shown, or required for the status. You can use predefined attributes, modify the attributes, or create dependent attributes.

6. Click Save.
   The Request/Incident/Problem Status page appears.

7. Click Close Window.
   The modified request/incident/problem status appears in the Request/Incident/Problem Status List when you redisplay the list.

Define Dependent Attribute Controls

You can designate certain attributes as required or locked depending on the status of the CA SDM ticket (change order, issue, incident/problem/request). For example, a manager can prevent an analyst from editing the summary of a request after approval. For each ticket type, you can use predefined attribute controls, edit the attribute controls, or define attribute controls.

Note: When defining "required" dependent attribute controls for a particular status (all ticket types), be aware that the Edit in List option available on the ticket's list page cannot present the dependent attributes field values that are required. If the required attribute field value is not already part of the saved ticket, and if the required attribute field is not presented in the edit in list format to display its values, then the end user cannot save the ticket. Consequently, the ticket's detail page must be used instead of the Edit in List option to edit the dependent attribute fields values that are required.

Follow these steps:

1. On the ticket's detail page for the status, select the Request/Incident/Problem Dependent Attribute Control tab at the bottom of the page.
   The Attribute Control List appears.

2. Click Create.
   The Update Request Status Acknowledged Dependent Attribute Control page appears

3. Complete the following fields as appropriate:

   - **Tenant**
     Specifies the name of the tenant.

- **Attribute**
  Specifies the name of the attribute control, for example, Summary.

- **Locked**
  Specifies the attribute as locked (read only) while the ticket is in the status for which the dependent attribute is defined.

- **Required**
  Specifies the attribute as required (must be supplied).

4. Click Save.
   The attribute control for the status appears on the list page.

Define Status Transitions

Contents

You can define a subset of the full status list and determine the next status of the ticket as it continues through its lifecycle.

You can also specify how strictly the system enforces status transition policies by configuring the Status Policy Violations option in Options Manager (General Options).

Note: Because status transitions can be shared between integrations such as CA Workflow and Events and Macros, do not inactivate predefined status transitions unless explicitly requested.

To define a status transition

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, and specify one of the following:

2. Incident Transitions

   - Problem Transitions

   - Request Transitions

   The Transition List page appears.

3. Click Create.
   The Update Status Transitions page appears.

4. Complete the fields as appropriate.
   The transition is defined.

5. Click Save, Close Window.
   The transition appears in the Transition List when you refresh the page.

Edit Status Transitions

You can edit a status transition.

To edit a status transition

1. On the Transition List select a status from the list.
   The Transitions Details page appears.

2. Click Edit.
   The Update Transition Detail page appears.

3. Edit the fields as appropriate.

4. Click Save, Close Window.
   The updated status appears on the Transition Type list.

Update Initial Status Transitions

You can update the list of statuses that are valid at initial creation of the ticket.

To update an initial status transition

1. On the Transitions List page, click the Initial Transitions button.
   The Initial Transitions page appears and displays all available status codes and descriptions.

2. Fill in the following check boxes as appropriate:

   - **Allowed**
     Specifies a valid transition for the status list. Use this option to restrict status workflows.

   - **Default**
     Specifies the default status transition. CA SDM applies the default transition when a user clicks the default transition button on the ticket detail page, or when a user (including a web services user) updates the status to a <d> value. There is only one default transition for each status (or one for each tenant in a multi-tenanted system).

   - **Must Comment**
     Specifies that an activity log comment for the transition is required when changing the status on a ticket. An error message appears on the ticket form when the analyst attempts to close the ticket without adding a comment.

3. (Optional) Select a status code in the Name column to update its details.

4. Click Save.
   The updated status transition appears on the Transitions list.

View Status Transitions

The Transitions List page displays information about the transitions that let you control the movement of a ticket from one status to another (for example, from Open to Closed). The list records the current and new status values of the operation performed (update or insert). You can display the Transitions List for each ticket type.

To view status transitions

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, and specify one of the following:

2. Incident Transitions

   - Problem Transitions

   - Request Transitions

   The Transitions List page appears and lists attributes. The following fields require explanation:

   - **Status**
     Displays the current ticket status, for example, Open.

   - **New Status**
     Displays the new ticket status, for example, Closed.

   - **Tenant**
     Displays the tenant name.

   - **Default**
     Displays the default transition.

   - **Must Comment**
     Displays whether a comment for the status must be supplied.

   - **Status Description**
     Provides a brief description of the record.

Status Transition Fields

The following fields require explanation:

- **From Status**
  Defines the current status of the ticket, for example, Open.

- **To Status**
  Specifies a valid next status of the ticket, for example, Assigned.

- **Default Transition**
  Specifies the default status transition. CA SDM uses the default transition when a user clicks the default transition button on the ticket detail page, or when a user (including a web services user) updates the status to a <d> value. You can only configure one default transition for each status (or one for each tenant in a multi-tenanted system).

- **Must Comment**
  Indicates that a comment for the transition must be supplied. Specifying this option indicates that an analyst must supply an activity log comment when changing the status on a request.

- **Condition**
  Specifies the condition by which the transition is allowed. For example, when the condition "nonprty 1&2 assigned req" is associated with the Request Transition of Acknowledged to Hold, the condition verifies if the transition to move the status from Acknowledged to Hold is allowed.

- **Transition Type**
  Links a transition type to this transition. Transition types and their corresponding statuses control when employees can close and reopen Incidents and Requests using self-service. This field only displays for Incident and Request status transitions.

- **Condition Error Message**
  Specifies the message returned to the user if the transition is rejected.

- **Description**
  Specifies a description for the status transition.

Setting Up Category or Area

This topic contains the following information:

Change Order and Issue Categories

This article contains the following topics:

Change categories and issue categories define the logical groupings into which change orders and issues can be organized.

Note: Unlike request/incident/problem areas, change order categories and issues categories are managed separately:

- Set up change categories for internal and combined CA SDM models.
- Set up issue categories for external and combined CA SDM models.

You can use categories to specify default values for certain fields in tickets. You can automatically associate a level of service to tickets by assigning a default service type to categories. You can also associate a survey with a category.

For each category, you can specify attributes or qualities to be associated with the ticket and create a workflow that identifies all the individual tasks required to fulfill the ticket. By defining behaviors that are associated with the workflow tasks, you can notify key personnel when the status of the task changes or as activities close the ticket.

Whenever an analyst assigns a ticket to a category, all the information you have associated with the category is automatically entered on the ticket. For example, if you indicate a service type, it becomes associated with the ticket, and its associated service type events.

Predefined Change Categories

The following sets of predefined change categories are installed with CA SDM:

- Add
- Change
- Move
- Retire

Note: All these category sets are subdivided into more specific categories. For example, the Change category set includes categories for changing servers and workstations.

Predefined Issue Categories

The following predefined issue categories are installed with CA SDM:

- Hardware.pc.install
- Software.pc.install

You can set the status of any category to active or inactive. When you make a category inactive, it is no longer available for analysts to use, but it is not deleted from the database. If you decide at a later time to use the category, change the status back to active.

Rules for Changing Categories on a Ticket

The following rules affect only workflow tasks.

- If the previous category used Classic Workflow and the new category uses CA Process Automation, the CA Process Automation process definition links to a workflow on a CA Process Automation server.

- If both the old and new categories use CA SDM workflow, the rules from previous releases apply.
- If the new category uses CA Process Automation and the old uses CA SDM workflow, the following occurs:
  - All incomplete and pending (those tasks that can be updated) workflow tasks of the CA SDM 6.0 style, are set to Cancelled status, regardless of the KEEP_TASKS option. Any completed workflow tasks remain, but they cannot be reopened.
  - All incomplete and nonactive tasks (such as tasks in Wait status) are deleted.
  - The CA Process Automation definition instantiates.
- If the new category uses CA SDM workflow and the old category uses CA Process Automation, the following occurs:
  - The CA Process Automation instance is forcibly set to a status of Terminated.
  - The new category workflow tasks are added as normal.

In a CA SDM workflow, a ticket with a running CA Process Automation instance cannot be closed.

Create Workflow Task Types

Workflow task types specify lists of allowed status codes for workflow tasks assigned to those types. For example, Approval tasks may only allow Approve, Reject, Pending, and Wait status codes, while Install Software tasks may allow Pending, Wait, and Completed status codes.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration tab, browse to Service Desk and select any of the following:
   - Change Orders
   - Issues
   - Requests/ Incidents/ Problems
2. Select Workflow Task Types.

   The Task Type List displays.
3. Click Create New.

   The Create New Task Type page displays.
4. Complete the following fields as appropriate.

5. (Optional) Select Update Status Codes on the Status Codes tab and select the codes that you want to assign to the task type.

6. Click Save.

   The workflow task type is created.

Request/Incident/Problem Areas

Request areas define the logical groupings into which you can organize request, incident, and problem tickets. For example, tickets pertaining to an application can be assigned to the predefined Applications area. Whenever an analyst assigns a ticket to a request area, all the information you have associated with the request area is automatically entered on the ticket. For example, if you indicate a service type, it becomes associated with the ticket and all its associated service type events.

Note: The same area definitions are available for request, incident, and problem tickets. On the CA SDM Web Interface Administration tab, these areas are referred to as request /incident/problem areas. For brevity, they are referred to here simply as request areas.

You can set the status of any request area to active or inactive. When you make a request area inactive, it is no longer available for analysts to use, but it is not deleted from the database. If you decide later to use the request area, you need only change the status back to active.

You can use request areas to do the following:

- Specify default values for the group and assignee fields on tickets.
- Automatically associate a level of service to tickets by assigning a default service type to the request area.
- Associate a survey with a request area.
- Select and report on tickets by area by defining your own custom request areas. Eventually study request trends and analyze problem causes. Focusing your view to specific request areas can help make these studies more significant and revealing.

The following predefined request areas are installed with CA SDM:

- Applications
- Email
- Hardware
- Networks
- Printer

- Software
  Software is subdivided into several request areas.

Define a Category or Area

Contents

Issues or change orders can be assigned to categories so that default values defined for a category automatically appear in the fields while creating the issues or change orders.

Request/incident/problem areas define the general areas into which request, incident, and problem tickets can be organized. Categorizing these ticket types lets you generate reports, study trends, and analyze problem causes.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration tab, browse to Service Desk, and select any of the following:
   - Change Orders, Categories
   - Issues, Categories
   - Requests/Incidents/Problems, Areas

   The corresponding Area or Category List appears.
2. Click Create New and complete the fields, as appropriate:
   - For information about request/incident/problem areas, see Request/Incident/Problem Area Fields (see page 1055).
   - For information about issue category fields, see Issue Category Fields (see page 1056).

- For information about change category fields, see Change Category Fields (see page 1057)

3. (Optional) Add Properties to Requests/Incidents/Problems Areas (see page 1058) from the **Properties** tab.

4. (Optional) Attach a classic workflow (see page) or attach a CA Process Automation workflow (see page) (if you have integrated CA SDM with CA Process Automation).

> **Note:** You can attach classic workflow to each ticket type area only if you have applied a patch. Find the patch and download details from CA Support Online.

5. (Optional) Enable Auto Assignments (see page) from the **Auto Assignment** tab.

6. Click Save and close the window.
   The category or area is defined.

Request/Incident/Problem Area Fields

The following fields appear on the Create, Detail, and the Update pages for Request/Incident /Problem Areas:

- **Symbol**
  Defines a unique identifier for the record.

- **Organization**
  Specifies the company, division, or department that is associated with the request/incident /problem area. You can enter a value directly or click the magnifier to search for an organization.

- **Record Status**
  Shows whether the database record is active or inactive.

- **Group**
  Identifies the group that is responsible for this record.

- **Assignee**
  Shows the name of the person assigned to the record.

- **Service Type**
  Shows the level of support service received by the contact affected by the record.

> **Note:** Service types are automatically attached to issues based on the service type defined for its issue category. If different service types have been defined for other values on the issue (priority and contact, for example) the service type used is the one with the best (lowest) ranking. For example, if an issue is opened and the From contact has a 12-hour resolution service type, which is ranked as 2, while the priority code has a 4-hour resolution service type, which is ranked as 1, the service type for the issue is a 4-hour resolution.

- **Survey**
  Identifies the defined survey associated with this record. You can enter a value directly or click the magnifier to search for a survey.

- **Area Urgency**
  Specifies how critical the [Request, Incident, Problem] is to the business area.

- **Self-Service Include**
  Displays the request/incident/problem area in the self-service interface.

- **Self-Service Symbol**
  Defines a unique identifier for this request/incident/problem area in the self-service interface.

- **Description**
  Provides a detailed description of the record.

- **This category is valid for the following**
  Defines what ticket types the record is valid for. The default is enabled for all three ticket types (Requests, Incidents, and Problems).

Issue Category Fields

The following fields appear on the Create Issue Category, Issue Category Detail, and Update Issue Category pages:

- **Symbol**
  (Required) Defines an identifier for the category.

- **Code**
  (Required) Defines the internal code for the category.

- **Record Status**
  (Required) Indicates whether this database record is active or inactive. You can select a value from the drop-down list.

- **Group**
  Identifies the group that is responsible for the record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, change orders, and so on. Any individual contact assigned to the group can handle the task once it is assigned to the group. Enter a value directly or click the search icon to search for a group.

- **Assignee**
  Identifies the person assigned to the record. Enter a value directly or click the search icon to search for a contact.

- **Service Contract**
  Identifies the service contract name associated with this record. This field is read-only.

- **Service Type**
  Defines the level of support service received by the contact affected by the change order. For example, some users may have contracted for 24-hour support, while others might receive on-site training. Enter a value directly or click the search icon to select a defined service type.

- **Survey**
  Identifies the defined survey associated with this record. Enter a value directly or click the search icon to search for a survey.

- **Children Allowed**
  Allows issues assigned to this category to have subordinate issues. Organizes issues into a hierarchy of parent-child relationships to divide large issues into smaller, more manageable issues.

- **Self-Service Include**
  Displays this category in the self-service interface.

- **Self-Service Symbol**
  Defines a unique identifier for this category in the self-service interface.

- **Description**
  Gives a detailed description of the record.

Change Category Fields

The following fields appear on the Create Change Category, Change Category Detail, and Update Change Category pages:

- **Code**
  (Required) Defines the internal code for the category.

- **Type**
  Defines the level at which change orders are implemented within an organization.

- **Record Status**
  (Required) Indicates whether this database record is active or inactive. You can select a value from the drop-down list.

- **CAB**
  Specifies the group that is responsible for reviewing Requests for Changes (RFCs). The CAB provides multiple perspectives necessary to ensure proper decision making about implementing changes. The CAB can include members from the application team, development manager, component owner, QA, support, and any additional parties deemed necessary. You can enter the value directly or click the search icon to search for the group.

- **Organization**
  Identifies the company, division, or department that is associated with the change category. Enter a value directly or click the search icon to search for an organization.

- **Group**
  Identifies the group that is responsible for the record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, change orders, and so on. Any individual contact assigned to the group can handle the task once it is assigned to the group. Enter a value directly or click the search icon to search for a group.

- **Assignee**
  Identifies the person assigned to the record. Enter a value directly or click the search icon to search for a contact.

- **Service Type**
  Defines the level of support service received by the contact affected by the change order. For example, some users may have contracted for 24-hour support, while others might receive on-site training. Enter a value directly or click the search icon to select a defined service type.

- **Survey**
  Identifies the defined survey associated with this record. Enter a value directly or click the search icon to search for a survey.

- **Risk Survey**
  Indicates the defined risk for change orders associated with change categories.

- **Children Allowed**
  Allows change orders assigned to this category to have subordinate issues. Organizes issues into a hierarchy of parent-child relationships to divide large issues into smaller, more manageable issues.

- **Self-Service Include**
  Displays this category in the self-service interface.

- **Self-Service Symbol**
  Defines a unique identifier for this category in the self-service interface.

- **Service Contract**
  Identifies the service contract name associated with this record.

Add Properties

Properties are characteristics or attributes of tickets that are affected by the area or category the ticket is assigned to. For example, when you assign a request to a request area, the properties associated with that area are automatically assigned to the request.

Follow these steps:

1. On the Properties tab, click Add Property.
   The Create New Property Template page appears.

2. Complete the fields as appropriate. To limit the property values to selections from a predefined set, you can specify validation rules.

   The following values on the Properties pages are not self-explanatory:

   - **Sequence**
     Defines the order in which the properties appear on the Properties tab of the tickets assigned to this Area or Category. The property with the lowest sequence number is listed first.

   - **Active**
     Specifies whether the property is active or inactive.

- **Value Required**
  Indicates whether a value must be entered for this property on tickets assigned to this Area or Category. If selected, the word Yes appears in the Required column when this property is listed on the Properties tab of a ticket.

- **Validation Rule**
  Indicates the name of a rule that has been defined to validate user-entered values for this property. Enter the validation rule name directly or click the search button to search for a validation rule.

- **Label**
  The name of the property as it appears on the Properties tab.

- **Examples**
  Examples of appropriate values for the property. For example, if a freeform text field is intended to contain information about a network type, this field might include LAN, WAN, and SAN as example values. These examples appear on the ticket to provide guidance for entering the actual property value.

3. Click Save.
   The detail page lists the new property on the Properties tab.

   The keep_tasks option determines what happens when you assign an existing ticket to a different category:

   - If keep_tasks is not installed, existing properties and workflow tasks are removed from the ticket, and any properties or tasks associated with the new category are added.

   - If keep_tasks is installed, existing properties and tasks are retained on the ticket, and any properties or tasks associated with the new category are added.

Create Property Validation Rules

You can create validation rules to ensure that only valid values are assigned to custom properties. For example, if you have defined a property named Operating System, you can define the validation rule as a drop-down list containing the options Windows, UNIX, and Linux.

Properties that are defined without validation rules are presented to the user as freeform text boxes, which allow any text string to be entered. Validation rules make reporting on area and category values less complex and less error prone.

Note: Property validation rules are reusable. They are not specific to a particular property. You can apply any existing validation rule to properties defined for change categories, issue categories, or request/incident/problem areas.

Depending on which type of validation rule you have configured for a property, when the user assigns a ticket to the category or area to which that property is attached, one of the following controls appears on the ticket properties tab:

- Text Edit Box
- Check Box
- Drop-down List.

Follow these steps:

1. Access the create, detail, or update page for the custom property you want to assign a property validation rule. For example:

    a. Select Service Desk, Change Orders, Categories on the Administration tab.
    The Change Category List page appears.

    b. Click the Add.IT.Server link.
    The Add.IT.Server Change Category Detail page appears.

    c. Select the Properties tab and click the Add Property button.
    The Create New Property Template page appears.

