3. Click the Search icon in the Advanced Search box to enter a new advanced search query. The fields next to the Search icon expand so that you can enter an advanced search condition in the format property - operator - value, as follows:
    a. In the first (property) search field (a drop-down list), select the property for you want to search for, such as Action By User ID, Business unit Name, Request Priority, or Service Option Element Name.
    b. In the second (operator) search field (a drop-down list), select the operator to use for your search, such as Equals, Not Equals, Contains, Starts With, Ends With, or In. *In* is a special operator that you can use to select or specify multiple values as search criteria.
    c. In the third (value) search field, type or select your search criteria, as follows:

- For most properties, you type custom search criteria directly into this field. Examples include actual request IDs, user names, and business units.
  For example, to search for the request whose ID is 101, specify the following in the search fields:
  property: Request ID operator: Equals value: 101
  Similarly, to search for three requests whose IDs are 101, 102, and 103, specify the following in the search fields:
  property: Request ID operator: In value: 101,102,103

  
  Note: Use a comma to separate multiple values in the value field.

- If you are a Service Delivery administrator, and you plan to share the advanced search query with other users:
    - For the properties that include the user ID, specify the value as the $USERID$ variable.
    - For the properties that include the business unit ID, specify the value as the BU$ variable.

When other users run this query, the Catalog system dynamically replaces the variable with the user ID or business unit ID of the user running the query. This dynamic replacement is useful for complex advanced search queries that other users find beneficial but lack the expertise to create.

- For certain properties, this field changes to a drop-down list, and you select the value you want from the list. For example, if you are searching for a property related to the request status, you select the request status you want from the drop-down list. If your implementation includes custom statuses, they appear in this list.
  For example, to search for requests whose status is Approved, specify the following in the search fields:
  property: Request Current Status operator: Equals value: Approved
  Similarly, to search for requests whose statuses are Approval Done or Approval Not Needed, specify the following in these fields:
  property: Request Current Status operator: In value: Approval Done and Approval Not Needed

- If you are searching for a property related to the dates, if required, you can include multiple dates in your query by using operators such as Before or After, and by using multiple search conditions.
  For example, to find request created between July 27, 2011 and July 30, 2011, inclusive, specify both of the following conditions in your query:
  property: Request Date Created operator: After or On value: 07/27/2011
  property: Request Date Created operator: Before or On value: 07/30/2011

- To find requests related to inactive users, specify one or both of the following properties: *Requested For User Status* and *Requested By User Status*. For example, to find requests created by an inactive user, specify the following
  property: Requested By User Status operator: Equals value: Inactive

  Note: For queries involving inactive users, you must specify these properties first, before you specify any other search criteria.

You have completed this search condition.

4. Click the Plus sign (+) after the third search field to specify another search condition, if required.

5. Click the Remove (-) icon after the third search field of any additional search conditions that you want to remove from the advanced search query, if required.
   You have finished specifying this advanced search query.

Only Service Delivery administrators can share queries. A shared query appears as a saved query for all users when they click the Load icon. All users in all business units can view and run shared queries, but cannot modify them.

Follow these steps to share an advanced search query:

1. Click the Save icon.

2. Enter meaningful data in the Save Query dialog.

3. (Optional) Click Share to share the query with other users.

Note: The Catalog system includes several predefined shared queries at installation time. Service Delivery administrators can optionally unshare or delete any queries that do not apply to their implementation.

You can load an advanced search.

Follow these steps to load an advanced search:

1. Click the Load icon.

2. Filter the list to display all queries, shared queries only, or personal queries.

3. Select a query and click Search**.**

Use Widgets for Request Management

Service Managers work with application administrators, such as portal administrators and solution designers to embed CA Service Catalog widgets and let users access request life cycle functions.

You can embed CA Service Catalog widgets that fit either a broad or special-interest context. For example, on a web page that features virtual desktop services, you can embed the Browse widget to let catalog users view the services in the catalog. You can also add the Request widget to enable the users to request the virtual desktop services they want. Similarly, on a service desk page, you can use the Status, Request List, Edit Request widgets. These widgets work together to let request managers approve and reject their requests pending action. This setup enhances the user experience for both catalog users and request managers.

Embedding CA Service Catalog widgets provides the following benefits:

- Segregate the request life cycle functions from other software, including other portals and portlets.
- Simplify the process. Users can easily access the catalog, create and submit requests, and manage requests.
- Create different pages for a special folder, interest, or user group.

Follow these steps:

- Step 1 - Review the Prerequisites and Guidelines for Widgets Implementation (see page 2177)
- Step 2 - Understand the CA Service Catalog Widgets (see page 2179)
- Step 3 - Implement the Widgets in Liferay or SharePoint (see page 2182)
- Step 4 - Test the Widgets (see page 2196)

Step 1 - Review the Prerequisites and Guidelines for Widgets Implementation

This article contains the following topics:

Prerequisites for Embedding Widgets

To use CA Service Catalog widgets in other applications, verify that you meet these prerequisites:

General Prerequisites

- Understand the difference between widgets and portlets: Widgets are snippets of code that you can embed in an HTML page. The widget provides a UI that is typically a service. Portlets are mini Java Web applications that a Java portal server like Liferay hosts. Portlets can be embedded in other pages but the portlets require a portal server to function. Examples of widgets that are embedded in other applications include the Facebook Like button, Google embedded maps, and Twitter feeds.
  The CA Service Catalog widgets can include CSS, HTML, and JavaScript code in a script. Portal applications that use widgets include Liferay and SharePoint.

  Note: CA Service Catalog widgets are configured out-of-the-box with Unified Self-Service.

- (Recommended) Configure the portal or application in which you want to use widgets to use Single Sign-On (SSO). Typically, you use either Windows NTLM domain authentication or an SSO application, for example, CA SiteMinder. Configure CA Service Catalog to implement SSO using the same method as the portal or application.

- Decide which of the following widgets to use on which pages of your portal or application, and in what context.

  - Browse Widget
  - Request Widget
  - Status Widget
  - Request List
  - Edit Request

  For example, you can use the Browse and Request widgets together to let catalog users request a service.

You must also be:

- A proficient user and administrator of CA Service Catalog.
- A proficient user and administrator of the portal or application from which you want to call the widget.

- Familiar with JavaScript, HTML, and web page design.

Portal Prerequisites

- Ensure that you can create containers, portlets, and other required elements in the portal. For example, Liferay. The container stores the portlet, and the portlet calls the CA Service Catalog widget.
- Verify that your portal follows JSR-168 and JSR-286 standards for portlets, if you want to use widgets without coding source directly. The CA Service Catalog portlets follow these standards so that you can deploy them on any standard Java Portal container. Portals that meet these standards let you configure the function of the widgets using menu options rather than source code. The portal software then translates your menu selections into the required JavaScript automatically.

Guidelines for Widgets Implementation

Review the following guidelines so that you can implement widgets efficiently:

Portal Pages

- Do not use the Request and Edit Request widgets on the same portal page.

  Important! Placing both widgets on the same page can result in an error that indicates that one of the widgets cannot render forms or process JavaScript correctly. So, catalog users cannot complete and submit requests and request managers cannot approve and reject requests pending actions.

  To address this limitation, embed the widgets as designed in this scenario:

  - On page 1, embed the Browse and Request widgets.
  - On page 2, embed the Status, Request List, and Edit Request widgets.

- All widgets on the same portal page *must* connect to the same CA Service Catalog host. For example, the Browse and Request widgets must specify the same CA Service Catalog host.
- Specify uniform configuration parameters for all widgets on the same page.
  For example, suppose the value of the Business Unit parameter of the Status widget is SaoPaulo12. In that case, the value of this parameter for the Request List, and Edit Request widgets must also be SaoPaulo12.
- Ensure that your request URL does not exceed 8KB. You can, however, configure this value as follows.

  1. a. Include the maxHttpHeaderSize attribute in the connector tag of the server.xml file that is at USM_HOME/view/conf path.

     b. Specify the new value for the maxHttpHeaderSize attribute. For example, specify maxHttpHeaderSize=16384 to allow request URL up to 16KB.

- Use the CA Service Catalog UI and not the widgets to transfer, delegate, take, return, hold, resume, and push through requests.
- The following functionalities are not available in the widgets:
  - Pending Override icon
  - Gold brick icon for assigning assets from catalog request
  - Display Service Health option

Liferay and SharePoint

The Liferay procedures in this scenario are for Liferay Portal Community Edition 6.1.2 CE. For more information about how to configure portlets for other supported versions of Liferay, see your Liferay documentation.

The SharePoint procedure in this scenario is for Microsoft SharePoint 2013. For more information about how to configure portlets for other supported versions of Microsoft SharePoint, see your Microsoft SharePoint documentation.

- To embed widgets in portlets on Liferay pages, you can use *either* source code *or* menu options. The menu options are provided through CA Service Catalog WAR files.
- To embed widgets in portlets on Microsoft SharePoint pages, use source code *only*.

If you are using other portal software, see the documentation of that portal for more information.

Accessibility

Widgets and portlets are accessible to users with visual disabilities using a screen reader such as JAWS. This access affects widgets and portlets *only*. If you intend to utilize this access, ensure that the *container* is also accessible.

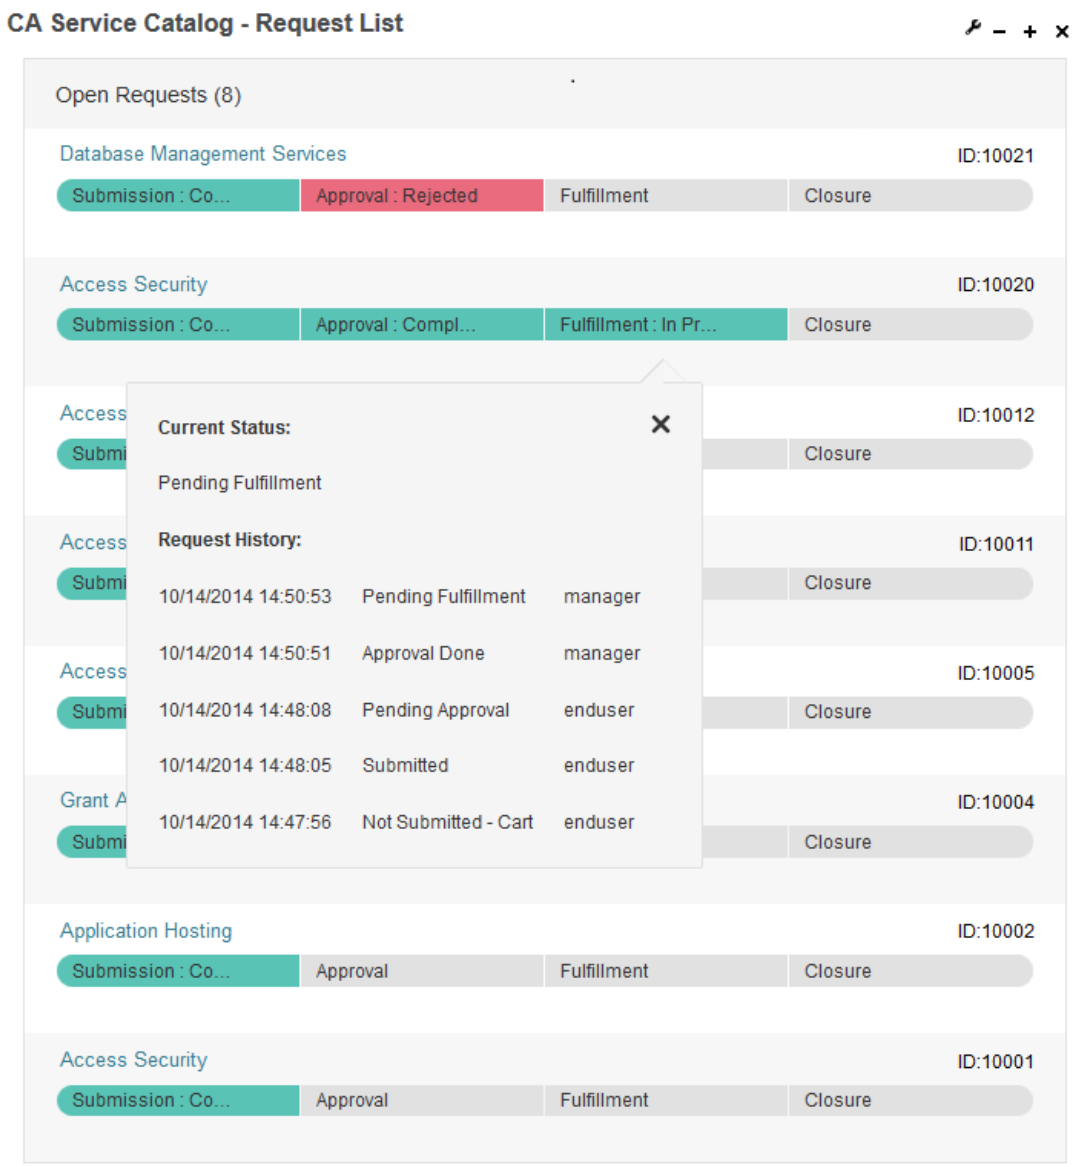
The keyboard shortcuts are as follows:

- Press Ctrl+Shift+Z to reach the first service offering from the category tree in the browse widget.
- Press letter V (small letter) to open the popup window when you click the links in the list widget.
- Press Ctrl+Shift+O to reach the first button in button area when a request form is loaded and the focus is at any place in between the form.

Step 2 - Understand the CA Service Catalog Widgets

Before implementing widgets, understand which widget to use when. On the first portal page, you embed the Browse and Request widgets. On the second portal page, you embed the Status, Request List, and Edit Request widgets.

The Request List widget displays the state that the request is in. Click on the bar to see the current status and request history of the request as shown in the following graphic:



Request List widget

- Use the Browse Widget to Display Services to Users (see page 2180)
- Use the Request Widget to Let Users Request Services (see page 2181)
- Use the Status, Request List, and Edit Request Widgets to Let Users Manage Their Unsubmitted Requests (see page 2181)
- Use the Status, Request List, and Edit Request Widgets to Let Users Manage Submitted Requests (see page 2181)
- Use the Status, Request List, and Edit Request Widgets to Let Users Manage Their Open Requests (see page 2181)
- Use the Status, Request List, and Edit Request Widgets to Let Approvers Approve or Reject Requests (see page 2181)

Use the Browse Widget to Display Services to Users

Use the Browse widget to offer services to users. You can use the Browse widget to offer the entire catalog or one specific folder or list of services. In this scenario, you offer the entire catalog through the Browse widget. Users can click any folder to display the services in the folder. Users can view the predefined folders and featured services to view their content.

Use the Request Widget to Let Users Request Services

Use the Request widget to let users request the services that you offer through the Browse widget. In this scenario, you add the Request widget next to the Browse widget. When the users click any service, the Request widget displays the service, including any forms. Users can complete the form and can submit the request.

For example, the user clicks the service "To host an application". The Request widget displays the service, so that the user can complete the form and can request the service. This action occurs automatically when you use the Browse and Request widgets on the same page and you select **Send local event which other widgets can listen** in the **Open In** parameter of the Browse widget.

Use the Status, Request List, and Edit Request Widgets to Let Users Manage Their Unsubmitted Requests

Use the Status and Request List widgets together, to provide the following function: When users click **Cart** on the status widget, the Request List widget opens the cart. **Cart** displays the number of items that the user has added to the cart but not submitted.

When the page includes Edit Request widget, users can view, add attachments, add notes, and change certain request details. Users *cannot* add more services, service option groups, or service options to the request.

Use the Status, Request List, and Edit Request Widgets to Let Users Manage Submitted Requests

Use the Status and Request List widgets together, to provide the following functions:

- Let users click **Open** to manage their open requests. Click **Open** to see the number of requests that the user has submitted but that have not been approved or rejected.
- Let users click **Closed** to view their completed or cancelled requests.

When the page includes Edit Request widget, the user can also act on these requests.

Use the Status, Request List, and Edit Request Widgets to Let Users Manage Their Open Requests

Use the Status and Request List widgets together, to display the *open requests* of the user when user clicks **Open**. Open requests are requests that the user has submitted but that the aprover has not yet approved or rejected. When the page includes the Edit Request widget, users can also make updates: Users can view, update (add notes or attachments), or cancel requests.

The user clicks **Open** on the Status widget, and the Request List widget opens the submitted requests.

Use the Status, Request List, and Edit Request Widgets to Let Approvers Approve or Reject Requests

Use the Status and Request List widgets together, to let users who have request approval rights open the requests pending action in their queues when they click **Pending** in the Status widget.

When the page includes the Edit Request widget, request approvers can also approve or reject these requests.

Step 3 - Implement the Widgets in Liferay or SharePoint

You can implement the CA Service Catalog widgets in Liferay or SharePoint. In Liferay, you can implement the widgets using the menu options (see page 2182) or using the source code (see page 218). In SharePoint, you can implement the widgets *only* using the source code (see page 2192).

Important! We recommend using the menu options to implement the widgets in Liferay.

(Recommended) Configure Widgets in Liferay using Menu Options

In Liferay 6.1.2 CE, as a CA Service Catalog administrator you deploy the CA Service Catalog WAR files and then configure the widgets using the menu options.

Follow these steps:

- Step a - Deploy the WAR files in Liferay 6.1.2 CE (see page 2182)
- Step b - Configure the Widgets (see page 2183)
  - Key Parameters for the Browse Widget (see page 2186)
  - Key parameters for the Request Widget (see page 2186)
  - Key Parameters for the Status Widget (see page 2187)
  - Key Parameters for the Edit Request Widget (see page 2188)
  - Key Parameters for the Request List Widget (see page 2188)

Step a - Deploy the WAR files in Liferay 6.1.2 CE

Deploy the CA Service Catalog Web Application Archive (WAR) file in Liferay 6.1.2 CE. The WAR files let you configure the display and behavior of CA Service Catalog widgets in portlets.

Follow these steps:

1. Copy the following WAR files stored in the *usm_home**filestore**portlets* folder from the CA Service Catalog computer to the deploy folder of the Liferay computer. The deploy folder is in the Liferay install location.
   - browse.war
   - request.war
   - request-list.war
   - request-edit.war
   - status.war

Note: All widgets on a page must use the same CA Service Catalog computer. If you are using a cluster, specify the computer name of the load balancer.

2. Run the startup.bat file on the Liferay computer.

Note: The startup.bat file is in tomcat-7.0.40\bin folder of the Liferay install location.

3. Log into Liferay portal with the credentials provided by your Liferay administrator.
   CA Service Catalog folder is displayed when you click **Add**, **More**. The WAR files have been deployed in Liferay.

Step b - Configure the Widgets

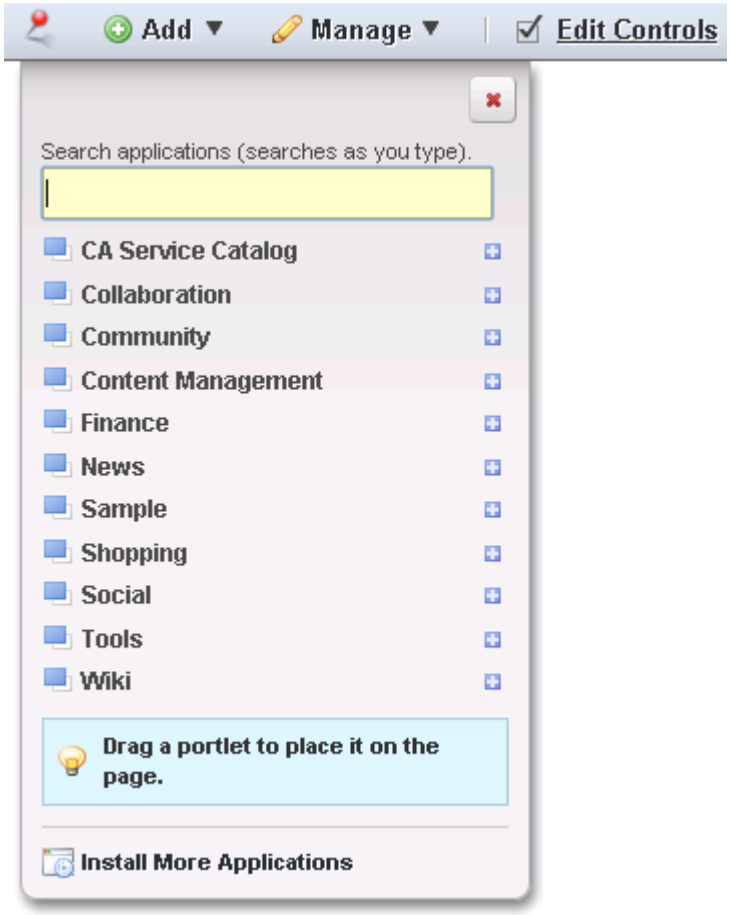
Use the CA Service Catalog WAR files to configure the display and behavior of CA Service Catalog widgets in portlets by using menu options.

Follow these steps:

1. Log into Liferay Portal with the credentials provided by your Liferay administrator.

2. Click **Add**, **Page** to create a page for your widgets.

3. Click **Add**, **More** on your portal page.
   The list of preconfigured portlets including a folder for CA Service Catalog appears as displayed in the following graphic:



List of Preconfigured Portlets

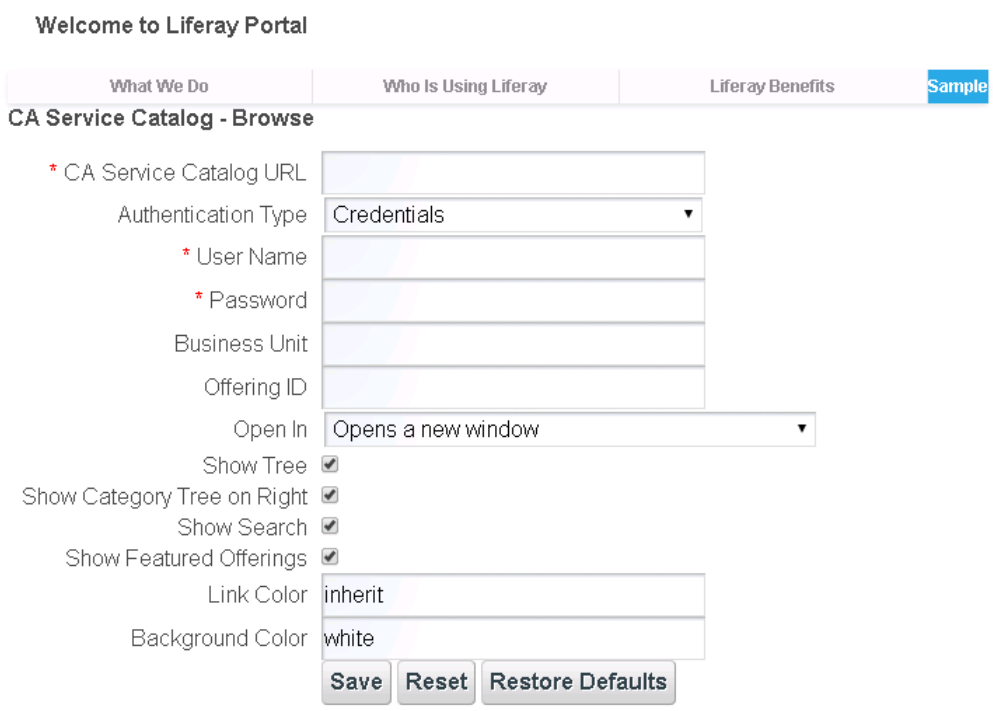
4. Expand **CA Service Catalog** on the list.

5. Select the widget you want to implement and click **Add**. Alternatively, drag-and-drop the widget onto the location you want.

6. Ensure that **Edit Controls** at the top of the page is selected.

7. Mouse over the widget, click the wrench (Options) icon, and select **Preferences** from the drop-down list.

8. Review and modify the parameters for the different widgets, as shown in the following graphic:



Modify the Widget Parameters

The key parameters for the different widgets are in the following sections:

- Key Parameters for the Browse Widget (see page 2186)
- Key Parameters for the Request Widget (see page 2182)
- Key Parameters for the Status Widget (see page 2182)
- Key Parameters for the Edit Request Widget (see page 2182)
- Key Parameters for the Request List Widget (see page 2188)

Note: There are other parameters available for the widgets. For example, background color or link color for the browse widget. You can modify any of these parameters depending upon your requirements.

9. Save your settings and review the portlet.
   The widget has been configured in Liferay.

Note: Embed the Browse and Request widgets on the first page (the Service Catalog page). These widgets work together to let catalog users browse the catalog and request services. Embed the Status, Request Edit, and Request List widgets in the second page (the Service Request page).

For each widget, ensure that:

Catalog URL=http://*host-name*:*port-number*/usm specifies the same CA Service Catalog host name and CA Service Catalog port number that you deployed the WAR Files in Liferay. Include the "/usm" in the URL for the portlet to render correctly.

Authentication Type specifies how to authenticate users. We recommend Single-Sign On for widgets.

Key Parameters for the Browse Widget

The key parameters for the Browse widget follow:

- **Business Unit**
  Specifies the business unit that catalog users can access while utilizing this Browse widget. Catalog users can browse services that they are entitled to. If you do not specify a value, the Catalog system uses the default business unit of the user accessing the widget.

- **Offering ID**
  Specifies the object ID of a single folder only or list of services that the Browse widget displays. You can specify either a single folder or a comma-separated list of services, using their object IDs.

  Note: The folder or list of services that you specify must exist in a business unit that the user can access. Do not provide both folder IDs and service IDs in the list.

- **Open In**
  Specifies how a service opens in the Request view when the user clicks the service on the Browse widget.
  Values:

  - **Opens a new window**
    Opens the service in the catalog, on a new page. The user requests the service on that page.

  - **Raise request in top most frame**
    Performs the same function as **Opens a new window**, except that the service opens in the top-most frame of the browser. If the service is a frame, then the first associated frame in service option element is selected.

  - **Raise request in same page**
    Opens the service in the catalog, on the same page.

  - **Send local event which other widgets can listen**
    Specifies that another widget on the same page listens to events from the Browse widget and responds to them. When the user clicks a service, the Request widget responds by opening the service. Add the Request widget to this page to enable this function.

  - **URL**
    Opens the service using a custom URL. The URL can include a placeholder for the object ID of the service. For example, http://www.google.com?id={action}

Key parameters for the Request Widget

The key parameters for the Request widget follow:

- **Business Unit**
  Specifies the business unit that catalog users can access while utilizing this Request widget. Users can request services that they are entitled to. If you do not specify a value, the Catalog system uses the default business unit of the user accessing the widget.

- **Offering Id**
  Specifies the service to display when the Request widget opens initially. When the user clicks a service in the Browse widget, the Request widget displays that service.

  Allowed Values: Valid Offering ID that must exist in a business unit that the user can access. If you specify -1 or leave this parameter blank, the widget displays nothing.

Key Parameters for the Status Widget

The key parameters for the Status widget follow:

- **Business Unit**
  Specifies the business unit that catalog users can access while utilizing this Status widget. Users can view the status of the requests that they are entitled to.

  - Users who are not request managers can view the status of their own requests only.

  - Request managers can view the status of both their own requests and the requests pending action that is assigned to them.

  If you do not specify a value, the Catalog system uses the default business unit of the user accessing the widget.

- **Layout**
  Specifies how the options on the Status widget are displayed.
  Box Layout displays the options as buttons in a single row.
  Row Layout displays the options in each row in a table with a description.

- **Open In**
  Specifies how a target opens when the user clicks it on the Status widget. In this scenario, when the user clicks a service, another widget responds by opening the target. The targets are as follows:

Option	Target Function	Widget
Cart	Shopping Cart	Edit Request
Open	Open Requests	Request List
Closed	Closed Requests	Request List
Pending	Requests Pending Action	Request List

  For example, to enable these target functions to complete correctly when users click the option **Cart** in the cart, add the Edit Request widget .

Values:

-

- **New window**
  Opens the target on a new page.

- **Top frame**
  Performs the same function as **New window**, except that the target opens in the top-most frame of the browser. If the target is a frame, then the first associated frame in the service option element is selected.

- **Same page**
  Opens the target in the catalog, on the same page.

- **Other Widget**
  Indicates that another widget on the same page listens to events from the Status widget and responds to them.

- **URL**
  Opens the target using a custom URL. The URL can include a placeholder for the object ID of the source context, for example, the service.
  An example follows:

```
http://www.google.com?id={action}
```

Key Parameters for the Edit Request Widget

The key parameters for the Edit Request widget follow:

- **Business Unit**
  Specifies the business unit that catalog users can access while utilizing this Edit Request widget. Users can edit requests that they are entitled to.
  If you do not specify a value, the Catalog system uses the default business unit of the user accessing the widget.

- **Request ID**
  Specifies the request to display when the Request List widget opens initially.
  When the user clicks an option on the Status widget, the Request List widget displays the matching item: the cart, open requests, completed requests, or requests pending action.
  Allowed Values: Valid Request ID that must exist in a business unit that the user can access. If you specify an invalid Request ID or leave this parameter blank, the widget displays nothing.

Key Parameters for the Request List Widget

The key parameters for the Request List widget follow:

- **Business Unit**
  Specifies the business unit that catalog users can access while utilizing this Request List widget. Users can list and view requests that they are entitled to.
  If you do not specify a value, the Catalog system uses the default business unit of the user accessing the widget.

- **Type**
  Specifies that the default setting for this Request List widget is to display pending requests (requests pending action). Other options include open, closed, or recent requests.

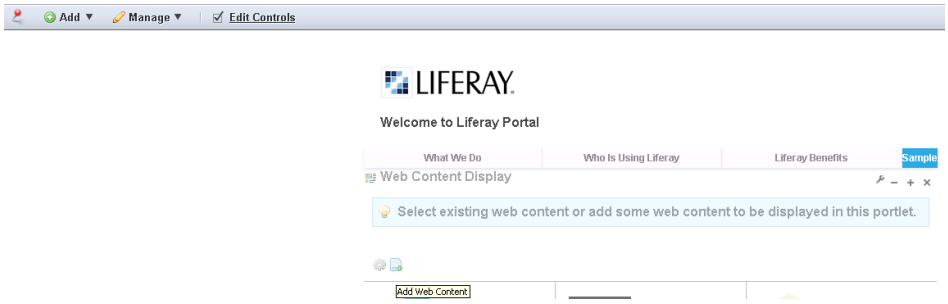
Configure Widgets in Liferay using Source Code

In Liferay 6.1.2 CE, as a CA Service Catalog administrator you can also call the widget by creating the portlet and specifying the source code. To configure the display and behavior of the widget in your implementation, follow the source code examples as a model.

Important! Ensure that you review the source code HTML example files for the widgets you want to implement before modifying the parameters. The source code HTML files are available at USM_HOME\view\webapps\usm path.

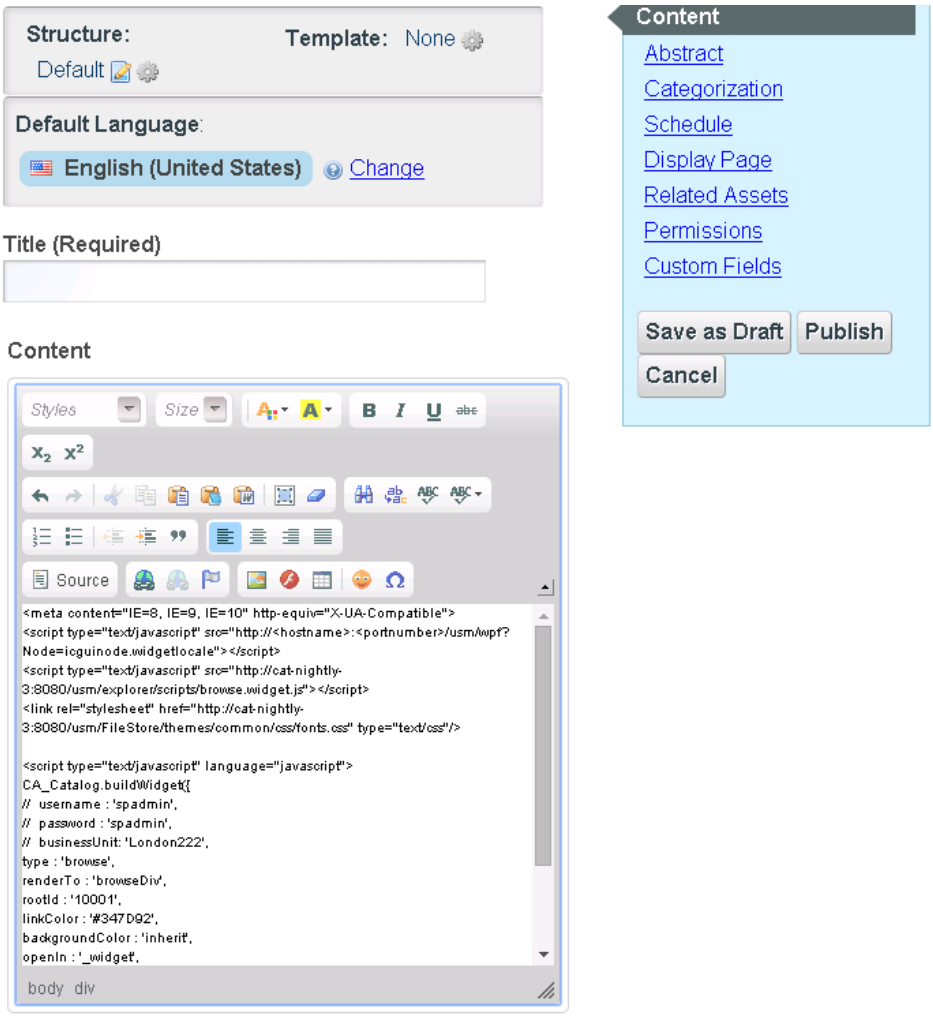
Follow these steps:

1. Log into Liferay Portal with the credentials provided by your Liferay administrator.
2. Click **Add**, **Page** to create a page for your widgets.
3. Perform these actions to create the portlet in the portal page:
   a. Click **Add**, **Web Content Display**.
   b. Click **Add Web Content** as shown in the following graphic:



Liferay Portal Page

   c. Copy the source code for the widget that you want to embed in the **Content** section as shown in the following graphic:



Content section of Liferay Portal Page

The following HTML files are available for the widgets:

- browse html

  Specifies the HTML code for the Browse widget

- broswe_request html

  Specifies the combined HTML code for the Browse and Request widgets.

- status

  Specifies the HTML code for the Status widget

- status_list

  Specifies the combined HTML code for the Status and Request List widgets.

- status_list_editrequest

Specifies the combined HTML code for the Status, Request List, and Edit Request widgets.

Note: Embed the Browse and Request portlets on the first page (the Service Catalog page). Embed the Status, Request Edit, and Request List portlets in the second page (the Service Request page).

d. Specify the host name and the port number of the CA Service Catalog computer in each line of the source code for the different widgets as follows:

```
<script type="text/javascript" src="http://<hostname>:<portnumber>/usm
/explorer/scripts/browse.widget.js"> </script>
```

Update each of the following lines in the source code for the different widgets with the host name and port number information of the CA Service Catalog computer:

- browse.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/browse.
widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- browse_request.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/browse.
widget.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/request.
widget.js"></script>
<script type="text/javascript" src="/usm/gwt/fdRenderer/fdRenderer.
nocache.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- status.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/status.
widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- status_list.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/status.
widget.js"></script>
<script type="text/javascript" src="/usm/gwt/requestList/requestList.
nocache.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/request-
list.widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- status_list_editrequest.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/gwt/fdRenderer/fdRenderer.
nocache.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/status.
widget.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/request-
list.widget.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/edit.
request.widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

e. Specify the other required fields and close the window.

> **Note:** There are other parameters available for the widgets. For example, background color or link color for the browse widget. You can modify any of these parameters depending upon your requirements.

The new portlet gets added to Liferay.

4. (Optional) Perform these actions to edit the portlet in the portal page.

   a. Ensure that **Edit Controls** at the top of the page is selected.

   b. Mouse-over the portlet, and click the pencil (Edit Web Content) icon.

   c. Click **Source** in the Content window.

   d. Modify the parameters in the source file.
   The portlet is modified.

5. Close the Source container and click **Publish** to review the updated portlet.
   The widget is configured in Liferay using source code.

Configure Widgets in SharePoint using Source Code

In Microsoft SharePoint 2013, as a CA Service Catalog administrator you call the widget by creating the portlet and specifying the source code. To configure the display and behavior of the widget in your implementation, follow the source code examples as a model:

> **Important!** Ensure that you review the source code HTML example files for the widgets you want to implement before modifying the parameters. The source code HTML files are available at USM_HOME\view\webapps\usm path.

Follow these steps:

1. Verify with your Microsoft SharePoint administrator that a site page has been created for your organization. Ensure that you can access this site page.

2. Log into your Microsoft SharePoint site page with the credentials provided by your SharePoint administrator.

3. Perform these actions to create the portlet in the portal page:

    a. Click **EDIT** in the upper right corner of your SharePoint page.

    b. Click **INSERT**, **Embed Code** to insert the source code of the widget you want to embed in the page.

    c. Copy the source code for the widget that you want to embed. The following HTML files are available for the widgets:

    - browse html

      Specifies the HTML code for the Browse widget

    - broswe_request html

      Specifies the combined HTML code for the Browse and Request widgets.

    - status

      Specifies the HTML code for the Status widget

    - status_list

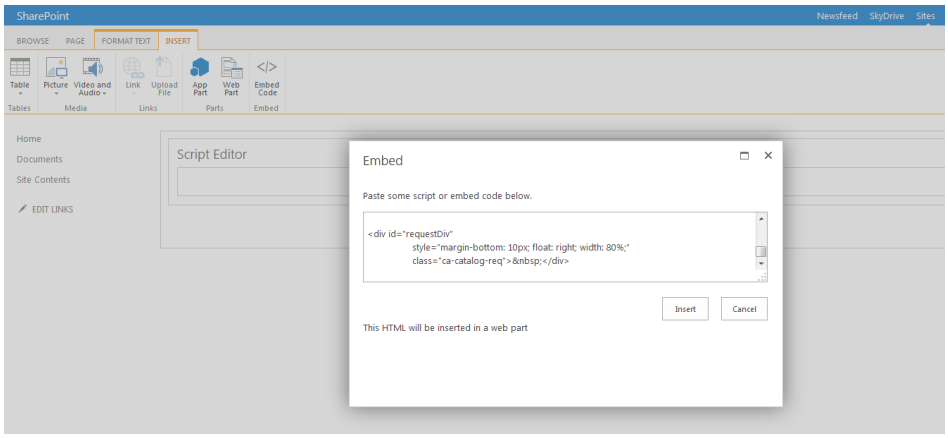
      Specifies the combined HTML code for the Status and Request List widgets.

    - status_list_editrequest

      Specifies the combined HTML code for the Status, Request List, and Edit Request widgets.

    Note: Embed the Browse and Request portlets on the first page (the Service Catalog page). Embed the Status, Request Edit, and Request List portlets in the second page (the Service Request page).



Embed code

d. Click **Insert**.

e. Specify the host name and the port number of the CA Service Catalog computer as follows:

```
<script type="text/javascript" src="http://<hostname>:<portnumber>/usm
/explorer/scripts/browse.widget.js"> </script>
```

Update each of the following lines in the source code for the different widgets with the host name and port number information of the CA Service Catalog computer:

- browse.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/browse.
widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- browse_request.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/browse.
widget.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/request.
widget.js"></script>
<script type="text/javascript" src="/usm/gwt/fdRenderer/fdRenderer.
nocache.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- status.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/status.
widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- status_list.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/explorer/scripts/status.
widget.js"></script>
<script type="text/javascript" src="/usm/gwt/requestList/requestList.
nocache.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/request-
list.widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

- status_list_editrequest.html file:

```
<script type="text/javascript" src="/usm/wpf?Node=icguinode.
widgetlocale"></script>
<script type="text/javascript" src="/usm/gwt/fdRenderer/fdRenderer.
nocache.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/status.
widget.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/request-
list.widget.js"></script>
<script type="text/javascript" src="/usm/explorer/scripts/edit.
request.widget.js"></script>
<link rel="stylesheet" href="/usm/FileStore/themes/common/css/fonts.
css" type="text/css"/>
```

Note: There are other parameters available for the widgets. For example, background color or link color for the browse widget. You can modify any of these parameters depending upon your requirements.

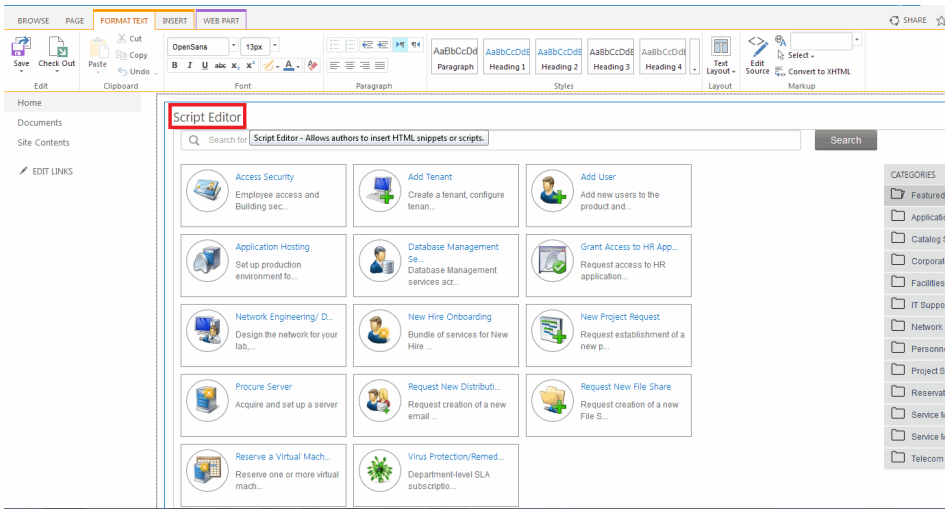
f. Click **SAVE**.

The widget is added to your Microsoft SharePoint page.

4. (Optional) Perform these actions to edit the portlet in the portal page.

   a. Click **EDIT** in the upper right corner of the SharePoint page.

   b. Click **Script Editor**.

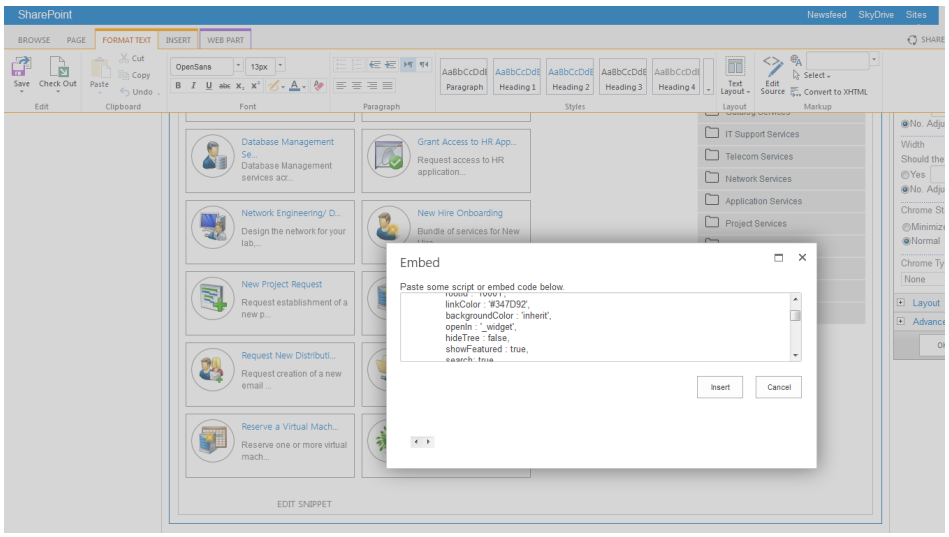


Script Editor

c. Click **WEB PART**, **Web Part Properties**.

d. Scroll to the end of the page and Click **EDIT SNIPPET** in Script Editor.

e. Modify the required parameters and click **Insert**.



Modify parameters

f. Click **SAVE**.
The widget is modified.

Step 4 - Test the Widgets

Verify that the widgets appear and function as intended on portal pages or other pages on which you embedded them.

Follow these steps:

1. Access the pages that include the widgets.

2. Verify the following functions on the first page:
   - The Browse and Request widgets appear as intended.
   - The widgets work together to let catalog users view and request services.
3. Verify the following functions on the second page:
   - The Status, Edit Request, and Request List widgets appear as intended.
   - Catalog users can perform the following tasks:
     - Review the status of their submitted requests.
     - Add notes and attachments for submitted requests that have not yet been approved or rejected.
   - Request managers can manage their requests pending action by approving or rejecting them.

You have tested the widgets.

Request Management from a User Perspective

After you have submitted your cart, you have launched your new request into its life cycle. Each requested service option in the request has a status that reflects its current step in the request life cycle. The overall request also has a milestone status that reflects the aggregate values of the statuses of the requested service options. The milestone statuses are:

- Not Submitted
- Submitted
- Pending Approval
- Approved/Rejected
- Pending Fulfillment
- Fulfilled
- Completed/Cancelled

Each status range contains various detailed status values. The status values are customizable by your catalog administrator. During the approval and fulfillment phases for your request, you can receive emails informing you of the progress of your request through its life cycle. The business process for approval and fulfillment, the status values used and whether you receive emails depends on the approval and fulfillment business processes of your service provider.

For example, you request a Desktop service which includes a Standard Desktop service option and Microsoft Visio service option. Your request includes one service which contains two service options. If your service provider requires manager approval, the first step is for your manager to approve or reject your request for the Desktop service. After approval phase is complete for the two service

options Standard Desktop and Microsoft Visio, the fulfillment phase begins. If the fulfillment process for these two service options includes checking available inventory, an asset manager checks the inventory.

Assuming both the Standard Desktop and a Microsoft Visio license are found in inventory, the status of each service option changes to Filled From Inventory. The next step in the fulfillment process is to notify IT Services to configure and deliver the Standard Desktop and Microsoft Visio so the status of each service option changes to Notified IT Services. After each service option is configured and delivered to you, the status of each service option changes to Fulfilled. After each service option in the request is set to Fulfilled, the status of all service options is set to Completed. The request is considered completed or closed.

For this example, for each requested service option, you can view the following status values over time (in chronological order):

- Not Submitted - Cart
- Submitted
- Pending Approval
- Approved
- Approval Done
- Pending Fulfillment
- Check Availability
- Filled From Inventory
- Notified IT Services
- Fulfilled
- Completed

Manage Requests

You can view, modify, copy, and search requests. View requests to check their status, tracking, audit trail, and other details. You can also email copies of requests. The details of a request that you can view and modify vary according to:

- Your role
- The request status
- The configuration options set by your catalog administrator

Follow these steps:

1. Log in to CA Service Catalog, as follows:

a. Enter the URL for CA Service Catalog, in the format http://*computer-name*:*port-number* . Your catalog administrator provides the URL.
If CA Service Catalog is configured to use single sign-on, you are automatically authenticated and the initial page appears. Otherwise the Log In page appears.

b. If the Log In page appears, enter your assigned user name and password.

> **Note:** If you have a user ID in multiple business units, click Advanced. Specify the business unit that you want to log in to.

2. Click Home, Requests.

> **Note:** The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

3. Click the My Requests drop-down if the page does not list requests and select the option of your choice.

4. If applicable, click the list of requests that contains the request that you want to copy. For example, if you want to copy a completed request, click Completed Requests.

5. Click the name of the request that you want, and proceed as follows:

   - View and optionally update the request, as applicable.

   - Copy the request.

     > **Note:** The notes and attachments for the original request are not copied to the new request. The status of the new request is Not Submitted, so that you can delete the existing services or can add new services in the request.
     > Update the fields as needed, including the *Requested By* and *Requested For* users.

   - To search for requests by request ID or according to the predefined categories on the screen, use the Request Lookup section of the Requests window. You can view only the requests that your role permits.

Review the following information to understand what you can do when you view and can modify requests:

All Statuses

- View the requested services and service options, and other details of the request.
  View the status, which appears in the Status column of any request list, for example, My Recent Requests, Completed Requests. The request status also appears when you view the details of a request.

- View the request status history, by clicking the name of the status in the request details or the Status column.
  Status values appear for the entire request and for each service and service option in the request.
  Review the numbers, names, and meanings of default status values (see page 2108).

- Display and add and attachments.

- Refresh the display.

- Copy the request, as explained earlier in this topic.

- Email a copy of the request.
  To email the details of a request, click the Email button or link, specify the details, and click Send.
  Optionally click Include Request Snapshot to include details of the request in the email.
  Otherwise, the email contains only the text that you specify for the Subject line and the Message Body.
  In the address fields, you can enter email addresses, user IDs, account names, or the *last name, first name* values of user names. Separate multiple entries with a semi-colon (;). If you enter an account name, the Catalog system uses the email address on the account profile.

- View and edit the additional information sections.

- View the subscriptions for service options, if applicable.

Not Submitted Requests

- Submit the request.

- Add or delete services.

- Delete the request.

Open Requests

An open request is one whose status is not Completed or Cancelled.

- View the status history.

- View the details of a request.

- Edit the request.

- Email the request.

Administrators can configure the display of columns on the Open Requests page to display some or all of the following columns:

- ID - Assigned by the system
- Name
- Requested By
- Requested For
- Priority
- Date Created
- Date Modified
- Status

Requests Pending Action

Request managers can approve, reject, fulfill, and perform several other actions for the requests pending action that are assigned to them.

Completed Status

- Cancel a requested service.
- Cancel the request which cancels all the services in the request.

Tracking

If permitted by your role and the configuration options set by your catalog administrator, you can view and click the Tracking tab. This tab displays any CA Process Automation process instances that are related to the requested services and service options. This tab also provides the status and other details of these processes.

Audit Trail

If permitted by your role and the configuration options set by your catalog administrator, you can view and click the Audit Trail tab. This tab displays each service option element and its status changes over time. Each service option is comprised of service option elements.

Request a Service

Users browse or search the catalog, view services, and request the services that they want. The entries in the service catalog that you view are managed by your service provider's catalog administrator. Your catalog administrator can choose to feature certain services from the catalog when you select a category or other service. If so, you can view the Featured Services section of the window appear when you select a related category or service.

The catalog is organized by a category hierarchy created by your catalog administrator. As you drill down into a category, the sub-categories contained in that category appear in the Browse section. Services can be contained in any category or in no category (shown by clicking the Not Categorized link in the initial Browse window). After you have selected a category that contains services, they appear in the Catalog Services section of the window. To further examine or select a service, click its name in the Catalog Services section of the window.

After you have selected a service by clicking its name, the Service Options page appears. This page displays all the service options available with the service. Related service options are organized into a service option group. A service can include several service option groups, each displayed in its own collapsible section of the Service Options page. Some service option groups require a choice of one or more options (presented using a radio button). Other service option groups allow you to select one or more check boxes with the option of not selecting any check boxes. The third type of service option group automatically includes the service options displayed and you cannot clear the service options.

Follow these steps:

1. Log in to CA Service Catalog, as follows:

    a. Enter the URL for CA Service Catalog, in the format http://*computer-name*:*port-number* . Your catalog administrator provides the URL.
    If CA Service Catalog is configured to use single sign-on, you are automatically authenticated and the initial page appears. Otherwise the Log In page appears.

    b. If the Log In page appears, enter your assigned user name and password.

    Note: If you have a user ID in multiple business units, click Advanced. Specify the business unit that you want to log in to.

2. Select **Home**, **Requests**.

3. Browse or search the catalog to find the service you want.
    For example, if you search for "Asset Service", all the services that contain "Asset Service" in any of the following attributes are displayed in the search results:

    - Service Offering Name
    - Offering Description
    - Option Group Name
    - Option Group Description
    - Option Name
    - Option Description

4. Select the required service offering.

5. Select the options that you want. Complete the fields and confirm your selections as needed.

6. (Optional) Update the *Requested For* field if your role permits and if applicable. Request this service for a different user or account.

7. Click Submit if the service includes a Submit button (not a shopping cart).

> **Note:** Service designers configure each service (see page 2997) to use *either* a shopping cart or a Submit button as the method for users to request the service. If the service uses a cart, you can add more services to a cart, remove services, or save the cart.

If one or more service options or services in your request requires approval, the Catalog system sends them to the required request manager or managers.

Occasionally, you cannot submit a service. For example, because a form does not appear correctly or the Submit or Check Out button does not function. In such cases, contact your administrator. Your administrator can typically fix such problems. For example, by updating forms for the service or by updating configuration settings for your business unit or your user ID.

Add Notes or an Attachment

You can add notes or an attachment for a request or a service option, if the administrator for your business unit has enabled these features for your role. If you want to add notes for a request or service option but do not see the corresponding option on the UI, contact your administrator. The UI behavior varies slightly depending on whether the service uses a shopping cart or one-click submit. The service designer selects one of these options when configuring the details of the service (see page 2997).

> **Note:** To enable these features, administrators select **Catalog**, **Configuration**, **Request Management Configuration**. To let users add notes for a request, use the *Access Control: Show General Information* option. To let users add notes for a service option, use the Allow Notes at Service Option Level option.

Follow these steps:

1. Click **Home**, **Requests**.

2. Perform the action that applies:

   - If the request is already submitted, click My Request, Open Requests, find the request, and open it.

   - If the request is not yet submitted and includes a service that uses a shopping cart click, Click Cart (if necessary) to display the request in the cart. Next, click Checkout.

- If the request is not yet submitted and includes a service that uses one-click submit, go to the next step. You select such services from the catalog and submit them using the same single page. So, you add notes while completing the fields on this page.

3. Add notes or an attachment to a service option, as follows:

   a. Click Show Details in the My Selections box.
   This box appears near the top left portion of the screen.

   b. Find the service option and click the Add Note icon or the Add Attachment in the Action column.

   c. Enter the text of the note or browse to select a file and attach. Click OK. For an attachment, verify the Display Name and also provide a Description.

4. Add notes or an attachment to the entire request, as follows:

   a. Verify that the service contains only one service option. If the service contains multiple service options, you cannot add notes to the entire request.

   b. Scroll down to the Notes box or the Attachments box on the right side of the page. The Notes box appears under the Request Information box and above the Attachments box.

   c. Click Add or browse to select a file and attach.

   d. Enter the text of the note and click OK. For an attachment, verify the Display Name and also provide a Description.

   Note: Use any of the rich text options available on the Add Note dialog to enhance the appearance of your note. You cannot delete or alter a note after you click OK. To delete an attached file, locate the file in the Attachments box, scroll right, and click the Delete icon. To update the display name or description of an attached file, click the Edit icon.

   You have added notes and/or attachment.

   Note: CA Service Catalog sends an email notification to end users and approvers when a note and/or attachment is added or edited for a request or an issue. CA Service Catalog also provides you the option of configuring the Request Details Link for E-Mail Notification. This capability is available only if you have installed the CA Service Catalog 14.1.01 patch updates from CA Support.

   For more information on Request Details Link for E-Mail Notifications parameter, refer to Request Management Configuration parameters (https://wiki.ca.com/display/CASM/.Other+Parameters+v14.1).

Manage Requests Pending Action

When a user submits a request, it enters the approval and subsequent fulfillment phase. Your service provider determines the business processes for approval and fulfillment of the services, and service options in the catalog. During approval and fulfillment, usually a person is assigned an approval or fulfillment task.

You can receive an email notification if a request approval or fulfillment task is assigned to you or to a group of which you are a member. You can view the requests which have an approval or fulfillment task that you are assigned. To do so, view your Pending Action list. Click the **Pending My Action** link in the **Request Lookup** section of the Requests window.

The Requests Pending Action list displays the list of requests which have an approval or fulfillment task that you are assigned. You can optionally filter this list of assignments by user name, group name, or all.

Request administrators can *search* for all requests, including requests that are assigned to other users. Request administrators have one of the following roles: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Catalog Administrator, and Request Manager. If the requests are already assigned to a user for approval or fulfillment, administrators can either complete these requests or they can transfer them to other users.

Rules for Requests Pending Action

Here, the term *request pending action* refers to one or more services or service options in a request that are pending approval or pending fulfillment. In both single-service and multi-service requests, all services are part of the request, but the term request pending action applies only to the services or service options that are pending approval or pending fulfillment. Specifically, pending *approval* status applies to *services* only, while pending *fulfillment* status applies to *service options* only.

- Both CA Service Catalog administrators and non-administrator users can transfer or delegate requests pending action in their own queues to other users. When you either transfer or delegate a request pending action, the user who receives the request becomes the new assignee. The major difference between transferring and delegating follows: When you delegate a request, it stays in both your queue and the queue of the new assignee. When you transfer a request, it leaves your queue and moves to the queue of the new assignee.

- Thus, as an administrator, you can decide to delegate a request pending action if you want to monitor it within your own queue. Conversely, you can decide to transfer a request pending action if you do not want to monitor it. After you delegate a request, the new assignee (User B) or an administrator can transfer the request to someone else (User C). When User B or another transfers the request, the request moves from both your queue and User B's queue to User C's queue only.

- Only requests pending action that is assigned to a user can be delegated. When a request pending action is assigned to a user and a group, only the one that is assigned to a user can be delegated. The one assigned to a group cannot be delegated.

- A request pending action can be delegated only once. This limitation includes auto-delegation; a request that has already been delegated manually cannot be auto-delegated. Therefore, before you delegate a task to a user, ensure that the user does not have auto-delegation enabled. However, the request can be transferred multiple times. You can delegate requests to an individual user only, not to a group.

- A request pending action is transferred or completed by the primary assignee of a pending action, by administrators, and by a user with the required access control settings. A request pending action can be transferred to only one user or one group.

- Both administrators and non-administrative users can also take ownership of a request pending action that is assigned to a group queue to which they belong. Users can return to the group queue a request pending action that they have previously taken but have not completed.

- A request pending action can only be returned by the primary owner of a taken pending action. The administrator (or any other user) cannot return a request pending action on another user's behalf.

To manage requests pending action, follow this process:

1. Act on requests pending action that can be assigned to you or other request managers, as follows:
   - Approve or reject (see page 2207)
   - Fulfill (see page 2210)
   - Transfer (see page 2212)
   - Delegate or auto-delegate (see page 2214)
2. Act on requests pending action that can be assigned to you, other request managers, or a group queue:
   - Take or return (see page 2217)
   - Ignore, retry, or override alerts (see page 2218)
   - Hold or resume (see page 2219)
   - Cancel (see page 2221)

Typically, the Status drop-down list includes several options. The names of these options and the order in which they appear are specified in the requestshared.xml file. For more information about how to update the values and the order of the options, see the Modify the Request Status List (see page 2006) section.

Note: Warning messages can appear if a user with the Services Manager role handles a requests pending action, for example, by approving and rejecting requests. In such cases, the approvals and rejections proceed successfully even though the warning messages appear.

To prevent such warning messages from appearing, follow these steps:

1. Log in to CA Service Catalog as a Service Delivery administrator or business unit administrator.
2. Change the default access rights of the Services Manager role for a specific business unit, as follows:
    a. Log in to the business unit.
    b. Select **Catalog**, **Configuration**, **Request Management Configuration**.
    c. Add the **Access Control: Add Request** setting to this role.
    d. Save your changes.

Approve or Reject Requests Pending Action

Request managers approve and reject the requests pending action that is assigned to themselves or other request managers. Approving or rejecting requests pending action is an essential step in the process of managing requests from creation through fulfillment.

All CA Service Catalog users can approve or reject requests pending action that is assigned to them.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page to display requests. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.
2. Click Pending My Action.
3. Locate the request and click the Approve/Reject icon in the Actions column.
4. View the details of requested services, including their statuses.
5. Focus on the services for which you are assigned an approval task.

    Decide which items in the request to approve or reject.
6. If you have *not* implemented multi-item approval (see page 2116), perform this step only.
7. In the Item Status drop-down list, select the appropriate status to approve or reject each service, and click OK. The statuses are typically named Approved and Rejected, respectively.

- If you have *not* implemented discrete approval (see page 2120), the following rules apply:
  - Rejecting a service rejects the entire request. The request is returned to the user who submitted it. That user decides whether to update the request and resubmit it or accept the rejection as final.
  - Once all services in the request are approved, the request moves the request to the next phase of the request life cycle. For example, the second level of approval (if applicable) or the fulfillment stage. After you have approved a service, the approval processes of your service provider can require a second level of approval. In such a scenario, the second-level approver is assigned an approval task.
- You can optionally implement discrete approval so that you can approve or reject the following *individually*:
  - Services in a request
  - Service options in a service

If the approval task was assigned to more than one user or a group, once any assigned user completes that pending action, the request is removed from the Pending Action list for all assigned users. If the request contains multiple services, it is not removed until either all services are approved or one service is rejected.
You are returned to the Request Details window. If you return to the Pending Action list, you can see that the request is removed from your list.

8. If you have implemented multi-item approval perform this step only.
9. Perform one or both of the following actions:

- Select all or multiple services in the request and click Approve or Reject.
  This option appears when multi-item approval is implemented but discrete approval is *not* implemented.
- Select all or multiple service options in each service and click Approve or Reject.
  This option appears when both multi-item approval and discrete approval are implemented.

Approve or Reject the Requests Pending Action of Other Users

Only CA Service Catalog administrators and other users with the required access control setting can approve or reject requests pending action that is assigned to other users. The access control setting *Access Control: Proxy Action* under Catalog, Configuration, Options, Request Management Configuration determines the such roles.

Note: For more information, see the section Set CA Service Catalog Configuration Options (see page 1449).

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page. The Requests page can either display requests and the search box directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Search for requests, using the Advanced Search.

3. In the Query drop-down list, perform the following actions:

    a. Ensure that Action Request is selected.

    b. (Optional) Enter the user ID of interest, in the Userid field.

    c. Click Search.

4. Click the Approve/Reject icon next to the name of the service of interest, in the Actions column.

    Note: The Item Status drop-down list is disabled. You enable it and use it in the next steps.

5. Click the Override (Push-Through) icon in the Actions column.

6. Confirm that you want to override a pending action that is not assigned to you.
   The Item Status drop-down list is enabled, meaning that you can now approve or reject each service in the request.

7. (If the request contains multiple services) Click the alert status icon. Enable the Item Status drop-down list for each service that you want to approve or reject.
   The status of each service option matches the status of the service during the approval phase of the request life cycle.

8. Decide which items in the request to approve or reject.

9. If you have *not* implemented multi-item approval (see page 2116), perform this step only.
   In the Item Status drop-down list, select the appropriate status to approve or reject each service, and click OK. The statuses are typically named Approved and Rejected, respectively.

    - If you have *not* implemented discrete approval (see page 2120), the following rules apply:

        - Rejecting a service rejects the entire request. The request is returned to the user who submitted it. That user decides whether to update the request and resubmit it or accept the rejection as final.

        - Once all services in the request are approved, the request moves the request to the next phase of the request life cycle. For example, the second level of approval (if applicable) or the fulfillment stage. After you have approved a service, the approval processes of your service provider can require a second level of approval. In such a scenario, the second-level approver is assigned an approval task.

- You can optionally implement discrete approval so that you can approve or reject the following *individually*:
  - Services in a request
  - Service options in a service

  If the approval task was assigned to more than one user or a group, once any assigned user completes that pending action, the request is removed from the Pending Action list for all assigned users. If the request contains multiple services, it is not removed until either all services are approved or one service is rejected.

10. If you have implemented multi-item approval perform this step only.
    Perform one or both of the following actions:
    - Select all or multiple services in the request and click Approve or Reject.
      This option appears when multi-item approval is implemented but discrete approval is *not* implemented.
    - Select all or multiple service options in each service and click Approve or Reject.
      This option appears when both multi-item approval and discrete approval are implemented.

Fulfill Requests Pending Action

Request managers fulfill the approved requests pending actions that are assigned to themselves or other request managers. Fulfilling requests pending action is the final step in the process of managing requests from creation through fulfillment.

All CA Service Catalog users can fulfill requests pending action that is assigned to them.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.
2. Click Pending My Action.
3. Locate the request and click the Fulfill icon in the Actions column.
4. View the details of requested services. Focus on the services for which you are assigned a fulfillment task.
   The status of each service option matches the status of the service during the fulfillment phase.
5. Decide and select the next status for each service for which you are assigned a fulfillment task. The exact statuses available can vary, based on the business processes of your service provider. Two significant statuses are Fulfilled and Fulfillment Cancelled, both of which end the fulfillment process for that service option.

- If you are using CA APM and the service is eligible for asset assignment, select the available inventory of assets. Assign assets or indicate that no assets are available for assignment. Using the assign assets functionality changes the status of the related service option.

- If you are *not* using CA APM or the service is *not* eligible for asset assignment, in the Item Status drop-down list, select the appropriate status for each service.

6. Optionally add notes or attachments as supporting documents.

7. When you are finished, click OK.
   You are returned to the Request Details window. If all pending action assigned to you have been completed, the request is removed from your list. If the fulfillment task was assigned to more than one user or a group, once any assigned user completes that pending action, the request is removed from the Pending Action list for all assigned users. If the request contains multiple services, it is not removed until either all services are either fulfilled or have their fulfillment that is cancelled.

Note: The fulfillment processes of your service provider can require more fulfillment steps. In such cases, the next fulfiller is assigned a fulfillment task.

Fulfill the Requests Pending Action of Other Users

Only CA Service Catalog administrators and other users with the required access control setting can fulfill requests pending action that is assigned to other users. The access control setting *Access Control: Proxy Action* determines such roles. This setting is under Catalog, Configuration, Options, Request Management Configuration.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page. The Requests page can either display requests and the search box directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Search for requests, using the Advanced Search.

3. In the Query drop-down list, perform the following actions:

   a. Ensure that Action Request is selected.

   b. (Optional) Enter the user ID of interest in the Userid field

   c. Click Search.

4. Click the name of the request of interest to open it.

5. View the details of requested services. Focus on the services whose fulfillment status you want to update.
   The status of each service option matches the status of the service during the fulfillment phase.

6. Click the alert status icon in the Actions column.

7. Confirm that you want to override a pending action that is not assigned to you, when prompted.
   The Item Status drop-down list is enabled, meaning that you can now update the fulfillment status of the service.

8. Click the alert status icon. Enable the Item Status drop-down list for each service whose fulfillment status you want to update, if the request contains multiple service. The status of each service option matches the status of the service during the fulfillment phase.

9. Decide and select the next status for each service whose fulfillment status you want to update. The exact statuses available can vary, based on the business processes of your service provider. Two significant statuses are Fulfilled and Fulfillment Cancelled, both of which end the fulfillment process for that service option.

   - If you are using CA APM and the service is eligible for asset assignment, select the available inventory of assets. Assign assets or indicate that no assets are available for assignment. Using the assign assets functionality changes the status of the related service option.

   - If you are *not* using CA APM or the service is *not* eligible for asset assignment, in the Item Status drop-down list, select the appropriate status for each relevant service.

10. Optionally add notes or attachments as supporting documents, and click OK.
    You are returned to the Request Details window. If you return to the Pending Action list after all pending action assigned to you have been completed, the request is removed from your list. If the fulfillment task was assigned to more than one user or a group, once any assigned user completes that pending action, the request is removed from the Pending Action list for all assigned users. If the request contains multiple services, it is not removed until either all services are either fulfilled or have their fulfillment cancelled.

Note: The fulfillment processes of your service provider can require more fulfillment steps. In such cases, the next fulfiller is assigned a fulfillment task.

Transfer Requests Pending Action

Request managers can transfer the requests pending actions that are assigned to themselves or other request managers. You can transfer a request pending action that is assigned to you or another user. For example, when you or other user become sick or otherwise are unavailable to perform or approve an assigned task.

All users can transfer their own requests pending action.

Follow these steps:

1. Click Home, Requests.

2. Click Pending My Action.
   To open the request of interest, click the request name.
   The Requests Details window appears, displaying the details of the request you just opened. The details for the selected request appear, with a Requested Services section at the top of the screen. That section lists all services in the request. If the request contains multiple services, you can transfer them either individually or in groups of two or more.

   Note: A service can be transferred if you can select it. If you cannot select the service, it cannot be transferred. For example, a multiservice request can contain one or more services that are not pending approval or fulfillment and therefore cannot be transferred.

3. Select the service or services and click Transfer.
   The Search User window appears.

4. Review the list of users and select *one* user to whom the selected services are transferred.
   You return to the Requested Services section. In the Item Status column, the selected request or requests are marked for Transfer to *username. username* is the user to whom you transferred those requests.

5. Verify that the correct user is designated for the transfer and click OK.

Transfer the Request Pending Action of Other Users

Only CA Service Catalog administrators and other users with the required access control setting can transfer requests pending action that is assigned to other users. The access control setting *Access Control: Proxy Action* determines such roles. This setting is under Catalog, Configuration, Options, Request Management Configuration The *Access Control: Transfer Request Pending Action* setting determines the roles that have access to the Transfer button. This button is hidden from other roles.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page. The Requests page can either display requests and the search box directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.
   Search for requests, using the Advanced Search.

2. In the Query drop-down list, perform the following actions:

   a. Ensure that Action Request is selected.

   b. (Optional) Enter the user ID of interest, in the Userid field.

   c. Click Search.

3. To open the request, click the request name.
   The Requests Details window appears. The Requested Services section lists all services in the request. If the request contains multiple services, you can transfer them either individually or in groups of two or more.

   Note: A service can be transferred if you can select it. If you cannot select the service, it cannot be transferred. For example, a multiservice request can contain one or more services that are not pending approval or fulfillment and therefore cannot be transferred.