2. Click the Validation Rule link.
    The Property Validation Rule Search page appears.

3. Specify any filter criteria and then click Search.
    The rules that match your filter criteria are displayed.

    Note: Validation rules are not specific to a particular category or area type. You can apply any existing validation rule to properties for change categories, issue categories, or request/incident/problem areas. Although you can create multiple checkbox validation rules, it is not necessary to do so. You can reuse an existing checkbox rule as many times times as you want by applying a different label. For example, if you have an existing checkbox rule named CB, and you later want to apply a checkbox validation rule to a different property, you can select CB from the Property Validation Rule List and then enter a different label on the Create New Property Template page.

4. Click Create New if there is no existing validation rule that meets your needs.
    The Create New Property Validation Rule page appears.

5. Complete the fields as appropriate.

6. For Dropdown validation rules only, the Property Value List tab appears on the Create New Property Validation Rule page. To specify the list of options that appears in the dropdown menu:

    a. Click Add Property Value.
    The Create New Property Value page appears.

    b. Complete the fields as appropriate and click Accept.

> **Note**: The Accept button accepts the changes, closes the window, and applies them to the current record, but you must still click the Save button on the main record window to make the changes permanent.

The Create New Property Validation Rule page appears with a highlighted status indicator showing the number of property values that are pending.

c. Repeat the above steps until you have added all the property values you want the dropdown list to contain.

7. Click Save on the Create New Property Value page.
   The Create New Property Template page appears, with the validation rule name filled in.

Attach a CA Process Automation Workflow

A workflow *process definition* identifies a collective series of tasks, steps, and conditions that are structured in a specific order for individuals or parties to initiate and complete. An administrator creates the workflow process definition and stores it on the CA Process Automation server.

From CA SDM, you attach a workflow process definition to a ticket area or category. Later, when a user creates a ticket with the area or category, the system automatically launches a workflow process instance. The Workflow Tasks tab tracks the workflow progress to completion.

> **Note: (Applicable, if you have applied the patch)** You can attach this workflow for each ticket type (request or problem or incident).

Follow these steps:

1. Click Use ITPAM from the Workflow tab.
   The CA Start Request Form is displayed with the following fields:

   - **Name**
     Specifies a name of CA Process Automation workflow process definition.

   - **Path**
     Specifies the location where the CA Process Automation process is stored on the CA Process Automation server. For example: ServiceDesk/Process/.

   - **Description**
     Describes the workflow.

2. Select the process definition.
   The Start Request Form closes and the process definition appears on the Workflow tab.

3. Click Save.
   The system saves the process settings. The next ticket that a user creates in the specified ticket category or area automatically attaches the workflow and creates a process instance. When the ticket area or category has an attached CA Process Automation process definition, the Workflow Tab contains the following fields:

   - **CA IT PAM Start Request Form**
     Searches for CA IT PAM Start Request forms.

   - **CA IT PAM Process Name**
     Specifies a CA Process Automation workflow process name. The process name you specify must match one of the processes that you specified in the Options Manager *caextwf_log_categories* parameter.

   - **CA IT PAM Process Path**
     Specifies the location where the process is stored on the CA Process Automation server. For example: ServiceDesk/Process/.

Attach a Classic Workflow

Classic workflow is provided as a standard CA SDM component. To allow flexibility, you can define workflow tasks as optional, which allows the analyst to delete them from the task list. All mandatory workflow tasks must be complete before the ticket can be closed. The only exception is that if the ticket status is set to Cancelled, the workflow process terminates automatically. If a ticket is removed from a category with an attached workflow, or assigned to a different category, the workflow process terminates automatically. If the new category has an attached workflow, its process starts automatically.

Ensure that you apply the patch before attaching this workflow to the request/incident/problem area. If you have customized the following files, ensure that you save the customization, apply the patch and then reapply the changes to these files:

- detail_pcat.htmpl
- pcat_wftpl_tab.htmpl
- detail_in.htmpl
- detail_cr.htmpl
- detail_pr.htmpl
- detail_pr.htmpl
- detail_pcat.htmpl
- list_wftpl.htmpl
- detail_wftpl.htmpl
- detail_bhvtpl.htmpl

- detail_cr.htmpl
- detail_in.htmpl
- list_ntfl.htmpl
- list_ntfm.htmpl
- detail_act_type_assoc.htmpl
- detail_evt.htmpl
- detail_macro.htmpl
- list_act_type_assoc.htmpl
- detail_ntfm.htmpl
- list_evt.htmpl
- detail_ntfl.htmpl
- list_slatpl.htmpl
- std_head.htmpl
- detail_sdsc.htmpl
- list_macro.htmpl
- xx_wf_tab.htmpl

Follow these steps:

1. Click Add Classic Workflow from the Workflow tab.

   Note: (Applicable, if you have applied the patch) For each ticket type (request or problem or incident), you can attach a classic workflow. For example, select the Request tab and click Add Classic Workflow. Similarly click Incident or Problem tab to attach the classic workflow, if required.

   The Workflow Definition List appears.

2. Complete the following fields as appropriate:

   - **Task** -- (Required) Defines the CA SDM workflow task type. Click this link to select a task from the Task Type List. For more information about task types, see Define Workflow Task Types (see page 1052).

- **Sequence** -- The order in which this task appears on the ticket's Workflow Tasks tab. The task with the lowest sequence number is listed first. Numbers do not need to be sequential.
- **Record Status** -- (Required) Identifies whether the database record is active or inactive. Select a value from the drop-down list.
- **Assignee** -- The name of the person assigned to the ticket. Enter a value directly or click the search icon to search for a contact.
- **Group** -- The group that is responsible for the ticket. Any individual contact assigned to the group can handle the task once it has been assigned to the group. Enter a value directly or click the search icon to search for a group.
- **Deleteable** -- Determines whether the user can delete this task from tickets.
- **Service Type** -- The level of support received by the organization. For example, some users may have contracted for 24-hour support, and others might receive on-site training. Enter the service type directly into the field, or click the search icon to select the desired service type.
- **Estimated Duration** -- Indicates the estimated date when the task should be finished. The date and time display in mm/dd/yyyy hh:mm am | pm format. Enter the date and time directly or click the calendar icon to select a date.
- **Estimated Cost** -- Estimates how much it costs to complete the task. Enter the amount as an integer without commas or periods. It is best to enter the amount in dollars only.

3. Click Accept. Repeat steps 1 and 2 to add more workflows.
   The workflow tasks appear on the Workflow tab.
4. Use the controls on the following tabs to configure the workflow tasks:
   - **Behaviors**
     Specifies behavior macros to perform actions based on conditions associated with the issue workflow status. For details about working with this tab, see Create a Behavior (see page).
   - **Auto Assignment**
     (Optional) Specifies how workflow tasks are automatically assigned to groups. For details about working with this tab, see Enable Workflow Auto Assignment (see page).

Create a Behavior

You can configure behavior macros to perform specified actions automatically, based on conditions associated with the issue workflow status.

Follow these steps:

1. Click Add Behavior.
   The Create New Behavior Template page appears.

2. Select a workflow task status and active or inactive from the drop-down lists and enter a description of what activities the behavior is configured to perform, then click Save.

   Note: You cannot define the actual functionality of the behavior until it has been saved.

3. Click the behavior's workflow status code on the Behavior tab of the Workflow Template page.
   The Behavior Template Detail page appears.

4. Click the To Do tab.
   Any conditions and macros that have been defined for the behavior appear in the Macro List.

5. Click Edit to update the Macro List.
   Any conditions and macros that have been defined for the behavior appear in the Macro List.

6. Click the Condition link.
   Macro List page appears, displaying the available condition macros.

7. Select a macro from the list.
   The macro symbol appears in the Condition field of the To Do tab on the Update Behavior Template page. For more information about macros, see create a macro from the How to Configure SLAs (see page 1099) topic.

8. Click Update Actions On True.
   The Macro List page appears.

9. Select Action in the Type drop-down list and click Search.
   The Actions On True Update page appears.

10. Select the actions you want to apply when the condition is true and click the arrow button to move them to the selected list, then click OK.
    The Update Behavior Template page appears, displaying your action selections.

11. Click Update Actions On False.
    The Macro List page appears.

12. Select Action in the Type drop-down list and click Search.
    The Actions On False Update page appears.

13. Select the actions you want to apply when the condition is false and click the arrow button to move them to the selected list, then click OK.
    The Update Behavior Template page appears, displaying your action selections.

Enable Auto Assignment

You can specify how CA SDM automatically assigns tickets in an area. You can select location-based auto assignment or CI-based auto assignment.

Note: The Options Manager autoasg_override option controls the circumstances under which auto assignment takes place. If the value of this option is set to 1 (default), CA SDM ignores any existing assignee and group settings and auto assigns tickets in all cases. If you want CA SDM to auto assign tickets only if they are not already assigned, set the option value to 0.

Follow these steps:

Complete the following fields from the Auto Assignment tab and click Save.

- **Auto Assignment Mode**
  Specifies how auto-assignment occurs. You use the Configuration Item Based option to base the auto assignment on the CI Assignable Attribute value.
  - **Disabled** -- Bases the auto-assignment on the Area Defaults option when it is installed.
  - **Configuration Item Based** -- Bases the auto-assignment on the CI Assignable Attribute value.
  - **Location Based** -- Bases the auto-assignment on the location value.
    The automatic assignment process begins with the workshifts defined for the area, proceeds next to groups, and finally to locations. If at any point relationships are defined that fail to satisfy the requirements of the auto assignment process, the process attempts to assign the Default Assignee and Default Group of the area. If no defaults have been defined, the ticket assignment is not changed.

  Note: For details about the auto assignment processing logic, see the Auto Assignment (see page 1132) topic.

- **Assignable CI Attribute**
  Specifies the configuration item attribute to use for the group assignment. You can enter a value directly or click the magnifier to search for an attribute.

Assign Groups

To configure auto assignment for a request/incident/problem area, you must at a minimum define the relationships between analyst groups and the area.

Assignees are chosen from groups that meet all of your specified auto assignment criteria. If no additional constraints are defined, tickets are auto assigned to the group member with the fewest active tickets.

If no groups are associated with the area, the default group and assignee are assigned. If these defaults are not defined, the ticket is left for manual assignment.

Follow these steps:

1. On the Auto Assignment tab of one of the pages, click Update Groups.
   - Change Orders Detail
   - Issues Detail
   - Requests/Incidents/Problems, Areas Detail

   The Group Search window opens.
2. To filter the search, complete one or more of the search fields, or leave all fields blank to search for all groups, then click Search.
   The Groups Assigned Update window opens.
3. Use the arrow buttons to move available groups to or from the Groups Assigned list.
4. Click OK.

Assign Locations

If you assign a location to a request/incident/problem area, the tickets in that area are auto assigned only if a matching location is found. For example, a request ticket is auto assigned if there is an eligible analyst at:

- The affected asset's location
- The affected customer's location

If the affected asset or customer has no specified location, the request is assigned to the default group and assignee. If these defaults are not defined, the request is left for manual assignment.

Follow these steps:

1. On the Auto Assignment tab of one of the following pages, click Update Locations.
   - Change Orders Detail
   - Issues Detail
   - Requests/Incidents/Problems, Areas Detail

   The Location Search window opens.
2. To filter the search, complete one or more of the search fields, or leave all fields blank to search for all locations, then click Search.
   The Locations Assigned Update window opens.

3. Use the arrow buttons to move available locations to or from the Locations Assigned list.

4. Click OK.

Assign Workshifts

You can constrain auto assignment by relating the request/incident/problem area to a workshift. The workshift determines the timeframe within which tickets are eligible for auto assignment. Tickets opened outside the hours of the workshift are assigned to the default group and analyst or left for manual assignment.

Follow these steps:

1. On the Auto Assignment tab of one of the following pages, click Update Workshifts.
   - Change Orders Detail
   - Issues Detail
   - Requests/Incidents/Problems, Areas Detail

   The Workshift Search window opens.

2. To filter the search, complete one or more of the search fields, or leave all fields blank to search for all workshifts, then click Search.
   The Workshifts Assigned Update window opens.

3. Use the arrow buttons to move available workshifts to or from the Workshifts Assigned list.

4. Click OK.

Define Behavior Template

A behavior template defines an action when a task changes status. For example, an email notification can be sent to a manager when the status of an approval task changes to Pending.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

The Create New Behavior Template page contains the following fields:

- **Status**
  Specifies the status of the template, such as Approve or Pending.

- **Active**
  Specifies if the template is active or inactive.

- **Description**
  Specifies a description of the template.

This page also contains the following tabs:

- **To Do**
  Identifies selected macros to run when the status change identified in the Status field takes place.

- **Transition Information**
  Identifies conditions that prevent the task from reaching the specified status, prior to the macros on the To Do tab run.

Note: All behaviors defined for a specific issue or change category are listed on the Workflow Task Template Detail window for that category and become part of any issue or change order that is assigned to that category.

Define Change and Issue Categories for Self-Service

You can use the Self-Service Include option to define which change and issue categories to include on tickets for self-service. You can also define different self-service symbols than the ones viewed by the analyst. When the ticket is saved, the self-service symbol appears in the Change (or Issue) Category field. If the ticket displays in the analyst interface, the normal symbol for the category appears.

Follow these steps:

1. On the Administration tab, select Service Desk, Change Orders (or Issues), Categories.
   The Category List page appears.

2. Select Edit In List.
   The top portion of the page displays the editable fields.

3. Select the desired category from the Symbol list.

4. Complete the following fields:

   - **Self-Service Include**
     Specifies whether this category is shown in the self-service interface.
     Default: Yes

   - **Self-Service Symbol**
     Specifies a unique identifier for this category in the self-service interface.

   - **Active**
     Specifies whether the category is active or inactive.

   The category is defined for self-service.

5. Click Save.
   The updated category appears in the Change (or Issue) Category List when you redisplay the list.

Change Category Fields

The following fields appear on the Create Change Category, Change Category Detail, and Update Change Category pages:

- **Symbol**
  (Required) Defines an identifier for the category. This is a required field.

- **Code**
  (Required) Defines the internal code for the category. This is a required field.

- **Type**
  Defines the level at which change orders are implemented within an organization.

- **Record Status**
  (Required) Indicates whether this database record is active or inactive. You can select a value from the drop-down list.

- **CAB**
  Specifies the group that is responsible for reviewing Requests for Changes (RFCs). The CAB provides multiple perspectives necessary to ensure proper decision making about implementing changes. The CAB can include members from the application team, development manager, component owner, QA, support, and any additional parties deemed necessary. You can enter the value directly or click the search icon to search for the group.

- **Organization**
  Identifies the company, division, or department that is associated with the change category. Enter a value directly or click the search icon to search for an organization.

- **Group**
  Identifies the group that is responsible for the record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, change orders, and so on. Any individual contact assigned to the group can handle the task once it is assigned to the group. Enter a value directly or click the search icon to search for a group.

- **Assignee**
  Identifies the person assigned to the record. Enter a value directly or click the search icon to search for a contact.

- **Service Type**
  Defines the level of support service received by the contact affected by the change order. For example, some users may have contracted for 24-hour support, while others might receive on-site training. Enter a value directly or click the search icon to select a defined service type.

- **Survey**
  Identifies the defined survey associated with this record. Enter a value directly or click the search icon to search for a survey.

- **Risk Survey**
  Indicates the defined risk for change orders associated with change categories.

- **Children Allowed**
  Allows change orders assigned to this category to have subordinate issues. Organizes issues into a hierarchy of parent-child relationships to divide large issues into smaller, more manageable issues.

- **Self-Service Include**
  Displays this category in the self-service interface.

- **Self-Service Symbol**
  Defines a unique identifier for this category in the self-service interface.

- **Description**
  Gives a detailed description of the record.

- **Last Modified Date**
  Displays when the record was last modified, in the time zone of the server. This field is read-only, and is filled automatically each time the record is updated.

- **Last Modified By**
  Displays the name of the contact who last updated this record. This field is read-only, and is filled automatically each time the record is updated.

- **Service Contract**
  Identifies the service contract name associated with this record.

Add Properties to Change Categories

Properties are characteristics or attributes of tickets that are affected by the area or category the ticket is assigned to. For example, when you assign a change order to a change category, the properties associated with that category are assigned to the change order automatically.

To add properties to a change order category

1. Click CA SDM, Change Orders, Categories on the Administration tab.
   The Change Category List page appears.

2. Select the category to which you want to add properties.
   The Change Category Detail page appears.

3. On the Properties tab, click Add Property.
   The Create New Property Template page appears.

4. Complete the fields as appropriate.

> **Note**: Properties that are defined without validation rules are presented as freeform text fields, which allow the user to enter any text string. To limit the property values to selections from a predefined set, you can specify validation rules.

5. Click Save.
   The Change Category Detail page lists the new property on the Properties tab.

Category Property Fields

The Properties pages allow you to define, view, and edit custom properties for an Area or Category.

The following values on the Properties pages are not self-explanatory:

- **Sequence**
  Defines the order in which properties appears on the Properties tab of the tickets assigned to this Area or Category. The property with the lowest sequence number is listed first.

- **Active**
  Specifies whether the property is active or inactive.

- **Value Required**
  Indicates whether a value must be entered for this property on tickets assigned to this Area or Category. If selected, the word Yes appears in the Required column when this property is listed on the Properties tab of a ticket.

- **Validation Rule**
  Indicates the name of a rule that has been defined to validate user-entered values for this property. Enter the validation rule name directly or click the search button to search for a validation rule.

- **Label**
  The name of the property as it appears on the Properties tab.

- **Examples**
  Examples of appropriate values for the property. For example, if a freeform text field is intended to contain information about a network type, this field might include LAN, WAN, and SAN as example values. These examples appear on the ticket to provide guidance for entering the actual property value.

Install Incident Tracking

This article contains the following topics:

Incident tracking lets analysts track an incident by selecting one or more flags for the incident. The information that analysts specify provides your organization with metrics about incidents for reports. For example, analysts can indicate that an incident was assigned incorrectly. When a large percentage of incorrectly assigned tickets appears in a report, your organization is aware that assignments must be adjusted.

For example, analysts can specify information to help your organization do the following:

- Improve SLA responsiveness and closure at lower levels within the support organization.

- Identify tickets that are incorrectly assigned.

- Indicate that a remote control tool was used to resolve the ticket.

You install the efficiency_tracking Options Manager option, so that analysts can use tracking options that appear on the Efficiency Tracking tab of incident detail pages.

Install Incident Tracking

You can install an option to let analysts track an incident by setting particular flags for the incident. The information that analysts specify provides your organization with metrics about incidents for reports. After you install the option, the tracking flags appear on the Efficiency Tracking tab of the Incident Detail pages.

Follow these steps:

1. On the Administration tab, browse to Options Manager, Request Mgr.
   The Options List appears.

2. Click efficiency_tracking.
   The efficiency_tracking Options Detail page appears with default values set.

3. Click Edit.
   The efficiency_tracking Options Update page appears with default values set, and you can edit the Description.

4. Click Install.
   The efficiency_tracking Options Detail page appears.

5. Click Close Window.
   Incident tracking is installed; however, the Efficiency Tracking tab does not appear on incident detail pages.

6. Restart CA SDM.
   The Efficiency Tracking tab appears on incident detail pages.

Related Ticket Activities

This article contains the following topics:

When an activity is generated for a CA SDM ticket, you can propagate the activity to one or more related tickets. For example, a Problem record created from an Incident can update the Incident record when the Problem is resolved. When the activity occurs, an activity log is generated for the related ticket that includes the following information:

- Related ticket activity type, for example, Update Status
- Contact name
- Parent ticket type and its reference number

- Activity log description, for example, status updated from Work in Progress to Open

Activity logs are propagated to related tickets based on the properties set within each activity notification. The attributes of the related tickets are not modified. The following relationships are propagated:

Problems propagate to all active Incidents.

- Change Orders propagate to all active Problems and Incidents.

As a system administrator, you can perform the following actions:

- Set up activity notifications to propagate related ticket activities.
- Configure a Related Ticket activity notification to notify the appropriate contacts when the activity is propagated to related tickets.

How to Define Activity Notifications for Related Tickets

You can propagate activity logs to related tickets based on the properties set in each activity notification. The attributes of the related tickets are not modified.

To define an activity notification for related ticket activities, do the following:

1. On the Administration tab, select Notifications, Activity Notifications.
2. Open the appropriate activity notification for editing.
3. On the detail page, click the Related Ticket Activity check box to mark it as active.
4. If you have multi-tenancy, perform the following:
   - Specify the appropriate tenant type from the Related Ticket Activity drop-down list.
   - Enter the name of the tenant in the tenant field, or click the search icon to search for a tenant.
5. (Optional) Update the default Notification Rule and specify contacts to receive notification.
6. Click Save, Close Window.
   The updated activity notification appears in the Activity Notification List when you redisplay the list.

How to Define Related Ticket Activity Notifications

You can change the default settings in the Related Ticket activity notification to notify the appropriate contacts when the activity logs are propagated to related tickets (requests/incidents /problems, change orders, and issues).

To define a related ticket activity notification, do the following:

1. Open the Related Tickets activity notification on the Activity Notification List page.

2. Click Edit and change one or more of the fields as appropriate on the detail page.

3. (Optional) Update the default Notification Rule for and specify contacts to receive notification.

4. Click Save, Close Window.
   The updated Related Ticket activity notification appears in the Activity Notification List when you redisplay the list.

Audit Log Use

CA SDM creates an audit log that records the following information:

- All changes to an issue (Issue)
- All changes to a request (Call_Req)
- All changes to a change order (Change_Request)
- All changes to a data partition (Domain) tables
- The login ID of the person associated with the change and an associated day/date/time stamp
- The before and after values of the update, insert, or delete
- The creation of contacts
- Creation and update activities to the nr object

Note: The audit log captures modifications to only the contact data partition field, but no other contact record updates.

The audit log feature is automatically installed, and you can enable it by installing two Audit Log options with the Options Manager: audit_ins and audit_upd. After you have installed these options, you can access the audit log on the Administration Tab by selecting Service Desk, Audit Log List. You can search the audit log list with a built-in search tool, and use it to facilitate report generation.

Priority Calculation

This article contains the following topics:

Priority calculation is a predefined set of values that automatically set Priority, Urgency, and Impact fields on problems and incidents. Priority calculation helps you manage incidents and problems for your business needs and IT capabilities. ITIL recommends that you prioritize tickets by using a data calculation that is based on Urgency and Impact values. Support organizations define this calculation

based on their unique processes, how this calculation determines Service Level Agreements (SLAs), and other key events in the system. This calculation can also include the criticality of the CI that is linked to the incident and problem. Prioritizing tickets effectively helps you accomplish the following:

- Allocate IT resources for tickets
- Better serve customers
- Reduce costs

The CA SDM solution for Priority Calculation includes the following components:

- A Priority Calculation Matrix based on the Urgency and Impact values
- Default values for Urgency and Impact
- Urgency and Impact adjustment options based on Affected Service, Open Date, Affected End User, and Incident or Problem Area
- A Capture Reason option for manually modifying Urgency or Impact
- An Enable for Templates option for creating a ticket from a Template

When you install CA SDM, a Default priority calculation automatically manages ticket values. You can modify the Default priority calculation settings, or create additional priority calculations to manage incidents or problems. In the priority calculation, you define the outcome based on business scenarios to make the level of importance and ticket handling more consistent. Users can override some settings, but they cannot set the Priority on the ticket because this value is data-driven. For multi-tenancy, you or the tenants can create additional priority calculations with specific settings for each tenant.

When an analyst opens an incident or problem, the system automatically uses an active priority calculation and ticket values to generate Priority, Urgency, and Impact settings. The settings are based on one or more of the following fields:

- Urgency
- Impact
- Affected End User
- Incident or problem Area
- Open Date
- Affected Service

Analysts can override Urgency and Impact values as necessary. Depending on how you configure Options Manager, employees can only override incident Urgency values when the *urgency_on_employee* option is installed. When the Capture Reason flag is enabled and users override Urgency or Impact values and click Save, the Escalate Detail page appears to let users describe a reason for the change.

All ticket priority calculations, manual overrides, and reason information appear in the New Activity Log. If no priority calculation adjustments occur, the system does not create an activity log entry.

Note: If you migrated from a previous version, priority calculation is disabled by default.

Priorities

Priority codes indicate the amount of attention a ticket should receive. Priority codes are used when defining automatic notification and external processing for specific types of situations. They are also used as a label in the scoreboard to prioritize tickets.

The predefined priority codes are:

1 = High priority

2 = Medium-high priority

3 = Medium priority

4 = Medium-low priority

5 = Low priority

None = No priority is assigned.

You can modify a priority code's symbol. For example, your site might decide not to use numbers at all and assign priority codes of low, medium, high, and so on.

You can modify a priority code's associated service type. For example, you could change the service type for priority code 1 from the default value of 04hr resolution to a custom service type of 02hr resolution.

Note: You can edit the predefined priority codes, but you cannot delete them or create new ones.

How Priority Calculation Manages Ticket Values

The system adjusts problem and incident values based on active priority calculation settings to assist Analysts in handling tickets more effectively. The following table summarizes how priority calculation changes fields based on the priority calculation and user actions for problems, incidents, web service, email, and the Text API:

Action	Automatic Field Changes	Description
User changes Affected Service	Impact Priority	The system evaluates the Service Impact value on the CI of type Service to calculate the new Impact value. The CIs of type Service are defined as CIs with their class defined in the Enterprise Service family. If the open date of the ticket is within the blackout window time frame, the system increments a new Impact value based on the Impact Increment field. The system only replaces the Impact value when the new value is greater than the initial Impact value.
User changes Incident Area	Urgency	The Urgency value changes only when the new value is greater than the default value.
User changes Incident Area *and* Affected End User	Urgency Priority	If the user sets the Incident Area field first, the Urgency value changes after the user sets the Affected End User. The priority calculation sets the Priority.
User changes Urgency *and* Impact	Priority Impact	The system evaluates the Service Impact value on the CI of type Service to calculate the new Impact value. If the open date of the ticket is within a time defined by a blackout window, the system increments a new Impact value based on the Impact Increment field. The system only replaces the Impact value when the new value is greater than the initial Impact value. If the Administrator sets Capture Reason, the user must provide a reason for the modification. If the user changes the Urgency or Impact values, these values remain the same throughout entire ticket creation or ticket update unless the user modifies them again. However, the system can update the overridden values for Urgency or Impact the next time the user updates the ticket. After the system adjusts Urgency and Impact, the priority calculation sets the Priority value.
User selects New Incident based on the Knowledge Document and system has overrides for Knowledge Documents (see page 1087 1087)	Impact Urgency	The system always uses the Knowledge Document or knowledge solution values irrespective of whether the values are greater than or lesser than the default priority calculation values. For example, if a priority calculation has an Impact value of 3-Single Group and Urgency value of 3-Quickly, and Knowledge Documents have an Impact value of 2-Multiple Groups and Urgency value of 4-Very Quickly, the system applies the values from the Knowledge Document to the incident. The priority value always derives from the priority calculation.
User accepts Knowledge Document as solution to problem or incident	Impact Urgency	The system uses the values from the Knowledge Document for Impact and Urgency. The system also uses the priority calculation to set the Priority value.
User derives incident from Knowledge Document by selecting New Incident	Impact Urgency Priority	The system uses the priority calculation values.

Action	Automatic Field Changes	Description
User derives incident from Knowledge Document without system overrides for Knowledge documents (see page 1087)	Impact Urgency Priority	The system uses the priority calculation values regardless of how the user created the incident for the Knowledge Document or knowledge solution.
Ticket accepts Knowledge Document as solution to problem or incident and the system does not override for knowledge documents	Impact Urgency Priority	The system uses values from problem or incident. The Priority value originates from the priority calculation.
Ticket that is in Read Only Mode accepts Knowledge Document as solution to the problem or incident and system overrides for Knowledge Documents	Impact Urgency Priority	The system uses the Impact and Urgency values from the Knowledge Document when the values are not empty. If the Impact/Urgency value in the Knowledge Document is empty the system uses values from the problem or incident. The Priority value originates from the priority calculation.
Ticket that is in Edit Mode accepts Knowledge Document as solution to the problem or incident and system overrides for knowledge documents.	Impact Urgency Priority	The system uses values from the problem or incident. The Priority value originates from the priority calculation.

Priority Calculation Generates Urgency Value After Saving Self-Service Tickets

By design, priority calculation generates Urgency values only after self-service users save incidents. Self-service users, such as VIP employees, employees, and anonymous users, can view the generated value after saving a ticket.

For self-service users, priority calculation uses the following settings and values to generate Urgency values:

- Urgency_On_Employee is set to Yes in Options Manager
- Override Urgency value is enabled in the active priority calculation for incidents
- *Web.cfg* Urgency settings such as AnonymousUrg for anonymous users, ESCEmpUrg for VIP employees, and EmpUrg for all other employees

- Area Urgency values
- Manual user overrides

The following table summarizes how priority calculation sets the Urgency value for self-service incidents:

Self-Service User Action	Urgency Value
The user saves an incident with the default Urgency and an empty Incident Area.	The ticket shows the default Urgency value from the *web.cfg*.
The user saves an incident after overriding the Urgency value.	Regardless of the Area Urgency, *web.cfg*, or priority calculation settings, the ticket shows the Urgency value that the user selected.
The user saves an incident after selecting an Incident Area. The Incident Area does not have a predefined Area Urgency value.	The ticket shows the default Urgency value from the *web.cfg*.
The user saves an incident after selecting an Incident Area that has a predefined Area Urgency value. The Override Urgency option is also enabled on the active priority calculation for incidents.	If the Area Urgency value is greater than the Urgency in the *web.cfg*, the ticket shows the Area Urgency value. However, the updated Urgency field is not visible while the user is creating or editing the ticket. When the user saves and reopens the incident, the updated Urgency value appears on the incident.
The user saves an incident after selecting an Incident Area that has a predefined Area Urgency value. However, the Override Urgency option is disabled on the active priority calculation for incidents.	The ticket shows an Urgency value from the *web.cfg*.
The user edits an existing incident that has an Incident Area with a predefined Area Urgency value.	The Urgency drop-down list shows the Area Urgency value and all applicable *web.cfg* values.

How to Set Priority Calculation

This article contains the following topics:

By default, ticket values such as priority are based on a priority calculation. You can find and adjust the initial values for Priority and Urgency in the web.cfg. The web.cfg has separate settings for various users such as guest, VIP-user, and employee.

Note: If you migrated from a previous version, priority calculation is disabled by default. Modified Incident and Problem Detail pages require additional configuration to operate properly.

To set priority calculation, do the following:

1. On the Administration tab, select Service Desk, Request/Incidents/Problems, Priority Calculation.
   The Priority Calculation List appears.

2. Right-click the default priority calculation and select Edit from the short-cut menu.
   The default Priority Calculation Detail page shows default settings for incident and problem tickets.

3. Review default priority calculation and adjust the values accordingly. When you set priority calculation values, consider the following issues for your working environment:

   - **Issue escalation** -- When tickets require escalation to a particular VIP, you can increase the value for Urgency.

   - **Critical CIs** -- For critical CIs, you can configure Service Impact for each CI.

   - **Critical Service Uptime** -- When CIs require high availability, add a blackout window.

   - **Blackout window** -- When CI-related tickets use a particular blackout window, you can increase the Service Impact value on the priority calculation.

4. Use the Manual Override setting to allow users to change tickets settings as necessary.

5. If you want a separate priority calculation to manage, problems or incidents, configure the ticket type (see page 1085).

6. Click Save.
   On the next new or updated ticket or Knowledge Document, the fields update according to the values in the active priority calculation.

7. Consider creating additional priority calculations for each ticket type. For multi-tenancy, create and activate additional priority calculations to manage tickets for each tenant.

Define a Priority Calculation

Priority calculation is a predefined set of values that automatically set Priority, Urgency, and Impact values on problems and incident tickets.

Note: If you migrated from a previous release, the priority calculation values must be enabled after the migration.

You can define a priority calculation to handle, incidents, problems, or both. However because two priority calculations cannot handle the same ticket type, you can review and update existing priority calculations before you create ones. For example, if you want to add a priority calculation to manage problem tickets, first clear the Problem field on the active priority calculation. Then, create a priority calculation to manage problem tickets.

If multi-tenancy is installed, you can use one public priority calculation that applies to all tenants or several tenant-specific priority calculations.

Follow these steps:

1. On the Administration tab, select Service Desk, Request/Incidents/Problems, Priority Calculation.
   The Priority Calculation List page appears.

2. Click Create New.
   The Create Priority Calculation page appears.

3. Complete the following fields as appropriate:

   - **Name**
     Identifies the priority calculation.

   - **Status**
     Specifies the ticket status for this priority calculation.

   - **Incidents**
     Specifies whether this priority calculation applies to incident ticket types.

   - **Problems**
     Specifies whether this priority calculation applies to problem ticket types.

   - **Spelling**
     Verifies the spelling of text in the Description field.

   - **Description**
     Specifies the purpose of the priority calculation.

4. Complete the priority calculation by setting the Priority value based on Impact and Urgency. For example, if the Urgency is 5-Immediate and the Impact affects the 1-Entire Organization, you can select the Priority value of 1 from the drop-down list.

5. Set the following Priority Calculation Options as appropriate:

   - **Impact Default**
     Specifies the initial Impact value to display when the user creates a ticket.

   - **Override Impact**
     Works with the Impact Increment field. Specifies whether the user can override the ticket Impact value with the Impact level specified in the attached Affected Service.

   - **Impact Increment**
     Works with the Override Impact field. Increments the Impact by the specified amount when the user overrides the Impact value. When the ticket uses a blackout window, the Impact value increments only when the open date is within the blackout window time frame. The Impact value can only raise to a maximum of 1-High. For example, if you set the value to 2 and the default Impact is 3-Medium, the user can only override the Impact on a ticket to 1-High.

   - **Urgency Default**
     Specifies the Urgency value to display when the user creates a ticket.

   - **Override Urgency**
     Specifies whether the user can override the ticket Urgency value with the Area Urgency level specified in Incident or Problem area.

   - **Urgency Increment**
     Works with the Override Urgency field. Increments the Urgency level by the specified amount when the affected end user sets the Escalate Urgency flag.

   - **Capture Reason**
     Specifies whether the user is required to enter the reason for changing the Urgency or Impact values. If the user changes the Urgency or Impact values, the Escalate Detail page appears while saving the ticket. The user is required to describe the reason for changing the Urgency or Impact values.

   - **Enable for Templates**
     Specifies whether to use the priority calculation for tickets that use templates.

6. Click Reset Matrix if necessary to restore the settings to the defaults.
   The default values reset.

7. Click Save.
   The Update Priority Detail page appears. On the next new or updated ticket or Knowledge Document, the fields update according to the values in the active priority calculation. If no priority calculation is active for a ticket type, the system clears the Priority, Urgency, and Impact fields.

Use Ticket Templates to Calculate Priority Values

If you want ticket templates to calculate priority, you configure the priority calculation with the *Enable for Templates* option. If you enable this option the Urgency and Impact values come from the template, but the priority field comes from priority calculation record. The priority value displays as read-only.

If you do not enable this option, the Urgency, Impact and Priority fields come from the template. You can edit the priority field and no priority calculation is done for the ticket until it is saved.

To use ticket templates to calculate priority values

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Priority Calculation.
   The Priority Calculation List appears.

2. Select the priority calculation that you want to use for calculating priority with templates.
   You can also create a priority calculation to use ticket templates to calculate priority values.

3. Select *Enable for Templates* from the Priority Calculation Options list.

4. Click Save.
   The option is enabled.

Multiple Priority Calculations

You can set up more than one priority calculation. However, only one active priority calculation handles problems, or incidents, or both. For example, you can have an active priority calculation for problems, and another for incidents. You can also save several inactive priority calculations for future use.

Priority Calculation Assignment for Multi-Tenancy

You or your tenants can create tenant-specific priority calculations to manage incidents and problems. When you assign priority calculations for multi-tenancy, consider the following:

- When a priority calculation has no assigned tenant, it is considered public. The status of a public priority calculation is either Active or Inactive. A priority calculation is no longer considered public when it is assigned to a tenant.

- If a tenant has no priority calculation assignment, the Default priority calculation or another active public priority calculation automatically manages problems and incidents.

- A priority calculation manages problems and incidents for one tenant. However, a separate tenant-specific priority calculation can handle each ticket type. For example, Company X has one priority calculation to handle incidents and another to manage problems.

- When tenants create their own priority calculations while public priority calculations are active, the tenant-specific priority calculation applies only to tickets for the respective tenant.
  For example, if the Default priority calculation is active, Company X tenant can create a tenant-specific priority calculation named new_priority_calculation. The new_priority_calculation settings and configurations apply only to Company X incidents and problems.

- If the tenant inactivates a priority calculation, the system uses an active public priority calculation to manage tenant problems and incidents.
  For example, Company X inactivates the tenant-specific priority calculation while there is still an active Default priority calculation. Priority calculation remains enabled for Company X because the system uses the Default priority calculation to manage incidents and problems for Company X.

Note: Because tenants can delete their own priority calculation records, we recommend that you inactivate the public priority calculations that manage incidents and problems. Instead, you or the tenants can create tenant-specific priority calculations.

- When you disable multi-tenancy and there is more than one active priority calculation that manages tenants, leave *only one* priority calculation to manage incidents and problems. For example, you can inactivate all priority calculations except one to manage incidents and another to handle problems.