4. Click the Transfer button at the top of the window.

   Note: The Item Status drop-down list is disabled. You enable it and use it in the next steps.

5. Click the alert status icon in the Actions column.

6. Confirm that you want to override a pending action not assigned to you, when prompted.

7. If the request contains multiple services, click the alert status icon and enable the Item Status drop-down list for each service that you want to approve or reject.
   The status of each service option matches the status of the service during the approval phase.

8. Select the service and click Transfer.
   The Search User window appears.

9. Review the list of users and select *one* user to whom the selected services are transferred.
   You return to the Requested Services section. In the Item Status column, the selected request or requests are marked for Transfer to *username. username* is the user to whom you transferred those requests.

10. Verify that the correct user is designated for the transfer and click OK.

Delegate or Auto-Delegate Request Pending Action

Request managers can *delegate* their requests pending action. Request managers can *auto-delegate* requests pending actions that are assigned to themselves or other request managers. For example, when you or others are unavailable to perform or approve an assigned task. Auto-delegation is useful for managers who monitor requests but who do not address requests directly. Thus, auto-delegation helps ensure that requests are addressed in a timely manner. A request pending action can be delegated only once.

Only the owner of the request pending action can delegate, if the owner has the required access control setting. The access control setting named **Access Control: Delegate Request Pending Action**. This setting is under Catalog, Configuration, Options, Request Management Configuration.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page to display requests. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Perform *one* of the following actions:

   - Click **Pending** in **My Request(s)**.
     Click the **Delegate** button for the request pending approval or fulfillment.

   - Click **Find Requests** in **My Request(s)**.

     a. Search in the Request Lookup section.

     b. Verify that **Action By User ID** is selected.

     c. Enter your user ID in the search field and click **Search**.
     The Search Results window appears, displaying all requests that are assigned to you.

     d. Click the **Delegate** button for a request pending approval or fulfillment.

   The details for the selected request appear, with a Requested Services section at the top of the screen. That section lists all services and service options in the request. If the request contains multiple services and service options, they can be delegated either individually or in groups.

   Note: A service can be delegated if you can select it. If you cannot select the service, it cannot be delegated. For example, a multi-service request can contain one or more services or service options that are not pending approval or fulfillment. Such a request cannot be delegated.

3. Select the service or service options and click **Delegate**.
   The Search User Accounts window appears.

   Note: The Search User scope is based on the administration configuration of either all users or only users in the same business unit. For more information about setting this configuration, see the User Default (see page 1484)section.

4. Review the list of users and select *one* user to whom you delegate the selected services or service options.
   You return to the Requested Services section. In the Item Status column, the selected service or service options are marked for delegation to *username. username* is the user whom you selected.

5. Verify that the correct user is named for the delegation and click OK.

Use auto-delegation and specify all of your newly assigned or transferred requests pending action are automatically delegated to another user.

Note: The access control setting **Access Control: Allow Request Auto-Delegation via User Profile** determines whether users can view and change auto-delegation settings, according to their user roles. For more information, see the Administration Configuration Settings (see page 1477).

Follow these steps:

1. Move the cursor to the top right portion on the screen. Click the Profile button next to the Help button.
   The User Profile window appears; the fields are read-only.

2. Click the Edit button.

3. Click the down-arrow icon next to the Request Auto-Delegation heading.
   The Request Auto-Delegation setting for your user ID opens, so that you can view and optionally change it.

4. To remove an existing auto-delegation (if applicable), click the red "minus sign" icon.

5. To add or change auto-delegation, click the magnifying glass icon.
   The Search and Select User Search dialog appears.

6. Click the name of the user to designate for auto-delegation.
   The dialog closes, and you return to the Edit User Profile window. The user that you selected is named in the Delegate field.

7. Verify that the correct user is designated for auto-delegation and click OK. Click Done.

Auto-Delegate the Requests Pending Action of Other Users

Use auto-delegation and specify that any *new* requests assigned to a specific user are automatically delegated to a different user. Here, *new* request means any newly assigned or transferred pending action.

Follow these steps:

1. Click Administration, Users.

2. Enter search criteria in the User ID field to find the user whose requests you want to auto-delegate to another user.

3. Click the name of the user whose requests you want to auto-delegate, and click Edit.

4. Click the drop-down icon next to the Request Auto-Delegation heading.
   The user in the Delegate field is the one to whom requests are currently auto-delegated.

5. To remove an existing auto-delegation (if applicable), click the red "minus sign" icon.

6. To add or change auto-delegation, click the magnifying glass icon, and review the list of users.

7. Click the name of the user to designate for auto-delegation.

8. Verify that the correct user is designated for auto-delegation and click OK. Click Done.

Take or Return a Request Pending Action

From the Take/Return window, you can take or return ownership of requests pending action. You can take ownership from a group queue or the queue of another user in the same business unit or sub-business unit. Similarly, you can return ownership of requests pending action from your queue to the queue of your group. You can take or return ownership of requests pending action that is assigned to your group.

The Take and Return functions work *only* if you are logged in as a user of the group to which the request pending action is assigned. Only CA Service Catalog administrators and other users with the required access control setting can do so. The access control option *Access Control: Take/Return Request Pending Action* under Catalog, Configuration, Options, Request Management Configuration determines such roles. For more information about setting this option, see the Request Management Configuration (see page 1450) section.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page to display requests. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Click Pending My Action.

3. Click the Take/Return button for a request pending approval or fulfillment.
   The Take/Return window shows the details for the selected request, including a Requested Services section. That section lists all services and service options in the request. If the request contains multiple services or service options, they can be taken or returned individually or in groups.

   Note: A service or service option can be taken or returned if you can select it. If you cannot select the service or service option, it cannot be taken or returned. For example, a multi-service request can contain one or more services or service options that are not pending approval or fulfillment. Therefore, the service or service option cannot be taken or returned.

4. (To *take* one or more services from a request pending action) Select the services or service options. Click Take.
   The request is marked and your user ID can take it.
   If a request is already taken, the status indicating “taken by *username*” appears. Therefore, you cannot take it. Other users in the same group can still approve or fulfill a taken service, if

necessary. Either the user who has taken the service must return it or an authorized user must transfer it to the new assigned user. If a request is not taken but the Take option is not available, then the action is not assigned to your group.

5. (To *return* one or more service or service options from a request pending action) Select the services or service options. Click Return.
   The only services that you can return are services already marked as taken by your user ID.

6. Click OK to perform the take or return action.
   Your action is confirmed: Any requests that you have taken are marked as taken by your user ID. Similarly, any requests that you have returned are no longer marked as taken.

Ignore, Retry, or Override Alerts

During the submitted state or the approval process, requests can occasionally become marked with an alert status indicating a potential problem. For example, because of a system error or a user error. The alert is indicated in the Status column of several request windows. If the role of a user does not permit access to this option, then that user cannot see the status, even if the user's request is stuck. We recommend that you ignore, retry, or override (push through) alerts as soon as you become aware of them. Only CA Service Catalog administrators and other users with the required access control setting can ignore, retry, or override alerts.

The access control option *Access Control: Push Through Request* determines such roles. This setting is under Catalog, Configuration, Options, Request Management Configuration. The access control option named *Access Control: Display Request Warning* determines which roles are able to see the warning icon indicating that a request is stuck. For more information about setting this option, see the Request Management Configuration (see page 1450) section.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page to display requests. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Find the "alert" request on any of the following windows: Open Requests, Completed Requests, Pending My Action, Request Search, or Recent Requests Lists.
   The request can be marked with an alert status, because of one or more information-only alerts that are logged during the request flow. In this case, ignore the alerts, as follows:

   a. Open the window that includes the alert request.

   b. In the Action column, click the Actions drop-down and select Push Through from the list.
      The Push Through Request window appears, and the Push Through Request tab is selected by default.

      The details for the selected request appear, with a Requested Services section at the top of the screen. That section lists all services in the request. If the request contains multiple services, they can be pushed through. You can push them either individually or in groups of two or more at a time.

c. In the Override Status column, select the status for the request to acquire from the drop-down list.

d. Click Save.

3. For each stuck service, click the Item Status drop-down list. Select the Approval or Fulfillment status that best meets your needs.
   The options for any service vary, according to its status. To view all available options, use the drop-down list.

4. Click OK.
   Each service whose status you changed has its alerts that are removed (overridden). The service is "pushed through" to the selected status.

   Note: If a request is in queued status before being pushed through, it carries its (queued) prefix state along with new status of the request. Push Through can be performed for both queued and nonqueued requests.

   The alerts are made inactive, and the status is removed.
   When the status of a requested service is either Pending or Completed, you can either ignore or push through the alert.

Hold and Resume Requests, Services, or Service Options

Holding requests, services, or service options ensures to anyone monitoring a request that the processing of the request, service, or service option has been *intentionally* suspended. Only CA Service Catalog administrators and other users with the required access control setting can hold and resume requests.

The access control setting *Access Control: Hold/Resume Request* determines such roles. This setting is under Catalog, Configuration, Options, Request Management Configuration. For more information about setting this option, see the Request Management Configuration (see page 1450) section.

How Hold and Resume Actions Work

Reasons for holding a request include:

- The temporary unavailability of the requestor or approver.
- The temporary unavailability of requested items, such as the items being in back-ordered status.

When a service option is held, the monitoring of time stops for any request SLAs attached to the service option. The request SLAs are stopped to prevent related SLA warnings and SLA violations from being issued.

When an item is held, no status changes can occur for it until you *resume* it. That is, you change its status to Resume. When you resume an item, it returns to its last previous status before it was held.

If you hold only selected services within a request or only selected service options within a service, the services or services options that you did not hold continue the normal request life cycle, except that they cannot reach Completed status until the held items are resumed and are also completed.

When resumed, service options that were formerly held, move to a temporary Resume status. The service options then automatically move back to the status they were at before they put on Hold. Checking Resume status is useful for history purposes. Doing so helps you set up optional rules and actions, automated processing using CA Process Automation, or automatic email notifications.

Automatic Email Notifications

You can use the events, rules, and actions (see page 3040) for sending automatic email notifications when a request, service, or service option is held or resumed.

The events *Request Change* and *Request/Subscription Item Change* include two rules that are related to hold-resume functions:

- When Status is Hold
- When Status is Resumed

For the *Request Change* event, the *When Status is Hold* rule includes an action that sends an automatic email notification when a request is held. Similarly, the *When Status is Resumed* rule includes an action that sends an automatic email notification when a request is resumed.

For the *Request/Subscription Item Change* event, the *When Status is Hold* rule includes an action that sends an automatic email notification when a service option is held. Similarly, the *When* Status is Resumed rule sends includes an action that sends an automatic email notification when a service option is resumed.

Hold and Resume Requests, Services, or Service Options

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page to display requests. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Click Pending My Action or Open Requests. Alternatively, click Advanced Search for requests.
   The Requests Pending Action window appears, or the Open Requests window appears.
   Click the Hold/Resume icon for the request you want.
   The Hold/Resume window appears including a Requested Services section. That section lists all services and service options in the request. If the request contains multiple services or service options, you can hold or resume them either individually or in groups.

3. To *hold* one or more services or service options, select the services or service options and click Hold.
   Each service option that you selected is marked *to be held* by your user ID.
   If a request is already held, the status indicating “held by *username*” appears next to the Item Status field of the request item. Therefore, you cannot hold it again. The *username* identifies the user who has held the request.

4. To *hold* an entire request, select the All check box for the request and click Hold.
   All service options in the request are marked *to be held* by your user ID.

5. Add a note to the request for the services or service options that you held explaining why you held them. Provide any information that helps other administrators determine when to resume a service or service option.

Verify that all reasons have been addressed before resuming the request.

- To *resume* one or more services or service options, select the services or service options and click Resume.

  Note: When you resume a previously held service or service option, the monitoring of time is resumed for any request SLA attached to the service or service option.

  The only services that you can resume are those services already marked as held.

- Click Save to perform the hold or resume action.

Cancel a Request

Administrators can cancel a request for several possible reasons. For example, the wrong items were requested or the requested items are no longer wanted or needed.

Only CA Service Catalog administrators and other users with the required access control setting can see the Cancel button. The access control setting *Access Control: Cancel Request* determines such roles. The setting is under Catalog, Configuration, Options, Request Management Configuration. For more information, see the Set CA Service Catalog Configuration Options (see page 1449) section.

You can cancel a request *only* if the status of the request has not exceeded the status that *Allow Cancellation Through* specifies. This setting is in the Catalog, Configuration, Options, Request Management Configuration. This setting defines the status through which a request can be canceled. After the request moves to the next status, it cannot be canceled.

Note: By default, for the event *Request/Subscription Item Change*, for the rule *When Status is Canceled*, an action is enabled. The action aborts CA Process Automation instances when a request is canceled. For best performance, keep this default setting. For more information about setting this option, see the Set CA Service Catalog Configuration Options (see page 1449) section.

Follow these steps:

1. Click Home, Requests. If applicable, click the My Requests drop-down list on the Requests page to display requests. The Requests page can either display requests directly or provide access to them indirectly through the My Requests drop-down list. Administrators optionally configure the page to use either setup.

2. Click the list of requests that contains the request that you want to cancel. For example, if you want to cancel a request pending action, click Pending My Action.

3. Click the request that you want, and click Cancel.

> **Note:** If the requirements for cancellation are not met, the Cancel button is disabled. The request cannot be canceled. Moreover, items in the same request can be at different statuses. Some items may have exceeded the *Allow Cancellation Through* status while others have not yet done so. In such cases, you can cancel *only* the items that have *not* exceeded the *Allow Cancellation Through* status.

4. Confirm the cancellation and click OK.

Delegate Catalog

This article contains the following topics:

Delegating the use of your catalog to another user (a delegate) lets the delegate browse your catalog. The delegate can also create and submit requests on behalf of you (the delegator). Administrators assign this right to individual roles by setting the configuration option named *Access Control: Add Request* in the Request Management Configuration section of the Administration Configuration page. For more information about this parameter, see the Access Control Parameters (see page 1450) section.

The catalog of a delegator typically contains services that are not available in the catalog of the delegate.

Delegators are typically executives or managers but can be any user whose role permits creating and submitting requests. Delegates are typically employees who report to the delegator. But the delegates can also be any user whose role permits creating and submitting requests.

> Typically, a delegate creates and submits requests for the delegator from the catalog of the delegator. In such a scenario, the *Requested For field* shows the name of the delegator. The field cannot be changed.

History, auditing, and logging records for a request show that the delegate created and submitted the request on behalf of the delegator.

Comparison to Related Features

Delegation of catalogs is related to, but not the same as, the following features:

- Requesting a service for another user, using your own catalog. Specify the name of the other user in the *Requested For* field when you view and change more information in the request before submitting it.
- Delegating a request (see page 2214). You manually delegate a request pending action, from either yourself or another request manager, to a different request manager. The delegated request manager can then approve, reject, or transfer the request.
- Auto-delegating your own requests pending action or auto-delegating requests pending action of other users. The auto-delegated request manager can then approve, reject, or transfer the request.

In contrast to these features, delegating the use of your catalog lets another user browse your catalog. The other user can create, edit, and submit requests on your behalf.

Limitations of Catalog Delegation

The following limitations apply when you delegate the use of your catalog to another user:

- Delegates must create and submit requests themselves from the catalog of the delegator catalog.
- Delegates *cannot* change the Requested For field to request services for any user other than the delegator.
- Users who have a role that cannot create a request (such as Service Manager) *can* delegate their catalogs. However, delegates of such users *cannot* browse or create requests from the catalogs of those delegators. Therefore, as a best practice, users whose roles prohibit them from creating requests do *not* delegate their catalogs.
- All users can delegate the use of *their own catalog* to another user. If you have the Super Business Unit Administrator or Service Delivery Administrator role, you can delegate the use of either *your own catalog* or *the catalog of any other user ID* to another user. If an administrator delegates the use of your catalog to another user, the Catalog system does not automatically notify you or the other user. However, in such cases, the delegate does appear in the list of delegates on your User Profile page. You can manually remove that delegate. As a best practice, administrators who perform such actions notify affected users personally.

Important! The delegate must have a role in the business unit of the delegator. Otherwise, the catalog of the delegator is not made available to the delegate.

Considerations for Business Units

You can delegate your catalog to a user in your own business unit or any other business unit. For example, the top-level (service provider) business unit.

If you delegate your catalog to a user in the same business unit, the delegate can use your catalog immediately. When the delegate logs in to CA Service Catalog, the delegate can see and select your name in the *Use Catalog Of* field of the Requests home page. (This page appears when you select Home, Requests). Then, the delegate can browse and use your catalog.

When you delegate your catalog to a user in another business unit, you must have a role in that business unit. Otherwise, the delegate cannot see and select your name in the *Use Catalog Of* field of the Requests home page and cannot use your catalog. If necessary, you or an administrator can edit your user profile to add a role for your user ID in that business unit.

For example, suppose that your organization is grouped into business units according to department. If you work in the Finance department, and you delegate use of your catalog to a user in the Human Resources department (a different business unit). Verify that you have a role in Human Resources.

Sample Scenarios

The following scenarios illustrate possible instances of delegating the use of a catalog--either your own catalog or another catalog.

- **Scenario 1**
  A CIO delegates her catalog to her executive assistant, with instructions to create and submit requests for ten items on her behalf.
  The items are not available in the assistant's catalog, so the CIO delegates use of her catalog to the assistant. The assistant uses the CIO's catalog as a delegate and requests the ten items for the CIO.
  History, auditing, and logging records for the requests show that the assistant created and submitted the requests on behalf of the CIO.

- **Scenario 2**
  An administrator (User A) delegates the use of the catalog of another user (User B) to a different user (User C). Doing so requires the Super Business Unit Administrator or Service Delivery Administrator role.
  In this scenario, the CIO requires the ten items that are requested not for herself but for a vice president who reports to her. That vice president is on leave without access to CA Service Catalog but needs the items when returning to work next week.
  In this scenario, the CIO delegates the use of the vice president's catalog (not her own catalog) to her assistant. Before the vice president returns to work, the assistant uses the vice president's catalog as a delegate and requests the ten items for the vice president.
  Scenario 3
  The CIO begins to create a request for herself but must stop and save the request to address an emergency issue. When she realizes that the issue requires long, uninterrupted effort, she stops the effort. She cancels the request, and instructs her assistant to create and submit the request as a delegate.
  History, auditing, and logging records for the request show that the delegator created the request, but the assistant edited and submitted the request on behalf of the delegator.

Administrators configure CA Service Catalog to let users (*delegators*) delegate their catalog to other users (*delegates*). Delegates work on behalf of delegators who are unable or unavailable to create and submit their own requests. The catalog of a delegator typically contains services that are not available in the catalog of a delegate.

1. Administrators configure CA Service Catalog to enable the delegation of catalogs (see page 222).

2. Delegators edit their profile to delegate the use of their catalogs (see page 2226) to one or more delegates.
   The delegates use the catalog of a delegator (see page 2227) to create, edit, and submit requests.
   If necessary, delegates, delegators, and administrators work together to manage unsubmitted requests that delegates (see page 2228) create.

Step 1 - Enable or Disable Delegation of Catalogs

Users with the Super Business Unit Administrator or Service Delivery Administrator role can enable or disable delegation of catalogs within the business unit--and any subbusiness units--to which their role applies. Users with other roles can optionally delegate the use of their catalogs to any other user. Delegation of catalogs is enabled by default, but enable it explicitly if it was disabled earlier.

Follow these steps:

1. Click Catalog, Configuration, Request Management Configuration.

2. Locate the option *Enable Delegation of Catalog*. Set this option to Yes to enable the feature or No to disable it.

   - If this option is set to No, enable it. To enable it, click the Edit icon, select the check box, and click Update Configuration.

   - If this option is set to Yes, disable it. To disable it, click the Edit icon, clear the check box, and click Update Configuration.

When this option is enabled, no users are *required to* delegate use of their catalogs. When this option is enabled, users can *optionally* delegate use of their catalogs.

Note: Delegating a catalog does *not* affect the Catalog configuration of the CA Service Catalog, such as the *Use Service Provider Catalog Only* and *Pass Through Catalog* parameters. Similarly, the delegation of a catalog is *not* directly related to the configuration options named *Access Control: Add Request*, *Access Control: Edit Request that also exists* in the same Request Management Configuration section as Enable Delegation of Catalog.

Step 2 - Delegate the Use of a Catalog

When you delegate the use of your catalog to other users, they can browse your catalog. They can also create and submit requests on your behalf. Typically, you delegate the use of your catalog to other users when you are unavailable to perform this work yourself but the work must continue with minimal supervision. As a prerequisite, review the limitations of delegation of catalogs.

Follow these steps:

1. Verify with your Super Business Unit Administrator or Service Delivery Administrator that this feature is enabled.
2. Click Home, Administration, Users.
3. Click the Search button on the Users search dialog.
   The user IDs that you can update appear.
4. Click the Edit icon for the user ID you want to edit.
5. Click the Open icon for the Delegate Use of Catalog box.
6. Click the Search icon next to the Delegates field.
7. Click the user ID to which you want to delegate use of your catalog.
8. Click the Add icon.
   The user ID you selected is moved from the Delegates field to the list of delegates underneath it. The user ID is added to your list of delegates.

   Important! The delegate *must* have a role in the business unit of the delegator. Otherwise, the catalog of the delegator is *not* made available to the delegate.

   Also:

   - Delegates *cannot* edit and submit existing requests that the delegator creates.
   - A single user can be a delegate for multiple delegators.
   - Delegates can create and submit requests using the catalog of the delegator.
9. If applicable, add another delegate by clicking the Search icon and repeating the previous two steps.
10. When you are finished adding delegates, click OK.

If you delegated the use of your own catalog, all delegates you selected can browse your catalog. They also can create, edit, and submit requests on behalf of you. If you are a Super Business Unit Administrator or Service Delivery Administrator who delegated the use of the catalog of another user, the delegates you selected can browse the catalog. They also can create, edit, and submit requests on behalf of that user.

Step 3 - Use the Catalog of a Delegator

When another user specifies you as a delegate, you can use the catalog of the delegator instead of your own. The catalog of the delegator likely includes more services and service options than your own. You can access the catalog and can browse it. You can use the catalog to create, edit, and submit requests on behalf of the delegator.

Follow these steps:

1. Click Home, Requests.
2. Click the Use Catalog Of drop-down list.
   The list displays your delegators, the users for whom you are a delegate in your currently logged in business unit or one of its subbusiness units.
   If no users appear:
   - Contact users for whom you are a delegate. Verify that they have delegated the use of their catalogs (see page 2226) to you.
   - Verify the business unit in which the delegator has specified you as a delegate. Verify that you have a role in the business unit.
   - Verify that the delegation of catalogs (see page 2225) option is enabled.
3. Select the delegator.

You can now browse the catalog of the delegator and create, edit, and submit requests on behalf of the delegator. History, auditing, and logging records show that the delegate created, edited, and submitted the request on behalf of the delegator.

Remove a Delegate

When you remove a user from your list of delegates, the user can no longer browse your catalog. The user also cannot create and submit requests on your behalf. Remove a user from your list of delegates when appropriate for business reasons. For example: the delegate leaves the organization, or you transfer to another department, or you no longer need the user as a delegate. Typically, you remove delegates from using your catalog. If you are a Super Business Unit Administrator or Service Delivery Administrator, you can remove delegates from using the catalog of another user.

Follow these steps:

1. Click Home, Administration, Users.
2. Click the Search button on the Users search dialog.

3. Click the Edit icon for the user ID you want to edit.
   To reveal the list of delegates for a user, select the Open icon for the Delegate Use of Catalog check box.

4. Select the user or users whom you want to remove as delegates.

5. Click the Delete icon.

6. Click OK.

Step 4 - Manage Unsubmitted Requests Created by Delegates

A delegate can create and save requests using a catalog of a delegator. The delegate can also submit the requests later, on behalf of the delegator. However, before the delegate submits the request, the following events can occur:

- The delegator (or an administrator) removes a delegate (see page 2227) from using the catalog of the delegator.
- An administrator disables the delegation of catalogs (see page 2225) in one or more business units or throughout the Catalog system.

In both cases, delegates are *not* notified automatically, and delegates are no longer able to submit the requests. The only exception is that delegates whose roles permit them to override alerts (see page 2218) can optionally "push through" the request to the next status and so, submit the request. Similarly, delegates can optionally delete such requests, because delegates own the requests.

Delegators can view requests that are made on their behalf (whether submitted or not) in the Open Requests queue. However, delegators *cannot* delete or submit such requests. The only exception is that delegators whose roles permit them to override alerts can optionally "push through" the request to the next status and so, submit the request.

Delegators and delegates decide together how to manage saved but requests not submitted, so that such requests do not remain open. Options are as follows:

- Delete the request. Only the delegate can delete the request.
- Push through the request. The delegate, delegator, or an administrator with the required role (upon request).
- Temporarily make the user as a delegate.
- Ask an administrator to re-enable the delegation of catalogs in your business unit long enough for the delegate to submit the request.

Change Management

Change Management for CA SDM is a set of features for Change Managers and Change Advisory Board (CAB) members to coordinate the review and approval of change requests for CI components and services. For example, Change Managers can review and approve all changes to CI components and services to ensure that no new security vulnerabilities are introduced into the production environment. The Change Manager leads the CAB and is responsible for the ultimate approval of change requests.

Change Management includes the following components:

- **Change Calendar:** Displays a graphical view of change events (see page 2292), including all scheduled, failed, and in-progress change requests for CIs and services in a configurable calendar view (see page 2267). The calendar also displays black-out dates, which are freeze periods. Users can create a change order from the context menu on the daily, weekly, and monthly calendar views. The Change Manager, Level 2 Analysts, and CAB members use this feature.

- **Change Scheduler:** Displays scheduled time periods (see page) during which CI changes can or cannot occur in the Change Calendar. The Change Manager uses this feature to view and create change schedules and CI associations during the time period.

- **Conflict Analysis and Collision Detection:** Analyze change orders to help identify potential implementation conflicts (see page 2245) that could increase risk of failure. The Change Manager uses this feature.

- **CAB Console and Reporting:** Displays a dashboard (see page) that facilitates quick online approvals of change orders that require CAB approval. In CA SDM, the Change Manager can generate a report with details about the proposed requests for changes ready for CAB review and electronically distribute the reports to all CAB members.

  Users with appropriate privileges can display Compliance, Forecast, Trend, and Volume predefined reports for change management in Business Intelligence Launch Pad with CA Business Intelligence.

- **Risk Assessment:** Provides the ability to attach risk assessments for each change request submitted. The Risk Survey Option lets you create surveys to evaluate risks, and associate them with change categories. The risk survey lists a series of single or multiple choice questions.

- **Impact Explorer:** Displays CI-to-CI relationships for CIs that are attached to a change order. Impact Explorer is launched from the Change Order Detail page to facilitate on-demand impact analysis (see page 2253). The Change Manager uses this feature.

- **Change Verification:** Verifies that changes execute accurately and no unauthorized changes occur, so that CMDB contains an accurate and current representation of all managed CIs.

Configuration Audit and Control Facility

This article contains the following topics:

Configuration Audit and Control Facility (CACF) combines Change Management, Configuration Management (CMDB), and Discovery Management to provide change verification. Change verification helps ensure that the CMDB reflects any changes accurately, and the Discovery Management tools verify the changes.

Select the Configuration Management tab to define change specifications, CIs, and view the Verification log.

You administer the CACF components in the Configuration Control node in the CMDB section of the Administration tab and define and view CACF change specifications from the Change Order, CI and Incident forms.

The CMDB Administrator defines the CIs and attributes to manage and defines the policy for updating those CIs and attributes.

The Administrator must consider allowing standard changes, defining authoritative and trusted sources of data, and defining which CIs and CI attributes are under CACF management. If an incorrectly executed change or rogue change occurs (also referred to as a variance), CA SDM can accept the new value, create an Incident, or copy the data to the TWA for later processing. CA SDM can also use any combination of these actions.

The Configuration and Change Administrators *must* define a change verification strategy for your environment. For more information, see Planning and Implementing Change Verification topic.

How to Define Policies for Change Verification

Complete the following recommended steps to begin using CACF in your CA SDM environment:

1. Review the Managed Change States in the CA SDM environment. Update the default Managed Change States or add states as necessary to suit your change management strategy. Change verification initiates when the status of a Change Order changes to a Change State that CACF manages, such as Verification in Progress.

2. Identify the available CI Managed Attributes that you want CACF to manage for change verification.

   - For example, you want to manage changes to Memory Installed (phys_mem) so that the attribute *must* have a matching Change Order for the test* server. You also consider changes to IP Address (alarm_id) as normal and always allowed.

   - For example, you want to manage changes to Memory Installed (phys_mem), MAC Address (mac_address), and IP Address (alarm_id) so that the attribute must have a matching Change Order for prod*. You do not want MDR1 to update IP Address and prefer MDR2 to complete this update. When you have a problem, create an Incident. Closing the Change Order also closes the Incidents automatically.

3. Determine what CIs or subset of the CIs in your system that you want to monitor.
   For example, you want to control all servers name test* and prod*. In addition, you control what CIs based on CI Class and CI Location.

4. Determine what MDRs and sources of data that you want to monitor.
   For example, you want to restrict data from MDR1 for the IP Address attribute from updating any CIs.

5. Determine the appropriate verification policy to manage the following types of change:

   - The CI changes that match change orders.

   - The CI changes that match the attributes in a Change Order, but do not match the value.

   - The CI changes that you consider as rogue updates.

   - Then CI changes that you consider as rogue inserts.

6. Determine the appropriate update behavior that CACF takes when it detects a variance for a policy:

   - Always allow the attribute update request.

   - Allow the attribute update only when a corresponding change specification is specified for the update.

   - Always cancel the entire transaction.

   - Keep the existing attribute value.

   - Write data to the TWA.

   - Create an Incident when CACF detects a variance.

   - Automatically close any Incidents after Change Order verification.

For more information about change verification planning and implementation, see Planning and Implementing Change Verification topic.

Example Change Specification in the Pending Verification Status

In this example, the Configuration Administrator established a verification policy for the Memory Installed (phys_mem) attribute to Allow Update Only if Matches Change Specification. CACF monitors a change specification for this attribute with the status Verification Pending, and sets the Change Specification to the Verified or Failed Verification status.

The following steps describe the lifecycle of this change specification:

1. A Change Order requests an update to the Memory Installed (phys_mem) attribute of a CI.
2. You create a change specification for the Memory Installed (phys_mem) Managed Attribute with a Planned Value of 4gb with the initial status as Verification Pending.
3. The Change Order moves to a status with change verification active such as Verification in Progress.
4. The change specification waits for a discovery tool to discover CI details and export the values to the CMDB.
5. One of the following actions occurs after the discovery tool exports the value to the CMDB:
   - The value for Memory Installed matches the 4gb value that you specified in the change specification. CACF sets the status from Verification Pending to Verified. CACF closes the Change Order.
   - The value for Memory Installed does not match the value that you specified. CACF sets the status from Verification Pending to Failed Verification.

Example Change Specification in the Verified Status

In this example, CACF verified a change specification and set the status to Verified. This change specification contained an initial status such as Verification Pending.

The following steps describe the lifecycle of this change specification:

1. A Change Order requests an update to the Serial Number (serial_number) attribute of a CI.
2. Create a change specification for the Serial Number managed attribute and enter **12345** as the planned value.
3. The Change Order moves to a managed state so that Change Verification is active.
   For example, Verification in Progress.
4. The change specification waits for a discovery tool to discover CI details and imports the updated Serial Number values to the CMDB.
5. The discovery tool exports the value to the CMDB and matches the value that you specified in the change specifications.

6. CACF sets the status to Verified.
   Note: If the CI update to the attribute does not match the planned value, CACF considers the update as a variance and sets the status to Failed Verification.

Example Change Specification in the Set After Change Verified Status

In this example, CACF updates the CMDB with the value that you want to use after the Change Order exits a managed change state with change verification active. For example, your environment uses Verification in Progress as the managed change state with change verification active enabled.

The following steps describe the lifecycle of this change specification:

1. A Change Order requests an update to the Serial Number (serial_number) attribute of a CI.
2. You create a change specification, specify Serial Number, and enter a planned value for an attribute.
3. You set the Change Order state to from RFC to Verification in Progress to Closed.
4. The CI attribute value is updated with the planned value after the Change Order exits a state with Change Verification Active (Verification In Progress) to a state that does not have change verification active (Closed).
5. The change specification sets to Was Set to Planned Value to indicate that the set was completed successfully.

Example Accept the Planned Value

In this example, the Change Analyst researches the correct attribute value for a CI and accepts the planned value.

Follow these steps:

1. Open a Change Specification that an end user created in your environment.
2. View the detail page to see the planned value for the CI attribute that the Change Analyst modified.
3. Research the attribute value for the CI.
   For example, your research indicates that the Change Analyst entered the correct value.
4. Click Accept Planned Value to update the CI with the corresponding planned value.
   CACF sets the state of the Change Specification to Accepted Planned Value.

Example Accept the Discovered Value

In this example, the Change Analyst determines that the CI has been updated to a correct attribute value for a CI and accepts the discovered value.

Follow these steps:

1. Open a Change Specification that a Change Analyst created in your environment.

2. View the detail page to see the planned value for the CI attribute that the Change Analyst specified.

3. Research the attribute value for the CI.
   For example, discovery indicates that the Change Analyst entered the incorrect value.

4. Click Accept Discovered Value.
   The CI updates with the discovered value and CACF sets the status of the change specification from Verification Pending to Accepted Discovered Value.

5. If you configured the managed state to enable the Promote Change Order After Verification option, CACF closes the Change Order after all change specifications are in a final state.

Example Manage Changes from an Unauthorized MDR

In this example, the Configuration Administrator established a verification policy to manage changes from an unauthorized MDR named MDR1. The policy rejects all updates to CIs from MDR1.

The following steps describe the lifecycle of this verification policy:

1. You create a Verification Policy with an MDR Name pattern of MDR1 and an Update Behavior of Always Cancel Entire Transaction.

2. Enable all Change Order alignment options.

3. Specify Any Managed Attribute and an asterisk (*) for all filters.

4. When the discovery tool (MDR1) runs and exports the data to the CMDB, the verification policy rejects all the updates.

How to Archive and Purge Audit Data

We recommend that you archive and purge obsolete Verification Log entries, CACF audit history, and CI audit history as part of your periodic database maintenance.

The CACF CA Business Intelligence reports typically present monthly reports with a yearly summary. The default archive purge time value for the archive purge rules for the log, CACF audit history, and CI audit history tables is 30 days. Use the same value in the archive and purge rules to help ensure data consistency between verification log entries, Incidents, and Change Orders. You can probably change the 30 day default to something more in keeping with your reporting requirements.

Complete the following actions to archive and purge audit data:

1. Use the current Incident rule to archive and purge inactive Incidents older than *nn* days.
   CA SDM archives and purges verification log entries only after archiving and purging associated Incidents. If you associate a Change order with an Incident, CA SDM does not check if the Change Order is active.