How to Assign a Tenant to a Priority Calculation

For multi-tenancy, you can assign a tenant to a priority calculation. First, you inactivate public priority calculations. Then, you assign the tenant to a priority calculation and activate it.

To assign a tenant to a priority calculation, do the following:

1. On the Administration tab, select Service Desk, Request/Incidents/Problems, Priority Calculation.
   The Priority Calculation List appears.

2. Edit each public priority calculation, such as Default. Set the status to Inactive and click Save.
   The system disables the public priority calculations.

3. For each tenant, create or edit a priority calculation with tenant-specific settings for Impact, Urgency, and Priority.
   The Create Priority Calculation or Update Priority Calculation page appears.

4. In the Name field, specify the tenant.

5. In the Status field, select Active.

6. Click Save.
   The system applies tenant-specific values for Impact, Urgency, and Priority on new incidents and problems.

Ticket Type Considerations for Priority Calculation

When you configure ticket types for a priority calculation, consider the following:

- The default priority calculation lets you manage both incident and problem ticket types.

- If you are migrating from a previous release, you enable the default priority calculation or create a priority calculation to manage problems and incidents.

- Although you can have many priority calculations, only one active priority calculation can handle a particular ticket type. For example, one active priority calculation can manage problems and another can manage incidents.

- If you want to create a priority calculation and an active priority calculation already handles a particular ticket type, you first disable the ticket type on the active priority calculation. For example, if you want a priority calculation to manage problems, you disable the problem ticket type on the active priority calculation and create an active priority calculation that manages problems.

Configure Ticket Types for a Priority Calculation

You can specify the ticket types that the priority calculation manages. When the priority calculation is active, it manages Priority, Impact, and Urgency values on new tickets.

To configure ticket types for a priority calculation

1. On the Administration tab, select Service Desk, Request/Incidents/Problems, Priority Calculation.
   The Priority Calculation List appears.

2. Right-click a priority calculation and select Edit.
   The Update Priority Calculation page appears.

3. Select or clear one or more of the following options:

   - **Incidents**
     Enables or disables the priority calculation to manage new incidents.

   - **Problems**
     Enables or disables this priority calculation to manage new problem tickets.

4. Click Save.
   CA SDM uses the settings in the priority calculation to manage ticket values for new incidents, problems or both.

Use Ticket Templates to Calculate Priority Values

If you want ticket templates to calculate priority, you configure the priority calculation with the *Enable for Templates* option. If you enable this option the Urgency and Impact values come from the template, but the priority field comes from priority calculation record. The priority value displays as read-only.

If you do not enable this option, the Urgency, Impact and Priority fields come from the template. You can edit the priority field and no priority calculation is done for the ticket until it is saved.

To use ticket templates to calculate priority values

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Priority Calculation.
   The Priority Calculation List appears.

2. Select the priority calculation that you want to use for calculating priority with templates.
   You can also create a priority calculation to use ticket templates to calculate priority values.

3. Select *Enable for Templates* from the Priority Calculation Options list.

4. Click Save.
   The option is enabled.

Use Knowledge Documents to Calculate Priority Values

If you want knowledge documents to calculate priority, you can update the field mapping. After you configure the field mapping, the analyst can create incident or problem tickets from knowledge documents. The knowledge document calculates Impact and Urgency values on the tickets. If the Impact or Urgency value is missing, the values originate from the priority calculation.

Important! If you modify and save a ticket that already contains Impact and Urgency values calculated by a knowledge document, the priority calculation overrides the values set by Knowledge Management. The audit log displays these activities.

To use knowledge documents to calculate priority values

1. On the Administration tab, select Knowledge, Service Desk Integration.
2. Select Field Mapping.
   The Field Mapping page appears.
3. For Impact and Urgency, select the following check boxes as appropriate:
   - **Populate Empty Service Desk values**
     Specifies whether to use information from Knowledge Management to populate fields in issues or requests.
   - **Overwrite Service Desk values**
     Identifies the fields in issues or requests that correspond to fields listed in the Knowledge Management column.

   Note: When the Override Service Desk values field is not enabled but Populate Empty Service Desk values field is enabled for Impact and Urgency, the knowledge values for Impact and Urgency override the Incident values.
4. Click Save.
   Incidents and problems are created, using the Impact and Urgency values from the knowledge document to calculate the Priority value. If the values are missing, the ticket obtains the values from an active priority calculation. If no priority calculation is active for the ticket type, the system clears the Priority, Urgency, and Impact fields.

Manually Override the Impact Value

When you manually override the Impact value on a problem or incident, the active priority calculation that manages the ticket type automatically adjusts the Priority value.

To manually override the Impact value

1. Open the details page for the problem or incident you want to change.

2. Change the Impact value.
   If there is an active priority calculation that manages the ticket type, the Priority value automatically changes based on the settings in the priority calculation.

3. Save the incident.
   The Activity Log on the Incident Detail page reflects the Impact values changes.

Example: Manually override the Impact value on a new incident

1. Create an incident.
   By default, the Urgency value is 3-Quickly. The Impact value is 3-Single Group. The Priority value is 3.

2. Override the Impact value to 1-Entire Organization.
   The Priority value automatically changes based on the values in the active priority calculation that manages incidents.

3. Save the incident.
   The Activity Log on the Incident Detail page reflects the Impact value changes.

Manually Override the Urgency Value

When you manually override the Urgency value on a ticket, the active priority calculation that manages the ticket type automatically adjusts the Priority value.

To manually override the Urgency value

1. Open the details page for the incident you want to change.

2. Change the Urgency value.
   If there is an active priority calculation that manages the ticket type, the Priority value automatically changes based on the settings in the priority calculation.

3. Save the incident.
   The Activity Log on the Incident Detail page reflects the Urgency values changes.

Example: Manually Override the Urgency Value on a New Incident

1. Create an incident.
   By default, the Urgency value is 3-Quickly. The Impact value is 3-Single Group. The Priority value is 3.

2. Override the Urgency value to 5-Immediate.
   The Priority value automatically changes based on the values in the active priority calculation that manages incidents.

3. Save the incident.
   The Activity Log on the Incident Detail page reflects the change in the Urgency value.

Automatically Adjust Impact for a Problem or Incident

For Configuration Items defined with a family of Enterprise Service, you can automatically adjust the Impact value for problems or incidents. When you select the Problem or Incident Area and select an Affected Service, the impact adjusts according to the CI Service Impact settings for Enterprise Service CI's and the priority calculation.

To automatically adjust Impact for a Problem of Incident

1. Create a problem or incident for an Enterprise Service type CI.

2. Select an Affected Service.

3. Select a Problem or Incident Area.
   If there is an active priority calculation that manages the ticket type, the Impact value changes based on the Increment Impact value (used for Blackout Window impact assessment) in the priority calculation and the Service Impact value from the affected service.
   If you are using the default priority calculation, with a Service Impact for the Enterprise Service CI set to 1-Entire Organization, and the Problem or Incident is not opened within a Blackout Window the Impact value in the Problem or Incident is set to 1 and the Priority value on the ticket raises to a 2.

4. Save the ticket.
   The Activity Log on the Incident Detail page reflects the Impact value's changes.

Adjust Impact for a Problem or Incident Example

The following example shows you how to adjust impact for a Problem or Incident.

1. Create an Enterprise Service CI named CI-APC and set the class as one that comes under the family Enterprise Service.
   For example, you can set the class as Other Service, Business Services, or Infrastructure Service.

2. In the Service tab within the CI Detail page, set the Service Impact field to 2-Multiple Groups.

3. On the Service Desk tab, create an incident and set the Affected Service to CI-APC.

4. Save the ticket.
   The Impact field in the incident reflects the value from the Service Impact of the selected affected service (CI-APC). In this case, the Impact value is set to 2 -Multiple Groups.
   Note: If you are using the default priority calculation and the current ticket is created during a Blackout Window period then the Impact value increments by 1 and in the case above the Impact value is then set to 1-Entire organization.

Automatically Adjust Urgency for a Problem or Incident

For problems and incidents, you can automatically adjust Urgency and Priority by specifying an affected end user that requires Special Handling or by specifying a Problem/Incident Area that has an Area Urgency value.

When you assign special handling, with the Escalate Urgency turned on, for a contact or set an Area Urgency value for a Problem/Incident area, the Urgency value within the Problem/Incident automatically adjusts according to the values in the priority calculation and the Area Urgency value for the affected end user.

Follow these steps:

1. Create a problem or incident.

2. Select an Affected End user. For an elevated urgency, select an Affected End user that requires Special Handling that has the Escalate Urgency on.
   If there is an active priority calculation that manages the ticket type, the Urgency value changes based on the Urgency Increment value in the active priority calculation.

3. Select a Problem or Incident Area.
   If there is an active priority calculation that manages the ticket type, the Urgency value changes based on the Area Urgency value in the Problem/Incident Area definition.

4. Save the ticket.
   A confirmation message reminds you that the ticket requires special handling. The Activity Log on the Problem/Incident Detail page reflects the changes of the Urgency value.

Adjust Urgency for a Problem or Incident Example

The following example shows you how to adjust urgency for a Problem or Incident:

1. On the Administrator tab, create a contact named Non-VIP.

2. Create a special handling contact named VIP and set the Escalate Urgency value on.

3. Create an area named Test Area and specify Area Urgency as 2-Very Quickly.

4. On the Service Desk tab, create an incident.

5. For the Affected End User, select Non-VIP.

6. In the Incident Area, select Test Area and save the ticket.
   The Urgency field reflects the Area Urgency value from the Incident Area definition. In this case, the Urgency is set to 2-Very Quickly.

7. Change the Affected End User to VIP and save the ticket.
   If the default Priority Calculation matrix is being used, the Urgency value is incremented by 1 and is set to 1-Immediate. A confirmation message appears that reminds you that the ticket requires special handling. The Activity Log on the Incident Detail page reflects the Urgency value's changes.

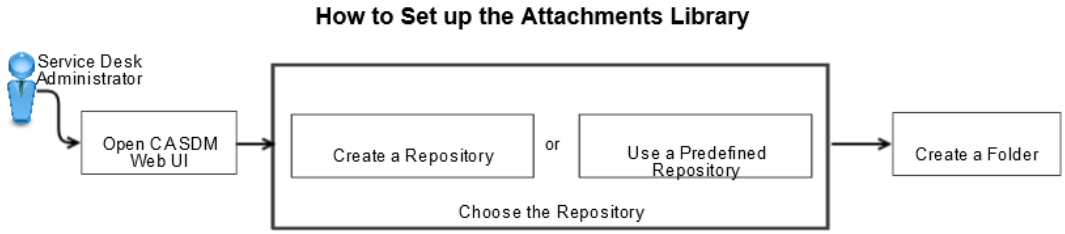
How to Set Up the Attachments Library

You can add different types of attachments to the various CA SDM entities. For example, a customer can attach a snapshot of an error to the incident. As an administrator, you set up the attachments library from where users can upload or download attachments.

Attachments can be classified, as follows:

- **Stored**: The web server uses the HTTP protocol to upload and store the stored attachments in a repository. When an analyst reviews a stored attachment, the file is retrieved from the repository and the file is displayed locally. Utilizing a web server for file storage allows storage and retrieval from the user interface.
- **Linked**: Stores only a link to the file in the database.

The following diagram shows how to set up an attachments library:



Follow these steps:

- Open CA SDM Web UI (see page 1091)
- Choose the Repository (see page 1091)
  - Setup a Repository on a Remote Computer (see page 1092)
  - Create a Repository (see page 1093)
  - Use a Predefined Repository (see page 1094)
  - Repository Fields (see page 1094)
    - Create UNC Credentials (see page 1096)
- Create a Folder (see page 1097)
  - Access Rights (see page 1097)
- Add a File to a Folder or Repository (see page 1098)

Open CA SDM Web UI

Log in to the web UI from the following servers, depending on your CA SDM configuration:

- Conventional: Primary or secondary servers
- Advanced availability: Application or background servers

Choose the Repository

The attachments are stored in repositories and you required to set up the repositories before users can work with attachments. You can add as many repositories to best suit your organization needs. For example, you might add separate repositories to store the file attachments and images. You can also add folders to your repositories to further organize your files, then upload files to the appropriate locations.

All client interfaces can access existing repositories for the upload and download of file attachments except as follows:

- Shared file repositories can be accessed only if the repository daemon is running on a computer that can access the shared file. The server name on the repository record (detail form) must be a Windows computer that has access to the share. A CA SDM repository daemon must also be running on the computer.

- Download of zip files is based on when they were uploaded. Attachments from earlier releases are downloaded without unzipping them. Unzip the file on the client computer; otherwise, attachments that are uploaded from a client interface, are also downloaded without unzipping them. That is, the server unzips the file before returning it, during a client download request.

The distributed architecture lets a site configure their repositories according to their needs. The servlet for a repository does not have to reside on the same server as the attached files. Sites can have a central servlet to access all their distributed repositories or have a dedicated servlet for each of their repository servers.

Consider the following setups when configuring repositories:

- **Repository server on a protected CA SDM server** -- Sites that designate a repository server on a protected CA SDM server behind the firewall do not need to expose the servlet on that computer. Rather, specify a servlet running on another CA SDM server or an unrestricted CA SDM server and still upload and download successfully to that repository. Depending on the network between the repository server and servlet server, some performance impact on the upload and download can occur. A good way to set up a remote repository is to install and configure another server with the repository on the remote server, and set the upload path to a local path. For more information, see the Setup a Repository on a Remote Computer (see page 1092) topic.

- **Servlet on the same server as the repository server** -- Sites that want the optimal performance for the attachment upload and download, and if the network performance is an issue and if very large files are being attached, should consider this setup. This approach requires exposing the Tomcat port (typically 8080) on the server and should be noted if the computer is behind a firewall.

CA SDM provides predefined repositories and also lets you create your own repositories to best suit your organization needs. Choose from the following options:

- Create a repository (see page 1093).

- Use a predefined repository (see page 1094).

Setup a Repository on a Remote Computer

By default, the repositories are located on the following server, depending on your CA SDM configuration:

- Conventional: Primary server

- Advanced availability: Background server

The default repositories use both the servlet and the repository daemon (rep_daemon) from these servers. To create a repository on a remote computer you must install and configure the following servers, depending on your CA SDM configuration:

- Conventional: Secondary server. The servlet runs on the primary server and the rep_daemon runs on the secondary server.
- Advanced availability: Background server. The servlet runs on the application server and the rep_daemon runs on the background server.

In the advanced availability configuration, the rep_daemon runs on all the servers, by default.

In the conventional configuration, the rep_daemon runs on the primary server, by default and you are required to verify that the rep_daemon runs on the secondary server for this setup.

(Conventional configuration only) Follow these steps:

1. Select **System**, **Configurations** on the **Administration** tab.
   The **Configuration List** page opens.
2. Select the configuration for the secondary server.
   The **Configuration Detail** page opens.
3. Click **Additional Processes**.
   The **Additional Process List** is displayed.
4. Click **Add Process**.
5. Select **Repository Deamon** as the **Process**.
6. Click **Save**.
   The repository is set up on the secondary server.

Create a Repository

Depending upon your organization needs, you can have one large repository or several small ones. Moving or combining repositories is simple because all the attributes about a repository are defined in the repository record.

Follow these steps:

1. Select **Attachments Library**, **Repositories** on the **Administration** tab.
   The **Repositories** page opens.
2. Click **Create New**.
   The **Create New Repository** page opens.

   Note: If you are the service provider, select the appropriate tenant from the **Create New Repository** page. The public (shared) option makes the repository available for all tenants.

3. Complete the Repository Fields (see page 1094) as appropriate.

4. Click **Save**.
   The repository is created.

> **Note:** To delete a repository, select Attachments Library, Repositories from the Administration tab, r ight-click on the repository, and select Delete. When you delete a repository, all files and folders within a repository are deleted as well.

Use a Predefined Repository

You can use a predefined repository (Service Desk or Knowledge or Images).You can edit a repository to best suit your organization needs.

Follow these steps:

1. Select **Attachments Library**, **Repositories** on the **Administration** tab.
   The **Repositories List** page opens.

2. Right-click the repository that you want to edit and select **Edit**.
   The **Update Repository** page opens.

3. Edit the fields as appropriate. For more information, see the Repository Fields topic.

4. Click **Save**.
   The repository definition is saved.

Repository Fields

The following fields are used to edit or create a repository.

Name

Specifies the name to uniquely identify the repository. For example, Incident Images repository can store all the images that are related to an incident.

- **Repository Type**
  Indicates the type of content that is stored in the repository. For example, to store image attachments, select **Images**.

- **Default**
  Indicates whether this is the default repository for the specified repository type. For example, when the user is creating the incident and user wants to attach an attachment to the incident, the default repository is displayed for the selection. You can only set one repository to default.

- **File Limit Size (KB)**
  Specifies the maximum size of file, in kilobytes, that a user can upload to the repository.

- **Upload Path**
  Specifies the full root directory path or the UNC path where files uploaded to the repository reside.

- **UNC Credentials**
  Specifies the credentials to access the UNC path specified in the **Upload Path** field. Click **UNC Credentials** to open the **Credentials Search** page.

  - If you have already created the credentials to access the specified UNC path, search using the fields and select the credentials.

  - If you want to create the credentials, click **Create New**. For more information about creating credentials, see the Create UNC Credentials (see page 1096) topic.

- **Background Services**

  Note: The options for background server services appears only in Advanced Availability configuration.

  Specifies the background server services for the servlet path and rep_daemon.

  - **None**
    Indicates that the background server is not used for the servlet path or for the rep_daemon. If you select this option, enter the values for **Servlet Server** and the **Repository Server** fields.

  - **Servlet Only**
    Indicates that servlet is hosted on the background server. If you select this option, the **Servlet Server** field is auto-populated with **Background Server** value. Enter the value for the **Repository Server** field. If the background server shuts down and if the standby server is promoted as the new background server, the **Servlet Server** field is populated with the new background server value.

  - **Daemon Only**
    Indicates that the rep_daemon is running on the background server. If you select this option, the **Repository Server** field is auto-populated with **Background Server** value. Enter the value for the **Servlet Server** field. If the background server shuts down and if the standby server is promoted as the new background server, the **Repository Server** field is populated with the new background server value.

  - **Servlet and Daemon**
    Indicates that background server is used for the servlet path and the rep_daemon. If you select this option, **Servlet Server** and **Repository Server** fields are auto-populated with the **Background Server** value. If the background server shuts down and if the standby server is promoted as the new background server, these fields are populated with the new background server value.

- **Servlet Server**
  Specifies the server where the servlet is running.

- **Repository Server**
  Specifies the server where the rep_daemon is up and running.

- **Archive Type**
  The archive and purge action to be taken on the contents of the repository.

- **None**
  No archive and purge process is performed.

- **Archive and Purge**
  The historic records are written to the file specified in the archive field and purged from the database.

- **Purge Only**
  The historic records are purged from the database, but are not written to the archive file.

- **Archive Path**
  Specifies the directory path or the UNC path to which files in the repository are moved during the archive process.

- **UNC Credentials**
  Specifies the credentials to access the UNC path. Click **UNC Credentials** to open the **Credentials Search** page.

  - If you have already created the credentials to access the specified UNC path, search using the fields and select the credentials.

  - If you want to create the credentials, click **Create New**. For more information, see Create UNC Credentials (see page 1096).

- **Prohibited File Types**
  The file extensions that users may not upload to the repository.

  Note: If the value in this field begins with an exclamation point (!), these file types are allowed in the current repository. For example, a value of jpg,gif in the list denotes that files with .jpg and .gif extensions are prohibited in the repository. However, a value of !jpg, gif denotes that only files with .jpg and .gif extensions are allowed in the repository.

Create UNC Credentials

You create the UNC credentials to allow users to access shared resources from the CA SDM servers using UNC path.

Important! The UNC component does not work when the CA SDM server is in the domain and the shared location is in the WORKGROUP. The UNC credentials that you use, must exist on the CA SDM server.

Follow these steps:

1. Click the UNC Credentials in the General Setting page or select Security and Role Management, UNC Credentials on the Administration tab.
   The Credentials List page opens.

2. Click Create New.
   The Create New Credentials page opens.

3. Complete the following fields as appropriate:

   - **Symbol**
     Specifies the unique identifier to identify the credentials during a search easily.

   - **Userid**
     Specifies the username to access the UNC path. The user can be a local or domain Windows user having access to the Service Desk server.

   - **Password**
     Specifies the password to access the UNC path.

   - **Active**
     Specifies if the UNC credentials are active or inactive. The inactive credentials cannot be used.

4. Click Save.
   The UNC credentials are created.

Create a Folder

Folders are used to organize the documents in repositories. For example, you can create a folder Error Images under the Images repository. This folder can contain all the snapshots of errors messages that the user has encountered.You cannot create a folder for the Service Desk Attachments repository type.

Follow these steps:

1. Select **Attachments Library**, **Repositories** on the **Administration** tab.
   The **Repositories List** page opens.

2. Right-click the repository where you want to create the folder and select **Add Folder**.
   The **Create New Folder** page opens.

3. Enter the name of the folder and a description of its contents.

4. Select the **Permissions** tab and specify the appropriate access rights (see page 1097).

5. Click **Save**.
   The folder is created.

Access Rights

You can add the following access rights to the folder in the repository:

- **Inherit from Parent**
  Indicates that this folder has the same permission settings as its parent folder. This option is only displayed for sub-folders.

- **Control by Group**
  Indicated the read or write access on this folder for specified groups. This option appears for all folders and sub-folders.

  - **Grant Write Permission to Everyone**
    Indicates that all users have write access to the folder.

  - **Grant Read Permission to Everyone**
    Indicates that all users have read access to the folder. Read permission indicates that you can view the folder, but you cannot edit, delete, or store files in it. Users with administrative rights can edit a folder even if their associated permission group cannot. If a user belongs to multiple permission groups with varying levels of access to the document, the user gets the highest available access level (for example, if one group has read-only access and the other write access, the user gets write access).

    Note: The **Grant Read Permission to Everyone** check box is automatically selected if you select the **Grant Write Permission to Everyone** check box.

  - **Available Groups**
    Displays all the groups. You can choose the groups from this list. For example, select a group and click > for **Groups with Write Permission** to provide read and write access to this folder for all the users in that group. Use **Show Filter** to specify criteria and filter the groups.

Add a File to a Folder or Repository

A knowledge administrator or a knowledge analyst can add a file to a folder or a repository. Ensure that you have an attachment library in place before proceeding.

Follow these steps:

1. Select **Attachments Library**, **Repositories** on the **Administration** tab.
   The **Repositories List** page opens.

2. Expand the repository, right-click the folder where you want to add the file, and select **Add File**.
   The **Add File** page opens.

3. Click **Browse** to navigate to the desired file and select it.

4. Enter a name for identifying the file, and a description, if necessary.

5. Click **Upload**.
   The file is uploaded to the folder of the repository.

Service Level Agreements (SLA)

This article contains the topics:

- How to Create Service Targets (see page 1111)
- Service Contracts (see page 1117)

A service level agreement (SLA) or service type is an agreement between a service desk and its customers and usually describes the level of service to be provided by the service desk. If this level of service is not provided, the service desk can be penalized. For example, a service desk that operates on a “pay per service” basis may not receive full payment for service that does not meet an agreed upon level of service. Thus, most service desks view service level agreements very seriously and make every effort to meet the type of service specified in these agreements.

In addition, most service desks keep meticulous records when service level agreements are met or violated. The service types defined with CA SDM are designed to help the service desk personnel meet their service level agreements and keep the records they need to verify that their service level agreements have been met.

How to Configure SLAs

In CA SDM, the SLA or service type describes the level of service that the service desk analyst provides to the customer. To track your enterprise commitments and schedules (as they relate to specific tickets), events are attached to service types. Events are used to define the condition under which the service type is violated and the actions to be taken after the violation. Each event has three generic behavior characteristics: conditions, actions on true, and actions on false.

- Condition identifies the measurable state of a ticket.
- Action identifies the processes that occur automatically when the condition is true or false after a specified amount of time.

Example: As a system administrator, you want to set up an SLA of 24-hours for a hardware request, failing which an email notification is sent to the Customer Support Manager and the analyst. This example is used throughout the scenario to explain how the email notification is configured for an SLA.

The following diagram shows how to configure the 24 hours. The SLA which sends an email notification, upon violation:

Follow these steps:

1. Open the CA SDM Web UI (see page).
2. Verify the Prerequisites (see page 1100).
3. Create a Macro (see page 1103).
4. Create an Event (see page 1108).
5. Create a Service Type (see page).
6. Attach the Service Type to an Object (see page).

Open CA SDM Web UI

Log in to the web UI from the following servers, depending on your CA SDM configuration:

- Conventional: Primary or secondary servers
- Advanced availability: Application or background servers

Verify the Prerequisites

Before you configure the service level agreement, ensure that you have completed the following steps:

- Installed the SLA options (see page 1100) which are necessary for your organization needs.
- Verified the Notification Method for the Recipient (see page 846)
- Created a Message Template (see page 848), if you want send an email notification upon an SLA violation and if you do not want to use a predefined message.

SLA Options

Depending on your organization needs, install the SLA options that you require to set up the SLA.

For example, in "classic" SLA processing (enabled if the classic_sla_processing option is installed in Options Manager) only one service type can apply to a ticket at any given time. When different attributes on a ticket have different service types associated with them, the higher ranked service type is used. The rank of a service type is defined when the service type is created, with the highest ranking being 1, the next being 2, and so on. For example, assume that the issue has a service type of 12-hour resolution (ranking 2), was assigned a priority code of 1, which has a service type of 4-hour resolution (ranking 1). The higher ranked service type determines the service behavior for the associated issue. In this example, 4-hour resolution is ranked higher than 12-hour resolution, so the 4-hour resolution service type is applied to the issue.

The following options can be installed from the Options Manager:

Option	Description
change_allow_sla_downgrade	Alters the behavior of the chg_sla option by allowing the system to automatically downgrade a change order's Service Type. The chg_sla option selects the best Service Type from among several change order attributes, but cannot replace the change order's current Service Type with one of lesser rank. If this option is installed, the Service Types for all affected attributes are evaluated whenever one of the attributes changes. The change order's Service Type is set to highest ranked Type found, even if the new Service Type is lesser in rank to the change order's current Service Type. The Service Type with the smallest Rank value is considered the best service. If all the Service Types considered are equal in Rank (including Service Types with empty Rank values), the Service Type created first in the database is selected. The chg_sla option must be installed for this option to function correctly. You can install similar option for issue, and request.
ttv_enabled	Runs the Time to Violation daemon, which monitors the SLAs for all open tickets and tasks. This process does not set the SLA violation, but records the date the ticket or task is violated in its current state. This projection is updated when the ticket or task is updated. This option must be installed in order for the other Time to Violation options to function correctly. **Important!** This option does not require you to install the classic_sla_processing option.

set_sl a_evt _ope n_dat e	Uses the open date/time value of a change order, issue, or request as the start date/time of attached events. The attached events are triggered as soon as the ticket is saved.

Verify the Notification Method for the Recipient

Ensure that the contact to whom you want to send the notification, is assigned to that particular notification method.

Follow these steps:

1. Select Security and Role Management, Contacts on the Administration tab.
   The Contact Search page opens.

2. Search for the contact using the filter and select the contact that you want to notify from the search result.
   The contact detail page opens.

3. Select Notification on the Contact Details tab.

4. Verify the notification method. Based on your notification priority, choose the required option. For example, you want to send an email notification for any emergency notification. Select the Email option in the Emergency field.

5. To change the notification method, click Edit, change the option, and click Save.
   The notification method for the contact is verified.

Create Message Templates

Create a message template that contains the values to use for the notification message. When you send multiple notification messages, you can use the message templates to simplify your workload.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Notifications, Message Templates from the Administration tab.
   The Message Template List page opens.

2. Click Create New.
   The Create New Message Template page opens.

3. Complete the fields as appropriate.

   - **Symbol**
     Defines a unique identifier for this message template.

- **Object Type**
  Specifies the object type associated with this template. For example, select Request/ Incident/ Problem for any notification related to a ticket.

- **Record Status**
  Specifies the status of the template as either active or inactive. Set the status to Active to use the message template.

- **Auto Notification**
  Specifies to send the notification associated with this template automatically, when the activity occurs. For example, you set up an initial notification, set up the objects to notify, and set up the message template, but you are not ready to turn on the notifications. In this case, you do not select Auto Notification. When you are ready to start automatic notifications, you select the check box. The notification becomes active and occurs as defined.

- **Notify Level**
  Indicates the relative importance of sending this notification. For example, select Emergency if you want to send the email notification to the contact immediately when the associated activity occurs.

- **Notification Message Title**
  Specifies the summary title of the message. You can use variables to insert the incident number in the message title. For example, @{call_req_id.type.sym} @{call_req_id. ref_num} @{type.sym}.

- **Notification Message Body**
  Specifies the content of the message. You can use variables to insert the analyst name, end-user name, and description into the message. For example,

```
@{call_req_id.type.sym} @{call_req_id.ref_num} @{type.sym}.

Assigned to: @{call_req_id.assignee.combo_name}

Customer: @{call_req_id.customer.combo_name}

Description: @{call_req_id.description}

Click on the following URL to view:

@{call_req_id.web_url}
```

  You can use the ARTIFACT keyword to specify how artifacts are handled in outbound messages, message templates, notifications, and auto-replies. The ARTIFACT keyword uses the following values:

  - **NONE** -- Specifies no validation of artifacts. This value is the same as not using the keyword.

  - **PROTECTED** -- Validates a ticket against the hash for confirmation. If confirmation fails, the artifact is considered invalid and filtering fails when filtering searching for an artifact ({{object_id}}).

- **SECURE** -- Decrypts the ticket number. If the value is not a valid password, the artifact is considered invalid and filtering fails when filtering is searching for an artifact ({{object_id}}).

- **HTML Message**
  Specifies the HTML message that is displayed to the recipient. If the recipient receives the message on an external device, such as a cell phone or PDA, the message displays in plain text only. Click Edit HTML Message to open the HTML Editor.

- **Quick View**
  Displays the message as it appears to the recipient.

- **HTML Source**
  Displays the message in the HTML source code.

4. Click Save.
   The message template is created.

Create a Macro

Macros are small scripts that define either conditions or actions. When Events or Behaviors execute, they can execute one or more Action macros. Before the macros are executed, you can use a conditional macro to determine which set of Action macros to execute.

You can use macros in the following areas:

- Events
- Behavior templates
- Activity Notifications

CA SDM includes several macros. Users can create their own macros too.

Note: Customers cannot add Action or Condition macros but can create simple macros with site-defined conditions. The Site-defined conditions are noncomplex macros that are created from GUI dialogs; they are not replacements for condition-type macros.

For each macro, you specify the object type that you want the macro to use. If you create a site-defined conditional to verify a Requests value, you set the type to Request. CA SDM displays only those object type macros that match the ones on the Events or Behaviors.

Create a macro. Use this macro to add actions to objects, check for certain characteristics, or conditions.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select **Events and Macros**, **Macros** on the **Administration** tab.
2. Click **Create New**.
3. Complete the fields as follows:
   - **Symbol**
     Enter a descriptive identifier for the macro.
   - **Macro Type**
     Select the type for this macro. The selected macro type controls the remaining data that is supplied.

     Note: The **Execute CA IT PAM Action** selection is only available when CA Process Automation Workflow is configured with CA SDM.
   - **Object Type**
     Select the type of object on which the macro can be run.
4. Click **Continue**.
   The page fills in with the remaining data.

Attach Event Macro

This macro type attaches an event object to a change order, issue, or request.

Example: Use Macros in the Behavior of Category or Area

You can also use macros in the Behavior for Issue and Change categories, and also for the Request/ Incident/ Problem areas. On a Category/ Area detail, select the Workflow tab, Workflow status, Workflow detail. Click Behavior and specify a Conditional-type macro. The macro is executed when a user tries to change the task status value to a new or different value. If the condition is set to false, updating the task status is not allowed.

Note: Use an Attach Event macro to attach an event to a workflow task.

Follow these steps:

1. Type the event name directly in the **Event** field, or click the search icon to select the desired event.
2. Click **Save**.
   The attach event macro is created.

Execute Remote Reference Macro

This type of macro launches an external program on the server.

Follow these steps:

1. Complete the following fields:

   - **Remote Reference**
     The name of the remote reference to the external program you want the macro to launch. Type the remote reference name directly into this field, or click the search icon to select the remote reference.

   - **Parameters to Command**
     Additional parameters required for running the command.

2. Click **Save**.
   The execute remote reference macro is created.

Create Multiple Notification Macro

This macro type lets you send a notification to one or more contacts. You can specify the message to send, the recipients of the message, and the urgency level.

Multiple Notification

The message body of the multiple notification points directly to the table of the object selected. Therefore, when referencing fields on the object table, (CR (Call_Req) for example,) you can reference the field attribute name. If you want to specify the description information of the Call Request ticket, enter the following command:

```
Description: @{description}
```

A QREL (Query Relation) is a relation which contains a list of objects. The list of objects are by an SQL type WHERE clause. You can add the QREL to the description of a multiple notification macro. To use the QREL in the act_log QREL <-- alg, enter the following command in a notification macro:

```
@{act_log.0.description}
```

You can use replacement variables to make notification messages more relevant and dynamic. These replacement variables take the form of @{attribute_path_here} where attribute_path_here is an attribute of some CA SDM object. When the notification is sent, the variable is replaced with the attribute value specified.
A notification (from an activity log or a multiple notification) always has some base context (a ticket or a workflow task). On multiple notification, the Notification macro type field specifies the base object. You use the @{} syntax to reference any attribute on that object.

Example: A Multiple Notification of type Request references any attribute in the 'cr' (Call_Req) object. To include the Request description, specify @{description} (dot-notation is used to follow references to other objects). For example, to include the Request assignee last name: @{assignee. last_name}.

Follow these steps:

1. Type the template name directly in the **Message Template** field, or click the search icon to select the desired template. This template is used to create the notification message.

2. Click **Save**.

3. Choose the appropriate contacts to notify from the following tabs:

   Note: Use the **Update Contacts** button that appears on each tab to search for and select more contacts to notify.

   - **Object Contacts**
     The available organizations, vendors, and configuration items for the selected Object type. For example, you can select Affected End User or Affected End User's Org to notify.

   - **Contacts**
     The individuals who are added to the notification macro, regardless of their association with the ticket.

   - **Contact Types**
     The users who are defined within the notification macro with the same classification, such as analyst or customer.

4. Click **Save**.
   The multiple notification macro is created.

Create a Site-Defined Condition Macro

This type of macro evaluates true and false conditional statements, and can be created by administrators to provide specific behaviors to individual sites.

Site-Defined Condition
The Conditional macro is made up of one or more *atomic* conditions. Each atom tests the value of a single attribute. The Conditional macro uses two atoms, one for Assignee and one for Category. The individual atoms in the Conditional Macro event are connected with a Boolean operator 'AND' or 'OR'. The Conditional Macro Detail shows a list of Atoms, which is read from left to right as follows:

Attribute	Operator	Value	Logical	Translation
Assignee	Equals	Jones	AND	The assignee is Jones and…
Cost	Less than	600	OR	Cost is an integer value less than 600 or…
Group	Empty/NULL		AND	The Group field is blank.

Note: The Logical connectors (AND, OR) connect two atoms. When there are two atoms, Atom A and Atom B, the atom A connector connects the atom. Atom B connector is not used.

Follow these steps:

1. Complete the following fields:
   - **If All Conditions Succeed Return**
     Select the value you want to return if all conditions succeed. Valid values are True or False.
   - **Record Status**
     Select whether the macro is Active or Inactive.
2. Click **Save**.
3. Click **Add Condition** on the **Conditions** tab.
   The **Create New Atomic Condition** page opens.
4. Fill in the following fields as appropriate:
   - **Sequence**
     The order in which the condition is evaluated within the site-defined condition.
   - **Select an Attribute**
     The attribute to be evaluated. Enter the attribute name directly in this field or click the search icon to select the desired attribute.
   - **Choose Operator**
     Select the conditional operator to use in the evaluation. Valid values are: Equals, Does Not Equal, Greater Than, Less Than, Empty/Null, Not Empty/Null.
   - **Select Attribute or Data Value**
     Choose either Attribute or Data Value to be evaluated.
   - **Attribute Value/Data Value**
     The value to be evaluated. Enter the attribute or data value directly into the field, or click the search icon to select the desired value.
5. Click **Save**.
6. Repeat this process until all the desired conditions have been created.
   The site-defined macro is created.

Execute CA IT PAM Action Macro

You can create a macro to initiate a CA Process Automation process. This process definition can be associated with any CA SDM ticket type. The change category, issues category, or request/incident /problem area the ticket is assigned to determines the process definition that is applied to the individual tickets. If a CA Process Automation workflow has been attached to the selected category, the workflow is automatically attached and initiated when the ticket is saved.

Complete the macro description, record status, and the **CA IT PAM** start form and click **Save**.

Create an Event

You can configure events that are attached to objects to execute configured actions. Events are procedures that execute after a certain amount of time has elapsed. For example, an event sends a message to a service desk analyst if a "priority 1" issue is not received within an hour. Other parts of the system use events, for example, Service Types.

You can define events for Requests, incidents, problems, change orders, issues, contacts, configuration items, and global and specific tenants. CA SDM schedules the events execution time that is based on the delay time and workshift.