2. Use the current Change Order rule to archive and purge inactive Change Orders older than *nn* days.
   CA SDM archives and purges verification log entries and change specifications only after archiving and purging associated Change Orders. If you associated an Incident with a Change Order, CA SDM does not archive and purge the Change Order.

3. Use the Rogue Change Verification Log rule for rogue changes that did not create an Incident. Use this rule to archive and purge verification log entries older than *nn* days. By definition, rogue changes are not associated with Change Orders.

4. Use the CMDB Audit rule to archive information that is shown in the Change Specification History, Verification Policy History, Managed Change State History, and Managed Attribute History tabs show in the respective Change Specifications, Verification Policy, Managed Change State, and Managed Attributes detail forms. CA SDM stores this information in the ci_audit table.

Change Manager Responsibilities

This article contains the following topics:

The Change Manager is responsible for the overall enterprise change management process and for the ultimate approval of change orders. They also generate the change management metrics analysis reports and they do the following tasks:

- Review change requests and add appropriate stakeholders and approvers as needed.
- Facilitate resolution of issues, such as detecting collisions and scheduling conflicts in the calendar.
- Review installation, back-out, and fallback plans for accessibility and soundness.
- Understand the risk of each change and ensure that the appropriate risk level is assigned to the change.
- Monitor changes for their respective areas to ensure that they comply with Technology Change Management requirements.
- Represent their respective areas and communicate the impact of high-level risk changes at weekly CAB meeting.
- Facilitate in reviews after the installation is complete for problem installations and failed changes.
- Serve as the escalation point for change requesters, stakeholders, approvers, implementers, and support groups.

How the Change Manager Role Works

Change Managers are responsible for monitoring change orders to ensure that the operation team members comply with business policies and processes. The Change Calendar can facilitate resolution of issues such as change order conflicts by scheduling black-out dates and freeze periods during which a CI or a set of CIs can be changed. Change Managers also do the following tasks:

1. Oversee the CAB Console from which online and quick approvals of change orders and requests for changes are managed.
2. Organize CABs with members appropriate for the change orders under consideration and conduct regularly scheduled CAB meetings to review incoming change orders.
3. Create reports with details about the proposed requests for changes ready for CAB review and electronically distribute the reports to all CAB members.
4. Perform a real-time review of each request for change and update the record with the CAB decision during the CAB meeting.
5. Use BusinessObjects Business Intelligence Launch Pad to manage Compliance, Forecast, Trend, and Volume reports and create on-demand reports.
6. Represent their respective areas and communicate the impact of high-level risk changes at CAB meetings.
7. Evaluate the risk of each change and ensure that the appropriate risk level is assigned to the change.

Define Tasks for the Change Manager Role

You can define tasks for the Change Manager role.

Follow these steps:

1. On the Administration tab, select Security and Role Management, Role Management, Role List.
   The Role List page appears.
2. Select the Change Manager role.
   The Change Manager Role Detail page appears.
3. Click Edit.
   The Change Manager Update Role page appears.
4. Use the following tabs and fields to configure tasks and access permissions for the Change Manager role:
   - Authorization
   - Function Access
   - Web Interface
   - Knowledge Management

- KT Document Visibility
- Tabs
- Report Web Forms
- Go Resources
- Tenant Read Access
- Tenant Write Access

5. Click Save, Close Window.
   The Change Manager role record is updated.

Configure Change Manager Options

You can configure options for the Change Manager role.

Follow these steps:

1. Select Options Manager on the Administration tab.
2. Expand the Change Order Mgr node.
   The Option List appears.
3. Right-click the option that you want and select Edit from the context menu.
   The Update Option page appears.
4. Edit the option as appropriate.
5. Click Save, Close Window.
   The updated option appears on the Options list.

Change Categories, Status, and Risk Levels

You can define how change orders operate within your service environment. You can edit the default values that are installed with CA SDM, or can define your own.

Follow these steps:

1. Select Service Desk, Change Orders on the Administration tab.
2. Expand the Change Order node and select *one* of the following items:
   - Categories
   - Change Types
   - Closure Codes
   - Conflict Status

- Risk Level
- Risk Survey
- Status
- Workflow Task Status Code
- Workflow Task Types

The List page for the selected item appears.

3. Select the item to edit.
   The Update Details page appears.
4. Use the controls available on the tabs at the bottom of the page to define how change orders operate within your environment.
5. Click Save, Close Window.
   The updated item appears in the list.

View the Change Order Scoreboard

The Change Order scoreboard shows the change orders, conflicts, and scheduled tasks that are assigned to Level 2 Analysts, Change Managers, Change Coordinators, or CAB members. Users can view their assigned and unassigned records by priority.

Follow these steps:

1. Navigate to Change Orders on the CA SDM scoreboard.
2. Expand the folders to reveal nested folders for the following items:
   - Assigned or unassigned Open and Closed items
   - Resolved or unresolved conflicts
   - Scheduled tasks that start today or next week.
3. Select the folder for the items you want to see.
   The List page appears.
4. (Optional) Click Show Filter and complete one or more of the fields to specify search criteria that restrict the list to comments of interest.
5. Click Search.
   The List page displays summaries of the items that match your search criteria.
6. (Optional) Click the Edit in List button to display some additional fields that can be associated with an item.

Define a Change Order Stored Query

Defining the stored queries that are available to users on the Change Order scoreboard is an administrative task. You can modify the predefined stored queries that are installed with CA SDM, or can define your own.

Follow these steps:

1. Select Service Desk, Application Data, Stored Queries on the Administration tab.
   The Stored Query List appears.

2. Select the stored query that you want to edit.
   The Stored Query Detail page appears.

3. Click Edit.
   The Update Stored Query page appears.

4. Edit the field values as appropriate.

5. Click Save, Close Window.
   The updated stored query appears in the Stored Query List.

Example: Define a Stored Query to List Change Orders Assigned to a CAB to Which the Logged In User Belongs

This example demonstrates how you can create a stored query that lists only change orders that are assigned to a CAB to which the logged in user belongs.

Follow these steps:

1. Navigate the Scoreboard to the Update Stored Query page.

2. Edit the field values as follows:

   a. Select Scoreboard Usage.

   b. Set Type to Change Order.

   c. Enter the Where clause:

   ```
   cab.[group]group_list.member IN (@cnt.id) AND active = 1
   ```

3. Click Save, Close Window.
   The stored query appears in the Stored Query List.

CAB Responsibilities and CAB Groups

Contents

CAB Responsibilities

The Change Advisory Board (CAB) coordinates the review and approval or rejection of change requests for CI components and services. The CAB members are responsible for the following tasks:

- Reviewing all major changes to production systems.
- Attending all relevant CAB meetings as required by the Change Manager.
- Reviewing all submitted requests for changes to determine their impact, resources that are required to implement them and any ongoing costs.
- Participating in scheduling and coordination of the Change Calendar.
- Helping to ensure that all changes are adequately assessed and prioritized.
- Participating in reviews after the installation is complete.

CAB Approvals

If the CAB Approval field is set to YES, the CAB must approve a change order before implementing the change order. During the approval process, the change manager clicks Approve or Reject. If you want to use different status values, you can update the Approve or Reject button code using Web Screen Painter.

How the CAB Process Works

The CAB is responsible for reviewing all major changes to production systems. The CAB members are notified that a change request requires their approval, and they take the following actions:

1. List change requests that the CAB must review.
2. Open the CAB Console and view the information that is contained in the request.
3. View the business justification, implementation plan, configuration items, and supporting documentation that is associated with the request and decide to approve it or reject it.
4. Approve or reject the change order, and the next change order in the list appears automatically.
   The person requesting that the change is notified automatically that the CAB status is updated for the change request.

Manage CAB Groups

You can create and manage the CAB groups with members appropriate for the change orders under consideration. The CAB can include members from the application team, development manager, component owner, QA, support, and any additional parties deemed necessary.

Before you implement a CAB group, configure the appropriate contacts for your business structure.

Create a CAB Group

1. On the Administration tab, select Groups.
   The Group Search page appears.
2. Click Create New.
   The Create New Group page appears.
3. Complete the fields as appropriate.
4. Click Save.
   The CAB Group appears on the Group List page.

Assign Members to the CAB Group

1. On the Group Detail page, select the Members tab.
2. Click Update Members.
   The Contact Search page displays.
3. Enter the search criteria to display the desired contacts and click Search.
   The Members Update page displays, listing the contacts that matched the search criteria.
4. From the list on the left, select the contacts that you want to assign to this group. To select multiple items, hold down the Ctrl key while clicking the left mouse button.
5. When you have selected all the contacts that you want, click the selection button (>>).
   The selected contacts move to the Members list on the right.
6. Click OK.
   The Group Detail page displays, with the selected contacts listed on the Members tab.

Add the CAB Group to a Change Category

Note: Ensure that the Category_Defaults option is installed, so that the CAB field on change orders defaults to a CAB group.

1. On the Administration tab, select CA SDM, Change Orders, Categories.
   The Change Category List appears.

2. Select a category from the list.
   The Update Change Category page appears.

3. Select the appropriate CAB group from the CAB field.

4. Complete other fields as appropriate.

5. Click Save.
   The Change Category Detail page displays a successful save message.

6. Click Close Window.
   The CAB group is associated with the change category and the change order.

CAB Console and Reporting

Contents

The CAB Console is a dashboard that facilitates online and quick approvals of change orders that require CAB approval. The Change Manager and other CAB members use the console to view details about a change order (and its associated Workflow tasks and configuration items) and approve or reject the change order. The CAB Console lets team members review, approve or reject a change order, and continue to the next change order quickly. For change order requests, the CAB can deal with the request by satisfying it directly or by escalating/referring the request to an appropriate group.

The Change Manager can use CA SDM built-in summary and detail reporting options to accomplish the following tasks:

- Report approved and rejected change orders.
- Report change orders awaiting approval.

To print or view summary and detail reports, first select the records that you want to include in the report. You can select specific records for a report using the search feature of the list pages.

For example, from the Change Order list you can search for a list of change orders that are awaiting CAB approval that you can then use to generate a report. For more information, see Summary and Detail Reports (see page 3230).

Work with the CAB Console

The CAB Console provides Change Managers and CAB members with a visual rendering of the approval process for a selected change request. The CAB deals with the request in the most appropriate manner, either by satisfying the request directly or by escalating/referring the request to an appropriate group.

Approve or Reject Change Orders

Change Managers can quickly approve or reject change orders that are awaiting CAB approval, without needing to open each change order.

Follow these steps:

1. On the Service Desk tab, search for change orders that include values to indicate that CAB Approval is required and that the approval is not completed. For example, you can use the following values:

   - YES for the CAB Approval drop-down list.
   - Not Approved for the Status field.

   The Change Order List page shows change orders that are awaiting CAB approval.

2. Do one of the following steps:

   - Click CAB Console.
     The CAB Console appears and shows the change order details in read-only form for the first change order in the list.
   - Right-click any change order and select CAB Console from the shortcut menu.
     The CAB Console appears and shows the change order details in read-only form for the change order you selected.

3. Review the change order details and decide whether to approve or reject the change order.
4. (Optional) Enter the comments about the approval or rejection in the Comments field.
5. Click Approve Change or Reject Change.
   The first change order status is changed, any comments are saved, and the details for the next change order in the list appear automatically.

   You can use the Previous and Next buttons to navigate to next or previous change orders without updating the change.

6. Continue reviewing change orders, and approving or rejecting them until you reach the final change order in the list.
   The change orders are approved or rejected and their statuses are changed to Approved or Rejected, respectively.

7. Close the CAB Console.

Change CAB Console Properties

Using Web Screen Painter, you can change the CAB Console properties that appear on web forms in the CAB Console. For example, you can do the following actions:

Note: For more information, see Installing Web Screen Painter (see page 498) and Using the Web Screen Painter (see page 1898).

- Rename the Approve and Reject buttons. This button is the property on the order_approval_console.htmpl (change orders) web forms.
- Modify the status values of the Approve and Reject buttons by changing the 'REJ' or 'APR' values.
  - The ‘Reject Task’ button calls a function approve_reject(‘REJ’).
  - The ‘Approve Task’ button calls a function approve_reject(‘APR’).

You can only associate an active transition with a button. Do not deactivate a predefined status transition that is associated with a button. Otherwise, the predefined status transition no longer functions.

Follow these steps:

1. In Web Screen Painter, open the CAB Console form that you want to change.
   Web Screen Painter opens and displays the form.
2. On the Design tab, right-click the control that you want to change, and select Properties.
   The Properties - *control* page appears.
3. Change the properties that you want by entering a new value for each one.
   Changes take effect as soon as you click outside the field, and when you close the Properties page.
   The Web Screen Painter displays a brief summary of the significance of a property in a note that appears at the bottom of the Properties form when you select the property.

Example: Modify the CAB Console for Change Workflow Tasks

This example shows how to modify the task status using Web Screen Painter.

1. In Web Screen Painter, open the orderwf_approval_console.htmpl web form.
   Web Screen Painter opens and displays the form.
2. On the Design tab, right-click the Reject Task button, and select Properties.
   The Properties - Button page opens.

3. Find the function approve_reject('REJ').
   'REJ' is the status code for the Task status Reject.

4. Enter a new value for 'REJ'.
   Changes take effect as soon as you click outside the field, and when you close the Properties page.
   The Web Screen Painter displays a brief summary of the significance of a property in a note that appears at the bottom of the Properties form when you select the property.

Change Management Reporting

The Change Manager with appropriate privileges can use Business Intelligence Launch Pad to accomplish the following tasks:

- Report change volume by operating system, change category, group, implementer, risk, status, implementation date, affected configuration items (CIs), and changes originating from incident or problem tickets.
- Report successfully implemented changes grouped by change category, urgency, priority, impact, % successful vs. total for the specified period, and for the group of the change requestor
- Report failed changes grouped by category, urgency, priority, impact, reason for back out, % failed vs. total for the specified period, and the change requestor's group.
- Report the total number of change requests grouped by change category Change Coordinator, Change Manager, risk level, priority, and affected CIs for a specific time period.

You can navigate to the predefined reports in the left pane of the Business Intelligence Launch Pad window to view, schedule, modify, or run the report or to view the history and properties for a report. For more information about using Business Intelligence Launch Pad, see CA Business Intelligence Reports (see page 3182).

Conflict Analysis and Collision Detection

Contents

Conflict analysis detects and shows collisions that occur when two or more changes to the same configuration item are scheduled for implementation at the same time. The change management team handles scheduling collisions in the following ways:

- Uses the change calendar to see RFC-related CI collisions and makes adjustments to them to reduce potential impact.
- Searches for and detects collisions in a log.

You use the conflict status to help manage and identify conflicts. CA SDM provides the following default conflict statuses:

- **Researching**

Indicates the conflict is being researched by a user.

- **Resolved**

Indicates the conflict was researched and resolved by a user.

- **Unresolved**

Indicates the conflicts was not researched and resolved.

Resolve Scheduling Collisions

Conflict analysis detects and shows collisions that occur when two or more changes to the same configuration item are scheduled for implementation at the same time. You handle scheduling collisions as follows:

1. Navigate to the Change Order Detail page, and click the Conflicts tab.
   The Conflict List page appears.

2. Click Conflict Analysis.
   CA SDM detects scheduling collisions and the Conflict List page lists Schedule Collisions.

   The Conflict List and Change Calendar report any collisions to change orders. Each entry in the list or calendar represents a single collision that puts that change order at risk of failure. Collisions are detected only *after* you click Conflict Analysis for a change order.

3. Click Edit, and then click the Scheduler button.
   The Schedule for Change Order page appears and lists CIs that have scheduling collisions.

4. Investigate and resolve the collisions by updating the Schedule Start Date and Schedule End Date of a change order.

   The implementation schedule is the period between the Schedule Start Date and Schedule End Date of a change order.

5. Record your investigation of the collision.

Detect and Investigate Conflicts

You can detect and investigate change order conflicts to resolve scheduling problems.

Follow these steps:

1. Click the Conflicts tab on a change order.
   The Conflict List page appears.

2. Click Conflict Analysis.

   You can use the Search facility to search the Conflict List, however, searching does not run Conflict Analysis. Click Conflict Analysis to create or remove Conflict List entries.

   The conflicts that are detected for the change order are listed. The following listed information is not self-explanatory:

   - **Type Conflicting Change**
     Displays the type of change that is causing a conflict, for example, Scheduling Collision.

   - **Configuration Item Conflicting Change Summary**
     Identifies the configuration item that is causing the conflict and displays the configuration item summary.

3. Click a change or configuration item link.
   The details about the change or configuration item appear.

4. Investigate the cause of the conflict.

5. (Optional) Adjust the change schedule.

   The change schedule is the period between the Schedule Start Date and Schedule End Date. You have detected and investigated conflicts.

Define Conflict Logging

You can configure the Activity Log to generate entries when conflicts are created or updated so that you can track them. The Activity Log is predefined to generate entries when a conflict is updated. The Options Manager controls the Activity Log.

Follow these steps:

1. On the Administration tab, navigate to Options Manager, Change Order Mgr.
   The Option List page appears.

2. Install the following options:

   - **conflict added**
     Generates the Activity Log entries when conflicts are added.

- **conflict updated**
  Generates the Activity Log entries when conflicts are updated.

3. Save and restart the CA SDM server.
   Conflict logging is defined.

Report Change Order Conflicts

You can report details about change orders including information about change order conflicts, such as the conflict type, the change order that is affected by a conflict, and other conflict details.

Follow these steps:

1. Select the Service Desk tab.
2. Search for change orders.
3. Click Reports, Details.
   The Change Order Detail report appears.
4. (Optional) Scroll toward the end of the report to see conflict details.

Implement the Risk Survey

Contents

Risk assessments let you identify, evaluate, and quantify the risks of change orders that belong to change categories, before modifying a system or service in your environment. You create risk surveys to evaluate risks, and associate the surveys with change categories. When a user creates a change order and specifies a change category, the survey that is associated with that category is available for completion and submission.

The risk survey lists a series of single or multiple choice questions. Each answer has a weightage value. When creating a change order, the user selects the appropriate answers and submits the survey. The evaluated risk level is based on the weightages of answers that are selected by the user.

Implement the risk survey as follows:

1. Establish risk levels for your organization.
2. Create a risk survey (see page) or select from the default list (see page 2251). Create or modify risk survey questions and answers.

3. Modify risk ranges for the risk survey (see page 2251).
4. Associate the risk survey with a change category (see page 2252).
5. After you associate a risk survey with a change category, the Risk Survey button appears for the requester when they save a change order using the specified change category.
6. View the evaluated risk based on the risk survey results.
7. (Optional) Override the evaluated risk value from the Activities menu.

Create a Risk Survey

You can create a risk survey to assess risks for change orders that belong to a change category.

Follow these steps:

1. On the Administration tab, click Service Desk, Change Orders, Risk Survey.
   The Risk Survey Template List appears.
2. Click Create New.
   The Create New Risk Survey page appears.
3. Complete the following fields:
   - **Risk Survey Name**
     Specifies the name of the risk survey.
   - **Include Comments**
     Specifies to include comments in the survey.
   - **Comment Label**
     Specifies the caption to display for comments in the survey.
   - **Active?**
     Specifies if the survey is active or inactive.
   - **Risk Survey Description**
     Specifies a description of the risk survey.
4. Click Save.
   The Risk Survey Detail page appears. You can add questions (see page 2249) and answers to the survey (see page 2250).

Add Risk Survey Question

You can add questions to a survey to help assess risks for change orders that belong to a change category.

Follow these steps:

1. Open a risk survey, click the Questions tab, and click Add Question.
   The Create New Risk Survey Question Template page appears.

2. Complete the following fields:

   - **Sequence**
     Defines the order in which the question appears on the risk survey.

   - **Include Comments**
     Adds a text box to the end of the survey form for customer free-form comments.

   - **Comment Label**
     Adds a label to the comments text box.

   - **Active?**
     Specifies if the question is active or inactive.

   - **Multiple Response Question?**
     Indicates that this question has multiple answers.

   - **Question Text**
     Specifies the question text that appears in the survey.

3. Click Save.
   The question is added to the risk survey.

4. Close the page or create answers.

Add a Risk Survey Answer

After you save a risk survey question, you can add answers to the question to help assess risks for change orders that belong to a change category.

Follow these steps:

1. Open a risk survey, click the Answers tab, and click Add Answer.
   The Create New Risk Survey Answer Template appears.

2. Complete the following fields:

   - **Sequence**
     Defines the order in which the answer appears on the risk survey question.

   - **Active?**
     Specifies if the answer is active or inactive.

   - **Weightage**
     Specifies a numerical value that calculates risk.

   - **Answer Text**
     Specifies the answer text that appears in the survey.

3. Click Save.
   The Risk Survey Question Template detail page appears and the Answers tab updates with your answer.

4. Close the page or create more answers.

View a Default Risk Survey

CA SDM provides default risk surveys that you can associate with change categories.

Follow these steps:

1. Navigate to Service Desk, Change Orders, Risk Survey.

2. Select General from the Risk Survey Name column.
   The General Risk Survey Detail page appears..

3. Click View Survey.
   The risk survey appears, listing questions, answers, and weightage values for each answer. This survey applies to general changes within your organization.

4. Close the survey.

5. The General Risk Survey Detail page appears; close it.

Modify Risk Ranges

You can update risk range values for a survey. The sum of all selected answer weightages are compared with each risk range and the risk level are calculated.

Follow these steps:

1. Click Edit on the Risk Survey Template Detail page.

2. Click Edit in List to edit list items of risk range.

   The Minimum and Maximum Value fields appear.

3. Click on each row to modify minimum and maximum values. The values cannot overlap or you are unable to save the risk survey. Specify the range of values for each category of change that is based on the questions and their weight as follows:

   - High Risk Level -- 21-25
   - Medium-High Risk Level -- 16-20
   - Medium Risk Level -- 8-15
   - Low Risk Level -- 0-7

4. On the Risk Range tab, click Save(Y).

   The Risk Range List page updates.

5. Set the risk survey to Active.

6. Save and close the window.

Associate Risk Survey with a Change Category

You can associate a risk survey to help assess risk for change orders that belong to a change category.

Follow these steps:

1. Navigate to Service Desk, Change Orders, Categories.
   The Change Category List appears.

2. Click a change category in the Symbol column.
   The Change Category Detail page appears.

3. Click Edit.
   The Update Change Category page appears.

4. Click Risk Survey.
   The Risk Survey Template Search appears.

5. Search for the appropriate survey.
   Select the survey from the Risk Survey Name column.
   The Update Change Category page appears.

6. Click Accept.
   The change category updates and is associated with the risk survey.

Example: Deploy a Risk Survey

This example demonstrates how to deploy a default risk survey on your system using a default change category.

Follow these steps:

1. Navigate to Service Desk, Change Orders, Categories.
   The Change Category List appears.

2. Select Add.IT.Other from the Symbol column.
   The Add.IT.Other Category detail page appears.

3. Click Edit.
   The Add.IT.Other Update Change Category page appears.

4. Click Risk Survey.
   The Risk Survey Template Search appears.

5. Search for the risk survey. In this example, search for General and select the risk survey to add it to the detail form.
   The Risk Survey field populates with General.

6. Save and close the window.

If a user creates a change order using the Add.IT.Other category, the Risk Survey button when they save the change order.

Impact Explorer

This article contains the following topics:

Impact Explorer is an advanced tool for managing and controlling change within an organization. Impact Explorer allows the Change Manager to explore CIs that are attached to a change order and also interact directly with an attached CI or its child CIs.

Impact Explorer provides these advantages:

- Displays all CIs that are attached to a change order.
- Displays all child and peer-to-peer relationships for attached CIs.
- Provides the ability to attach any related CI to the change order.
- Displays a Descendants List of successively related CIs for any attached CI.
- Provides the ability to launch CMDB Visualizer for a CI.

Launch Impact Explorer

You can access Impact Explorer from the Config. Items tab of any change order.

Follow these steps:

1. Open a Change Order Detail page.
2. Select the Config. Items tab.
3. Click Impact Explorer.
   The Impact Explorer page appears.

If you close the Change Order Detail page, the Impact Explorer page also closes. If Impact Explorer is launched from multiple change orders, multiple Impact Explorer pages are displayed.

Explore Attached CIs

The Impact Explorer tree contains a node for each CI that is attached to a change order. A plus (+) symbol indicates that a CI has at least one child CI.

If more than 100 CIs are attached to the change order, only the first 100 are displayed. To view the next 100 CIs, click More...

To display the relationships for an attached CI, click the plus (+) symbol for the CI. The related CIs appear in the tree. In addition to the related CI names, the tree also displays relationship types in brackets.

View a CI in Impact Explorer

The Impact Explorer tree displays a node for each CI that is linked to a change order. A plus (+) symbol indicates that a CI has at least one child CI.

Follow these steps:

1. Click a CI node in the left pane.
   The Configuration Item Detail page appears in the right pane.

You can also display the CI Detail page in the right pane by right-clicking on the CI and selecting View from its context menu.

2. Click the change order node at the top of the left pane.
   The Change Order Detail page appears.

If the change order has more than 100 attached CIs, only the first 100 are displayed. To view the next 100 CIs, click More...

Add a Related CI to a Change Order

To maintain CI relationships, you may want to attach a related CI to the change order.

Follow these steps:

1. Click the Config. Items tab for a change order.
   The Configuration Items List page appears.

2. Click Impact Explorer.
   The Impact Explorer tree displays attached CIs.

3. Click any plus (+) for an attached CI node.
   CIs related to the node appear.

4. Right-click it a related CI and select Add to Change Order from the context menu.
   The new attached CI appears in the Config. Items tab for the change order.

Display the CI Descendants List

For any CI, you can display lines of related CIs (named *descendants*). In addition to basic information about each CI, the CI Descendants List displays relationship levels, with the originating CI as level 1. CI children begin at level 2, and their children at 3, and so on. If a CI is encountered more than once among the relationships, only its closest relationship level is displayed.

Example: Multiple Descendant Paths for One CI

Due to multiple relationships, a descendant search finds the same related CI at level 2 and also at level 4. The descendant CI is displayed only at level 2.

To list descendants for a CI

1. From a Change Order Detail page, select the Config. Items tab.

2. Click Impact Explorer to display attached CIs.

3. Expand a CI node if needed.

4. Right-click a CI and select List Descendants.
   The CI Descendants List is displayed.

Launch CMDB Visualizer from Impact Explorer

Impact Explorer provides the capability to launch CMDB Visualizer from an attached or related CI.

Follow these steps:

1. From a Change Order Detail page, click Impact Explorer.
   The Impact Explorer page displays.

2. Right-click any CI and select Launch Visualizer from its context menu.
   CMDB Visualizer is launched with the CI as the focus.

Configuring Impact Explorer

An Administrator can configure the Impact Explorer as follows:

- Specify the number of child CIs displayed for an attached CI.
- Specify the number of relationship levels that are displayed in the CI Descendants List,
- Suppress the display of child CIs,

The number of child CIs displayed is configurable by adding a NX_IMPACT_EXPLORER_MAX_CHILD_NODES setting to the NX.env configuration file. The default is 100.

Example: Configure the Display of Child CIs

Using the following setting, Impact Explorer only displays ten children at a time for an attached CI:

@NX_IMPACT_EXPLORER_MAX_CHILD_NODES=10

The default depth of the CI Descendants List is nine (9) levels. The depth is configurable by adding a NX_IMPACT_EXPLORER_MAX_LEVELS setting to the NX.env configuration file.

Example: Configure the Number of Descendant Levels

Using the following setting, the CI Descendants List displays the originating CI and only its relationally adjacent child CIs:

@NX_IMPACT_EXPLORER_MAX_LEVELS=2

Use the following Options Manager option to suppress the display of a certain type of child CI:

IMPACT_EXPLORER_EXCLUDE_HIER=boolean

If the IMPACT_EXPLORER_EXCLUDE_HIER option is installed and set to Yes, child CIs that are related through the CMDB Relationships tab of a CI Detail page are not displayed in the Impact Explorer tree or in the CI Descendants List.

Child CIs that are related through CA CMDB are still displayed.

Define a Change Order Stored Query

Defining the stored queries that are available to users on the Change Order scoreboard is an administrative task. You can modify the predefined stored queries that are installed with CA SDM, or can define your own.

Follow these steps:

1. Select Service Desk, Application Data, Stored Queries on the Administration tab.
   The Stored Query List appears.

2. Select the stored query that you want to edit.
   The Stored Query Detail page appears.

3. Click Edit.
   The Update Stored Query page appears.

4. Edit the field values as appropriate.

5. Click Save, Close Window.
   The updated stored query appears in the Stored Query List.

Example: Define a Stored Query to List Change Orders Assigned to a CAB to Which the Logged In User Belongs

This example demonstrates how you can create a stored query that lists only change orders that are assigned to a CAB to which the logged in user belongs.

To create the stored query:

1. Navigate the Scoreboard to the Update Stored Query page.
2. Edit the field values as follows:
   a. Select Scoreboard Usage.
   b. Set Type to Change Order.
   c. Enter the Where clause:

```
cab.[group]group_list.member IN (@cnt.id) AND active = 1
```

3. Click Save, Close Window.
   The stored query appears in the Stored Query List.

Change Orders

Contents

Change orders are requested changes that vary from the original scope of a specific project or task.

Create a Change Order

You can either create a change order from scratch or use an existing template.

Important! Depending on your role, you do not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create new ones. Other roles, such as Configuration Viewer, can view Change Order information, but cannot create or edit change orders.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type that you want to create. For example, to create a request from scratch, click File, New Request. To create a request from a template, Click File, New Request from Template.
2. Complete the Change Order Fields (see page 2260) as appropriate for the change order.
3. Use the controls available on the Change Order Tabs (see page 2264) as appropriate.
4. Click one of the following buttons:

   Auto Assign -- Triggers an auto assignment task, and updates the activity log. This button appears only when the ticket specifies a category or area that has auto-assignment enabled.

   Create Incident – Opens the Create New Incident page so you can create an associated incident ticket. This button appears only when you create change orders and requests.

   Find Similar -- Opens the Find Similar page to search for similar problems.**Quick Profile** -- Displays the contact information for the specified user in the **Affected End User** field. You can also view their environment details and their entire ticket history.

   Use Template -- Displays a list of available templates for the selected ticket type. You can select the template that you want to use for creating this ticket.

Note: You can use the Quick Profile to identify a contact to be the affected end user of your new ticket. Quick Profile allows you to search for a contact, and view the history of the issues, requests, change orders, incidents, and problems that are assigned to that contact. When you have identified a contact, you can create the incident ticket directly from the Quick Profile.

Create a Change Order from an Incident, Problem, or Request

While creating or editing an incident, problem, or request, you can define a change order to be associated with the incident, problem, or request.

Follow these steps:

1. On the Create New or Update page for your incident, problem, or request, click Create Change Order.
   The Create New Change Order page displays.

The Create New Change Order page opens only if all the required fields are defined for your incident, problem, or request.

2. Complete the fields as appropriate for the change order.
   See Change Order Fields (see page 2260) for field definitions.

3. Use the controls available on the tabs at the bottom of this page to process the change order as appropriate.
   See Change Order Tabs (see page 2264) for more information.

4. Save and close the window.

Create a Change Order from the Calendar

You can create a Change Order from the context menu on the daily, weekly and monthly calendar views. The context menu also allows you to create a Change Order from a template.

You cannot create a change order by right clicking on a range of dates in the weekly view.

Follow these steps:

1. Right click a date on the calendar.
   The context menu appears.

2. Select one of the following:

   - **Create Change Order**
     The Create Change Order detail page appears and pre-populates the following fields:

     - Requester and Affected End User (always set to the login user)
     - Schedule Start Date (set to midnight of the selected day)
     - Scheduled Duration (always set to 00:00:00)

   - **Create Change Order from Template**
     The Change Order Template list view appears.
     Select a template and the Change Order detail page appears with pre-populated fields.

3. Complete the fields as appropriate for the change order.
   See Change Order Fields (see page 2260) for field definitions.

4. Use the controls available on the tabs at the bottom of this page to process the change order as appropriate.
   See Change Order Tabs (see page 2264) for more information.

5. Click an execution option. Following are options that are not self-explanatory:
   Create Incident
   Opens the Create New Incident page so you can create a incident ticket associated with this change order.
   Quick Profile
   Displays the contact information for the user entered in the Affected End User field.
   If you are creating a change order, a list of available users appears. You can select the user that is in the Affected End User field.
   Use Template
   Displays a list of available change order templates. You can select the template you want to use for creating this change order.

Change Order Fields

The following fields are required to create or update a change order:

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Note: When the Change Order is in Edit mode, the Update CI button is disabled to prevent the possibility of duplicate CIs being added. To add CIs to a Change Order, save the Change Order, and the Update CI button is available for your use.

- **Change Reference Number**
  This is a unique reference number assigned by CA Service Desk Manager for all change order tickets. This is used by analysts and customers to refer to a particular change order ticket.

- **Requester**
  Specifies the name of the person who initiated the ticket. This person must be a defined contact. You can enter a value directly or click the magnifier to search for the name.

- **Affected End User**
  Specifies the contact name of the person who is affected by the record. If the contact is assigned to a special handling type, special handling indicators are displayed. You can enter a value directly or click the magnifier to search for a contact name.

- **Category**
  Indicates the general category of the change within your IT environment (for example, Change.IT. Server.Configuration or Move.IT.Workstation). Change categories provide default values that are entered automatically on all change orders assigned to the category. In addition to the predefined change categories, your system administrator may define custom change categories. You can enter a value directly or click the magnifier to search for a category. When you edit the Category and a CA Process Automation workflow is already running, the workflow cancels.

If a risk is associated with the specified change category, a Risk Survey button appears when you save the change order. This option opens a risk survey questionnaire for that change category.

Your system administrator has the option of adding custom properties to change order categories. If custom properties have been added, they are displayed on the Properties tab when you create, edit, or view a change order. Some custom properties require that you enter a value.

- **Status**
  Specifies the status code of the record. For example, you can list only the tickets with a status code of Fix in Progress, or can Close Requested. You can enter a value directly or click the magnifier to search for a status. The blue button (on the left side of the Status field) lets you change the current status to the next default status.

- **Priority**
  Specifies the priority ranking of the record. The ranking determines the amount of attention the ticket receives. The predefined priority levels are 1 (highest) through 5 (lowest). Your system administrator or an active priority calculation can generate the appropriate Priority values for various installations and tenants. When priority calculation is enabled, this field updates based on Impact, Urgency, Affected Service, and Affected User settings. When your administrator disables priority calculation and uninstalls the urgency_on_employee option, Self Service Users see the Priority field on the Request Detail page.

- **Type**
  Specifies the ITIL change type as Standard, Normal, or Emergency. A default value may be defined the change category.

- **Risk**
  Identifies the risk level of the change order. The risk level is determined by evaluating the risk survey associated with the change order.

Detail Fields

- **Created By**
  Specifies the name of the person who created or reported the record. This field is filled automatically with the current user's login information when the record is created.

- **Assignee**
  Specifies the name of the person who is assigned to handle the record. You can enter a value directly or click the magnifier to search for a name. Selecting an assignee populates the groups that the assignee belongs to in the **Group** field.

- **Group**
  Specifies the group that is responsible for this record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, or problems. Any contact who is part of the group can handle the record after it is assigned to the group. You can enter a value directly or click the magnifier to search for a group. Selecting a group populates the **Assignee** field with the corresponding assignee name, which belong to the group.

- **CAB**
  Specifies the group that is responsible for reviewing Requests for Changes (RFCs). The CAB provides multiple perspectives necessary to ensure proper decision making about implementing changes. The CAB can include members from the application team, development manager, component owner, QA, support, and any additional parties deemed necessary. You can enter a value directly or click the magnifier to search for a group.

- **Impact**
  Specifies an impact code, such as 1 -- Entire Organization, that indicates how a ticket affects work being performed. For example, a ticket that requires a network outage for several hours would have a higher impact than a ticket that takes a printer off-line. Your system administrator can modify the default impact codes, so they can vary from one installation to another

- **Active**
  Indicates whether the record is Active or Inactive. This value applies to the current record only, not the associated template.

- **Need By Date**
  Displays the date that the change order needs to be completed by. You can enter the date in mm /dd/yyyy hh:mm am | pm format, or click the calendar icon to select a date.

- **Call Back Date/Time**
  Indicates the date on which a follow-up call for this change order should be made. On the date you specify, the change order displays on your scoreboard under the Today's Issue Callbacks category. You can enter the date in mm/dd/yyyy hh:mm am | pm format, or click the calendar icon to select a date.

- **Root Cause**
  Identifies the code associated with the core reason why the ticket was opened. Your service desk can use generic root cause codes, such as Hardware Failure or Software Failure, or more specific codes, such as Network.Cable, Network.Card, or Network.Response. You can enter a value directly or click the magnifier to search for a code.

- **Organization**
  Specifies the company, division, or department that is associated with the change order. You can select a value from the drop-down list.

- **Project**
  Identifies the project. You can associate a change order with a project in order to establish a connection to an external project in another product such as CA Clarity PPM or CA SCM. The Project you enter in this field contains the external project information, such as the project name or ID, to make the connection and integration between CA SDM and the external project. You can enter a value directly or click the search icon to search for a project.

- **Closure Code**
  Indicates the final outcome of a completed change as Successful, Unsuccessful, or Successful with Errors. You can also create custom closure codes.

- **Business Classification**
  Classifies the change order into Major, Minor, or Significant. The classification helps to assess the change order magnitude.

- **External System Ticket**
  Specifies an identification for a ticket that belongs to an external system that integrates with CA SDM. This field stores hyperlinks and displays functional links in read-only mode.

Summary Information Fields

- **Order Summary**
  Gives an abbreviated description of the change order.

- **Spelling**
  Checks the spelling of the text you enter in the Order Summary field.

- **Order Description**
  Gives a detailed description of the change order.

- **Spelling**
  Checks the spelling of the text you enter in the Order Description field.

- **Schedule Start Date**
  Specifies the start date and time a change order appears on the Change Calendar pages. This field is optional, but must contain a date value if the Schedule Duration field contains a date value. Changes without an implementation date do not appear on the Change Calendar pages.

- **Schedule Duration**
  Indicates the amount of time required to implement the change in hours and minutes.

- **Schedule End Date**
  Indicates the end date and time a change order appears on the Change Calendar pages. This field is read-only. Its value is calculated from Schedule Start Date and Schedule Duration values.

- **CAB Approval**
  Indicates (Y/N) whether the change requires approval from a CAB. You can specify which changes are to be considered for CAB approval, by doing any of the following:

  - Set this option at change creation time or any subsequent time throughout the approval process.

  - Add an Action macro to set this field to Yes or No for use within classic workflow.

- **Open Date**
  Indicates the date and time at which the record was first created, in the time zone of the server. This field is filled in automatically when the change order is created. The date and time appear in mm/dd/yyyy hh:mm am | pm format.

- **Actual Start Date**
  Indicates the date and time at which the word Pending appears in the Status field for the change order. The date and time appear in mm/dd/yyyy hh:mm am | pm format.

- **Last Modified Date/Time**
  Displays the date that this change order was last modified.

- **Last Modified By**
  Displays the name of the last person who edited the change order.

- **Resolve Date**
  Indicates the date and time at which the change order is resolved. The date and time appear in mm/dd/yyyy hh:mm am | pm format.

- **Close Date**
  Indicates the date and time at which the change order is closed. The date and time appear in mm /dd/yyyy hh:mm am | pm format.

Change Order Tabs

The following tabs are available on the Create Change Order, Change Order Detail, and Update Change Order pages:

Related Tickets

- **Related Orders:** Allows you to create a parent/child relationship between the change order and another CA SDM record.

- **Incidents / Problems:** Attaches related incidents (see page 2266) and problems to a change order for analysts to reference.

- **Caused Requests:** Attaches requests that the change order causes for analysts to reference.

Configuration Management

- **Configuration Items:** Links configuration items (see page 2274) (CIs) to a change order to provide information to analysts about the system that the ticket affects. Configuration Items are automatically added to this list when a Change Specification is created.

- **Change Specifications:** Lists the change specifications (see page 2622) that are associated with the CI and the verification status. Change specifications are highlighted in red if they have failed verification or require manual verification.

- **Verification Log:** Displays logged information about change verification (see page 2230) activity for this Change Order. For example, this log identifies a CI where CACF detected a variance or rogue change. Verification log entries highlighted in red indicate the corresponding change specification is either Failed Verification or Manual Verification Active and may need further attention from the user.

Additional Information

- **Properties:** Defines custom properties for change order categories.

- **Workflow Tasks:** Associates workflow tasks with a change order. For more information, see Define a Category or Area (see page 1054) topic.

- **Service Type:** Allows you to attach a service type event (see page 2313) to indicate the level of support for the ticket.

- **Attachments:** Attaches a document or a link to a URL to the change order.
- **Conflicts:** Identifies change orders that conflict with the one being viewed. For more information, see Conflict Analysis and Collision Detection (see page 2245) topic.
- **Templates:** Allows you to create a template (see page 2315) using the current ticket as a model.
- **Costs / Plans:** Calculates estimated cost and duration of the entire change order by adding the estimated cost and duration (see page 2273) of each task.

Logs

- **Activities:** Displays a log of the activities performed to resolve the change order. For more information, see Add an Activity from the Ticket Management (see page 2308) topic.
- **Event Log:** Displays a record of significant actions that occur regarding the change order.
- **Support Automation:** Displays the assistance session log and lets you invite the end user to an assistance session.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

View Global Change Order Queue List

This window only appears in a multi-site installation and allows you to search and list change orders across the regions defined to your multi-site setup.

The Global Queue list forms can be used by analysts that work tickets across multiple regions. Each queue is a read-only list page that relates to tickets on remote (or local) regions. Once an item is selected from the queue, the analyst is re-directed to the appropriate regions to continue to process the ticket. Only enough information is replicated to allow analysts to make decisions on which ticket to process.

Only tickets that are assigned to groups belonging to a Global Group are selected for replication. Once selected for replication, it is replicated from that point forward even if no longer assigned to a Global Group. A Global Queue ticket is marked Inactive if no longer assigned to a Global Group. Marking the Global Queue ticket inactive does not affect the status of the original ticket that the Global Queue ticket references.

- **Change #**
  Specifies the number assigned to the change order.
- **Priority**
  Specifies a priority ranking for the change order.
- **Queue**
  Specifies is the name of the multi-site Region. This value is for display purposes only.

- **Status**
  Displays a specific status code for the change order. For example, you may want to list only the tickets with a status code of Fix in Progress, or Close Requested. Click the search icon to search for the status of interest.

- **Open Date**
  Displays the date the change order was opened. This field also displays the region of the ticket.

- **Contacts**
  Displays contacts associated with the change order, such as the assignee and end user.

- **Category**
  Displays the category of the change order. Categories designate an area of responsibility, such as adding or moving a workstation, and auto-populate certain fields on the tickets assigned to that category.

Attach Incidents, Problems, or Requests to a Change Order

You can attach related incidents, problems, or requests to a change order so that they can be referenced when editing or reviewing the change order.

Follow these steps:

1. On the Service Desk tab, browse to Change Orders, Assigned or Unassigned. Select the priority for the change order you want to edit.
   The Change Order List displays.

2. Select the change order.
   The Change Detail page displays.

3. Choose the Incidents/Problems tab and click Attach Incidents.

4. Complete the appropriate search fields, and click Search.

5. Select the incidents/problems/requests you want to attach to the change order, and click  .
   The selected items are added to the list on the right.

   > **Note:** Use the CTRL or SHIFT keys plus the left mouse button to select multiple incidents.

6. Click OK.
   The selected items appear in the Related Requests List on the Incidents/Problems tab of the Change Detail page.

Expedite a Change Order

You can use the Expedite Change Order command to change the status of unnecessary tasks to Skip so the change order can be completed quickly.

Note: Skip must be defined as a valid status for the task.

Follow these steps:

1. Select Change Orders from the Scoreboard.
   The Change Orders folder expands to reveal nested folders for Assigned, Unassigned, and All Scheduled change orders.

2. Select the appropriate folder under Assigned, Unassigned, and All Scheduled for the change order whose children you want to expedite.
   The Change Order List page appears.

3. Click the change order number.
   The Change Order Detail page appears.

4. Select Expedite Change Order from the Actions menu.
   The Expedite Change Order page appears.

5. (Optional) Enter comments in the Remarks field to explain the action.

6. Click OK.
   The Expedite Change Order page closes and the Workflow Tasks tab on the Change Order Detail page shows all unnecessary tasks with status of Skip.

How to Schedule Change Orders

Contents

You can view the schedule of all configuration items associated with a change order. Consider scheduling information when you create, edit, or view a change order, or when you update the Change Calendar. Viewing the schedule can help you avoid scheduling collisions.

Follow these steps:

1. Create or open a change order.

2. Associate CIs with the change order.

Note: If you do not associate a CI with the change order, an error appears when you click the Scheduler button.

3. Click View Scheduler.
   The Change Scheduler appears and displays the following views:

   - **Daily**
     (Default) Displays the time period of the change order for the selected date and time. If no date is associated with the change order, the view defaults on the current day.

   - **Weekly**
     Displays the time period of the change order in the current week and includes the implementation start date, which can be configured to the Change Calendar start date.

   Note: The schedule duration determines the length of shading on the schedule. For example, if you create a change order with a two hour duration, the light-yellow shading on the scheduler displays for the two hour defined duration.

4. (Optional) Click a CI to view its details. Hover over the CI name to view its full name.

5. (Optional) Modify the Implementation Start Date or Duration.

   a. Click View Schedule to preview the updated schedule.

   b. Click Update Schedule to update the schedule.

   Note: You can only modify the schedule in edit mode.

6. Save the change order.

7. Refresh the Change Calendar to view global and CI-associated change windows.

Use the Change Scheduler Example

The following example demonstrates how to use the change scheduler when creating a change order.

Follow these steps:

1. On the Service Desk tab, select File, New Change Order.
   The Create New Change Order page appears.

2. Select Update CIs on the Config. Items tab.
   The Configuration Item Search page appears.

3. Create or search for CIs.

4. Using the Affected Configuration Items Update page, add CIs to the change order.

5. Click OK.
   The Create New Change Order page updates.

6. Click the Scheduler button.
   The Schedule for Change Order page appears.

7. Select a view and do *any* of the following:

   - Click within the table cells to modify the Schedule Start Date.
   - Click Schedule Start Date to use the Date Helper.

8. Modify the Duration and click View Schedule.
   The schedule previews your changes.

9. Click Update Schedule.
   The schedule updates with your changes.

10. Save the change order.

Set the Maximum Number of CIs

You can set the maximum number of CIs that display in the change scheduler.

Follow these steps:

1. Open *NX.env*.
   You can locate this file in the following directory:

   ```
   $NX_ROOT\
   ```

2. Modify the value of *@NX_CHANGE_SCHEDULER_MAX_CI_CNT* to the maximum number you want.

   Note: By default, the variable is set to 100. If you set the maximum number of CIs greater than 100, only the first 100 display and you get a warning.

3. Save *NX.env* and cycle CA SDM.
   The maximum number of CIs is set.

Example: Set the Maximum Number of CIs to 25

With the following setting, only the first 25 CIs will display on the change scheduler.

```
@NX_CHANGE_SCHEDULER_MAX_CI_CNT=25
```

Modify Change Order Duration Background Color

You can change the background color of the change order duration. Modify the following lines in *schedule.css* to change the highlighting of the green change order duration bar.

Follow these steps:

1. Open *schedule.css*.
   You can locate this file in the following directory:

   ```
   $NX_ROOT\bopcfg\www\wwwroot\css
   ```

   Important! $NX_ROOT\sdk also contains a file called schedule.css that contains helpful comments about css controls.

2. Modify the following lines with the color code you want:

   ```
   td.noBorderBackColor{border-left:none;border-right:none;background-color:
   #F6E3CE;}
   td.withBorderBackColor{border-right:none;border-left:1px solid;background-color:
   #F6E3CE;}
   ```

3. Save *schedule.css*.

In the following example, the change duration background color is #FF0000.

Example: Modify the Change Duration Background Color to #FF0000

```
td.noBorderBackColor{border-left:none;border-right:none;background-color:#FF0000;}
td.withBorderBackColor{border-right:none;border-left:1px solid;background-color:
#FF0000;}
```

Modify Change Window Colors in the Change Scheduler

You can change colors that indicate change windows by modifying lines in *schedule.css.*

Note: If you modify *schedule.css* to change the formatting of windows on the Change Scheduler, you must also modify the schedGroup macros used by the Change Calendar if you want its formatting to be consistent with the Scheduler.

Follow these steps:

1. Open *schedule.css* in a text editor.
   You can locate this file in the following directory:

   ```
   $NX_ROOT\bopcfg\www\wwwroot\css
   ```

2. Modify the following lines with the color code you want:

   ```
   .schedConflict { background-color: #ff0000; font-size: 4px }
   .schedBusy { background-color: #0176ff; font-size: 4px}
   .schedCurrent { background-color: #008000; font-size: 4px; }
   .schedMW { background-color: #40ff40; font-size: 4px; }
   .schedBW { background-color: black; font-size: 4px; }
   .schedNone {font-size: 4px; }
   ```

```
.schedDialog { width: 100%; height: 4px; margin-left: 0px; margin-right: 0px;
margin-top: 4px; margin-bottom: 4px; }
```

3. Save *schedule.css*.
   The background color is modified.

View or Update a Change Schedule

You can view and update a change schedule to help avoid scheduling collisions, or to streamline and balance the work effort.

Follow these steps:

1. Create, edit, or view a change order.

   Note: You can only modify the schedule in edit mode.

   The Change Order Detail page appears.

2. On the Config. Items tab, click Update CIs to add CIs to the change order.

3. Click the Scheduler button.
   The Schedule for Change Order page appears.

4. Modify the Schedule Start Date and Duration as appropriate, for example, to resolve scheduling collisions.

   Note: You can edit the start date by clicking within the table cells. Clicking the table cells on the daily view shifts the schedule in 10-minute increments. Clicking the table cells on the weekly view shifts the schedule in one hour increments.

   Details of the change order display when you hover over a line in the table cells.
   The change scheduler indicates the following types of schedules:

   - Blue -- Regular change order
   - Green -- Global maintenance window or CI-associated window
   - Dark Green -- Schedule of the current change order
   - Black -- Blackout window
   - Red -- If the current change order conflicts with other scheduled change orders.

Note: This indicator only displays conflicts with the current change order, not change conflicts in general. The red conflict only appears after the change order is saved. Use the highlighted change scheduler durations to determine conflicts.

For information about modifying colors in the change scheduler, see Modify Change Window Colors in the Change Scheduler (see page 2270)

5. Click Update Schedule and save the change order.

6. View the updated Change Calendar.

Update the Change Scheduler

You can update the Change Scheduler when you create or edit a change order.

Follow these steps:

1. Select the change order from the Change Order List page on the Scoreboard.
   The Change Order Detail page appears.

2. Select Activities, Update Schedule on the menu bar.
   The Update Schedule page appears.

3. Enter a new start date, duration, and date of activity.

   Note: You can enter the values directly or click the icon to open the Date Helper.

4. Change any other activities fields as appropriate.

5. Click Save.
   The Change Scheduler is updated, and the activity is recorded on the Activities tab on the Change Order Detail page.

Create Change Windows

Create change windows to avoid collisions in the Change Calendar.

Follow these steps:

1. On the Administration tab, click Service Desk, Change Orders, Change Windows.
   The Change Windows List appears.

2. Click Create New.
   The Create New Change Window page appears.

3. Complete the appropriate fields.

4. Save and close the change window.
   The change window appears in the Change Windows List.

Associate a CI with a Maintenance Window

To control when a CI undergoes maintenance, you can associate that CI to a maintenance window.

Follow these steps:

1. Navigate to the Change Window Detail page.
2. Click the Associated CIs tab.
   The Associated CIs list appears.
3. Click Update Configuration Items.
   The CI Search page appears.
4. Specify information for the required CIs.
5. Click Search
   The Available CIs page appears.
6. Move any required CIs in the Available CIs list to the Associated CIs list.
7. Click OK.
   The Change Window Detail page appears.
8. Click Save.
   The CI is associated with a maintenance window.

The change window, the CIs and the selected window associations are saved.

Accumulate Costs and Time to a Change Order

The accumulate feature allows you to calculate the estimated cost and duration of the entire change order by adding together the estimated cost and duration of each task. You can also choose to accumulate the change order and all of its children. Children are additional records entered as a result of attempting to resolve the original change order.

Follow these steps:

1. Select Change Orders, Assigned or Unassigned, and priority level on the Service Desk tab.
   The Change Order List appears.
2. Select the change order of interest.
   The Change Detail page appears.
3. Select Actions, Accumulate Change Order on the menu bar.
   The Accumulate Change Order page appears.
4. Click one of the following buttons:

- **Accumulate this Change Order and All Children**
  Calculates the estimated cost and duration of the change order by adding together the estimated cost and duration of tasks for this change order and all of its children.

- **Accumulate Only this Change Order**
  Calculates the estimated cost and duration of the change order by adding together the estimated cost and duration of tasks for only this change order.

- **Cancel**
  Closes the Accumulate Change Order page without accumulating the change order.

The estimated cost and duration are accumulated and you are returned to the Change Detail page.

5. Select the Costs/Plans tab on the Change Detail page.
   The tab displays the estimated cost and duration for the change order based on the values accumulated.

Change Order Configuration Items

Configuration items include all the hardware, software, and services associated with your system. Configuration item records uniquely identify each item and its exact location. These records are part of the inventory components that make up your database.

You can link configuration items to an issue or change order in order to give analysts information about the system that is affected by the ticket. Consider using change verification in your CMDB environment to verify that changes execute correctly.

Follow these steps:

1. On the Scoreboard, browse to Change Orders, Assigned or Unassigned. Select the priority for the change order you want to edit.
   The Change Order List displays.

2. Select the change order.
   The Change Detail page displays.

3. (Optional) Select the Change Specifications tab to view or create change specification to associate with the ticket.

4. Select the Configuration Items List tab, and click Update CIs.
   The Configuration Item Search page displays.

5. Complete one or more of the search fields, and click Search.
   A list of available configuration items displays.

6. Select the configuration items you want to link to the change order, and click  .
   The selected configuration items are added to the list on the right.

> **Note:** Use the CTRL or SHIFT keys plus the left mouse button to select multiple configuration items.

7. Click OK.
   The selected configuration items appear on the Config. Items tab on the Change Detail page.

8. Click Close Window.
   The updated change order appears in the Change Order List when you redisplay the list.

Create a Change Order Template

This article contains the following topics:

You can define a ticket, such as an incident, problem, issue, change order, or request, to serve as a model for future tickets. You can then save it as a template. Tickets that are created with that template have certain fields auto-populated with your specified values.

Create a Template from a New Ticket

You can use a new ticket to create a template to be used when creating future tickets.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type for the template. For example, to create an incident template, click File, New Incident.

2. Complete the fields as appropriate for the template in the page that opens.

3. Select the Template tab at the bottom of the page.

4. Complete the following fields:

   Template Name
   This name appears in the list of available templates.

   Template Class
   (Optional) You can assign a class to the template.

   Quick Template Type
   You can use quick templates to define new requests on the Quick Profile Scratchpad. Select one of the following options:

   - None
   - Quick
   - Review Before Save

Template Active
Specifies whether the template is active or inactive in the database.

Description
Describe the template settings and intended usage. This field can be used as a filter when searching for a template. Wildcard searches are supported.

5. Click Save.

Create a Template from an Existing Ticket

You can use an existing ticket to create a template.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Select the desired ticket from the list that appears.

> **Note:** Some roles can only access certain ticket types through the Search menu on the Service Desk menu bar.

4. Click Edit.
5. (Optional) Edit the fields as appropriate.
6. Select the Template tab at the bottom of the page.
7. Complete the following fields:

Template Name
This name appears in the list of available templates.

Template Class
(Optional) You can assign a class to the template.

Quick Template Type
You can use quick templates to define new requests on the Quick Profile Scratchpad. Select one of the following options:

- None
- Quick
- Review Before Save

Template Active
Specifies whether the template is active or inactive in the database.

Description
Describe the template settings and intended usage. This field can be used as a filter when searching for a template. Wildcard searches are supported.

8. Click Save.

Create a Change Order

This article contains the following topics:

You can create a ticket such as an incident, problem, request, issue, or change order, using various methods. This article explains these methods.

Important! Depending on your role, you do not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create new ones.

Create a Ticket from the File Menu

You can either create a ticket from scratch or use an existing template.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type that you want to create. For example, to create a request from scratch, click File, New Request. To create a request from a template, Click File, New Request from Template.

2. Fill in the fields as appropriate for the ticket. See the field definitions at the end of this page. Use the controls available on the tabs at the bottom of this page to process the ticket as appropriate.

3. Click one of the following buttons:

   Save -- Saves the incident and closes the page.

   Auto Assign -- Triggers an auto assignment task, and updates the activity log.

   Note: This button appears only when the ticket specifies a category or area that has auto-assignment enabled.
   Create Change Order -- Opens the Create New Change Order page. You can create a change order ticket that is associated with this incident.**Note:** This button appears only when you create incidents, problems, and requests.

   Create Problem -- Opens the Create New Problem page so you can create a problem ticket associated with this incident.**Note:** This button appears only when you create incidents and requests.

   Create Incident – Opens the Create New Incident page so you can create an associated incident ticket.**Note:** This button appears only when you create change orders and requests.

   Reset -- Resets all fields to the last saved values.

   Find Similar -- Opens the Find Similar page to search for similar problems.**Quick Profile --** Displays the contact information for the specified user in the **Affected End User** field. You can also view their environment details and their entire ticket history.

   Use Template -- Displays a list of available templates for the selected ticket type. You can select the template that you want to use for creating this ticket.

Create a Ticket Using Quick Profile

You can use the Quick Profile to identify a contact to be the affected end user of your new ticket. Quick Profile allows you to search for a contact, and view the history of the issues, requests, change orders, incidents, and problems that are assigned to that contact. When you have identified a contact, you can create the incident ticket directly from the Quick Profile.

Follow these steps:

1. Select View, Quick Profile on the menu bar of the Scoreboard.
   The Quick Profile Contact Search window opens.

2. (Optional) Complete one or more of the filter fields to list only the contacts of interest.

3. Click Search.
   Note: All search fields that allow text entry support use of the % wildcard character.
   The Quick Profile Contact List page lists the contacts that match your search criteria.

4. Select the user who is the affected end user of the new ticket.
   The contact pane displays contact information and the ticket history for the contact.

5. In the Scratchpad pane, do the following actions:

    a. Enter a description for the new record in the Scratchpad text field.

    b. Select the ticket type from the Type drop-down list.

    c. (Optional) Enter a Template name for the new record. You can enter a value directly or click the search icon to search for available templates.

6. Click New.
   A new window opens and displays the information that you entered in the Scratchpad.

7. Complete the empty fields as appropriate.
   See the field definitions at the end of this page.

8. Use the controls available on the tabs at the bottom of this page to process the ticket as appropriate.

Add Attachments to Tickets

You can attach a document or a link to a URL to a ticket. The document or URL provides more explanation or justification for the report.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Open the desired ticket from the list that appears.

4. Select the Attachments tab, and then click one of the following options:

    - Attach Document

    - Attach URL

5. Follow the on-screen instructions to attach a file or URL to the incident.
   The URL or the document is added to the record and is listed on the Attachments tab of the Incident Detail page.

View Tickets

You can view summary information for tickets after you create them.

If you are using multi-tenancy, a tenant drop-down list appears in the search filter. If you select <empty> in this drop-down list, the search is public.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Select the folder for the tickets that you want to see.

4. (Optional) Click Show Filter and complete one or more of the fields to specify search criteria that restricts the list to the tickets of interest.

5. Click Search.
   The search result displays the tickets that match the criteria.

6. Click the ticket # link to view the incident of interest.
   The detail page appears.

Create a Change Order from an Incident, Problem, or Request

While creating or editing an incident, problem, or request, you can define a change order to be associated with the incident, problem, or request.

To create a change order from an incident, problem, or request

1. On the Create New or Update page for your incident, problem, or request, click Create Change Order.
   The Create New Change Order page displays.

   The Create New Change Order page opens only if all the required fields are defined for your incident, problem, or request.

2. Complete the fields as appropriate for the change order.
   See Change Order Fields (see page 2281) for field definitions.

3. Use the controls available on the tabs at the bottom of this page to process the change order as appropriate.
   See Change Order Tabs (see page 2285) for more information.

4. Save and close the window.

Create a Change Order from the Calendar

You can create a Change Order from the context menu on the daily, weekly and monthly calendar views. The context menu also allows you to create a Change Order from a template.

You cannot create a change order by right clicking on a range of dates in the weekly view.

To create a change order from the calendar

1. Right click a date on the calendar.
   The context menu appears.

2. Select one of the following:

   - **Create Change Order**
     The Create Change Order detail page appears and pre-populates the following fields:

     - Requester and Affected End User (always set to the login user)
     - Schedule Start Date (set to midnight of the selected day)
     - Scheduled Duration (always set to 00:00:00)

   - **Create Change Order from Template**
     The Change Order Template list view appears.
     Select a template and the Change Order detail page appears with pre-populated fields.

3. Complete the fields as appropriate for the change order.
   See Change Order Fields (see page 2281) for field definitions.

4. Use the controls available on the tabs at the bottom of this page to process the change order as appropriate.
   See Change Order Tabs (see page 2285) for more information.

5. Click an execution option. Following are options that are not self-explanatory:
   Create Incident
   Opens the Create New Incident page so you can create a incident ticket associated with this change order.
   Quick Profile
   Displays the contact information for the user entered in the Affected End User field.
   If you are creating a change order, a list of available users appears. You can select the user that is in the Affected End User field.
   Use Template
   Displays a list of available change order templates. You can select the template you want to use for creating this change order.

Change Order Fields

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

The following fields require explanation:

Note: When the Change Order is in Edit mode, the Update CI button is disabled to prevent the possibility of duplicate CIs being added. To add CIs to a Change Order, save the Change Order, and the Update CI button is available for your use.

- **Requester**

  Specifies the name of the person who initiated the ticket. This person must be a defined contact. You can enter a value directly or click the magnifier to search for the name.

- **Affected End User**

  Specifies the contact name of the person who is affected by the record. If the contact is assigned to a special handling type, special handling indicators are displayed. You can enter a value directly or click the magnifier to search for a contact name.

- **Category**
  Indicates the general category of the change within your IT environment (for example, Change.IT. Server.Configuration or Move.IT.Workstation). Change categories provide default values that are entered automatically on all change orders assigned to the category. In addition to the predefined change categories, your system administrator may define custom change categories. You can enter a value directly or click the magnifier to search for a category. When you edit the Category and a CA Process Automation workflow is already running, the workflow cancels.

  If a risk is associated with the specified change category, a Risk Survey button appears when you save the change order. This option opens a risk survey questionnaire for that change category.

  Your system administrator has the option of adding custom properties to change order categories. If custom properties have been added, they are displayed on the Properties tab when you create, edit, or view a change order. Some custom properties require that you enter a value.

- **Status**
  Specifies the status code of the record. For example, you can list only the tickets with a status code of Fix in Progress, or can Close Requested. You can enter a value directly or click the magnifier to search for a status. The blue button (on the left side of the Status field) lets you change the current status to the next default status.

- **Priority**

  Specifies the priority ranking of the record. The ranking determines the amount of attention the ticket receives. The predefined priority levels are 1 (highest) through 5 (lowest). Your system administrator or an active priority calculation can generate the appropriate Priority values for

various installations and tenants. When priority calculation is enabled, this field updates based on Impact, Urgency, Affected Service, and Affected User settings. When your administrator disables priority calculation and uninstalls the urgency_on_employee option, Self Service Users see the Priority field on the Request Detail page.

- **Type**
  Specifies the ITIL change type as Standard, Normal, or Emergency. A default value may be defined the change category.

- **Risk**
  Identifies the risk level of the change order. The risk level is determined by evaluating the risk survey associated with the change order.

The following fields provide change order details:

- **Created By**
  Specifies the name of the person who created or reported the record. This field is filled automatically with the current user's login information when the record is created.

- **Assignee**
  Specifies the name of the person who is assigned to handle the record. You can enter a value directly or click the magnifier to search for a name.

- **Group**
  Specifies the group that is responsible for this record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, or problems. Any contact who is part of the group can handle the record after it is assigned to the group. You can enter a value directly or click the magnifier to search for a group.

- **CAB**
  Specifies the group that is responsible for reviewing Requests for Changes (RFCs). The CAB provides multiple perspectives necessary to ensure proper decision making about implementing changes. The CAB can include members from the application team, development manager, component owner, QA, support, and any additional parties deemed necessary. You can enter a value directly or click the magnifier to search for a group.

- **ImpactImpact**

  Specifies an impact code, such as 1 -- Entire Organization, that indicates how a ticket affects work being performed. For example, a ticket that requires a network outage for several hours would have a higher impact than a ticket that takes a printer off-line. Your system administrator can modify the default impact codes, so they can vary from one installation to another.

- **Active**
  Indicates whether the record is Active or Inactive. This value applies to the current record only, not the associated template.

- **Need By Date**
  Displays the date that the change order needs to be completed by. You can enter the date in mm /dd/yyyy hh:mm am | pm format, or click the calendar icon to select a date.

- **Call Back Date/Time**
  Indicates the date on which a follow-up call for this change order should be made. On the date you specify, the change order displays on your scoreboard under the Today's Issue Callbacks category. You can enter the date in mm/dd/yyyy hh:mm am | pm format, or click the calendar icon to select a date.

- **Root Cause**
  Identifies the code associated with the core reason why the ticket was opened. Your service desk can use generic root cause codes, such as Hardware Failure or Software Failure, or more specific codes, such as Network.Cable, Network.Card, or Network.Response. You can enter a value directly or click the magnifier to search for a code.

- **Organization**
  Specifies the company, division, or department that is associated with the change order. You can select a value from the drop-down list.

- **Project**
  Identifies the project. You can associate a change order with a project in order to establish a connection to an external project in another product such as CA Clarity PPM or CA SCM. The Project you enter in this field contains the external project information, such as the project name or ID, to make the connection and integration between CA SDM and the external project. You can enter a value directly or click the search icon to search for a project.

- **Closure Code**
  Indicates the final outcome of a completed change as Successful, Unsuccessful, or Successful with Errors. You can also create custom closure codes.

- **External System Ticket**

  Specifies an identification for a ticket that belongs to an external system that integrates with CA SDM. This field stores hyperlinks and displays functional links in read-only mode.

The following fields provide change order summary information:

- **Order Summary**
  Gives an abbreviated description of the change order.

- **Spelling**
  Checks the spelling of the text you enter in the Order Summary field.

- **Order Description**
  Gives a detailed description of the change order.

- **Spelling**
  Checks the spelling of the text you enter in the Order Description field.

- **Schedule Start Date**
  Specifies the start date and time a change order appears on the Change Calendar pages. This field is optional, but must contain a date value if the Schedule Duration field contains a date value. Changes without an implementation date do not appear on the Change Calendar pages.

- **Schedule Duration**
  Indicates the amount of time required to implement the change in hours and minutes.

- **Schedule End Date**
  Indicates the end date and time a change order appears on the Change Calendar pages. This field is read-only. Its value is calculated from Schedule Start Date and Schedule Duration values.

- **CAB Approval**
  Indicates (Y/N) whether the change requires approval from a CAB. You can specify which changes are to be considered for CAB approval, by doing any of the following:

  - Set this option at change creation time or any subsequent time throughout the approval process.

  - Add an Action macro to set this field to Yes or No for use within classic workflow.

- **Open Date**
  Indicates the date and time at which the record was first created, in the time zone of the server. This field is filled in automatically when the change order is created. The date and time appear in mm/dd/yyyy hh:mm am | pm format.

- **Actual Start Date**
  Indicates the date and time at which the word Pending appears in the Status field for the change order. The date and time appear in mm/dd/yyyy hh:mm am | pm format.

- **Resolve Date**
  Indicates the date and time at which the change order is resolved. The date and time appear in mm/dd/yyyy hh:mm am | pm format.

- **Close Date**
  Indicates the date and time at which the change order is closed. The date and time appear in mm /dd/yyyy hh:mm am | pm format.

Change Order Tabs

The following tabs are available on the Create Change Order, Change Order Detail, and Update Change Order pages:

Related Tickets

- **Related Orders**
  Creates a parent and child relationship (see page 2277) between the change order and another change order.

- **Incidents / Problems**
  Attaches related incidents (see page 2266) and problems to a change order for analysts to reference.

- **Caused Requests**
  Attaches requests that the change order causes for analysts to reference.

Configuration Management

- **Configuration Items**
  Links configuration items (see page 2274) (CIs) to a change order to provide information to analysts about the system that the ticket affects. Configuration Items are automatically added to this list when a Change Specification is created.

- **Change Specifications**
  Lists the change specifications (see page 2622) that are associated with the CI and the verification status. Change specifications are highlighted in red if they have failed verification or require manual verification.

- **Verification Log**
  Displays logged information about change verification (see page 2230) activity for this Change Order. For example, this log identifies a CI where CACF detected a variance or rogue change. Verification log entries highlighted in red indicate the corresponding change specification is either Failed Verification or Manual Verification Active and may need further attention from the user.

Additional Information

- **Properties**
  Defines custom properties for change order categories.

- **Workflow Tasks**
  Associates Workflow (see page 1068) tasks with a change order.