Create an event and attach a macro to this event. This event is executed after certain time is elapsed. If any macro is attached, an action is performed.

1. Select Events and Macros , Events on the Administration tab.
2. Click Create New.
3. Complete the event fields (see page 1108) and the configuration information fields (see page 1108).
4. Click Save.
5. To add the macro to this event, complete the action information fields (http://wiki.ca.com#actioninformationfields).

   The new event is saved.

Event Fields

- **Object Type**
  Indicates if the event is attached to an issue, request, change order, workflow task, knowledge document, knowledge report card, assistance session, or managed survey.
  This field can only be edited when creating an event. This field is read-only when you want to update the event.
- **Record Status**
  Indicates whether the event is active or inactive. Only active events can be used.

Configuration Information Fields

Complete the following configuration information fields:

- **Delay Time**
  The time after which the event is triggered.
- **Repeat Delay Time**
  The interval of time after which you want the event to be triggered again.
- **Allow Time Resetting**
  Indicates that the desk analyst can change the **Delay Time**. Select this option to use an event as a Service Type event.

- **Work Shift**
  The dates, days, and hours when the service type is in effect.

- **On Done Event Flag**
  The action that is taken once the event is complete.

  - **Repeat Event**
    The event at the specified time interval until the issue is closed.

  - **Save History**
    Records the history of activities that are taken on the event.

  - **No History**
    Do not record any history of the event. The event does not appear in the **Event History** window.

- **Condition**
  Displays the macro (if associated with the event) indicating the condition that is checked for by the event.

- **Text**
  Defines the event configuration. For some action macros, this field is used for a specific purpose. For example, the **Transfer to Event Contact** action macro contains the User ID of the person to whom the ticket can be transferred.

Action Information Fields

Select the actions to be associated with the event as follows:

1. Click the **Action Information** tab.

2. Select one or both of the Set SLA Violation for Actions on True/False Macro check boxes. Selecting these check boxes logs a Service Level Agreement (SLA) violation when a true or false condition is encountered for the event.

   Note: Specify appropriate macros for true or false condition under the action list to log the SLA violations.

3. Click **Update Actions on True**.
   The **Macro Search** page opens.

4. Search for the macros to be performed if the event condition is true.

5. Select the desired macros from the list on the left, and click More (>>).
   The selected macros are added to the list on the right.

6. When all desired macros are in the list on the right, click **OK**.
   The selected macros appear in the **Actions on True Macro List**.

7. Click **Update Actions on False**, and repeat the previous procedure to select the macros to be performed if the event condition is false.

Create a Service Type

You can create a service type that suits your requirements. You can also modify a predefined service type.

Follow these steps:

1. Select **Service Desk**, **Service Types** on the **Administration** tab.
   The **Service Type List** page opens.

2. Click **Create New**.

   The **Create New Service Type** page opens.

3. If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

4. Complete the following fields, as appropriate:

   - **Symbol**
     Defines a unique identifier for the service type. In this example, you assign the symbol as 24_hr_resolution.

   - **Ranking**
     Defines a ranking for the service type. In this example, the hardware request ticket may be associated with multiple service types. The ranking value determines the applicable service type. The service type with low ranking has the highest priority.
     Enter 1.

   - **Workshift**
     Specifies the dates, days, and hours when the service type is in effect. The following rules apply to workshifts:

     - If you apply a workshift to a service type, stop and restart the service for the workshift to take effect immediately.

     - If a workshift for a service type has been specified, but not for an event, the service type workshift is in effect.

     - If a workshift for an event has been specified, but not for a service type, the service type workshift is ignored.

     - If a workshift for the event and service type have been specified, the service type workshift is ignored.

   - **Timezone**
     Specifies the time zone for the service type. This time zone is used for triggering events in the system if the **Use End User's Time Zone** option is not selected.

- **Use End User's Timezone**
  Specifies the timezone of the affected end user to trigger the events.

- **Violation Cost**
  Specifies the cost that is incurred if the service type time limit is violated.

5. Click **Save**.
   The service type is saved.

6. To attach a service type event, select the appropriate tab (Requests, Change Orders, Change Order Tasks, Issues, or Issue Tasks) and click **Add Service Type Event**.
   The **Create New Service Type Event** page opens.

7. Click **Event**.
   The **Event List page** opens.

8. Select one of the existing events from the list.
   The selected or created event is displayed in the **Event** field.

9. Click **Continue**.
   The service type detail page is displayed with the attached event.

Attach the Service Type to an Object

Service types can be associated with various objects such as contacts, organizations, categories, priority codes. According to the example, you attach the service type to the Incident Area, which is Hardware.

Follow these steps:

1. Open the related ticket for which you want to assign an SLA.

2. Click **Hardware** from the **Incident Area** field.
   The **Hardware Update Request/Incident/Problem Area** page opens.

3. Click **Edit**.

4. Click **Service Type**.
   The **Service Type List** page opens.

5. Search for 24_hr_resolution service type that you have created.

6. Click 24_hr_resolution from the search result.
   The **Hardware Update Request/ Incident/ Problem Area** page opens with the updated service type.

7. Click **Save**.
   The service type is attached to the Hardware incident area.

How to Create Service Targets

This article contains the following topics:

- Link a Service Target Template to a Service Type (see page 1114)
- View Ticket Counters and Timers for Service Targets (see page 1114)
- View Service Target Status (see page 1116)

To minimize the SLA violations, you can create a set of service target templates to measure each stage of ticket resolution. Like Service Types, each service target contains a condition and estimate of completion time. However, service targets do not provide an action mechanism.

During the ticket creation, a Service Type assigns one or more service targets to track each stage of the ticket resolution. Each time the ticket changes, the active service targets evaluate the condition. If the condition is met, the ticket and activity log show the actual completion time. When the time exceeds the estimated time, the ticket displays the amount of time by which the target was missed.

Service targets let you do the following actions:

- Verify that tickets of the same Service Type follow the same service targets.
- Monitor whether tickets are closed within the required time frames.
- View information such as the remaining number of minutes before a service target completes.

When creating service target templates, consider the following points:

- Consider the required outcome for meeting the service target. Use an existing Condition or Site-Defined Condition Macro to evaluate ticket data. If necessary, modify or write a new macro to manage the service target.
- Calculate the projected violation and penalty costs based on the SLA agreements.
- Assign at least one service target template to a Service Type.

Follow these steps:

1. Create a service target template (see page 1112) to manage requests, incidents, problems, change orders, or issues.
2. Link the service target template to a Service Type (see page 1114).
3. Assign the service target template detail to a ticket category such as request, incident, problem, change order, or issue tickets.
   At the time of ticket creation, the appropriate template automatically attaches to the ticket based on the Service Type. Each time a user creates a ticket, the status of the service target automatically displays in the Service Type tab.

Create a Service Target Template

You can create a service target template to measure service targets for requests, incidents, problems, issues, or change orders. After you create the template, you can link it to a service type.

Note: If multi-tenancy is installed, specify the tenant in the Tenant field.

Follow these steps:

1. Select **Service Desk**, **Service Target Templates** on the **Administration** tab.
   The **Service Target Template List** page opens.

2. Click **Create New**.
   The **Create New Service Target Template** page opens.

3. Select a ticket type from the **Object Type** field, and click **Continue**.

4. Complete the following fields as appropriate:

   - **Name**
     Defines a descriptive identifier for the service target.

   - **Object Type**
     Identifies the ticket type for this service target.

   - **Target Duration**
     Specifies the maximum amount of time for service target completion in the hh:mm:ss format.

   - **Workshift**
     Specifies the workshift which contains a range of working hours that are used in time calculations for a service target, for example, M-F 08:00-17:00.

   - **Cost**
     Defines information such as the estimated cost associated with missing the service target.

   - **Record Status**
     Indicates whether this target is active or inactive.

   - **Condition**
     Specifies the name of the condition macro or site-defined condition that evaluates the ticket data and determines whether the service target is met.

   - **Required Outcome**
     Specifies a True or False value that indicates whether the service target is complete.

   - **Allow Set Actual**
     Specifies whether to allow users to set the date and time for a service target.

   - **Allow Reset Actual**
     Specifies whether to allow users to reset the date and time for a service target.

5. Click **Save**.
   The service target template is created.

Link a Service Target Template to a Service Type

When you link a service target template to a service type, the targets are automatically attached to a ticket when the service type is assigned. You can only assign a service target template once to a service type. Many different service targets can be linked to a service type.

Follow these steps:

1. Select **Service Desk**, **Service Types** on the **Administration** tab.
   The **Service Type List** page opens.

2. Select a service type.
   The **Service Type Detail** page opens.

3. Select the target tab for the selected object type. For example, if you have created the service target for request, select **Request Targets** tab to manage problem, incident, and request tickets.

4. Click **Link Service Target Template**.
   The **Create New Linked Service Target Template** page opens.

5. You can enter a value directly or click the magnifying glass to search for a service type.

6. Click **Continue**.

7. Make changes to the service target template, if necessary.

8. Click **Save**.
   The service target template is linked to the service type.

View Ticket Counters and Timers for Service Targets

If an analyst assigned a set of service targets to a ticket, you can view the status and deadlines for completing each target.

Follow these steps:

1. On the Service Desk tab, display a list of Incidents, Problems, Requests, Change Orders, or Issues.
   The ticket detail page appears.

2. Click the Service Type tab.
   Additional Service Type information appears at the bottom of the ticket.

3. In the Target column, click the Service Target for additional information.
   The Ticket Counters and Timers section appears near the bottom of the Assigned Service Target Detail page. The Assigned Service Target Detail page displays the following fields:

   - **Name**
     Displays the name of the service target.

- **Target Duration**
  Displays the amount of allotted time to perform the service target. You can only override this value by editing the ticket.

- **Workshift**
  Displays the schedule used for time calculations for the service target.

- **Condition**
  Displays the condition or site-defined condition macro that evaluates the ticket data to determine whether the work can complete within the target time frame.

- **Required Outcome**
  Displays the required result of the condition or site-defined condition Macro.

- **Cost**
  Displays the penalty that incurs for missing the target. This information also displays on the ticket.

- **Target Date/Time**
  Displays the deadline for completing the target. If the ticket is in a Hold status or the service target has been met, this field is blank.

- **Actual Date/Time**
  Specifies the date and time that the condition was satisfied or the user clicked Set Actual.

- **Time Left**
  Displays the amount of remaining time for the service target. A negative value indicates the amount of time that exceeded the target time frame.

- **Allow Set Actual**
  Displays whether you can set the actual time. Yes indicates that you can set the Actual Date/Time of a Service Target. No indicates that you cannot override the Actual Date /Time.

- **Allow Reset Actual**
  Displays whether you can restart the time. Yes indicates that you can reset the Actual Date /Time of a Service Target. No indicates that you cannot reset the Actual Date/Time.

- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.

- **Last Modified By**
  Displays the name of the last person who edited the ticket.

- **Service Type**
  Displays the name of the service type that attached this service target.

- **Service Target Template**
  Displays the name of the service target template that was linked to the service type that was used to create this Service Target.

- **Lock Target Date/Time From Hold Recalculations**
  Locks the Target Date/Time from being automatically updated when the ticket goes on hold or is delayed.

- **Last Start Date/Time**
  Displays the last time the service target timer was started.

- **Ticket Status**
  Displays the value of the Status field of the ticket.

- **Hold Status**
  Displays whether the ticket status has placed the ticket on hold.

- **Last Hold Date/Time**
  Displays the last time the ticket was placed on hold.

- **Hold Count**
  Displays the number of times the ticket was placed on hold.

- **Last Resolved Date/Time**
  Displays the last time the ticket transitioned to a resolved status.

- **Resolved Count**
  Displays the number of times that the ticket changed to resolved status.

- **Last Closed Date/Time**
  Displays the last time the ticket was changed to a closed status.

- **Closed Count**
  Displays the number of times the ticket changed to a closed status.

- **Ticket Open Date/Time**
  Displays the date and time the ticket opened.

- **Ticket Resolved Date/Time**
  Displays the date and time the ticket resolved.

- **Ticket Closed Date/Time**
  Displays the date and time the ticket closed.

View Service Target Status

On an open ticket, you can view the status for each service target. Status information such as Time Left and Violation Cost help you prioritize your work.

Follow these steps:

1. On the Service Desk tab, display a list of Incidents, Problems, Requests, Change Orders, or Issues.
   The respective ticket list displays with the following Service Target information:

- **Service Target**
  Displays the time that the next service target is due.

- **Projected Violation**
  Displays the incurred cost when the service type time limit is violated.

2. Select the ticket you want from the list page.
   The ticket detail page appears.

3. Select the Service Type tab.

> **Note:** Service targets appear on tickets that meet the conditions that the administrator sets up. Priority calculation can be a factor in how target information calculates and displays.

If the ticket meets pre-defined target conditions, the Service Targets List the following information about service targets:

- **Action**
  Sets or resets the Actual Date/Time to the current date and time.

- **Target**
  Specifies the current service target for the ticket.

- **Target Date/Time**
  Specifies date and time when this service target is due. If the ticket is in a Hold status, this value is blank.

- **Actual Date/Time**
  Specifies the time when the target condition was met. If no value appears, the target condition has not been met.

- **Time Left**
  Specifies the amount of remaining time for the service target when the ticket is on hold. If the service target has been met, the Time Left field shows the unused time. A negative value indicates the amount of time that elapsed since the missed target date.

- **Violation Cost**
  Displays the penalty that incurs for missing the target. This information also displays on the ticket.

Service Contracts

This article contains the following topics:

- How to Manage Multiple Time Zones for Service Types (see page 1120)
- Workshifts Setup (see page 1121)

The SLA model includes the Service Contract. The Service Contract defines the SLA for a particular organization, including its Service Types, Request areas, and Issue or Change Categories. These definitions are referred to as *private* Categories and *private* Service Types.

Note: The *private* Categories and Service Types can only be used on tickets where the Service Contract is used.

The Service Contract applicable to a ticket is determined by the ticket's *affected organization*, which is always the Organization of the Affected End User on the ticket (this is the Organization field on a Contact record). Only the Areas or Categories listed on the Service Contract can be selected for the ticket. In addition, the only Service Types that can be applied are the *private* ones listed on the Contract. This helps ensure that the SLAs for one Organization are not accidentally mixed with another's.

A Service Contract also maps Service Types to common reference fields on a ticket, such as Priority and Asset. This mapping associates Service Types with attributes of a ticket. For example, an Organization's contract can assign Service Types to each of the five Priority objects. When a ticket is created with a certain priority, the mapped Service Type is applied.

Categories and Service Types can be defined outside of a Contract and are considered *public*. The public definitions are used when a ticket has no Service Contract. The lack of a Service Contract can occur if the end user has no organization, or the organization's Contract is inactive. A public definition is a helpful backup or default mechanism. Public Service Types are set directly on categories and other reference field objects.

All applicable Service Types are assigned to the ticket. This ensures that all aspects of an SLA are visible and enforced, for example:

- A Printer may have a Service Type that requires a technician to be dispatched within two days.
- A priority object's Service Type may require a callback within one hour.

With both Service Types applied, these required actions are enforced.

Tracking multiple Service Types also helps prioritize tickets. For example, a ticket concerning a broken keyboard is assigned a low priority Service Type. However, if the affected end user is in urgent need of the keyboard, the service priority can be increased.

Note: The SLA model is enforced by default. Past versions of CA SDM applied only a single Service Type to a ticket. The Service Type selection involved finding the highest *ranked* Type among all the possible Service Types. A model using the ranking scheme can still be used by installing the Option 'classic_sla_processing'.

Service Contracts Migration

If CA SDM is installed as a migration, the Option classic_sla_processing is turned ON by default, so your SLA processing can continue as before the migration. This continuation gives you time to create appropriate Service Contracts and eventually deactivate classic_sla_processing.

When building Service Contracts, you do not have to create Service Types, Request Areas, or Categories. You can use the Copy button found on the Service Contract detail to copy existing objects to the Contract.

If the previous installation marked the support_lev field as required for any ticket type, this restriction must be removed. The support_lev field still exists, but is not set in the current model so a required field error results with new tickets. This affects the objects Request (cr), Issue (iss) or Change Order (chg).

Time to Violation

When the SLA model is in use, CA SDM's Time to Violation (TTV) system can help you track and prioritize tickets according to their projected violation time. This system monitors all active tickets and sets the projected violation time for each Service Type. You can report and sort tickets based on their violation time and cost, helping you resolve the most urgent and costly issues first.

The TTV system monitors all active tickets and evaluates their SLA events silently, to determine which events set the SLA violation flag. The events are not executed, but the system looks at the outcome of each event based on the current state of the ticket. If the evaluation results in an action that sets the SLA violation flag, the ticket's attached Service Type is updated with a Time to Violation value; this value is the date/time when the event fires that sets the SLA violation.

Evaluation occurs whenever a ticket is inserted or updated. Because tickets are often updated in rapid succession, the evaluation is delayed for a short period. The delay interval is controlled by the ttv_evaluation_delay Option. After the delay expires, the TTV system evaluates all the SLA events that might set the SLA violation flag.

Each Event has an optional condition and a set of actions (Macros) that start based on the outcome of the condition. To ensure adequate performance, Event template information is cached by the TTV system and is refreshed periodically. Projections made by TTV involving recently updated Event templates may be inaccurate for several minutes.

Note: The TTV projections appear on the Service Type tab of each ticket. The TTV system is activated with the ttv_enabled Option.

Time Zones and Workshifts

To address the complex business demands of automated application execution, CA SDM lets you define as many time zones and workshifts as you want, and to record them for easy reference.

- Time zones identify the time zone where the user, CI, and so forth, are located.
- Workshiftsdefine the period during which event monitoring or the work hours of a service type or SLA are in effect.

Being able to determine a course of action to perform based on when an event occurs can be critical to the proper handling of the event. The time zones and workshifts you define are available for use by any of the CA SDM functions.

Time Zones Setup

Time zone codesdefine the time zone from which a user usually accesses the system (that is, the user' s local time zone) or the time zone in which a CI is located. Business hours are always entered in the time zone of the CA SDM server. This means that business hours can always be compared uniformly.

Time zones are used to manage service types, escalations, and overall response to affected end users based on the ability of CA SDM to present the correct time across multiple time zones. CA SDM automatically adjusts the offset between the time zone where a user is logging in or a CI is located, and the time zone where the server is running. Time zones use the Greenwich Mean Time (GMT) format.

How to Manage Multiple Time Zones for Service Types

CA SDM servers and users can be located in different time zones. The time difference can cause users to miss Service Type expiration dates and times.

To correct the time difference, you can configure CA SDM to display Service Type expiration times in the end-user time zone. If two users in different time zones view the same ticket, each user sees Expiration Time values based on the local computer time zone. However, the Start Time values always reflect the server time zone.