- **Service Type**
  Associates a service event to indicate the level of support for the ticket.

- **Attachments**
  Attaches a document or a link to a URL to the change order (see page 2277).

- **Conflicts**
  Identifies change orders that conflict (see page 2246) with the one being viewed.

- **Templates**
  Creates a change order using a template (see page) using the current ticket as a model.

- **Costs / Plans**
  Calculates estimated cost and duration of the entire change order by adding the estimated cost and duration (see page 2273) of each task.

Logs

- **Activities**
  Displays a log of the activities (see page 2287) performed to resolve the change order.

- **Event Log**
  Displays a record of significant actions that occur regarding the change order (see page 2289).

- **Support Automation**
  Displays the assistance session log and lets you invite the end user to an assistance session.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Define a Category to a Change Order

For more information, see the Define a Category or Area (see page 1054) topic.

Add Activities to a Change Order

This article contains the following topics:

You can record all the actions that you are taking to resolve the ticket on the Activities tab. Activities can include actions such as research, calling a customer, and transferring responsibility to a different analyst. Some activities, such as "Initial" or "Field Update" are posted automatically when you create the ticket or update a field. Others, such as returning a call, changing the status, or transferring the ticket are posted when you select items from the Activities menu or from the Activities page itself.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. On the menu bar, click Activities, and then select one of the following options:
   - **Update Status** to update the status of the ticket.
   - **Callback** to record the time that is spent on the call.
   - **Research** to record the time spent conducting the research.
   - **Log Comment** to record your comments.
   - **Solution** to enter a description of the solution.
   - **Transfer** to reassign a problem to another technician.
   - **Escalate** to escalate the priority of a problem.
   - **Manual Notify** to send a manual notification to the user.
5. Edit the fields as appropriate. The following fields require explanation:

- **Internal?**
  Select this check box if the activity must only be visible to internal users.

- **Time Stamp**
  Specifies the date and time the activity began. This field shows the system date and time the activity record was opened. This field cannot be edited.

- **Date of Activity**
  The date and time the activity was performed. Defaults to the date and time the activity record was opened, but can be changed.

- **Time Spent**
  Specifies the amount of time that is spent on the activity. Enter this value in hours, minutes, and seconds (hh:mm:ss).

- **Related Ticket Activity Type**
  Specifies the type of activity that is generated for a related ticket, for example, Update Status

- **Change**
  Select an existing change order to which you want to attach the ticket.

- **Impact**
  Indicates the effect that the record has on tasks being performed. Your system administrator can modify the default impact codes, so they can vary from one installation to another.

6. Click Save.
   The activity is recorded on the Activities tab on the ticket details page.

Provide a Reason for Escalating the Ticket

If your priority calculation settings let you change Urgency and Impact values, you provide a reason for escalating the ticket. If priority calculation is not enabled, you can edit the priority field.

Follow these steps:

1. Open a ticket, such as an Incident or a Problem.
   The Ticket Detail page appears.

2. Modify the Urgency or Impact of the ticket.

3. Click Save.
   The Escalate Detail page appears and displays the current, read-only values for Priority, Urgency, and Impact.

4. Enter a reason for why you want to change the Urgency or Impact values.

5. Click Accept.
   The ticket is modified and the activity log updates with your changes.

Send a Manual Notification to a Temporary Email Address

You can send a manual notification to a temporary email address. For example, one that is not associated with a contact record.

Note: This operation is available only if the Administrator has installed the notification_allow_temp_address Update Options (Options Manager, Notifications).

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. On the menu bar, click Activities, Manual Notify.
   The Manual Notification page appears.
5. Complete the following field, and click Add Email.
   - **Email address**
     Specifies an SMTP address for an email recipient. You can specify temporary email addresses (for example, addresses not associated with a contact record). Separate multiple addresses with a semi-colon.

   Note: This field appears only if the Administrator installed the notification_allow_temp_address Update Options (Options Manager, Notifications).
   The address is added to the Recipients list.
6. Complete the remaining fields as appropriate.

   Note: You can also add a personalized response such as a generic or administrator signature to the notification. The response is added at the end of the message text. For more information about personalized responses, see Personalized Responses (see page 2287).
7. Click Notify.
   The manual notification is sent and the activity is recorded on the Activities tab of the ticket Detail page.

View Change Order Events

This article contains the following topics:

- Event Logs (see page 2291)

The Event List contains a record of the events that are associated with the ticket. Your administrator maintains events, or procedures the system perform after a certain amount of time has elapsed. For example, an event might send a message to an analyst if a Priority 1 ticket is not resolved within an hour.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Select the desired ticket from the list that appears.
4. Click the Event Log tab at the bottom of the details page.
   A list of events for this incident appears.

View the Event History

You can view the event history for a ticket to see what actions have been performed to resolve the ticket.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority level for the desired ticket.
3. Select the desired ticket from the list that appears.
4. Select View, Event History on the detail page menu bar.
   The Event History window displays the following fields:

   - **Condition**
     Indicates the condition checked for by the event. CA SDM provides macros that check for standard conditions such as priorities and object status (open or closed).
   - **Event**
     Indicates the name of event that is associated with this row in the Event History list.
   - **Status**
     Indicates whether the event is active or inactive.
   - **Check Time**
     Indicates the time that the event was checked, based on time parameters that are specified in the event configuration.
   - **Time Loaded**
     Indicates the time that the event was loaded, based on time parameters that are specified in the event configuration.

View the Event Delay History

You can view the event delay history for a ticket to see descriptions of the service type event delays. Service type event delays let you suspend a service type event to prevent a service level violation.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority level for the desired ticket.
3. Select the desired ticket from the list that appears.
4. Select View, Event Delay History on the detail page menu bar.
   The Event Delay History window displays the following fields:
   - **Start Time**
     Indicates the date and time the delay began.
   - **Stop Time**
     Indicates the date and time the delay ended.
   - **Actual Delay**
     Indicates the actual duration of delay.
   - **Effective Delay**
     Indicates the effective duration of delay.
   - **Service Type**
     Defines the support level that is assigned to the ticket (for example, four-hour service requirement).

Event Logs

The Event Log displays significant actions that are performed by the user, such as on tickets. For example, you submit a Knowledge Document and link it to an Incident. The Incident logs a failed status transition or detected Change Conflict. In this example, the Contact detail can display the following types of information:

- The log displays the time that the user logged in to CA SDM and when they closed the session.
- The user accepted the Terms of Usage.
- The user created a Knowledge Document.
- The user created a ticket, such as an Incident, Problem, Request, or Change Order.
- The user used a Knowledge Document to avoid creating a ticket.

Change Calendar

Contents

The *Change Calendar* provides a graphical view of change events with implementation start and end times. This calendar view of the change schedule provides analysts and managers a quick way to identify when events occur and how they affect the environment, organization, and resources.

The calendar lets you create change orders from the daily, weekly, and monthly views and also lets you view global change windows for scheduled change orders. If multiple change windows exist in a month, they are grouped, such as in a single Blackout Window group. Drill down to a weekly or daily view, or view hover information to see the individual window details.

You can only export (see page 2296) Change Order schedules, not Change Windows.

View the Change Calendar

You can configure the view of the Change Calendar page to display a calendar of the change orders of interest.

You can create a Change Order from the File menu, the Create New button on the Change Calendar page, or the context menu on the daily and monthly calendar views. The context menu also lets you create a Change Order from a template.

Follow these steps:

1. Click the Change Calendar tab.
   The Change Calendar filter fields appear.

2. Display a calendar view showing the schedule for the change orders of interest by completing the Change Calendar search fields (see page). Click Search.
   The Change Calendar provides the following filter fields to restrict the change orders displayed on the schedule:

   - **Active**
     Filters by whether the change orders are active (open) or inactive (complete).

   - **Priority**
     Filters by the priority ranking of the change orders.

- **Status**
  Filter by the status of the change order. You can enter the status directly or click the search icon to search for the desired status.

- **Category**
  Filters by the category of change order. You can enter a value directly or click the browse icon to select from defined categories.

- **Group**
  Filters by the group responsible for the change order. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, change orders, and so on. Any individual contact assigned to the group can handle the record once it has been assigned to the group. You can enter the value directly or click the search icon to search for the group.

- **Parent**
  Filters by the parent change order.

- **Change Type**
  Filters by the type of change order as Emergency, Normal, or Standard.

- **CI Name**
  Filters by the name of the Configuration Item. You can enter a value directly or click the browse icon to search for the desired Configuration Item.

- **CI Class**
  Filters by the class of the Configuration Item. You can enter a value directly or click the browse icon to select from defined categories.

- **CI Family**
  Filters by one of the following Configuration Item families:

  - Computer
  - Hardware
  - Other
  - Projects
  - Service
  - Software

- **Conflict Status**
  Filters by the conflict status of a change order. You can enter a value directly or click the browse icon to select from defined categories.

- **Closure Code**
  Filters by the closure code of a change orders.

- **CAB**
  Filters by CAB member. You can enter a value directly or click the browse icon to select from defined groups.

- **CAB Approval**
  Filters by change orders that do not require CAB approval (N) or that do require CAB approval (Y).

- **Risk**
  Filters by the risk level of a change order.

- **Schedule Start Date**
  Specifies the beginning of an implementation date range for the change orders you want displayed on the schedule. If you do not enter a value in this field, the filter selects all change orders with a non-null target implementation start date. Regardless of whether or not you enter a value in this field, the initial view always includes the first change order actually selected for the schedule.

- **Schedule End Date**
  Specifies the end of an implementation date range for the change orders you want displayed on the calendar. If you do not enter a value in this field, the filter selects all change orders with a non-null target implementation end date.

- **Schedule Timezone**
  Specifies a time zone to view your search results.

  
  If no time zone is selected, the events are displayed in your current time zone.

- **Initial View**
  Select the view of the Change Order Calendar you want to see:

  - **Month**
    Displays a schedule for the full month that includes the first change order selected by the filter. The schedule shows change orders grouped by change type and schedule start and end date.

  - **Week**
    Displays a schedule for a the week that includes the first change order selected by the filter. The schedule seven consecutive days in a single column, beginning with the weekday configured as the starting weekday at your installation. The schedule shows individual change orders, and includes summary information about each one

  - **Day**
    Displays a view similar to the week view, except that it shows only a single day's change orders.

  - **n Days**
    Displays a view similar to the week view, except that it can begin on any day of the week, and continues for the specified number of days.

- **List**
  Displays a standard list page.

iCalendar Event Templates

iCalendar event templates control the information that is exported to iCalendar format. The following predefined templates are installed with CA SDM:

- Change Schedule
- KnowledgeScheduleCreation
- KnowledgeScheduleExpired
- KnowledgeScheduleReview
- KnowledgeScheduleStart

You can edit the predefined iCalendar event template codes, but you cannot delete them or create new ones.

The SchedExpMaximum variable in web.cfg controls the maximum events allowed for an export. Increasing the default (1000) could cause system instability. If you attempt to export more than the value specified in SchedExpMaximum, a message appears refusing your exporting request.

iCalendar Event Template Fields

The following fields require explanation:

- **Symbol**
  Defines the display name by which you want to identify the event template within your system.
- **Code**
  Defines a localized and independent code for the event template.
- **Record Status**
  Specifies whether the record is active or inactive.
- **Object Type**
  Displays the object type such as Change Order or Knowledge Document.
- **Alarm**
  Allows you to set a display alarm (such as 1 Day before or 1 Hour before) for each event that creates a calendar.

- **Category**
  Displays the field property for the event template. This is similar to how message templates are processed.

- **URL**
  Displays the field property for the event template. This is similar to how message templates are processed.

- **Extra Entries**
  Allows you to add other properties (not managed by CA SDM) to the event.

Export Schedules to iCalendar

CA SDM lets you export Change Orders in the standard iCalendar format. This data exchange lets you import Change Order schedules into many widely used calendaring applications, including Microsoft Outlook and Lotus Notes.

When exporting schedules on some calendaring programs, choosing the Open option instead of Save causes the file to import incorrectly. To avoid this issue on Knowledge Management and Change Order schedules, select the Save option instead of Open. After you save the exported file, import it through the interface of the calendar program interface. You cannot export Change (blackout and maintenance) Windows, only Change Orders.

The data you export is based on the current view. If you want to export a custom range of dates, such as 32 days, the export should be done from the list view. Otherwise, the view is truncated to a month or week, and it only exports that amount.

Follow these steps:

1. Click the Change Calendar tab.
   The Change Calendar filter fields appear.

2. Complete the search fields to display a calendar or list view that includes the change orders of interest.

3. Click Export.
   The Schedule Export page appears.

The SchedExpMaximum variable in web.cfg controls the maximum events allowed for an export. Increasing the default (1000) could cause system instability. If you attempt to export more than the value specified in SchedExpMaximum, a message appears refusing your exporting request.

4. Enter the location where you want to save an iCalendar file.
   An iCalendar file containing all events in the current view is saved at the specified location.

Use the Change Calendar Tab

This tab displays only if you have access to the Change Calendar.

The Change Calendar tab provides access to the schedule to view change order impacts on your system. From the Change Calendar tab, you can:

- Search for change orders
- Filter and sort change orders and configuration items
- Create change orders
- View CIs associated with change orders
- View change windows
- View CIs associated with change windows

You can use the schedule (see page 2292) to view and manage change orders. Create change orders from the schedule and search for change orders and configuration items.

To search for items within the schedule, use the search filter. Complete one or more of the search entry fields and click Search. The list pane populates with all items that match your search criteria.

View and Configure Scheduling Views

This article contains the following topics:

Schedule Views

CA SDM provides the following scheduling views:

- **List**
  Displays a list page sorted by schedule start and end date.

- **Month**
  Displays a calendar for a full month.
  The view shows change orders in groups, with each entry collecting one or more change orders. You can see detailed information about the change orders in a group by hovering over the group with the mouse; by pressing Alt+Right Arrow when the focus is on the group; or by clicking on the group to display its contents in an n-day view.

- **Week**
  Displays a full week in a single column, starting with the day configured as the first weekday.
  The view shows changes individually and includes detailed information about each change order scheduled during the week.

- **Day**
  Displays change orders for a single day.
  The view shows changes individually and includes detailed information about each change order scheduled during the day.

- ***n* Days**
  Displays change orders for the number of days specified by the dropdown selector.
  The view shows changes individually and includes detailed information about each change order scheduled during the days selected.

Navigating the Schedule Views

You can use the arrow and tab keys to navigate the scheduling views. The following keyboard shortcuts are available:

- **Tab**
  Navigates to a later date. Use this from the last cell in the schedule to navigate to the Search button.

- **Shift+Tab**
  Navigates to a previous date. Use this from the first cell in the schedule to navigate to the Next Month button.

- **Shift+Arrow**
  Navigates around the calendar from date to date in the direction of the arrow.

- **Right Arrow**
  Displays the context menu for the currently focused date or event. If there is no context menu, it navigates to the next higher date (similar to Shift+Right Arrow).

- **Alt+Right Arrow**
  Displays a hover information popup for the currently focused date or event. If there is no hover information, it navigates to the next higher date (similar to Shift+Right Arrow).

- **Down Arrow**
  Navigates to the next event in the current cell. If there are no events in the current cell, or if the focus is already on the last event, it navigates to the date in the next cell down (similar to Shift+Down Arrow).

- **Up Arrow**
  Navigates to the previous event in the current cell. If focus is not on an event, it navigates to the date in the next cell up (similar to Shift+Up Arrow).

Calender View Hotkeys

Each schedule view supports hotkey access to its buttons. The following are the supported hotkeys:

- **Alt+0**
  Switch to list view.
- **Alt+1**
  Switch to daily view.
- **Alt+7**
  Switch to weekly view.
- **Alt+3**
  Switch to monthly view.
- **Alt+9**
  Switch to *n*-day view.
- **Alt+<**
  Move to previous time period in current view.
- **Alt+>**
  Move to next time period in current view.

Scheduling View Configuration

You configure the monthly and weekly scheduling views by specifying pdm_macro statements in the <head> section of the HTMPL forms defining the schedule. We recommend using the Source View of Web Screen Painter to edit these forms.

Any form that displays a schedule must contain the following:

- A schedConfig macro
- At least one schedAttr macro
- At least one schedGroup macro

The configuration macros are in a separate source file referenced by a pdm_include statement in the main source file. This file lets you configure your schedule without modifying the main source file.

For example, the configuration macros for the Change Calendar form list_chgsched.htmpl are in a file named list_chgsched_config.htmpl. For the Knowledge Lifecycle Schedule, you can modify the list_kdsched_config.htmpl using the same macros.

You can find list_chgsched_config.htmpl and list_kdsched_config.htmpl in the following directory:

$NX_ROOT\bopcfg\www\htmpl\web\analyst\

schedConfig Macro -- Configure Schedule

The schedConfig macro specifies that a form contains a schedule and provides basic configuration information. The following values are valid macro arguments:

- **autosearch=1|0**
  Specifies whether the schedule form reloads data from the server when the user selects a view outside the currently selected date range. Setting the value to 1 (default) causes the form to search automatically when the user selects a view with one or more days outside the date selection range of the search filter. Setting the value to 0 requires the user to press the Search button to initiate a search.

- **defaultView=0|1|7|30|99**
  Specifies the default view for the search filter as 0 (list), 1 (day), 7 (week), 30 (month), or 99 (n-day).
  The specification for defaultView affects only the initial display of the search filter. After the schedule displays, CA SDM automatically keeps the filter view selection aligned with the current view.
  Default: 30

- **firstday=0|1|2|3|4|5|6|7**
  Specifies the first weekday on the monthly view as a number between 0 (Sunday) and six (Saturday).
  Default: 0

- **export=xxx|0**
  Specifies the code name of the template used for exporting in iCalendar format. Setting the value to 0 indicates the export feature and button are disabled.
  Default: ChangeSchedule

- **legend=1|2|0**
  Specifies the location of the schedule legend showing the name and formatting of the groups on the schedule. You can set the value to 1 to position the legend above the schedule, or 2 to position the legend below the schedule. Set the value to 0 to disable the legend.
  Default: 2

- **maxGroups=0/*n***
  Specifies the maximum number of groups to be displayed in a single cell of the calendar month view.
  If there are more than maxGroups scheduled for a single day, CA SDM displays only the first maxGroups-1, and replaces the last with a "..nn more changes" hyperlink that the user can mouseover or click to see the full list. Set the value to 0 to disable this feature and allow an unlimited number of events in a calendar cell.
  Default: 4

- **nday=(n,n,...)**
  Specifies selections for the drop-down list for the n-day view.
  The specification is a list of day counts that are to be included in the drop-down list, or 0 to indicate that the n-day drop-down list is omitted from the schedule. The first value specified is the default for the drop-down list.
  Default: (3,7,14,28)

- **round=(*hr,min*)|0**
  Specifies whether schedule start and end dates are rounded when collecting change orders or knowledge documents into groups. Specify round=0 to disable rounding.
  By default, schedule start and end date groups objects. All CA SDM dates include a time, and without rounding, objects scheduled as little as a minute apart would be in separate groups. Rounding determines the group after adjusting the start date to an earlier hour or minute and the end date to a later hour or minute.
  The value of round specifies either an hour or a minute (but not both). Times are rounded to the nearest multiple of the value specified, for example:
  round=(0,15) rounds to the nearest quarter hour
  round=(0,30) rounds to the nearest half hour
  round=1 rounds to the nearest hour
  round=12 rounds to the nearest half day (12:00 AM or PM)
  round=24 rounds to the nearest day
  Default: (0,15)

- **timefmt=24hr|([am],[pm])**
  Specifies the format of times on the calendar views of the schedule.
  The default value of 24hr specifies that times are displays in 24 hour format (0:01 - 23:59). The alternative value of (am,pm) specifies a suffix for either morning or afternoon times, or both.

All schedConfig arguments are optional.

schedAttr Macro -- Specify a Stored Attribute

The schedAttr macro specifies an attribute stored for each item selected for the list. Stored attributes are available for hover information on the monthly view, for the detailed or summary information in views other than the monthly view, and in the setSchedEvents() JavaScript function. The following values are valid macro arguments:

- **attr=xxxx**
  (Required) Specifies an attribute from the object on the schedule, such as a change order or Knowledge Document. Dotted attributes are permitted. The keyword attribute name CI*nn* can be used on the Change Calendar to specify that first *nn* CIs associated with the change order are included with the information stored.

  This argument is the only required argument for the schedAttr macro.

- **attrRef=.COMMON_NAME|xxxx**
  Stores the attribute of the referenced table stored for an SREL attribute (ignored for non-SREL attributes). The attribute name specified must be prefixed with a dot.
  Default: .COMMON_NAME

- **label=**
  Displays a label for the attribute on the n-day view.
  Default: the Majic DISPLAY_NAME of the attribute

- **ident=1|0**
  Specifies whether the attribute is an identifier for the object (such as a reference number of a change order). Identifier attributes are displayed without a label in front of the group name in hover information and the n-day view.
  Default: 0

- **detail=1|0**
  Specifies whether the attribute is included in the detail information shown on views other than the monthly view. Detail information is the information shown when the Summary Only check box on the view is not selected.
  Default: 1

- **hoverInfo=1|0**
  Specifies whether the attribute is included in the hover information pop-up displayed on the monthly view when the mouse pointer hovers over a group, or the user presses Alt+Right Arrow when focus is on the group.
  Default: 0

- **summary=1|0**
  Specifies whether the attribute is included in the detail information shown on views other than the monthly view. Detail information is the information shown when the Summary Only check box on the view is not selected.
  Default: 0

CA SDM displays attributes in summary, detail, or hover information in the same order as their schedAttr macros.

schedGroup Macro -- Specify an Event Group

The schedGroup macro specifies the name and color coding of a group of items. The monthly view aggregates all items in a group into a single event. Views other than the monthly show individual items in the format for the group to which they belong. The following optional values are valid macro arguments:

- **grpname=xxx**
  (Required) Specifes the name of the group. The macro automatically assigns a number to the group and assigns the number to a JavaScript variable with a name of the form schedGroup_xxx, where xxx is the name of the group. This variable can be used in the setSchedEvents() JavaScript function to create an event belonging to the group.

  This argument is the only required argument for the schedGroup macro.

- **label=xxx**
  Specifies a label for the group. If specified, the label is displayed in all views.

- **legend=xxx|0**
  Displays a description of the group for the legend that appears at the bottom of the schedule. Groups appear in the legend if at least one example of the group exists in the current view. Specifying 0 causes the group always to be excluded from the legend.
  Default: 0

- **color=black|*color***
  Specifies the color of text in items of this group. You can specify color in CSS format, either a valid web color or a hexadecimal value preceded by a pound sign.
  Example: Enter either "#FF0000" or "red" for red.
  Default: black

- **bgcolor=white|*color***
  Specifies the background color of items of this group. You can specify bgcolor in CSS format, either a valid web color or a hexadecimal value preceded by a pound sign.
  Example: Enter either "#FF000" or "red" for red.
  Default: white.

- **style=normal|bold|italic**
  Specifies the style of text of this group in the normal, bold, or italic style.
  Default: normal

Configure Blackout and Maintenance Windows on the Change Calendar

You edit PDM_MACRO statements in list_chgsched_config.htmpl to modify colors, labels, legends, and icons for change windows.

If you use schedGroup macros to change the formatting of windows on the Change Calendar, you must also update *schedule.css* if you want the formatting to be consistent with the Change Scheduler.

To configure change windows

1. Open the *list_chgsched_config.htmpl* form in a text editor or WSP.
   You can locate this file in the following directory:

   ```
   $NX_ROOT\bopcfg\www\htmpl\web\analyst\
   ```

2. On the schedGroup macro, modify the following PDM_MACRO statements:
   For maintenance windows:

   ```
   <PDM_MACRO NAME=schedGroup grpname=maintWindow
       bgcolor=lightgreen
       label="Maintenance"
       legend="Maintenance Window"
       icon= "confirmation_12.png">
   ```

   For blackout windows:

```
<PDM_MACRO NAME=schedGroup grpname=blackoutWindow style=italic color=white
    bgcolor=black
    label="Blackout"
    legend="Blackout Window"
    icon= "warning_12.png">
```

- **bgcolor**
  Specifies the background color of the window.

- **label**
  Specifies the window label as Blackout or Maintenance.

- **legend**
  Specifies the text of the legend as it appears on the Change Calendar.

- **icon**
  Specifies an optional URL to a 12x12 pixel web graphic.
  This icon displays with a change order or group on the Change Calendar if the change order lies completely within a maintenance window or overlaps a blackout window.

3. Save the form.
   The change windows are configured.

The setSchedEvents() JavaScript Function

The setSchedEvents() JavaScript function creates events in the schedule. Modify this function when you want to view any new group objects. The predefined group objects appear by default.

CA SDM calls setSchedEvents() once for each object (change order or knowledge document) selected by the schedule search filter. The function creates events for the object by calling a second function, schedEvent(), and passing the group ID, start date, and end date of the event.

The function can create any number of events (including zero) for an object. The default setSchedEvents() function for the Change Calendar (list_chgsched.htmpl) creates one event for each change order and groups change orders by change type. This function is coded as follows:

```
1.    function setSchedEvents( chg )
2.    {
3.    var grpnum;
4.    switch( chg["chgtype"] - 0 ) {
5.        case 100: grpnum = schedGroup_std;  break;
6.        case 300: grpnum = schedGroup_emer; break;
7.        default:  grpnum = schedGroup_norm; break;
8.    }
9.    chg.schedEvent( grpnum, chg["sched_start_date"], chg["sched_end_date"] );
10.    }
```

The case parameter specifies the change type ID.

The function has a single argument of a JavaScript object containing the attributes specified by schedAttr macros. The switch statement in lines 4-8 examines the chgtype attribute of the change order, and assigns the appropriate group number from one of the schedGroup_xxxx variables defined by previous schedGroup macros. On line 9, it calls the schedEvent() function to create an event in the schedule, passing the group number previously assigned and the schedule start and end dates. The dates are available in the argument object because they were specified in earlier schedAttr macros.

How to Schedule Change Windows

Contents

Schedule Change Order

You can schedule change windows and view them in the Change Calendar. *Maintenance windows* establish time periods when CI changes should occur, and *blackout windows* establish time periods when CI changes should *not* occur. Change windows help you schedule changes to minimize their effect on critical business processes. CA SDM can implement change windows at the global or system level.

To schedule change windows, do the following:

1. View the Change Calendar to see where you want change windows.

2. Create the appropriate change windows for your organization.

   - **Maintenance Window**
     Indicates a scheduled time period during which a CI or a set of CIs can be changed. Because changes can involve downtime, these windows can be used to minimize disruptions to critical business processes. In general, scheduled changes should occur inside a maintenance window.

   - **Blackout Window**
     Indicates a scheduled time period during which CI changes should not occur. This blackout can indicate a reduced support period (for example, a holiday), a corporate event, or a critical business time, such as fiscal year-end. In general, scheduled changes should only occur outside blackout windows.

   - **Global Change Windows**
     Indicates a blackout or maintenance window that occur for your entire organization. For example, you want to create a global (see page 2308) blackout window named Holiday that starts in November and ends in January in the American - East timezone. This blackout window does *not* allow non-emergency changes between these dates. Global change windows do not associate with specific CIs because they apply to all CIs.

3. (Optional) Specify the recurrence patterns of the change windows.

4. Open the Change Calendar.
   The legend displays icons and colors to identify change windows in the schedule.

5. Create change orders associated with CIs.

6. Update the Change Calendar by using the Change Scheduler.

Define Change Windows

You can define change windows to avoid collisions on the Change Calendar. For example, you want to create a global (see page 2308) blackout window named Holiday that starts in November and ends in January in the Amercan - East timezone. This blackout window does *not* allow nonemergency changes between these dates.

Follow these steps:

1. On the Administration tab, select Service Desk, Change Orders, Change Windows.
   The Change Windows List appears.

2. Click Create New.
   The Create New Change Window page appears.

3. Complete the required fields for the change window.

4. Specify one of the following recurrence patterns:

   - **None**
     Specifies no recurrence pattern.

   - **Daily**
     Specify either the number of days between recurrences, or that the window should recur every day.

   - **Weekly**
     Specifies the number of weeks between recurrences, and the weekdays when the window recurs. Windows longer than 24 hours can only recur on a single weekday.

   - **Monthly**
     Specifies the number of months between occurrences, and the day of the recurrence. The day can be specified either absolutely (for example, the 7th of the month) or positionally (for example, the second Monday of the month).

   - **Yearly**
     Specifies the number of years between occurrences, and the day of the recurrence. The day can be specified either absolutely (for example, March 7th) or positionally (for example, the second Monday of March).

   - **End by**
     Specifies the end of the recurrence.

5. Save and close the window.
   The change window appears in the Change Window List.

Associate a CI with a Maintenance Window

To control when a CI undergoes maintenance, you can associate that CI to a maintenance window.

Follow these steps:

1. Navigate to the Change Window Detail page.
2. Click the Associated CIs tab.
   The Associated CIs list appears.
3. Click Update Configuration Items.
   The CI Search page appears.
4. Specify information for the required CIs.
5. Click Search
   The Available CIs page appears.
6. Move any required CIs in the Available CIs list to the Associated CIs list.
7. Click OK.
   The Change Window Detail page appears.
8. Click Save.
   The CI is associated with a maintenance window.

The change window, the CIs and the selected window associations are saved.

Create a Blackout Window Example

The following example creates a blackout window to indicate that your organization does not schedule change orders for a specific time period. You want this blackout window to last 48 hours and recur every Friday at 6:00 PM in your time zone.

Follow these steps:

1. On the Administration tab, click Service Desk, Change Orders, Change Windows.
   The Change Windows List appears.
2. Click Create New.
   The Create New Change Window page appears.
3. Complete the appropriate fields as follows:
   a. Enter **Friday_Blackout** as the window name.
   b. Select the type Blackout.

c. Select the Active status.

d. Select the upcoming Friday and 6:00 PM from the Date Helper as the Start Date.

e. Select the upcoming Sunday and 6:00 PM from the Date Helper as the End Date.

f. Select your time zone.

g. (Optional) Enter a description for the blackout window.

h. On the Recurrence Pattern tab, select Weekly.

- Set the recurrence to every **1** week.
- Select the date to end the recurrence.

4. Save and close the blackout window.

Create a Global Maintenance Window

Create a global maintenance window for your organization. For example, you do *not* want to define maintenance windows by server or CI and want to complete global changes during weekends.

Follow these steps:

1. Navigate to the Change Windows List page.
2. Click Create New.
3. The Create New Change Window page appears.
4. Enter or modify the necessary fields for the maintenance window.
5. Set Type to Maintenance.
6. Verify that the Global checkbox is checked.

A global maintenance window cannot be associated with CIs.

7. Enter Start Date, End Date, and Timezone.
8. Click Save.
   The global maintenance window is saved.

Ticket Management

Contents

A ticket can be an incident, problem, change order, issue or request

Use the Quick Profile

You can view detailed information about the contacts and organizations that make up your enterprise. Depending on your role, you can access the Quick Profile in the following ways:

- For the roles that use the Quick Profile frequently, click the Quick Profiles tab.
- For the roles that use the Quick Profile less often, select the View, Quick Profile command on the menu bar of a Scoreboard tab.
- For the roles that create new tickets using the Quick Profile, click the Quick Profile button on ticket detail pages.

You can use the Quick Profile as follows:

- Shows contact and organization information, environment, and history in the left pane.
- Display the windows for different types of contact history depending on your latest selection in the right pane.
- View the Scratchpad, which allows you to enter description information to the record you are creating in the bottom pane.

Quick Profile Scratchpad

You can use the Scratchpad Area at the bottom of the Quick Profile screen to merge information about the current user into new incidents, requests, issues, change orders, and activity logs. You can merge the text and contact information into a new record. You can also use existing templates to create records.

Note: The type of tickets that you can create from the Scratchpad Area depends on the Preferred Document setting for the Access type of the selected contact. Your administrator determines this setting. This setting also determines the type of tickets that the "Quick" button labels use in the Scratchpad Area.

The Quick Profile Scratchpad lets you perform the following tasks:

- Check the spelling of the text in the scratchpad by clicking Spelling.
- Search the knowledge base using the keywords that are entered in the scratchpad by clicking Search Knowledge.
- Clear all text from the scratchpad by clicking Clear Scratchpad.
- Create a ticket using the data from the scratchpad and immediate close the ticket by clicking Quick Close.
- Create a ticket quickly using the selected template by clicking Quick. No detail page displays, but a message indicating the results of the quick create process is displayed.
- Create a ticket by opening the detail page for the ticket type that is selected in the Type field. The text that is entered in the Scratchpad Area displays in the Description field of the new ticket, and the current contact is the Affected End User of the new ticket.

Add Activities to a Ticket

You can record all the actions that you are taking to resolve the ticket on the Activities tab. Activities can include actions such as research, calling a customer, and transferring responsibility to a different analyst. Some activities, such as "Initial" or "Field Update" are posted automatically when you create the ticket or update a field. Others, such as returning a call, changing the status, or transferring the ticket are posted when you select items from the Activities menu or from the Activities page itself.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. On the menu bar, click Activities, and then select one of the following options:
   - **Update Status** to update the status of the ticket.
   - **Callback** to record the time that is spent on the call.
   - **Research** to record the time spent conducting the research.
   - **Log Comment** to record your comments.
   - **Solution** to enter a description of the solution.
   - **Transfer** to reassign a problem to another technician.
   - **Escalate** to escalate the priority of a problem.
   - **Manual Notify** to send a manual notification to the user.

5. Edit the fields as appropriate. The following fields require explanation:

   - **Internal?**
     Select this check box if the activity must only be visible to internal users.

   - **Time Stamp**
     Specifies the date and time the activity began. This field shows the system date and time the activity record was opened. This field cannot be edited.

   - **Date of Activity**
     The date and time the activity was performed. Defaults to the date and time the activity record was opened, but can be changed.

   - **Time Spent**
     Specifies the amount of time that is spent on the activity. Enter this value in hours, minutes, and seconds (hh:mm:ss).

   - **Related Ticket Activity Type**
     Specifies the type of activity that is generated for a related ticket, for example, Update Status

   - **Change**
     Select an existing change order to which you want to attach the ticket.

   - **Impact**
     Indicates the effect that the record has on tasks being performed. Your system administrator can modify the default impact codes, so they can vary from one installation to another.

6. Click Save.
   The activity is recorded on the Activities tab on the ticket details page.

Provide a Reason for Escalating the Ticket

If your priority calculation settings let you change Urgency and Impact values, you provide a reason for escalating the ticket. If priority calculation is not enabled, you can edit the priority field.

Follow these steps:

1. Open a ticket, such as an Incident or a Problem.
   The Ticket Detail page appears.

2. Modify the Urgency or Impact of the ticket.

3. Click Save.
   The Escalate Detail page appears and displays the current, read-only values for Priority, Urgency, and Impact.

4. Enter a reason for why you want to change the Urgency or Impact values.

5. Click Accept.
   The ticket is modified and the activity log updates with your changes.

Send a Manual Notification to a Temporary Email Address

You can send a manual notification to a temporary email address. For example, one that is not associated with a contact record. This operation is available only if the Administrator has installed the notification_allow_temp_address Update Options (Options Manager, Notifications).

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. On the menu bar, click Activities, Manual Notify.
   The Manual Notification page appears.
5. Complete the following field, and click Add Email.
   - **Email address**
     Specifies an SMTP address for an email recipient. You can specify temporary email addresses (for example, addresses not associated with a contact record). Separate multiple addresses with a semi-colon. This field appears only if the Administrator installed the notification_allow_temp_address Update Options (Options Manager, Notifications).

   The address is added to the Recipients list.
6. Complete the remaining fields as appropriate.

   Note: You can also add a personalized response such as a generic or administrator signature to the notification. The response is added at the end of the message text. For more information about personalized responses, see Personalized Responses (see page 2316).
7. Click Notify.
   The manual notification is sent and the activity is recorded on the Activities tab of the ticket Detail page.

Attach to Existing Change Order

You can attach an incident, problem, or request, to a related change order. Change orders are requested changes that vary from the original scope of a specific project or task.

Follow these steps:

1. On the Service Desk tab, select the incident, problem, or request to which you want to attach the change order.
   The ticket detail page appears.

2. Select Activities, Attach to Existing Change Order on the menu bar.
   The Attach Change Order to Incident page appears.

3. Click Change.
   The Change Order Search page opens.

4. Enter the search criteria that you want to use and click Search.
   A list of change orders matching the search criteria appears.

5. Select the desired change order from the list.
   The Attach Change Order to Incident page displays the selected change order number in the Change field.

   Note: If you know the Change Order number, you can type it in the Change field.

6. (Optional) Enter the comments in the Remarks field.

7. Click Attach.
   The ticket is attached to the change order, and the activity is recorded on the Activities tab on the ticket detail page.

Detach Change Order

You can end the association between an incident and an attached change order.

Follow these steps:

1. On the Service Desk tab, select the desired incident, problem, or request from which you want to detach the change order.
   The ticket detail page appears.

2. Select Activities, Detach Change Order on the menu bar.
   The Detach Change Order from Incident page appears.

3. Click Detach.
   The ticket is detached from the change order, and the activity is recorded on the Activities tab on the ticket detail page.

_Attach a Service Type Event

Contents

- Delay or Resume a Service Type Event (see page 2314)

Attach a Service Type Event

Service types determine the level of support that is given for a ticket. You can associate service type events with tickets. An event that is associated with a service type is attached to records defined with that service type.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Select the desired ticket from the list that appears.
4. Choose the Service Type tab, and click Attach Service Type Event.
   OR
   Choose Actions, Attach Service Type Event.
   The Attach Service Type Event page appears.
5. Click Service Type Event.
   The Event Search page appears.
6. Complete one or more of the search fields, and click Search.
   The Event List displays the events that match your search criteria.
7. Select the desired event.
   The Attach Service Type Event page appears.
8. Click OK.
   The Delay Time field appears. The delay time indicates the interval of time after which the event occurs.
9. Specify the delay time as hh:mm:ss (hours, minutes, seconds).
   For example, if the event is attached to the incident at 2:20, and the Delay Time is 01:00:00 (one hour), the event occurs at 3:20.
10. Click OK.
    The ticket detail page appears with the event listed on the Service Type tab.

Delay or Resume a Service Type Event

You can delay and resume service type events.

Follow these steps:

1. Select the desired ticket from the list page on the Service Desk tab.
   The ticket detail page appears.
2. Select the Service Type tab.
   A list of any service type events that have been added to the ticket appears.

3. Click Delay or Resume.
   The Reason page appears.

4. Enter the reason, and click OK.
   The ticket detail page displays the Status of the event.

Create an Issue Template

You can define a ticket, such as an incident, problem, issue, change order, or request, to serve as a model for future tickets. You can then save it as a template. Tickets that are created with that template have certain fields auto-populated with your specified values.

Follow these steps:

- You can use a new ticket to create a template to be used when creating future tickets. Complete the following fields:

  1. a. On the Service Desk tab, click the File menu and select the ticket type for the template. For example, to create an incident template, click File, New Incident.

     b. Complete the ticket template fields (see page) as appropriate for the template in the page that opens.

     c. Select the Template tab at the bottom of the page.

     d. Click Save.

- You can use an existing ticket to create a template.Complete the following fields:

  1. a. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.

     b. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

     c. Select the desired ticket from the list that appears.

     > **Note:** Some roles can only access certain ticket types through the Search menu on the Service Desk menu bar.

     d. Click Edit.

     e. (Optional) Edit the ticket template fields (see page) as appropriate.

     f. Select the Template tab at the bottom of the page.

     g. Click Save

Ticket Template Fields

Complete the following fields:

Template Name
This name appears in the list of available templates.

Template Class
(Optional) You can assign a class to the template.

Quick Template Type
You can use quick templates to define new requests on the Quick Profile Scratchpad. Select one of the following options:

- None
- Quick
- Review Before Save

Template Active
Specifies whether the template is active or inactive in the database.

Description
Describe the template settings and intended usage. This field can be used as a filter when searching for a template. Wildcard searches are supported.

Personalized Response

Personalized Responses are frequently used when you respond to customers. You can create and attach these predefined responses to all ticket types when updating activities for the record. For example, you can append personalized response information to an updated status or a logged comment.

Create a Personalized Response

Create a personalized response so that you can add them in your response to customers.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. From the Scoreboard, choose File, New Personalized Response.
   The Create New Personalized Response page displays.

2. Fill in the fields as follows:

- **Name** -- Unique identifier and key for the response. This field can be up to 50 alphanumeric characters long.
- **Response Owner** -- Name of the contact that owns the personalized response. If this field is left blank, the response is available to all analysts. Enter the contact name directly into this field, or click the search icon to search for the desired contact name.
- **Record Status** -- Indicates whether the response is Active or Inactive.
- **Response** -- The personalized response text that is delivered to the customers. This field can be up to 1000 characters long.
  You can use variables in this field, for example:
  - Ticket ref_num: @{call_req_id.ref_num}
  - Assignee: @{call_req_id.assignee.combo_name}
  - Customer: @{call_req_id.customer.combo_name}
  - Description: @{call_req_id.description}
- **Display the Response For** -- Select the type of records for which you would like this response available. By default, Requests, Change Orders, and Issues are selected. For example, if you select the Requests option, you can append this response to a Request record.

The personalized response is created.

Add Personalized Response to a Ticket

Add a personalized response when you are sending a communication to a customer about a ticket.

Note: The tickets for which personalized responses are available depend on the type of tickets that are selected when the personalized response was created. For more information, refer to CreatePersonalizedResponse (see page).

To add a personalized response to a ticket:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.

   The ticket detail page appears.

2. Open the ticket for editing.

3. From the Activities menu, select the activity for which you want to add a personalized response.
   The Create New Activity form opens. You see the Personalized Response drop-down at the end of the form.

4. Select the response that you want to add to the ticket and save the form.
   The description is automatically updated with the personalized response. You also see this response in the Log, Activities tab of the ticket.

Edit Service Targets

Service targets determine whether Service Level Agreements (SLA) have been met within the required time frame. If a service type has a set of service targets, you can view the status and deadlines for completing each target on the ticket. If necessary, you can update or override service target values such as Workshift.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
   The ticket detail page appears.

2. Click the Service Type tab.
   Additional Service Type information appears at the bottom of the ticket.

   Note: Service targets appear on tickets that meet the conditions that the Administrator sets up. Priority calculation can be a factor in how target information calculates and displays.

3. In the Target column, click the target.
   The Service Target Detail page appears.

4. Click Edit.
   The Update Service Target page appears.

5. Complete the following fields as appropriate:

   - **Name**
     Identifies the service target.

   - **Target Duration**
     Specifies the amount of allotted time to perform the service target. You can only override this value by editing the ticket.

   - **Workshift**
     Displays the schedule to use for service target time calculations.

   - **Condition**
     Specifies the name of the condition or site-defined condition. The condition evaluates the ticket data to determine whether the service target is met.

   - **Required Outcome**
     Displays the required result of the condition or site-defined condition Macro.

- **Cost**
  Specifies the penalty that incurs for missing the target. This information also displays on the ticket.

- **Target Date/Time**
  Specifies the deadline for completing the target. If the ticket is in a Hold status or the target has been met, this field is blank.

- **Actual Date/Time**
  Specifies the date and time that the condition was satisfied or the user clicked Set Actual.

- **Time Left**
  Specifies the amount of remaining time for the service target. A negative value indicates the amount of time that exceeded the target time frame.

- **Allow Set Actual**
  Lets the users set the date and time of a service target.

- **Allow Reset Actual**
  Lets the users reset the service target.

- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.

- **Service Type**
  Displays the Service Type that is attached to this service target.

- **Service Target Template**
  Specifies the name of the service target template to link to the service type.

- **Last Modified By**
  Displays the name of the last person who edited the ticket.

- **Lock Target Date/Time From Hold Recalculations**
  Prevents automatic target date and time updates when the ticket goes on hold or when the ticket is delayed.

6. Click Save.
   The system saves and updates the service target.

View Ticket Counters and Timers for Service Targets

If an analyst assigned a set of service targets to a ticket, you can view the status and deadlines for completing each target.

Follow these steps:

1. On the Service Desk tab, display a list of Incidents, Problems, Requests, Change Orders, or Issues.
   The ticket detail page appears.

2. Click the Service Type tab.
   Additional Service Type information appears at the bottom of the ticket.

3. In the Target column, click the Service Target for additional information.
   The Ticket Counters and Timers section appears near the bottom of the Assigned Service Target Detail page. The Assigned Service Target Detail page displays the following fields:

   - **Name**
     Displays the name of the service target.

   - **Target Duration**
     Displays the amount of allotted time to perform the service target. You can only override this value by editing the ticket.

   - **Workshift**
     Displays the schedule used for time calculations for the service target.

   - **Condition**
     Displays the condition or site-defined condition macro that evaluates the ticket data to determine whether the work can complete within the target time frame.

   - **Required Outcome**
     Displays the required result of the condition or site-defined condition Macro.

   - **Cost**
     Displays the penalty that incurs for missing the target. This information also displays on the ticket.

   - **Target Date/Time**
     Displays the deadline for completing the target. If the ticket is in a Hold status or the service target has been met, this field is blank.

   - **Actual Date/Time**
     Specifies the date and time that the condition was satisfied or the user clicked Set Actual.

   - **Time Left**
     Displays the amount of remaining time for the service target. A negative value indicates the amount of time that exceeded the target time frame.

   - **Allow Set Actual**
     Displays whether you can set the actual time. Yes indicates that you can set the Actual Date/Time of a Service Target. No indicates that you cannot override the Actual Date /Time.

   - **Allow Reset Actual**
     Displays whether you can restart the time. Yes indicates that you can reset the Actual Date /Time of a Service Target. No indicates that you cannot reset the Actual Date/Time.

   - **Last Modified Date/Time**
     Displays the date that this ticket was last modified.

   - **Last Modified By**
     Displays the name of the last person who edited the ticket.

   - **Service Type**
     Displays the name of the service type that attached this service target.

- **Service Target Template**
  Displays the name of the service target template that was linked to the service type that was used to create this Service Target.

- **Lock Target Date/Time From Hold Recalculations**
  Locks the Target Date/Time from being automatically updated when the ticket goes on hold or is delayed.

- **Last Start Date/Time**
  Displays the last time the service target timer was started.

- **Ticket Status**
  Displays the value of the Status field of the ticket.

- **Hold Status**
  Displays whether the ticket status has placed the ticket on hold.

- **Last Hold Date/Time**
  Displays the last time that the ticket was placed on hold.

- **Hold Count**
  Displays the number of times the ticket was placed on hold.

- **Last Resolved Date/Time**
  Displays the last time that the ticket transitioned to a resolved status.

- **Resolved Count**
  Displays the number of times that the ticket changed to resolved status.

- **Last Closed Date/Time**
  Displays the last time the ticket was changed to a closed status.

- **Closed Count**
  Displays the number of times the ticket was changed to a closed status.

- **Ticket Open Date/Time**
  Displays the date and time the ticket was opened.

- **Ticket Resolved Date/Time**
  Displays the date and time the ticket was resolved.

- **Ticket Closed Date/Time**
  Displays the date and time the ticket was closed.

View Service Target Status

On an open ticket, you can view the status for each service target. Status information such as Time Left and Violation Cost help you prioritize your work.

Follow these steps:

1. On the Service Desk tab, display a list of Incidents, Problems, Requests, Change Orders, or Issues.
   The respective ticket list displays with the following Service Target information:

   - **Service Target**
     Displays the time that the next service target is due.

   - **Projected Violation**
     Displays the incurred cost when the service type time limit is violated.

2. Select the ticket that you want from the list page.
   The ticket detail page appears.

3. Select the Service Type tab.

   Note: Service targets appear on tickets that meet the conditions that the administrator sets up. Priority calculation can be a factor in how target information calculates and displays.

   If the ticket meets predefined target conditions, the Service Targets List the following information about service targets:

   - **Action**
     Sets or resets the Actual Date/Time to the current date and time.

   - **Target**
     Specifies the current service target for the ticket.

   - **Target Date/Time**
     Specifies date and time when this service target is due. If the ticket is in a Hold status, this value is blank.

   - **Actual Date/Time**
     Specifies the time when the target condition was met. If no value appears, the target condition has not been met.

   - **Time Left**
     Specifies the amount of remaining time for the service target when the ticket is on hold. If the service target has been met, the Time Left field shows the unused time. A negative value indicates the amount of time that elapsed since the missed target date.

   - **Violation Cost**
     Displays the penalty that incurs for missing the target. This information also displays on the ticket.

Save Search Filters

This article contains the following topics:

Basic Search

You can set filter values on the search page of an object to list the corresponding details, or leave the fields blank to display all the details.

Note: If you are using multi-tenancy, a tenant drop-down list appears in the search filter. If you select <empty> from the drop-down list, the search is public.

Follow these steps:

1. Navigate to **Service Desk**, **Search**, and select any object.
   The search page related to the object is displayed.

2. (Optional) Define the required fields for your search criteria. Click **Save As** to save the filters as your personalized search.

3. Click **Search** to display the search results.

4. Click any link to view the details of that specific result in the list.

   The object details are displayed.

Search Using Personalized Filters

As an Analyst, you can save your search conditions. These saved searches are displayed on the analysts' scoreboard. You need not define the search fields for such objects need not be defined every time a search is performed. Saving the search filters enables users to update the search criteria values and save it for future use. Other analysts can also customize their scoreboards and add these saved searches.

Note: You can save a filter only for those roles for which the scoreboard appears.

By default, you can save a filter for the following objects:

- Incident

- Problems
- Requests
- Change Orders
- Issues
- Announcements
- Configuration Items
- Contacts
- Change Workflow Tasks
- Issue Workflow Tasks

By default, personalized search options are enabled. For disabling the personalized search options, see the *Enable or Disable Personalized Search Options* section below.

Follow these steps:

1. Click a saved search from **My Saved Search** in the scoreboard.
   The search results appear based on the saved search criteria.
2. (Optional) Click **Show Filter** and update the required fields for your search criteria.
3. Do any *one* of the following tasks:
   a. Click **Save** to save the updated filters.
   b. Click **Save As** to save the search with another name.
   c. Click **Search**.
      The page displays search results based on the updated search criteria.
4. Click any link to view the details of that specific result in the list.

   The object details are displayed.

Enable or Disable Personalized Search Options

As an administrator, execute the following command to disable the search options:

```
pdm_options_mgr -c -s DISABLE_SAVED_SEARCHES -v 1 -a pdm_option.inst
```

To ensure that the search options update takes effect while running the pdm_configure command, execute the following command with the **-t** option.

```
pdm_options_mgr -c -s DISABLE_SAVED_SEARCHES -v 1 -a pdm_option.inst -t
```

Add Activities to a Ticket

You can record all the actions that you are taking to resolve the ticket on the Activities tab. Activities can include actions such as research, calling a customer, and transferring responsibility to a different analyst. Some activities, such as "Initial" or "Field Update" are posted automatically when you create the ticket or update a field. Others, such as returning a call, changing the status, or transferring the ticket are posted when you select items from the Activities menu or from the Activities page itself.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. On the menu bar, click Activities, and then select one of the following options:
   - **Update Status** to update the status of the ticket.
   - **Callback** to record the time that is spent on the call.
   - **Research** to record the time spent conducting the research.
   - **Log Comment** to record your comments.
   - **Solution** to enter a description of the solution.
   - **Transfer** to reassign a problem to another technician.
   - **Escalate** to escalate the priority of a problem.
   - **Manual Notify** to send a manual notification to the user.
5. Edit the fields as appropriate. The following fields require explanation:
   - **Internal?**
     Select this check box if the activity must only be visible to internal users.
   - **Time Stamp**
     Specifies the date and time the activity began. This field shows the system date and time the activity record was opened. This field cannot be edited.
   - **Date of Activity**
     The date and time the activity was performed. Defaults to the date and time the activity record was opened, but can be changed.
   - **Time Spent**
     Specifies the amount of time that is spent on the activity. Enter this value in hours, minutes, and seconds (hh:mm:ss).

- **Related Ticket Activity Type**
  Specifies the type of activity that is generated for a related ticket, for example, Update Status

- **Change**
  Select an existing change order to which you want to attach the ticket.

- **Impact**
  Indicates the effect that the record has on tasks being performed. Your system administrator can modify the default impact codes, so they can vary from one installation to another.

6. Click Save.
   The activity is recorded on the Activities tab on the ticket details page.

Provide a Reason for Escalating the Ticket

If your priority calculation settings let you change Urgency and Impact values, you provide a reason for escalating the ticket. If priority calculation is not enabled, you can edit the priority field.

Follow these steps:

1. Open a ticket, such as an Incident or a Problem.
   The Ticket Detail page appears.

2. Modify the Urgency or Impact of the ticket.

3. Click Save.
   The Escalate Detail page appears and displays the current, read-only values for Priority, Urgency, and Impact.

4. Enter a reason for why you want to change the Urgency or Impact values.

5. Click Accept.
   The ticket is modified and the activity log updates with your changes.

Send a Manual Notification to a Temporary Email Address

You can send a manual notification to a temporary email address. For example, one that is not associated with a contact record.

Note: This operation is available only if the Administrator has installed the notification_allow_temp_address Update Options (Options Manager, Notifications).

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Open the desired ticket from the list that appears.

4. On the menu bar, click Activities, Manual Notify.
   The Manual Notification page appears.

5. Complete the following field, and click Add Email.

   - **Email address**
     Specifies an SMTP address for an email recipient. You can specify temporary email addresses (for example, addresses not associated with a contact record). Separate multiple addresses with a semi-colon.

   Note: This field appears only if the Administrator installed the notification_allow_temp_address Update Options (Options Manager, Notifications).
   The address is added to the Recipients list.

6. Complete the remaining fields as appropriate.

   Note: You can also add a personalized response such as a generic or administrator signature to the notification. The response is added at the end of the message text. For more information about personalized responses, see Personalized Responses (see page 2325).

7. Click Notify.
   The manual notification is sent and the activity is recorded on the Activities tab of the ticket Detail page.

Attach or Detach Change Orders

Attach to Existing Change Order

You can attach an incident, problem, or request, to a related change order. Change orders are requested changes that vary from the original scope of a specific project or task.

Follow these steps:

1. On the Service Desk tab, select the incident, problem, or request to which you want to attach the change order.
   The ticket detail page appears.

2. Select Activities, Attach to Existing Change Order on the menu bar.
   The Attach Change Order to Incident page appears.

3. Click Change.
   The Change Order Search page opens.

4. Enter the search criteria that you want to use and click Search.
   A list of change orders matching the search criteria appears.

5. Select the desired change order from the list.
   The Attach Change Order to Incident page displays the selected change order number in the Change field.

> **Note:** If you know the Change Order number, you can type it in the Change field.

6. (Optional) Enter the comments in the Remarks field.

7. Click Attach.
   The ticket is attached to the change order, and the activity is recorded on the Activities tab on the ticket detail page.

Detach Change Order

You can end the association between an incident and an attached change order.

Follow these steps:

1. On the Service Desk tab, select the desired incident, problem, or request from which you want to detach the change order.
   The ticket detail page appears.

2. Select Activities, Detach Change Order on the menu bar.
   The Detach Change Order from Incident page appears.

3. Click Detach.
   The ticket is detached from the change order, and the activity is recorded on the Activities tab on the ticket detail page.

Attach a Service Type Event

Service types determine the level of support that is given for a ticket. You can associate service type events with tickets. An event that is associated with a service type is attached to records defined with that service type.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Select the desired ticket from the list that appears.

4. Choose the Service Type tab, and click Attach Service Type Event.
   OR
   Choose Actions, Attach Service Type Event.
   The Attach Service Type Event page appears.

5. Click Service Type Event.
   The Event Search page appears.

6. Complete one or more of the search fields, and click Search.
   The Event List displays the events that match your search criteria.

7. Select the desired event.
   The Attach Service Type Event page appears.

8. Click OK.
   The Delay Time field appears. The delay time indicates the interval of time after which the event occurs.

9. Specify the delay time as hh:mm:ss (hours, minutes, seconds).
   For example, if the event is attached to the incident at 2:20, and the Delay Time is 01:00:00 (one hour), the event occurs at 3:20.

10. Click OK.
    The ticket detail page appears with the event listed on the Service Type tab.

Delay or Resume a Service Type Event

You can delay and resume service type events.

Follow these steps:

1. Select the desired ticket from the list page on the Service Desk tab.
   The ticket detail page appears.

2. Select the Service Type tab.
   A list of any service type events that have been added to the ticket appears.

3. Click Delay or Resume.
   The Reason page appears.

4. Enter the reason, and click OK.
   The ticket detail page displays the Status of the event.

Create a Parent-Child Relationship

Records that are entered in the CA SDM system can be related to other records that are entered into the system. For example, a problem could result in two more problems when you attempt to resolve the original problem. The original record is referred to as the *parent*, and the additional records are referred to as *children*.

You can record such relationships in the CA SDM system for future references. The Parent/Child tab on the ticket detail page lists the parent and children tickets of a ticket.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Open the desired ticket from the list that appears.

4. Select the Parent/Child tab and click Update Children.
   The search page opens.

5. Complete one or more of the search fields for related ticket records, and click Search.
   A list of tickets matching the search criteria are displayed.

6. Select the related tickets from the list on the left, and click  .
   The selected tickets are added to the list on the right.

7. When all related tickets are in the list on the right, click OK.
   The detail page displays with the selected tickets listed on the Parent/Child tab.

Close All Children

You can close all the children tickets before closing the parent ticket.

Follow these steps:

1. Select the appropriate ticket type from the Scoreboard. For example, select Requests.

2. Open the parent ticket.

3. Click the Action menu and select Close All Children.

Create a Ticket Template

You can define a ticket, such as an incident, problem, issue, change order, or request, to serve as a model for future tickets. You can then save it as a template. Tickets that are created with that template have certain fields auto-populated with your specified values.

Create a Template from a New Ticket

You can use a new ticket to create a template to be used when creating future tickets.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type for the template. For example, to create an incident template, click File, New Incident.

2. Complete the fields as appropriate for the template in the page that opens.

3. Select the Template tab at the bottom of the page.

4. Complete the following fields:

   Template Name
   This name appears in the list of available templates.

Template Class
(Optional) You can assign a class to the template.

Quick Template Type
You can use quick templates to define new requests on the Quick Profile Scratchpad. Select one of the following options:

- None
- Quick
- Review Before Save

Template Active
Specifies whether the template is active or inactive in the database.

Description
Describe the template settings and intended usage. This field can be used as a filter when searching for a template. Wildcard searches are supported.

5. Click Save.

Create a Template from an Existing Ticket

You can use an existing ticket to create a template.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Select the desired ticket from the list that appears.

> **Note:** Some roles can only access certain ticket types through the Search menu on the Service Desk menu bar.

4. Click Edit.
5. (Optional) Edit the fields as appropriate.
6. Select the Template tab at the bottom of the page.
7. Complete the following fields:

Template Name
This name appears in the list of available templates.

Template Class
(Optional) You can assign a class to the template.

Quick Template Type
You can use quick templates to define new requests on the Quick Profile Scratchpad. Select one of the following options:

- None
- Quick
- Review Before Save

Template Active
Specifies whether the template is active or inactive in the database.

Description
Describe the template settings and intended usage. This field can be used as a filter when searching for a template. Wildcard searches are supported.

8. Click Save.

Create Tickets

You can create a ticket such as an incident, problem, request, issue, or change order, using various methods. This article explains these methods.

Important! Depending on your role, you do not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create new ones.

Create a Ticket from the File Menu

You can either create a ticket from scratch or use an existing template.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type that you want to create. For example, to create a request from scratch, click File, New Request. To create a request from a template, Click File, New Request from Template.

2. Fill in the fields as appropriate for the ticket. See the field definitions at the end of this page. Use the controls available on the tabs at the bottom of this page to process the ticket as appropriate.

3. Click one of the following buttons:

   Save -- Saves the incident and closes the page.

   Auto Assign -- Triggers an auto assignment task, and updates the activity log.

   Note: This button appears only when the ticket specifies a category or area that has auto-assignment enabled.
   Create Change Order -- Opens the Create New Change Order page. You can create a change order ticket that is associated with this incident.**Note:** This button appears only when you create incidents, problems, and requests.

   Create Problem -- Opens the Create New Problem page so you can create a problem ticket associated with this incident.**Note:** This button appears only when you create incidents and requests.

   Create Incident – Opens the Create New Incident page so you can create an associated incident ticket.**Note:** This button appears only when you create change orders and requests.

   Reset -- Resets all fields to the last saved values.

   Find Similar -- Opens the Find Similar page to search for similar problems.**Quick Profile --** Displays the contact information for the specified user in the **Affected End User** field. You can also view their environment details and their entire ticket history.

   Use Template -- Displays a list of available templates for the selected ticket type. You can select the template that you want to use for creating this ticket.

Create a Ticket Using Quick Profile

You can use the Quick Profile to identify a contact to be the affected end user of your new ticket. Quick Profile allows you to search for a contact, and view the history of the issues, requests, change orders, incidents, and problems that are assigned to that contact. When you have identified a contact, you can create the incident ticket directly from the Quick Profile.

Follow these steps:

1. Select View, Quick Profile on the menu bar of the Scoreboard.
   The Quick Profile Contact Search window opens.

2. (Optional) Complete one or more of the filter fields to list only the contacts of interest.

3. Click Search.
   Note: All search fields that allow text entry support use of the % wildcard character.
   The Quick Profile Contact List page lists the contacts that match your search criteria.

4. Select the user who is the affected end user of the new ticket.
   The contact pane displays contact information and the ticket history for the contact.

5. In the Scratchpad pane, do the following actions:
    a. Enter a description for the new record in the Scratchpad text field.
    b. Select the ticket type from the Type drop-down list.
    c. (Optional) Enter a Template name for the new record. You can enter a value directly or click the search icon to search for available templates.
6. Click New.
   A new window opens and displays the information that you entered in the Scratchpad.
7. Complete the empty fields as appropriate.
   See the field definitions at the end of this page.
8. Use the controls available on the tabs at the bottom of this page to process the ticket as appropriate.

Add Attachments to Tickets

You can attach a document or a link to a URL to a ticket. The document or URL provides more explanation or justification for the report.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. Select the Attachments tab, and then click one of the following options:
    - Attach Document
    - Attach URL
5. Follow the on-screen instructions to attach a file or URL to the incident.
   The URL or the document is added to the record and is listed on the Attachments tab of the Incident Detail page.

View Tickets

You can view summary information for tickets after you create them.

If you are using multi-tenancy, a tenant drop-down list appears in the search filter. If you select <empty> in this drop-down list, the search is public.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Select the folder for the tickets that you want to see.
4. (Optional) Click Show Filter and complete one or more of the fields to specify search criteria that restricts the list to the tickets of interest.
5. Click Search.
   The search result displays the tickets that match the criteria.
6. Click the ticket # link to view the incident of interest.
   The detail page appears.

Use Knowledge to Resolve a Ticket

You can search the CA SDM Knowledge Base to help resolve a ticket, such as an incident, problem, request, issue, or change order.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. Select the **Knowledge Management** tab.
5. Enter text in the search field to describe the problem, or copy text from the **Summary** or **Description** fields of the ticket.
6. From the drop-down list, select where you want to search.
7. Click **Search**.
   A list of documents matching the search criteria displays.
8. Look for the document that provides the solution to your ticket.
9. Right-click the document and select **Accept as Solution**.
   The knowledge document information is copied into the **Summary** and **Description** fields.

Submit a Knowledge Document

When you log a solution activity for a ticket, you can submit the solution to the knowledge base administrator as a candidate for publication.

Follow these steps:

1. Open a ticket, such as an Incident.
   The ticket detail page appears.

2. On the Knowledge tab, click Submit Knowledge.
   The Create New Document page displays.

For more information on creating knowledge documents, refer to Create Knowledge Documents (see page 2732).

After you submit a solution to the knowledge base, it becomes a candidate for publication in the knowledge base. A Knowledge Management administrator reviews the information and publishes it if it is deemed appropriate and accurate. After it is published, the information becomes available to other users.

View Events

The Event List contains a record of the events that are associated with the ticket. Your administrator maintains events, or procedures the system perform after a certain amount of time has elapsed. For example, an event might send a message to an analyst if a Priority 1 ticket is not resolved within an hour.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Select the desired ticket from the list that appears.

4. Click the Event Log tab at the bottom of the details page.
   A list of events for this incident appears.

View the Event History

You can view the event history for a ticket to see what actions have been performed to resolve the ticket.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority level for the desired ticket.

3. Select the desired ticket from the list that appears.

4. Select View, Event History on the detail page menu bar.
   The Event History window displays the following fields:

- **Condition**
  Indicates the condition checked for by the event. CA SDM provides macros that check for standard conditions such as priorities and object status (open or closed).

- **Event**
  Indicates the name of event that is associated with this row in the Event History list.

- **Status**
  Indicates whether the event is active or inactive.

- **Check Time**
  Indicates the time that the event was checked, based on time parameters that are specified in the event configuration.

- **Time Loaded**
  Indicates the time that the event was loaded, based on time parameters that are specified in the event configuration.

View the Event Delay History

You can view the event delay history for a ticket to see descriptions of the service type event delays. Service type event delays let you suspend a service type event to prevent a service level violation.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority level for the desired ticket.
3. Select the desired ticket from the list that appears.
4. Select View, Event Delay History on the detail page menu bar.
   The Event Delay History window displays the following fields:

   - **Start Time**
     Indicates the date and time the delay began.

   - **Stop Time**
     Indicates the date and time the delay ended.

   - **Actual Delay**
     Indicates the actual duration of delay.

   - **Effective Delay**
     Indicates the effective duration of delay.

   - **Service Type**
     Defines the support level that is assigned to the ticket (for example, four-hour service requirement).

Event Logs

The Event Log displays significant actions that are performed by the user, such as on tickets. For example, you submit a Knowledge Document and link it to an Incident. The Incident logs a failed status transition or detected Change Conflict. In this example, the Contact detail can display the following types of information:

- The log displays the time that the user logged in to CA SDM and when they closed the session.
- The user accepted the Terms of Usage.
- The user created a Knowledge Document.
- The user created a ticket, such as an Incident, Problem, Request, or Change Order.
- The user used a Knowledge Document to avoid creating a ticket.

Asset Management

This section contains the following articles:

Audit History

An *audit history* is a chronological list of changes that are made to an object record over time. Auditing records all changes that are made to each field in an object record. CA APM lets you use an audit history to view a list of changes that are made to a record.

You can use an audit history to see the changes that are made to the value of a particular field. You can also see who changed the value. If a field contains an incorrect entry or value, use the audit history to verify the last correct value and update the object record.

The following objects enable auditing by default and without any additional configuration:

- Models (including Model Pricing)
- Assets

- Companies
- Contacts
- Organizations
- Locations
- Sites
- Legal Documents (including Terms and Conditions)
- Legal Assets (including Terms and Conditions)
- Costs
- Payments
- Relationships
- Asset Configurations (Models and Assets)
- Software Internal Allocations (Locations, Companies, Contacts, and Assets)

View an Audit History of Object Changes

You can view an audit history for an object record to see the changes that are made to the record. The audit history maintains and displays the historical information of the changes that are made to an object.

Example: Review the Audit History to Change the Cost Center

In this example, a line manager discovers that the incorrect department is being charged for a laptop. The line manager investigates the situation and determines that the laptop is assigned to the incorrect cost center. To understand how this error occurred, the line manager configures and filters the audit history search criteria and results for the laptop to include the cost center. The line manager reviews the audit history for a specific time period to determine when the cost center value changed and who changed the value. The line manager contacts the asset manager to have the cost center changed to the correct value.

Follow these steps:

1. Click the tab and optional subtab for the object for which you want to view an audit history.
2. Search to find the list of available objects.
3. Click the object in the search results for which you want to view an audit history.
4. Click View Audit History.

   All changes that are made to the object record appear.
5. (Optional) To view the audit history for a relationship, complete the following steps:

a. Select the relationship (for example, Image Partitions).

b. Click the Edit Record icon, and click View Audit History.

6. (Optional) Complete any of the following steps in the Search Criteria to filter the audit history search results:

   a. Select a specific field in the Target Field drop-down list and click Go.
   The Search Results are limited to the field that you select. In addition, the standard auditing fields identify the user who changed the field and the type and date of change.

   b. Select the Highlight Changes check box and click Go.
   The Search Results highlight changes in adjacent rows. You can use this check box, in combination with a specific field in the Target Field drop-down list, to identify field-level changes that need correction.

7. Export the audit history to a CSV file or to return to the object details, click the hyperlink.

View an Audit History of Events

CA APM lets you view an audit history of all events that are created for an object. For example, you define a date event on the Terminate Date field for a legal document and a notification for the event is sent to the appropriate person on 3/1/2010. The audit history maintains and displays the event history for an object.

Follow these steps:

1. Click the tab and optional subtab for the object for which you want to view an audit history.

2. Search to find the list of available objects.

3. Click the object in the search results for which you want to view an audit history.

4. Click View Audit History.
   All changes that are made to the object record appear.

5. In the audit history results, click the icon in the Event History column.
   All events and their associated status (see page 2340) that is created for the audit record appear.

Event Status

When you view an audit history of events, you can see the associated status for each event.

Event Status	Description
Unprocessed	CA APM has created the event. However, the event has not been processed to map the workflow process attributes for notifications in CA Process Automation.
Started	The mapping for the workflow process attributes in CA Process Automation is complete. The associated notification process for the event has started.