To configure for the end-user time zone, do the following:

1. Create a server code that identifies the server name and time zone.

2. Create or update a Service Type. Set the Use End User Timezone field to Yes.
   A value of Yes causes the Expiration Time to display and update according to each user time zone.

Example: Show Service Type Expiration Dates in Any User Time Zone

In this example, you configure CA SDM to show Service Type expiration dates in any user time zone. The server and user are on separate computers and in different time zones.

To create a server code that identifies the server name and time zone

1. On the Administration Tab of the host server, select Service Desk, Application Code.

2. Click Codes, Servers.
   The Server List displays.

3. Click the Local Host server.
   The Server Name Detail page appears.

4. Set the Time Zone. For example, set the time zone to GMT (EU). The local host name must match the NX_LOCAL_HOST value stored in NX.env for the server

5. Click Save.
   The Host Server uses the new time zone. When the user views a ticket, the Start Time reflects the server time zone.

To create a service type

1. On the Administration Tab, select Service Types.
   The list of Service Types appears.

2. Click Priority 1 Resolution or another Service Type that manages Priority 1 Requests.
   The Update Service Type page displays.

3. Select the Use End User Time Zone check box.

4. Click Save.
   The Service Type record updates.

To view the time zones on the ticket

1. On another computer, open a Request ticket, and set the Priority to 1.

   Note: If you are using Service Targets, set the values in the ticket to cause the target to use Priority 1 Resolution.

2. View the ticket and click the Service Type tab.
   The Start Time reflects the server time zone. The Expiration Time reflects the time on the end-user local computer.

3. Close the page that displays the Request ticket.

4. Change the time zone on the end-user local computer.

5. View the ticket Service Type on the end-user local computer to see the corresponding Expiration Time values based on the user time zone.
   The Expiration Time reflects the new time zone.

Workshifts Setup

Workshiftsidentify the days, dates, and times when an event or schedule is in effect. You can specify days or dates, or days and dates. Specifying a time is optional.

When you are monitoring events for tickets, workshifts define when the event is monitored or, in other words, when the clock is running. For example, using the predefined event P1 Active Issue Notify assignee, if a priority 1 issue is opened at 4:45 PM and the workshift schedule is 9:00 AM to 5:00 PM, the monitored event automatically sends notification to the issue assignee at 9:45 AM the next day.

Note: Workshifts are also used for the purpose of automatically assigning tickets to contacts.

Create a Service Contract

You can create service contracts and map them to contacts, configuration items, and priorities.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Service Desk, Service Contracts on the Administration tab.
   The Service Contract List page appears.
2. Click Create New.
   The Create New Service Contract page appears.
3. Complete the Service Contract fields (see page 1122) as appropriate.
4. Configure the service contract mapping (see page 1123) as appropriate.
5. Click Save.
   The service contract definition is saved and the Service Contract Detail page appears.

Service Contract Fields

The following fields require explanation to create or update a service contract:

- **Client Advocate**
  The person within the company that runs the help desk. This person is the point of contact between the “Customer” company and the “Help Desk” company. This person is a member of the organization that would get special notifications
- **Client Contact**
  This is the contact person that would get notified on tickets/service types/etc.
- **Assigned to Organization(s)**
  Displays the name of an organization assigned to the service contract. If an organization has not been assigned, None appears.
  Add an organization to a service contract by first creating the new service contract. Then, access the Scoreboard tab, select File, Create New Organization and while creating the organization, select the contract previously saved. When you access the service contract, the Assigned to Organization(s) field is populated with the updated organization name.

- **Organization's Service Type**
  If set, this service type is ALWAYS applied to any ticket opened for the organization. This is useful for adding baseline events, notifications or SLA parameters that need to be on every ticket regardless of priority, category, etc. For example, the Client Advocate gets a notification for every ticket opened/closed for the Organization, so they have a general idea of how their customer is doing.

  If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Service Contract Tabs

The following tabs are available on the Service Contract Detail and Update Service Contract pages:

- **Contacts**
  Allows you to map one or more contacts to the service contract. Also allows you to update a contact's service type. Click Map Single Contact.

- **Groups**
  Allows you to map one or more groups to the service contract. Also allows you to update a group's service type. Click Map Single Group.

- **Config. Items**
  Allows you to map one or more configuration items to the service contract. Also allows you to update a configuration item's service type. Click Map Single CI.

- **Priorities**
  Allows you to map a priority to the service contract. Click Map Priority.

- **Urgencies**
  Allows you to map an urgency to the service contract. Click Map Urgency.

The following tabs appear on the Service Contract Detail page after a new service contract record has been saved:

- **Private_Service_Types**
  Allows you to create a new service type to map to this service contract. Click Add Private Service Type.**Request Areas**

- Allows you to create a new request area or copy an existing request area to map to the service contract. Click Add New Request Area.**Change Categories**

- Allows you to create a new change category or copy an existing change category to map to the service contract. Click Add New Change Category.**Issue Categories**

- Allows you to create a new issue category or copy an existing issue category to map to the service contract. Click Add New Issue Category.

Add an Issue Category to a Service Contract

You can create one or more new issue categories to associate with this service contract.

To create a new issue category for the service contract

1. Select the Issue Categories tab on the Service Contract Detail or Update Service Contract page.
2. Click Add New Issue Category.
   The Create New Issue Category page appears.
3. Fill in the fields as appropriate to define the area.
4. Click Save.
   The issue category definition is saved and the Issue Category Detail page appears, with the name of the associated contract in the Service Contract field.
5. Close the Issue Category Detail page and return to the Service Contract Detail page.
   The new issue category is listed on the Issue Categories tab.

To copy an existing issue category for the service contract

1. Select the Issue Categories tab on the Service Contract Detail or Update Service Contract page.
2. Click Copy Existing Issue Category.
   The Issue Category Search page appears.
3. (Optional) Complete one or more search fields to filter your search.
4. Click Search.
   The Issue Category List page lists the issue categories that match your search criteria.
5. Select the issue category you want to copy.
   The Create New Issue Category page appears with the fields of the copied issue category filled in.
6. (Optional) Update the fields as appropriate for the new issue category.
7. Click Save.
   The issue category definition is saved and the Issue Category Detail page appears, with the name of the associated contract in the Service Contract field.
8. Close the Issue Category Detail page and return to the Service Contract Detail page.
   The new issue category is listed on the Issue Categories tab.

Update a Service Contract

You can edit a service contract record that has already been created.

Note: When you update a service contract, the Private Service Types, Request Areas, Change Categories, and Issue Categories tabs are available on the Service Contract Detail and Update Service Contract pages.

To update a service contract

1. Select Service Desk, Service Contracts on the Administration tab.
   The Service Contracts List page appears.

2. Select the service contract to edit.
   The Service Contract Detail page appears.

3. Click Edit.
   The Update Service Contract page appears.

4. Edit the fields as appropriate.
   See Service Contract Fields (see page 1122) for field definitions.

5. (Optional) Use the controls available on the tabs at the bottom of the page to configure the service contract record.
   See Service Contract Tabs (see page 1123) for more information.

6. Click Save.
   The service contract definition is saved and the Service Contract Detail page appears.

Automatic Closure of Tickets

You can use a configurable setting to allow automatic closure of tickets (requests/incidents /problems, change orders, or issues). When a ticket is set to a Resolved status, the ticket is automatically closed in the number of business hours specified. The Auto Close activity notification sent to the end user displays the number of business hours before the ticket is closed. The number of hours is configurable and tenant-specific. If the status is changed before the configurable number of hours ends, the ticket closure is canceled.

Administrators, can perform the following actions:

- Define an Auto Close ticket setting to control the number of business hours, for the end user, before the ticket is automatically closed.
- Set up an Auto Close activity notification to notify the appropriate contacts when automatic closure is scheduled for a ticket.

If you use multi-tenancy, consider the following:

- The system uses the default public Auto Close setting when a tenant-specific Auto Close setting is not found.
- There is one Auto Close setting for each tenant.

How to Define Auto Close Ticket Settings

You can define the number of business hours before a ticket is closed (all ticket types) as follows:

1. On the Administration tab, select Service Desk, Application Data, Codes, Auto Close.

2. Click Create New on the list page.

3. Complete the following fields on the detail page:

   - **Symbol**
     Defines the system setting name.

   - **Request/Incident/Problem/Change Order/Issue**
     Defines the number of business hours, after the ticket is set to Resolved status, before the ticket is closed. If the status is changed before the number of hours ends, the ticket closure is canceled. 0 (zero) hours indicates that automatic closure is not implemented for the ticket type.

   - **Description**
     Provides a brief description of the record.

   - **Status**
     Indicates if the record is active or inactive.

   The auto close setting is defined.

4. Click Save, Close Window.
   The new setting appears on the Auto Close List page when you redisplay the list.

How to Define an Auto Close Activity Notification

You can change the settings in the default Auto Close activity notification to notify the appropriate contacts when automatic closure is scheduled for a ticket. The activity is valid for all CA SDM ticket types, and include a default notification rule for requests/incidents/problems, change orders and issues.

To define an auto close activity notification, do the following:

1. On the Administration tab, select Notifications, Activity Notifications.

2. Select the Auto Close activity notification on the list page to open it.

3. Update the default Auto Close Notification Rule and specify contacts to receive notification.

4. Click Save, Close window.
   The updated Auto Close activity notification appears in the Activity Notification List when you redisplay the list.

Search Attachments

You can enter search criteria to filter the Attachments List to display only the attachments you want to see. You can also search for individual attachments to view or edit.

Follow these steps:

1. From the Administration tab, select Attachments Library, Attachments.
   The Attachment Search page opens.

2. Complete the search fields. The following fields require explanation:

   Note: All search fields that allow text entry support use of the % wildcard character.

   - **Repository** -- The repository where the file resides.
   - **Status** -- Choose from one of the following values:
     - **Installed** - Attachment is available and in place.
     - **Link Only** - Attachment is a URL link.
     - **Not Installed** - Attachment is not in place. Request has not completed successfully.
     - **Archived** - Attachment is archived.
     - **Not Available** - The attachment could not be found after an archive and purge.
     - **Knowledge File** - Attachment is a text file.

3. Click Search.

   The Attachment List page displays the attachments that match your filter criteria. You can select an attachment to view or edit it.

   Note: If you are using multi-tenancy, a tenant drop-down list appears in the search filter. If you select <empty> in this drop-down list, the search is public.

Create an Announcement

You can use CA SDM to post announcements to users. Announcements help decrease the number of incoming calls and promote increased productivity through proactive resolution of tickets and communication of important information to all affected users. Users can scroll through stored multiple announcements.

Note: Announcements apply to all service desk models.

You can add new announcements and update existing ones. Announcements are part of the reference data function of CA SDM, so by using the access type you can control which contacts can create announcements.

An announcement can specify either or both of the following:

- **Location**
  Specifies a physical location, for example, a city, building, or floor.

- **Organization**
  Specifies an organization ID. When Organization is set for an Announcement, only individuals assigned to that Organization can see the Announcement.

When Location or Organization is set for an announcement, only contacts at that location or organization receive it. Any contact can still see all announcements that are not restricted by location or organization. For example, if neither is set, contacts in every location and organization can see an announcement.

Note: You can specify announcements using the administrative function of the web interface.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Scoreboard, select File, New Announcement.
   The Create New Announcement window opens.

2. Fill in the fields as appropriate. See Announcement Fields (see page 1129) for field definitions.

3. To insert a link to a Knowledge Document in the announcement, click Knowledge Doc.
   The Knowledge Document search page displays.

4. Search for the document you want to include. See Search Knowledge Documents for more information.

5. In the Link Text field, type the text to be used to link to the document.

6. Click Insert Document.
   The HTML code linking to the Knowledge Document is added to the Text field.

7. Click Save to save the announcement.
   The new announcement is added to the right pane of the main window.

Announcement Fields

- **Text** -- Enter the text of the announcement. Click Spelling to perform a spell check of the text you entered. This field is required.
  If you insert a link to a Knowledge Document, the HTML code for that link is displayed in this field.
- **Location** -- The location where the announcement is displayed. Enter the name of the location directly into the field, or click the search icon to search for the location.
- **Internal** -- Select this option if this announcement should only be shown to internal employees.
- **Organization** -- The organization where the announcement is displayed. Enter the name of the organization directly into the field, or click the search icon to search for the organization.
- **Announcement Type** -- Determines the urgency of the announcement and the color of the announcement text displayed in the window. Asterisks are displayed next to the posted date for color blind or visually impaired users.
  The possible values are:
  - **Routine --** Black text. No asterisks.
  - **Advisory** -- Orange text. One asterisk, after the date.
  - **Emergency** -- Red text. Two asterisks, after the date.
- **Status** -- Indicates whether the announcement is active (displayed) or inactive (not displayed).
- **Close Date/Time** -- The date and time to stop displaying the announcement. Enter the date and time in the format mm/dd/yyyy hh:mm AM | PM, or click the calendar icon to select the date and time.

Announcements

This article contains the following topics:

You can use CA SDM to post announcements to users. Announcements help decrease the number of incoming calls and promote increased productivity through proactive resolution of tickets and communication of important information to all affected users. Users can scroll through stored multiple announcements.

Note: Announcements apply to all service desk models.

You can add new announcements and update existing ones. Announcements are part of the reference data function of CA SDM, so by using the access type you can control which contacts can create announcements.

An announcement can specify either or both of the following:

- **Location**
  Specifies a physical location, for example, a city, building, or floor.

- **Organization**
  Specifies an organization ID. When Organization is set for an Announcement, only individuals assigned to that Organization can see the Announcement.

When Location or Organization is set for an announcement, only contacts at that location or organization receive it. Any contact can still see all announcements that are not restricted by location or organization. For example, if neither is set, contacts in every location and organization can see an announcement.

Note: You can specify announcements using the administrative function of the web interface.

View Announcements

Announcements are used to convey important information about the system to the users. Current announcements display in the right pane of the main window when you first login to the system.

To display the Announcements page, choose View, Announcements. To create a new announcement, choose File, New Announcement (refer to for more information).

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Create an Announcement

Announcements are used to convey important information about the system to the users.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Scoreboard, select File, New Announcement.
   The Create New Announcement window opens.

2. Fill in the fields as appropriate. See Announcement Fields (see page 1131) for field definitions.

3. To insert a link to a Knowledge Document in the announcement, click Knowledge Doc.
   The Knowledge Document search page displays.

4. Search for the document you want to include. See Search Knowledge Documents for more information.

5. In the Link Text field, type the text to be used to link to the document.

6. Click Insert Document.
   The HTML code linking to the Knowledge Document is added to the Text field.

7. Click Save to save the announcement.
   The new announcement is added to the right pane of the main window.

Announcement Fields

- **Text** -- Enter the text of the announcement. Click Spelling to perform a spell check of the text you entered. This field is required.
  If you insert a link to a Knowledge Document, the HTML code for that link is displayed in this field.

- **Location** -- The location where the announcement is displayed. Enter the name of the location directly into the field, or click the search icon to search for the location.

- **Internal** -- Select this option if this announcement should only be shown to internal employees.

- **Organization** -- The organization where the announcement is displayed. Enter the name of the organization directly into the field, or click the search icon to search for the organization.

- **Announcement Type** -- Determines the urgency of the announcement and the color of the announcement text displayed in the window. Asterisks are displayed next to the posted date for color blind or visually impaired users.
  The possible values are:

  - **Routine --** Black text. No asterisks.

  - **Advisory** -- Orange text. One asterisk, after the date.

  - **Emergency** -- Red text. Two asterisks, after the date.

- **Status** -- Indicates whether the announcement is active (displayed) or inactive (not displayed).

- **Close Date/Time** -- The date and time to stop displaying the announcement. Enter the date and time in the format mm/dd/yyyy hh:mm AM | PM, or click the calendar icon to select the date and time.

Internal Announcement Visibility

You can control whether an announcement is visible to internal users by using the Internal check box on the Create New Announcement page. The View Internal Logs setting of the access type of the logged in user controls whether a user can view items marked as internal.

Specify Announcement Urgency

You can specify the urgency of an announcement record.

To specify announcement urgency

1. Create an announcement or navigate to the Announcement Detail page to edit an existing announcement.

2. Select one of the following values from the Announcement Type drop-down list:

   - **Routine**
     Displays in black text.

   - **Advisory**
     Displays in orange text.

   - **Emergency**
     Displays in red text.

   Click Save.
   The announcement record is color-coded in the Announcements List page.

Auto Assignment

This article contains the following topics:

CA SDM *Auto Assignment* reduces the time that is required to manage tickets by automating the process of assigning them to analysts. This automation can make the tasks that are associated with balancing workloads and coordinating work schedules much more efficient.

You can configure auto assignment to assign tickets that are based on the following factors:

- Which analyst groups work on which tickets or tasks.
- When the work must be done.

The locations catering the affected customers.

- The workload and availability of each analyst.
- The value of an attribute of a configuration item that is associated with the ticket.

Note: Configuration item-based auto assignment (see page 1158) lets you create group-specific assignments for Request/Incident/Problem tickets only. You do not have to implement auto assignment all at once. You can develop a strategy for phasing it in gradually. For example, you can begin by enabling it only for selected ticket types, analyst groups, or locations.

Auto Assignment Relationships

The auto assignment process can involve many CA SDM elements. The element relationships are as follows:

- Areas and categories relate to groups, locations, and workshifts.
- Groups relate to locations and workshifts.

To make the auto assignment easy to administer, all relationships can be maintained from either related element. For example, when relating an analyst group to a change category, you can maintain the association from either the Change Category Detail page or the Group Detail page.

Auto Assignment Methods

The following basic methods let you auto assign tickets:

- **Location-based auto assignment**
  Creates assignments for all ticket types that are based on the following criteria:
  - Areas and categories that are related to groups, locations, and workshifts
  - Groups that are related to locations and workshifts

Note: The Location-based auto assignment is referred to simply as auto assignment.

- **Configuration item-based auto assignment**
  Creates group assignments for request, problem, and incident ticket types that are based on the following criteria:

  - Areas that are related to tickets associated with configuration items
  - Configuration item attributes used to record contact/group information

Location-based auto assignment and configuration item-based auto assignment are exclusive options. This is because you can select only one algorithm for use on a given Request/Incident /Problem Area. Location-based auto assignment and configuration item-based methods both serve to assign tickets when. However, Configuration item-based auto assignment is distinct, because it also reevaluates the assignments for a ticket upon changing the Area or configuration item of a Request /Incident/Problem ticket. If a configuration item-based auto assignment is specified, without successfully generating a group assignment for a ticket, the Area_Defaults option is consulted to determine whether the default Group and Assignee values on the Area should be used to assign the ticket.

Default Group and Assignee

When the auto assignment logic is unable to identify a suitable group or assignee, the ticket is assigned to the default group and assignee. You can specify these defaults in the Group and Assignee fields of the following web interface pages:

- Request/Incident/Problem Area Detail
- Change Category Detail
- Issue Detail

If auto assignment cannot identify a suitable group or assignee and the defaults are not specified, the ticket is left for manual assignment.

Auto Assignment Enablement

Options and controls let you configure auto assignment. You can control whether auto assignment processing occurs as follows:

- For requests, incidents, and problems assigned to that area, use the Auto Assignment Enabled tab on the Request/Incident/Problem Area Detail page.
- For change orders and issues, select the Auto Assignment tab and Auto Assignment Enabled check box on the Change Category Detail page, Issue Category Detail page.

Example: Enable Auto Assignment for a Request/Incident/Problem Area

This example demonstrates how to enable auto assignment for a Request/Incident/Problem area.

1. On the Administration tab, browse to Service Desk, Requests/Incidents/Problems, Areas.
   The Requests/Incidents/Problems Area List page appears.
2. Click the area for which you want to configure auto assignment.
   The Requests/Incidents/Problems Area Detail page appears.

3. Click Edit.
   The Update Requests/Incidents/Problems Area page appears.

4. Select the Auto Assignment tab, and complete the following fields as follows:

   - **Auto Assignment Mode**
     Specifies how auto-assignment occurs. You use the Configuration Item Based option to base the auto assignment on the CI Assignable Attribute value.

     - **Disabled** -- Bases the auto-assignment on the Area Defaults option when it is installed.
     - **Configuration Item Based** -- Bases the auto-assignment on the CI Assignable Attribute value.
     - **Location Based** -- Bases the auto-assignment on the location value.

   - **Assignable CI Attribute**
     Specifies the configuration item attribute to use for the group assignment. You can enter a value directly or click the magnifier to search for an attribute.

5. Click Save.
   The Request/Incident/Problem area is enabled to use default values that are entered automatically on the tickets that are assigned to the area.

Auto Assignment Override

You can use the Auto Assignment Override (autoasg_override) option in the Options Manager to determine if the auto assignment overrides an analyst or a group that is set when a ticket is created.

Other CA SDM features may have set the assignee and/or group before auto assignment obtains control. You can configure your system by setting this option to one of the following values:

- **0**
  Honors the existing assignee and/or group. If the assignee and/or group was set during the creation of the ticket, auto assignment processing does not occur.

- **1**
  Ignores the existing assignee and/or group. Auto assignment processing continues and attempts to find an assignee and/or group.

You can set the Assignee and/or Group in various ways:

- Manually by the Analyst
- Area Defaults and the Assignee set options
- Request Templates
- CA NSM integration

Note: Uninstalling the Auto Assignment Override option causes it to operate in its default mode, which is 0.

Configure Auto Assignment by Location

The Auto Assignment tab allows you to establish a relationship between this location and request areas, change categories, issues categories, and groups. This allows you to assign tickets to eligible members of the group within the location automatically.

Important! You must enable automatic assignment for each request area and category individually. Listing them on the Location Auto Assignment tab does not enable this function.

Follow these steps:

1. On the Location Detail page, click Edit and select the Auto Assignment tab.
2. Click one of the following buttons:
   - Update Request Areas to select request areas for auto assignment.
   - Update Change Categories to select change categories for auto assignment.
   - Update Issue Categories to select issue categories for auto assignment.
   - Update Groups to select groups for auto assignment.

   The Search page for the selected item appears.
3. Enter the search criteria to display the desired items and click Search.

   The Update page appears, listing the items that matched the search criteria.
4. From the list on the left, select the desired items. To select multiple items, hold down the CTRL key while clicking the left mouse button.
5. When you have selected all the items that you want, click the double right-arrow button.

   The selected items move to the Assigned list on the right.
6. Click OK.

   The Location Detail page displays, with the selected items listed on the Auto Assignment tab.

Assignment Controls

Options and controls let you configure the auto assignment. The CA SDM features can affect the assignee, the group fields, or both on a ticket before auto assignment processing occurs. We recommend that you review assignment controls before implementing auto assignment.

Manual Assignment

The analyst can manually select the assignee and/or group while creating a ticket.

Assignee_set Option

By default, CA SDM automatically sets the logged in analyst user as the assignee of the request. An Options Manager option, Assignee_set, lets you control this behavior. This option is typically installed by default.

Iss assignee_set

The Iss assignee_set option automatically sets the logged in analyst user as the assignee of the Issue. It is similar to Assignee_set, except it is for Issues instead of Requests.

Area_Defaults

The Area_Defaults option determines what happens when the request area is specified on a request detail page. This option lets you set the assignee and group whenever the request area changes. The default assignee and group from the request area are used, and this processing occurs before auto assignment processing.

This option is not installed by default.

Note: The Category_Defaults option provides similar functionality for change orders. The Iss_Category_Defaults option provides similar functionality for issues.

Require Assignee and Group Options

Several options are available in Options Manager for controlling the creation of unassigned tickets. These options are global in scope. They affect the creation of all of the indicated ticket types, regardless of whether auto assignment is in effect. If the indicated condition is not satisfied, the new or updated ticket cannot be saved.

The following options control the creation of tickets without an assignee specified:

- **require_change_assignee**
  Application: Change Order Mgr
  Description: Makes the Assignee field of a change order ticket required

- **require_issue_assignee**
  Application: Issue Mgr
  Description: Makes the Assignee field of an issue ticket required

- **require_incident_assignee**
  Application: Request Mgr
  Description: Makes the Assignee field of an incident ticket required

- **require_problem_assignee**
  Application: Request Mgr
  Description: Makes the Assignee field of a problem ticket required

- **require_request_assignee**
  Application: Request Mgr
  Description: Makes the Assignee field of a request ticket required

The following options control the creation of tickets without a group specified:

- **require_change_group**
  Application: Change Order Mgr
  Description: Makes the Group field of a change order ticket required

- **require_issue_group**
  Application: Issue Mgr
  Description: Makes the Group field of an issue ticket required

- **require_incident_group**
  Application: Request Mgr
  Description: Makes the Group field of an incident ticket required

- **require_request_group**
  Application: Request Mgr
  Description: Makes the Group field of a request ticket required

- **require_problem_group**
  Application: Request Mgr
  Description: Makes the Group field of a problem ticket required

Templates

You can use templates to set the values on a new request, change order, or issue. Templates can affect assignee and group fields.

CA Network and Systems Management Interface

When CA NSM and CA SDM are integrated and you are creating requests from CA NSM events, the user_parmsparameter in writer rule definitions is passed to the Text API. The CA SDM writer process (tngwriter) defines its own replacement parameters for changing the text before sending it to the Text API. The keyword LOG_AGENT is added to the end of the input to set the log_agent for the request.

Note: You must update the Text_API.cfg file for all additional fields that are passed from CA NSM Alert Management Systems to CA SDM. This file is used for integrations with web services, email, and AHD.DLL.

How Auto Assignment Assigns Tickets

This article contains the following topics:

Auto-assignment assigns tickets as follows:

1. The initial save operation of a new ticket invokes auto assignment.
   If an area or category is not configured for auto assignment, processing stops.

2. Auto assignment determines whether Autoasg_override is installed.
   If it is not installed and the ticket has an assignee or group, processing stops.

3. If work shifts are related to the ticket, the open date is evaluated to determine the inclusion of a ticket.
   If a work shift does not include the ticket, processing stops. Auto assignment attempts to assign the default group and assignee.

4. Auto assignment determines whether any groups are related to the ticket.
   If no groups are related, processing stops, and auto assignment attempts to assign the default group and assignee.

5. Auto assignment filters any groups with work shift, where the open date is outside the time frame of the work shift. Groups without a work shift bypass filtering.

6. The following processing occurs for locations that are related to the ticket:

   - If this ticket is a request, and it has a configuration item:
     The location of the configuration item is matched against the locations that are related to the request area. If no match occurs, processing stops, and auto assignment attempts to assign the default group and assignee. Otherwise, the customer location is matched against the locations that are related to the area or category. If no match occurs, processing stops, and auto assignment attempts to assign the default group and assignee.

   - If locations are associated with the request area or category:
     Suppose that locations are associated with the request area and the configuration item (during request auto assignment processing), or the customer has no location. Then auto assignment stops processing.

7. Auto assignment filters the groups that have related locations that do not match the configuration item location (for requests only) or customer location. If no groups remain, processing stops, and auto assignment attempts to assign the default group and assignee.

8. Auto assignment creates a list of analysts from each of the remaining eligible groups.

9. Unavailable analysts are filtered.

10. The remaining analysts are checked for Work Schedules. Available analysts that have Work Schedules are filtered when the open date is not within their work schedules.

11. If no analysts remain, processing stops and auto assignment attempts to assign the default group and assignee.

12. All the remaining analysts are ranked according to the number of active tickets that are assigned to them.

13. The analyst (and associated group) with the least number of active tickets is assigned to the ticket. If a tie occurs, the first analyst that occurs in the group is selected.

How Auto Assignment Assigns Workflow Tasks

Auto Assignment assigns workflow tasks as follows:

1. Auto assignment is invoked when the status of a workflow task changes to pending. If the workflow template that the workflow task was created from is not enabled for auto assignment, processing stops. If the parent change order category or Issue category is not enabled for auto assignment, processing stops.

2. Auto assignment checks to determine if Autoasg_override is installed. If not installed and the task has an assignee or group, processing stops.

3. The workflow template that the workflow task was created from is checked to see if any contacts are associated with it. If there are no contacts, processing stops.

4. Auto assignment builds a list of contacts that are members of the groups that are currently associated to the workflow template. The workflow template must be the template from which the workflow task was created. Any contacts in this list that are groups are filtered out.

5. All of the remaining contacts are ranked according to the number of active change order tasks or the corresponding issue tasks.

6. The contact and associated group with the least number of active tasks is assigned to the task.

How to Begin Implementing Auto Assignment

This article contains the following topics:

Follow these guidelines to begin implementing auto assignment for selected analyst groups and analysts:

1. Identify one or more areas or categories for which you want to enable auto assignment.

   Note: To review your site area and category configurations, examine the settings in the CA SDM web interface.

2. By default, auto assignment is disabled. Enable it only for the areas and categories (see page 1154) where you want to use it.

3. Build the relationships between an identified area or category and the analyst groups (see page 1155) that can be assigned tickets through that area or category.

4. Mark individual members of the analyst (see page 1155) groups as available.

Areas and Categories

Note: When you configure areas and categories, consider setting default groups and assignees (see page 1134).

To configure the auto assignment of request, incident, and problem tickets, use the following options in the Auto Assignment tab of Request/Incident/Problem Area Detail page:

- Update Groups
- Update Locations
- Update Workshifts

Note: The check box for enabling auto assignment is also on the Auto Assignment tab of each of these pages. It is visible only while the page is in edit mode.

The following pages on the interface provide the same controls for configuring auto assignment of change orders and issues:

- The Change Category Detail
- The Issue Category Detail

Analyst Groups

To configure auto assignment you must, at a minimum, define the relationships between analyst groups and areas or categories. Assignees are chosen from groups that meet *all* of your specified auto assignment criteria. If no additional constraints are defined, tickets are auto assigned to the group member with the fewest active tickets.

If no groups are associated with an area or category, the default group and assignee are assigned. If these defaults are not defined, the ticket is left for manual assignment.

You can maintain the relationships between groups and areas or categories on the area or category detail page.

Alternatively, use the following options to maintain the same relationships on the Auto Assignment tab of the Group Detail page:

- Update Request Areas
- Update Change Categories
- Update Issue Categories
- Update Locations

Analysts

Fields on the Analyst Detail page help determine whether the analyst is eligible for auto assignment.

Analysts are eligible for auto assignment only if they are marked as available.

The Analyst Detail page provides an Available check box that enables auto assignment.

Consider allowing analysts to control their own auto assignment availability. You can monitor analyst availability by using stored queries.

Note: The Available check box is not considered during auto assignment of workflow tasks.

The Work Schedule field allows analysts to have tickets auto-assigned only during their scheduled workshift. Analysts that are marked as available and are without work schedule are eligible for auto assignment at any time. However, no other constraints must result in an ineligible status.

Stored Queries

Two stored queries are provided for monitoring the availability of analysts. The CA SDM managers can add the following queries to their Scoreboard:

- **Available Analysts** -- Analysts that are marked as available for auto assignment
- **Unavailable Analysts** -- Analysts that are marked as unavailable for auto assignment

How to Auto Assign Tickets to a Group and Not to Contacts Within the Group

Auto assignment assigns tickets to contacts that have the Available option selected in the contact record. However, you can auto assign incidents/issues/change orders/requests to a group and not to contacts within the group. The NX_AUTOASG_GROUP_ONLY option controls the auto assignment behavior for groups. You install this option to auto assign the tickets to the group instead of individual contacts. NX_AUTOASG_GROUP_ONLY is not available on the web interface, you install it from the command prompt.

Follow these steps:

1. Verify that your CA SDM installation is at a minimum level of Release 12.9 Cumulative 2 patch.
2. Open the command prompt on any CA SDM server.
3. Run the following command:

   ```
   pdm_options_mgr -c -s AUTOASG_GROUP_ONLY -v 1 -a pdm_option.inst
   ```

   By default, new options that you add to the nx.env file are not saved after you run pdm_configure. You can save the changes permanently by specifying the -t option as follows:

   ```
   pdm_options_mgr -c -s AUTOASG_GROUP_ONLY -v 1 -a pdm_option.inst -t
   ```

   The commands update the following files in CA SDM with the new option:

   - Windows -- NX_ROOT/NX.env and NX_ROOT\pdmconf\nx.env.nt.tpl
   - UNIX/Linux -- NX_ROOT/pdmconf/NX.env.tpl
4. Open the NX.env file in the CA SDM installation folder and search for the variable @NX_AUTOASG_GROUP_ONLY=1. Typically, the variable is found at the end of the file.
5. Open the file nx.env.nt.tpl present under NX_ROOT/pdmconf and search for the @NX_AUTOASG_GROUP_ONLY=1 option.
6. Restart the CA SDM Daemon Server service.
   CA SDM auto assigns the tickets to the group only.
7. Restart the CA SDM servers (see page 866).

Auto Assignment by Location

If your service area is large and it consists of many locations that service different customer communities. You can use location as a factor in your auto assignment configuration as follows:

- **Location Assigned to an Area or Category** -- If you assign a location to an area or a category, tickets are auto assigned only when a matching location is found. For example, a request ticket is auto assigned if there is an eligible analyst at the following locations:
  1. The affected asset location.
  2. The affected customer location.

If the affected asset or customer has no specified location, the request is assigned to the default group and assignee. If these defaults are not defined, the request is left for manual assignment. You can use the area or category detail pages to maintain relationships between locations and areas or categories.

- **Location Assigned to a Group** -- When a location is associated with a group, only members of that group are eligible for auto assignment of tickets. Further, only the tickets that pertain to the location of the member can be assigned. You can use group detail pages to maintain relationships between groups and locations.

To maintain location relationships with areas, categories, or groups, use the following options on the Auto Assignment tab of Location Detail page:

- Update Request Areas
- Update Change Categories
- Update Issue Categories
- Update Groups

Examples: Use Location in Auto Assignment Configuration

The following are examples of how you can use location in your auto assignment configuration:

- **Auto assign tickets only at a specified location** -- Tickets from other locations receive the default group and assignee, or are left for manual assignment. For example, you can have many users at your company headquarters, and smaller groups of users at regional offices. An analyst group located at the headquarters services their local users, while mobile analyst groups visit the regional offices. You can configure auto assignment of tickets to the headquarters analysts only, and manually assign tickets to the mobile analysts.
- **Auto assign tickets by user or asset location** -- You can restrict auto assignment eligibility to analyst groups at locations that match the affected user location, or the affected asset location. For example, your organization can have many offices, but only the groups that are located in a particular office handle tickets for the office. You can relate each group to appropriate areas or categories *and* to the appropriate location. The auto assignment logic selects eligible analysts only from groups at the correct location.

Auto Assignment by Workshift

You can constrain auto assignment by relating an area or category to a workshift. The workshift determines the timeframe within which tickets are eligible for auto assignment. Tickets opened outside the workshift are assigned to the default group and analyst, or left for manual assignment.

You can also use workshifts to control group and analyst eligibility for assignment:

- If you assign a work schedule to a group. Analysts in that group are eligible for auto assignment only to tickets opened during their work schedule.

> **Note:** The workshift for a group is specified in the Work Schedule field of the Group Detail page.

- If you assign a work schedule to an individual analyst. The analyst is eligible for auto assignment only to tickets opened during that work schedule.

> **Note:** The workshift for an analyst is specified in the Work Schedule field of the Analyst Detail page.

When a ticket is created, the group that meets the assignment eligibility criteria is identified. Within the group, the analyst with the fewest active tickets is identified. If an appropriate analyst is not identified, the ticket is assigned to the default group and assignee. If these defaults are not defined, the ticket is left for manual assignment.

For workflow tasks associated with change orders or issues, auto assignment uses a simpler selection strategy. Assignees are selected from the groups that are associated with workflow templates. Workflow task assignees can be of any contact type except group. When a task changes to pending status, the contact that has the fewest change order or issue workflow tasks is selected. To prevent unwanted results, if the parent change order category or issue category is disabled for auto assignment, tasks are not assigned automatically. Workflow tasks may encompass individuals external to service desk. So, relying on them to reflect their availability with the available flag is not recommended.

You can use the area or category detail pages to relate a workshift to an area or category. Or, you can use the following controls on the Workshift Detail page:

- Update Request Areas
- Update Change Categories
- Update Issue Categories

Examples: Use Workshifts in Auto Assignment Configuration

The following examples show how you can use workshifts in your auto assignment configuration:

- **Auto assign tickets to the shift on duty** -- Suppose that your service desk operates 24 hours per day and you have tickets about network outage problems. You may want to configure auto assignment of such tickets to the shift on duty when the ticket is opened.
- **Allow auto assignment only during a specified shift** -- You may want to restrict further auto assignment of tickets in some areas or categories. For example, if analysts are on duty only during day shift, you may auto assign application problems only during the day shift.

Configuration Item-Based Auto Assignments

Configuration item-based auto assignment lets you create group-specific assignments that apply to specific scenarios. You can specify that for a particular Request/Incident/Problem area, the value of a configuration item attribute controls the assignment of the ticket.

Configuration item-based and location-based auto assignments are exclusive options because you can select only one algorithm for use. Configuration item-based and location-based auto assignment modes both serve to assign tickets. However, configuration item-based auto assignment is distinct, because it also reassigns tickets after changing the Request/Incident/Problem Area.

Example: Request/Incident/Problem Area Assigns Tickets to a Group