Event Status	Description
In Progress	The CA Process Automation notification process for the event is processing.
Completed	The CA Process Automation notification process for the event is completed.
Failed	The CA Process Automation notification process for the event has failed.
Aborted	The CA Process Automation notification process for the event has stopped.

Contract Management

After you negotiate contracts with your vendors, the supporting documentation is frequently archived and the terms are forgotten. Making contract information easily accessible lets you properly administer the terms of an agreement. CA APM lets you manage legal documents and standardize on terms and conditions for reporting and analysis. You can see the relationships between agreements and costs associated with vendor contracts to understand the financial impact. Finally, CA APM lets you attach electronic files or URL pages containing supporting documentation to objects, such as contract profiles, to quickly access the original document.

Contract management in CA APM involves working with the following objects:

- Legal documents (see page 2341)
- Terms and conditions (see page 2347)
- Attachments (see page 2349)

Legal Documents

This article contains the following topics:

A *legal document* describes a legal relationship or agreement between two or more parties. For example, contracts, notification letters, master agreements, lease agreements, volume purchase agreements, additions to agreements, letters of intent to purchase, and so forth, are all considered legal documents.

Legal document records are based on legal templates, which your CA APM administrator defines. When you define a legal document, you start by selecting the appropriate template. Templates provide fields that apply to specific types of legal documents. Regardless of the legal template you use, you can use legal documents to track the following information:

- Record information about parties to the legal document, both primary and other parties.
- Create relationships to associate related records (for example, to associate an amendment to its original agreement).
- Store attachments with your legal document record (for example, a scanned image of a document).
- Record associated cost information.

You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Manage Legal Documents

You can define, update, or delete a legal document. For example, you can define a legal document for a contract or negotiation letter, or you can change the termination date for an equipment lease. You can delete a contract or lease agreement that has expired. You cannot delete a legal document that is associated with an asset.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click Legal Document.
2. Perform one of the following actions.
3. Define a legal document.
    a. Click New Legal Document.
    b. Enter the legal document information.
    c. Click Save.

Note: You can also define a legal document by copying an existing legal document, supplying a new name, changing the information, and saving the new legal document.

4. Update a legal document.
    a. Search to find the list of available legal documents.
    b. Click the legal document that you want to update.
    c. Enter the new information for the legal document.
    d. Click Save.

    Note: You can also view the details for an object that is related to your legal document, if the related object has a Browse icon. When you click the Browse icon, you leave the legal document page and you navigate to the related object page. To keep the legal document page in view and preserve the legal document information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. Delete a legal document.
    a. Search to find the list of available legal documents.
    b. Click the legal document that you want to delete.
    c. Click Delete and confirm that you want to delete the legal document.

Associate a Governing Legal Document with a Legal Document

A governing legal document is the document on which a legal document is based. CA APM lets you associate a governing legal document with the legal documents on which it is based. This association is useful when tracking the source of the legal terms and conditions of a legal document.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of available legal documents.
3. Click the legal document to which you want to associate a governing legal document.
4. On the left, expand Relationships and click Governing Legal Document.
5. Click Select New and select a different legal document, other than the legal document previously selected.

6. Click Save.
   The governing document is associated with the legal document.

Track Amendments to a Legal Document

CA APM lets you create and track amendments that have been made to a legal document. Save the amendments as a separate legal document and associate the amendments with the parent legal document.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of available legal documents.
3. Click the legal document for which you want to enter amendment details.
4. On the left, expand Relationships and click Legal Amendment.
5. Click Select New and select a different legal document, other than the legal document previously selected.
6. Click Save.
   The amendment details are saved.

Associate an Asset with a Legal Document

CA APM lets you associate assets and legal documents to identify the assets that a legal document covers. Initiate this association from either the legal document or asset. You can associate multiple assets to a single legal document and multiple legal documents to a single asset.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of available legal documents.
3. Click the legal document that you want to associate with an asset.
4. On the left, expand Relationships and click Legal Asset.

5. Click Select New in the Legal Asset section, search for and select an asset.
   The asset name appears.

6. Click Save.
   The asset is associated with the legal document.

Add and Remove Asset Legal Document Terms and Conditions

Terms and conditions are specific areas of agreement that are defined in legal documents. For example, legal documents can have terms and conditions for a multi-product discount, a new pricing model, copyright protection, and so forth. After you associate an asset with a legal document, CA APM lets you add or remove terms and conditions for the asset legal document from the Asset or the Legal Document page.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Legal Document.

2. Search to find the list of available legal documents.

3. Click the legal document for which you want to add or remove terms and conditions.

4. On the left, expand Relationships and click Legal Asset.

5. Click the Edit Record icon for the asset for which you want to add or remove terms and conditions.

6. Click View Assigned T's & C's.

7. Select one of the following options:

   - Click Select New for the date-specific or non-date-specific T's and C's to add to the asset legal document.

   - Click the Mark for Deletion icon for the terms and conditions that you want to remove from the asset legal document.

8. Click Save.
   The terms and conditions are added or removed.

   For more information about defining date-specific and non-date-specific terms and conditions for legal documents, see Define Legal Document Terms and Conditions (see page 1535).

Associate a Legal Party with a Legal Document

CA APM lets you associate the people and entities involved in creating a legal document to the document record. For example, you can associate the lawyers and the law firm as legal parties for the legal document.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of legal documents.
3. Click the legal document for which you want to associate a legal party.
4. On the left, expand Relationships and click Legal Party.
5. Click Select New to search for and select a company.
6. Click Save.
   The company is defined as the legal party.

Make an Obsolete Legal Document Inactive

As a best practice, change the status of an obsolete legal document to inactive rather than deleting the legal document. We recommend this approach because when you delete a legal document record, the historical information for the legal document is permanently removed from the repository. In this way, you retain the legal document information for future reporting and reference.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of available legal documents.
3. Click the legal document that you want to make inactive.
4. Select the Inactive check box.
5. Click Save.
   The legal document status is changed to inactive.

Assign and Track the Status of a Legal Document

CA APM lets you assign and track the status of a legal document. For example, if the document has been signed, assign the status as executed. You can track the changes in the status of a legal document over time. The status identifies the stage of completion or implementation of the legal document.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of available legal documents.
3. Click the legal document for which you want to track the status.
   The legal document details appear. The status details are available in the Status section.
4. Click New in the Status section.
5. Specify the new status for the legal document.
6. Select the Current check box to indicate that the selected status is the current status of the legal document.
7. Click Save.
   The status is updated and the previous status is added to a chronological status list for the legal document. As a best practice, change the current status each time the status of a legal document changes. Only one status can be entered as the current status of a legal document. All dates are automatically updated.

Terms and Conditions

This article contains the following topics:

Terms and conditions are areas of agreement specified in legal documents. CA APM lets you track terms and conditions for the following reasons:

- To enforce order or comply with an existing legal document.
- To negotiate future legal documents.

Administrators and users with appropriate privileges create and maintain a master list of terms and conditions. When you work with legal documents, you use terms and conditions from this list. You can assign terms and conditions when you define legal document records or asset records.

When you define a legal document record, you start by selecting a legal template. The legal template contains the terms and conditions that typically apply to the legal document type. You can update the terms and conditions provided by the legal template to help ensure that the legal document record contains only the terms and conditions that apply.

A master terms and conditions list must exist in your repository before you can assign terms and conditions to your legal templates. You can assign a term or condition to one or more legal templates and legal document records.

Terms and conditions can be date-specific or non-date-specific. Date-specific terms and conditions include information about the start and end dates. For example, if one of your terms and conditions is Installation Date, you can have start and end date information included about the Installation Date.

You determine which terms and conditions are date-specific when you create new terms and conditions in Directory, List Management.
For more information about defining date-specific and non-date-specific terms and conditions for legal documents, see Define Legal Document Terms and Conditions (see page 1535).

We recommend that you do not include the following terms and conditions in your master list:

- Effective and termination dates, as they are recorded directly on legal document records.
- Cost-related terms and conditions, as they are recorded directly on cost records.
- Software licensing terms, as they are recorded on license records.

Note: When you define an asset, you can associate the asset to the legal document records that govern the asset. The terms and conditions that apply to the legal documents also apply to the asset. If a particular asset requires terms and conditions that the legal documents do not provide, you can change the terms as you associate the asset and legal document. The legal documents covering a particular asset must contain the terms and conditions that apply only to the asset.

Add and Remove Legal Document Terms and Conditions

Terms and conditions are specific areas of agreement that are defined in legal documents. For example, legal documents can have terms and conditions for a multi-product discount, a new pricing model, or a copyright protection. CA APM lets you add the terms and conditions that are required in a legal document and remove any that are inherited from the legal template but are not required in the legal document.

Note: After you associate an asset with a legal document, you can add or remove terms and conditions for the legal document from the Asset or Legal Document page.

Follow these steps:

1. Click Legal Document.
2. Search to find the list of available legal documents.
3. Click the legal document for which you want to add or remove terms and conditions.
4. On the left, click T's and C's.
5. Select one of the following options:
   - Click Select New for the date-specific or non-date-specific T's and C's to add to the legal document.

- Click the Mark for Deletion icon for the terms and conditions that you want to remove from the legal document.

6. Click Save.
   The terms and conditions are added or removed for the legal document.

For more information about defining date-specific and non-date-specific terms and conditions for legal documents, see Define Legal Document Terms and Conditions (see page 1535).

Manage an Attachment

Attachments are electronic files or URL pages containing supporting documentation that you associate with an object. For example, you can add an attachment of a scanned contract to the legal document record that represents the contract.

You can use the following types of attachments:

- **Web URL**. Provides direct access to the page specified in the URL. When you add this type of attachment, include the prefix http:// for the link to work correctly.
- **File**. Provides direct access to a file. The file opens using the default program for the file type. At the time that you create this attachment type, the file is copied from your file system to the file system on a CA APM server.

You can add attachments to the following objects:

- Model
- Asset
- Legal Document
- Contact
- Company
- Organization
- Location

You can add, update, and delete an attachment for an object. The following examples illustrate how you can manage an attachment:

- You can attach a scanned copy of an invoice to record all assets that are listed on the invoice.
- You can edit the URL to a scanned copy of an invoice if the location has changed.

When you delete an attachment, you delete only the reference to the attachment in the object record. If the deleted attachment is a file, the file remains in the file system on the CA APM server.

Follow these steps:

1. Click the tab and optional subtab for the object for which you want to manage an attachment.

2. Search to find the list of available objects.
3. Click the object for which you want to manage an attachment.
4. On the left, click Attachments.
5. **Add an Attachment.** Follow these steps:
    a. Click New.
    b. Complete the required information.
    c. In the File Path field, select a file from your local server, or enter a URL for the new attachment. For a URL, include the following prefix:

    ```
    http://
    ```

    If you are adding a file attachment, your selected file is copied to a CA APM server. This copy activity can take a few moments to complete. Wait for the file to finish copying before you click Save.

    Important! The file size is limited by the product environmental settings. For more information, contact your administrator or CA Support.

    Note: If you select a file that exists on the server, you are prompted to overwrite the existing file. Click Yes to overwrite the file, click No to use the existing file on the server, or click Cancel to clear the file selection.

6. **Update an Attachment.** Follow these steps:
    a. Click the Edit Record icon for the attachment.
    b. Change the information for the attachment.

    Note: For a file attachment, you can update the name and description for the attachment record. However, to update the file for a file attachment, you delete the existing attachment record and add a new attachment with a new file.

7. **Delete an Attachment.** Click the Mark for Deletion icon next to the attachment.
8. Click Save.
   The attachment is added, updated, or deleted.

Financial Management

Understanding the financial impact of your asset base lets you decide what costs are relevant to your business. CA APM helps you track, manage, and categorize all asset-related expenditures, including historical, current, and projected costs, so that you can analyze their financial impact.

Financial management in CA APM involves working with the following objects:

- Models (see page 2351)
- Assets (see page 2355)
- Asset Configurations (see page 2367)
- Costs and Payments (see page 2371)
- Events and Notifications (see page 2376)
- Notes (see page 2402)

Models

This article contains the following topics:

The repository contains two types of records that describe the basic characteristics of IT products:

- A *model* describes a product type that you have purchased or might purchase.
- An *asset*, which is based on a model, describes a product that you own or plan to acquire. You can create many assets that are based on a single model, and the new asset inherits the model attributes. For example, if you own 100 laptops of a particular model, you would have one model record describing the laptop and 100 asset records describing the individual laptops.

A model can be any of the following examples:

- A *computer model* such as Dell Optiplex GX270 and Dell Precision 410.
- A *hardware component* such as 104+ keyboard, 256 MB-RAM, Monitors, and Intel Pentium processor.

You manage *hardware models* to describe the following models:

- Configurations that the manufacturer offers.
- Substitutions or additions that you typically make to the configurations when you purchase them.

Each model configuration is composed of links between the models and their component model records (such as a monitor and a keyboard).

You can have some products that you want to group together to manage as models, such as the following examples:

- Standard, relatively inexpensive computer components in a configuration. For example, you can record a particular type of network card as a model. This model lets you determine which systems are using that type of network card without tracking details about individual network cards of that type. Other similar components include SCSI hard drives, memory, graphics cards, and CD or DVD devices.
- Products that your company purchases from different vendors at different times. This additional information lets you track pricing information for those products and select the best price.

Define models first in the repository for each asset that you want to manage. After you define a model, the model acts like a template for the physical assets that are created. The assets inherit the properties or attributes from the model, such as the name, asset family, and manufacturer. By using this template, a single model can represent many assets and the model information is common to many assets. However, each asset record contains information specific to that asset.

Manage Models

Managing models includes defining, updating, and deleting models for an asset. For example, you define Dell Precision Workstation 410 as a model to describe the workstation.

Follow these steps:

1. Click Model.
2. Perform one of the following actions.
3. **Define a model.**
    a. Click New Model.
    b. Enter the model information.

    Note: You can also define a model by copying an existing model, supplying a new name, changing the model information, and saving the new model.

4. **Update a model.**
    a. Search for the list of available models.
    b. Click the model that you want to update.
    c. Enter the new information for the model.

Note: You can also view the details for an object that is related to your model, if the related object has a Browse icon. When you click the Browse icon, you leave the model page and you navigate to the related object page. To keep the model page in view and preserve the model information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. **Delete a model.**
   a. Search for the list of available models.
   b. Click the model that you want to delete.
   c. Click Delete and confirm that you want to delete the model.
6. Click Save.

Define an Asset from a Model

You define an asset, which is based on a model, to describe a product that you own or plan to acquire. For example, you have defined Dell Precision Workstation 410 as a model. Your enterprise has purchased 100 individual computers, and you define 100 asset records that are based on the model to describe the individual computers.

Note: You cannot define an asset from a model that does not have an asset family.

Follow these steps:

1. Click Model, New Model.
2. Enter the model information with a valid asset family.
3. Click Save.
   The model is defined.
4. Click the Create Asset hyperlink.
5. Enter the asset-specific information.
6. Click Save.

Make an Obsolete Model Inactive

As a best practice, change the status of an obsolete model to inactive rather than deleting the model. For example, after replacing all Dell Precision Workstation 410 computers with laptops, you can change the status of the associated model to inactive.

We recommend this approach because deleting a model record permanently removes the historical information from the repository. Changing the status to inactive lets you retain the model information for future reporting and reference.

Note: Changing the status to inactive has no impact on the assets that are based on the model. If you want the assets to be inactive, search for the assets that are based on the model and manually indicate that they are inactive.

Follow these steps:

1. Click Model and search for the list of available models.
2. Click the model that you want to make inactive and select the Inactive check box.
3. Click Save.

Change a Model Asset Family

You can change the asset family of selected models. For example, you realize that a set of related computer models were imported into the product using the hardware asset family. You search for these models and select them. Then you can change the asset family for all selected models simultaneously.

Note: When you change the asset family for a model, the asset family is also changed for the associated assets.

Follow these steps:

1. Click Model.
2. Click Change Model Asset Family under Mass Change Utilities on the left.
3. Select the original asset family and the new asset family.

   Note: If the original asset family has extended fields that the new asset family does not have, a warning message and a check box appear. To proceed with changing the model asset family, select the check box Check to change model to new asset family. The extended fields are lost. To avoid the data loss, define the extended fields for the new asset family before you change the model asset family.

4. Click Go.
   All models that have the original asset family are listed in the Search results.

5. Select either the individual models that you want to change or all models.

6. Select a class for the models using one of the following actions:

   - Select the Assign a Single Class to All Models check box and select a class if you want to apply the same class to all selected models.

   - Select the class for each individual selected model.

7. Click Change Model Asset Family.
   Your request is submitted.

8. Click View Mass Change Utilities Progress to see the status of your job and verify completion.

Add Components in a Model Configuration

You associate a hardware model to its component models to define a model configuration. A generic model is a model that is not acquired as an asset, for example, keyboards and network cards. Generic models comprise a model configuration. This configuration is available to the inherited assets from the model.

Follow these steps:

1. Click Model and search for the list of available models.

2. Click the model for which you want to add components.

3. Expand Configurations on the left and click Model Configuration.

4. Click Select New, search for and select a model.

5. Click the Edit Record icon next to the model name to define the association between the hardware model and model components.

6. Click Save.

Assets

This article contains the following topics:

An *asset* is an IT product that you own or plan to acquire. Assets represent physical products with unique identifiers such as a serial number, a configuration, or a contact. You define assets that are based on a model and the information specific to the asset is added to the asset record. Define an asset record when you want to track cost, legal, and other ownership purposes of an asset.

You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Note: The search results only include assets that CA APM manages. If your repository contains assets that the product does not manage, those assets do not appear in the asset search results.

You can assign one lifecycle status to an asset to indicate its availability. If your administrator configured the asset search to include the Lifecycle Status field, you can retrieve information about assets based on the status.

Best Practices for Tracking Assets

When you manage assets, we recommend the following best practices:

- Enter useful information for cost, productivity, and decision making.
- If you cannot think of an immediate need, reconsider tracking the information.
- Keep the information accurate and up-to-date. If the information becomes outdated and obsolete, you do not know what information to trust. As a result, you can make incorrect purchasing and business decisions.
- Track expensive products and key components (such as system units, mainframes, large devices, printers, and monitors) as assets. Do not maintain information about IT assets that are not important when making purchasing and business decisions.
- Track a product as an asset only if you want to know the detailed information (such as the cost, serial number, bar code number, location) about each instance of that product. For example, if you want to know the location of each monitor of a particular model being used, or the cost of each monitor of a model.
- If you are using a discovery product to track the usage of hardware or software products, consider the following information:

- The discovery product, instead of CA APM, tracks the product types.
- The product types that the discovery product and CA APM must track support a comparison of usage and ownership information.

Asset Families

You can classify assets and models that are based on an asset family. An *asset family* is a way to organize and classify assets to track specialized information about products, services, or equipment that you use. The asset family determines the information that you see on the page when you enter an asset.

The product provides a set of predefined asset families, such as computer, hardware, other, projects, service, and software. Your administrator can create user-defined asset families based on the internal structure of your organization. When you define an asset, select either a predefined asset family or a user-defined asset family.

For each asset family, you can create a hierarchy to track an asset to a precise location. Assets inherit the asset family from the model records on which they are based.

Asset Classification

Asset classification helps reduce the number of records that are returned in searches and reports. When you define a model and asset, you can classify the objects by asset family. You can further classify models and assets in the following ways:

- **Class**. Broadly categorizes the product, such as a printer.
- **Subclass**. Provides additional refinement, such as inkjet or laser printer.

Assets inherit class and subclass assignments from the models on which they are based. Consider the following information when classifying assets:

- If you change the class and subclass for a model, the change is not automatically made to saved assets based on the model. The changes are not retroactive.
- You can change the class or subclass that an asset inherits from the model.

Manage Assets

You can add information about each asset to the repository so that you can manage assets throughout their lifecycle. Assets are defined based on models, and inherit data from the selected model. For example, you have defined Dell Precision Workstation 410 as a model. Your enterprise has purchased 100 individual computers, and you define 100 asset records that are based on the model to describe the individual computers.

Follow these steps:

1. Click Asset and perform one of the following actions.
   - **To define an asset, complete the following steps:**
     a. Click New Asset.

b. Enter the asset information.

c. Associate the asset with other objects such as contacts, organizations, and companies.
Associating assets with other objects enables data access to roles or users when you implement multi-tenancy.

Note: You can also define an asset by copying an existing asset, supplying a new name, changing the asset information, and saving the new asset.

- **To copy an asset, complete the following steps:**

  a. Search for the list of available assets.

  b. Click the asset that you want to copy.

  c. Click Copy.

  The Asset Copy wizard appears.

  d. Follow the on-screen instructions to define unique assets and to specify the data that you want to copy to the new assets.

  e. Click Finish when you have completed the wizard.

  f. Click Close and then click Save.

- **To update an asset, complete the following steps:**

  a. Search for the list of available assets.

  b. Click the asset that you want to update.

  c. Enter the new information for the asset.

Note: You can also view and edit an object that is related to your asset, if the related object has a Browse icon. When you click the Browse icon, you leave the asset page and you navigate to the related object page. To keep the asset page in view and preserve the asset information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished.

- **To delete an asset, complete the following steps:**

  a. Search for the list of available assets.

  b. Click the asset that you want to delete.

  c. Click Delete and confirm that you want to delete the asset.

Note: If the CI check box is selected (on the Asset Details page) for the asset you want to delete, you cannot delete the asset. The selected CI check box indicates that CA Service Desk Manager manages the asset. Delete the asset from CA Service Desk Manager.

Important! We do not recommend that you delete an asset because the audit history for the asset is permanently removed. For example, legal, cost, relationship, and other information that is related to the asset is also deleted. Instead, update the asset status to indicate that the asset has been disposed of, or is *obsolete*. Using this approach, you retain the information about the asset in your repository for future reporting and reference purposes.

2. Click Save.

Add an Asset that CMDB Manages

You can add assets to your repository that CMDB manages. CMDB is integrated with CA Service Desk Manager. After you add an asset that CMDB manages, you can then open CA Service Desk Manager from CA APM and view and manage the asset.

Note: You can also create a configuration item (CI) in CMDB and then view it as an asset in CA APM. For more information about creating a configuration item, see Configuration Items (see page 2470).

Important! You cannot delete an asset in CA APM that CMDB manages. You can only delete assets in CA APM that CA APM manages.

Follow these steps:

1. Click Asset, New Asset.
2. Enter the asset information.
3. Select the CI check box to have CMDB and CA Service Desk Manager manage the asset.

   Important! After you save an asset with the CI check box selected, you cannot update the asset to clear the CI check box.

4. Associate the asset with other objects such as contacts, organizations, and companies. This approach enables specific data access to roles or users when you implement multi-tenancy.
5. Click Save.

6. (Optional) View the new asset in CA Service Desk Manager by clicking the CMDB hyperlink at the top of the page.

7. Log in to CA Service Desk Manager.
   A CA Service Desk Manager window opens and the details of the selected asset appear.

Associate a Legal Document with an Asset

You associate assets and legal documents to identify the assets that a legal document covers. For example, you associate a volume purchase agreement with 100 laptops. Initiate this association from either the legal document or asset. You can associate multiple assets to a single legal document and multiple legal documents to a single asset.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Asset.

2. Search to find the list of available assets.

3. Click the asset that you want to associate with a legal document.

4. Expand Relationships (on the left) and click Legal Documents.

5. Click Select New in the Legal Document section, search for and select a legal document.

6. Click Save.

Add and Remove Asset Legal Document Terms and Conditions

Terms and conditions are specific areas of agreement that are defined in legal documents. For example, legal documents can have terms and conditions for a multiproduct discount, a new pricing model, or copyright protection. After you associate a legal document with an asset, add or remove terms and conditions for the asset legal document from the Asset or Legal Document page.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Asset.

2. Search for the list of available assets.

3. Click the asset for which you want to add or remove legal document terms and conditions.

4. Expand Relationships (on the left) and click Legal Documents.
5. Click the Edit Record icon for the legal document for which you want to add or remove terms and conditions.
6. Click View Assigned T's & C's.
7. Select one of the following options:
   - Click Select New for the date-specific or non-date-specific terms and conditions to add to the asset legal document.
   - Click the Mark for Deletion icon for the terms and conditions that you want to remove from the asset legal document.
8. Click Save.

Change an Asset Model

You can change the model for selected assets. For example, you identified 15 assets that were entered into the product with an incorrect server model. You search for the assets and select them. You then can change the server model for all selected assets simultaneously.

Follow these steps:

1. Click Asset.
2. Click Change Asset Model under Mass Change Utilities on the left.
3. Select the original model and the new model and click Go.
   All assets that have the original model are listed in the Search results. If you do not select an original model, all assets that do not have models are listed.

   Note: If the original model asset family has extended fields that the new model asset family does not have, a warning message appears. If you proceed with changing the asset model, the extended fields are lost. To avoid the data loss, define the extended fields for the new model asset family before you change the asset model.

4. (Optional) Select Assign Model Class to All Assets if you want all the listed assets to use the new model class.

   Note: This check box is available only if the new model has a class.

5. Select the individual assets that you want to change or select all assets.

6. Click Change Model.
   Your request is submitted.

7. Click View Mass Change Utilities Progress to see the status of your job.

View an Asset in CA Service Desk Manager

When you integrate the product with CA Service Desk Manager, you can select an asset in CA APM and view the asset information in CA Service Desk Manager.

Follow these steps:

1. Click Asset.

2. Search for the list of available assets.

3. Click the asset that you want to view in CA Service Desk Manager.

4. Click the CMDB hyperlink at the top of the page.

   Note: You can see the CMDB hyperlink only if the product is integrated with CA Service Desk Manager and if your user role includes asset configuration privileges.

5. Log in to CA Service Desk Manager.
   A CA Service Desk Manager window opens and the details of the selected asset appear.

   Note: Asset information that you enter in the product is not immediately available in CA Service Desk Manager. By default, a 10-minute delay exists from the time an asset is updated and the time you can view the asset in CA Service Desk Manager.

View Discovered and Owned Information for an Asset

You can view the discovered information for the owned assets that are linked with discovered assets during hardware reconciliation. Discovered information for an asset includes system configuration, operating system, system devices, file systems, and other information. You can also view the owned information for the assets that you define in the product. Owned information for an asset includes asset properties (for example, operating system and product version), legal information, installed software, components, and other information.

Follow these steps:

1. Click Asset.

2. Search for the list of available assets.

3. Click the asset for which you want to view the information and perform one of the following steps:

   - Click Discovered Information.

     Note: The Discovered Information hyperlink appears only for assets that are reconciled.

   - Click Owned Information.

     Note: If the product is integrated with CA Service Desk Manager, CA Client Automation, and CA SAM, you can see the asset information from those products.

   An asset viewer window opens and displays the information. The links on the window let you access more details.

4. Click each link to view the specific information.

5. Close the window when you are finished viewing the information.

Hardware Assets

CA APM lets you track the hardware asset information that your company is entitled to use. For each hardware asset, you can track the following information:

- Maintain a record of cost and legal information.
- Maintain a record of components in asset configuration and the configurations where the asset is a component.
- Maintain the availability status of the asset.
- Track the software details that are allocated to the asset.

Add Components in an Asset Configuration

An asset can inherit the components from a model. Unicenter APM lets you add components to an asset configuration, for example, an external hard drive or a DVD writer.

Follow these steps:

1. Click Asset.
2. Search for the list of available assets.
3. Click the asset for which you want to add components.
4. Expand Configurations on the left and click Asset Configuration.

5. Click Select New in the Asset Configuration section, search for and select an asset.

6. Click Save.

Update the Asset Status

CA APM lets you change the lifecycle status of an asset. For example, you can update the status when the asset changes from received to available.

To update the asset status

1. Click Asset.

2. Search to find the list of available assets.

3. Click the asset for which you want to update the status.

4. Change the Lifecycle Status and Lifecycle Status Date fields to the appropriate status and date for the asset.

5. Click Save.
   The status for the asset is updated.

Track Image Partitions

CA APM lets you enter image partition details for an existing asset and track them. For example, you can specify that the hard disk on a computer has two partitions and enter the size in GB for each partition. Create an image partition as a separate asset and associate it with the parent asset.

Note: You can view an audit history for this relationship.

To track image partition details

1. Click Asset.

2. Search to find the list of available assets.

3. Click the asset for which you want to enter image partition details.

4. On the left, expand Relationships and click Image Partitions.

5. Click Select New and select a different asset, other than the asset previously selected.

6. Click Save.
   The image partition details are saved and can be tracked.

Asset Groups

An *asset group* is a collection of assets that you acquire together and that are based on the same model. You define an asset group in one asset record. The value in the Quantity field on the Asset Details page indicates the number of assets in the group. The product tracks the asset information for the entire group, rather than for the individual assets. All members of an asset group share asset information.

Asset groups are useful in the following situations:

- The assets are covered under the same purchase or license agreement. You do not need to track cost, payment, licensing, and legal information separately for each asset.
- The assets share some common information, but some of the individual assets in the group have different information. In this situation, you first define the assets as a group and enter the common information one time. Then, you divide the asset group into individual assets (subgroup the asset group) and enter any information that is unique to the individual assets.

You do not have to use asset groups when you are billed for assets on a single invoice. You can record payments for assets that are tracked separately, regardless of whether they were billed on the same invoice.

Asset Subgrouping

CA APM lets you divide (subgroup) an asset group into individual assets using the product. When you subgroup assets, the data for the asset group is copied to the new individual assets, *except* for the following information:

- Serial Number
- Alt Asset ID
- Host Name
- DNS Name
- MAC Address

You can change any existing data or add unique information to the new individual assets. You track the new assets separately from that point forward.

Example: Subgroup Software Licenses

In this example, you purchase 100 licenses of Microsoft Visual Studio under a single purchasing agreement. You record the licenses as an asset group with a quantity of 100. Later, you allocate ten licenses to members of your development staff. You then subgroup the ten allocated licenses into individual assets and enter their allocation information. The 90 licenses that are not allocated remain in the asset group.

Define an Asset Group

CA APM lets you add information to the repository about a group of assets that share common information. You can then manage these assets as a group throughout their lifecycle. You can divide (subgroup) the asset group into individual assets later so that you can specify and track unique information for the individual assets.

Follow these steps:

1. Click Asset, New Asset.
2. Enter the asset information.
3. In the Quantity field, enter the total number of assets in the group. You enter a value greater than one for an asset group.
4. Associate the asset group with other objects such as contacts, organizations, and companies. This approach enables specific data access to roles or users when you implement multi-tenancy.
5. Click Save.

Subgroup an Asset Group

CA APM lets you divide an asset group into individual assets when you want to manage assets in the group separately. When you subgroup an asset group, the product removes assets from the group (decreases the group quantity) and creates either one new asset or multiple new assets (depending on your criteria). The product copies the information for the group to the new assets, except Serial Number, Alt Asset ID, Host Name, DNS Name, and MAC Address.

Follow these steps:

1. Click Asset.
2. Search to find the list of available assets.
3. Click the asset that you want to subgroup.
   The Asset Details page for the selected asset appears.
4. Click Subgroup.

   Note: The Subgroup button is enabled only for an asset with a quantity greater than one.

   The Subgroup Asset wizard appears.
5. Select a subgrouping option and click Next. The following fields require explanation:

- **Create a new asset**
  Divides the original asset group into two assets. You specify the quantity for the new asset. The remaining quantity is left with the original asset.
  For example, you have an asset group with a quantity of 50. You want to divide the group into two assets with a quantity of 35 for the new asset and 15 for the original asset. You use this subgrouping option and specify 35 for the new asset quantity.

- **Create individual assets each with a quantity of one**
  Divides the entire quantity of the original asset group into multiple assets. Each asset has a quantity of one.
  For example, you have an asset group with a quantity of 25. You want to divide the group into 25 individual assets. You use this option.

6. Follow the wizard to define unique asset names and to specify the data that you want to copy to the new assets.

   Note: If you do not define unique asset names, the new assets retain the name of the original asset group.

7. Click Finish when you have completed the wizard.

8. Click Save.

Asset Registration

Use the *asset registration process* to report on a single asset and identify the instances of the asset within all asset functional areas through asset registration fields. These fields help ensure that assets within an asset functional area are not duplicated.

The following fields on the Asset Details page represent the asset registration fields:

- Asset Name
- Serial Number
- Asset Tag (represented on the page as Alt Asset ID)
- Host Name
- DNS Name
- MAC Address

Asset Configurations

This article contains the following topics:

An *asset configuration* is a description of an asset (for example, a desktop computer) and its individual components (for example, personal productivity software, monitor, modem, and so forth). CA APM lets you track the configuration information for both an asset and model. In addition, you can associate an asset or model record to their component asset and model records to initiate a relationship between them.

This information helps you maintain historical information about the changes to a configuration for an asset over the course of its life. You can define configuration records for any model or asset in the repository.

Asset configuration records can be of the following types:

Model configuration. Describes the configurations that manufacturers currently offer and any substitutions or additions that your company typically makes to those configurations when you purchase them. Use this type of configuration record to describe configurations for hardware models.

- **Asset configuration**. Describes the configurations of existing hardware assets. Use this type of configuration record when the asset configurations are different from the standard model configurations to indicate the changes between the model and asset configurations. You can also use this configuration type to describe changes to existing configurations.

You can change these configuration types at any time and manage the changes.

Add Components in a Model Configuration

You associate a hardware model to its component models to define a model configuration. A generic model is a model that is not acquired as an asset, for example, keyboards and network cards. Generic models comprise a model configuration. This configuration is available to the inherited assets from the model.

Follow these steps:

1. Click Model and search for the list of available models.
2. Click the model for which you want to add components.
3. Expand Configurations on the left and click Model Configuration.
4. Click Select New, search for and select a model.
5. Click the Edit Record icon next to the model name to define the association between the hardware model and model components.
6. Click Save.

Define Generic Model Configuration Details

CA APM lets you define configuration details for a generic model on which an asset can be based.

Follow these steps:

1. Click Model.
2. Search for the list of available models.
3. Click the model for which you want to define a generic configuration.
4. Expand Configurations on the left and click Model Configuration.
5. Click Select New to search for and select a model.
6. Click Save.

Define Generic Asset Configuration Details

CA APM lets you define configuration details for a generic asset.

Follow these steps:

1. Click Asset.
2. Search for the list of available assets.
3. Click the asset for which you want to define a generic configuration.
4. Expand Configurations on the left and click Model Configuration.
5. Click Select New to search for and select a model.
6. Click Save.

Define Specific Asset Configuration Details

CA APM lets you define a specific asset configuration.

Follow these steps:

1. Click Asset.
2. Search for the list of available assets.
3. Click the asset for which you want to define a specific configuration.
4. Expand Configurations on the left and click Asset Configuration.
5. Click Select New to search for and select an asset.

6. Click Save.

Add Components in an Asset Configuration

An asset can inherit the components from a model. Unicenter APM lets you add components to an asset configuration, for example, an external hard drive or a DVD writer.

Follow these steps:

1. Click Asset.
2. Search for the list of available assets.
3. Click the asset for which you want to add components.
4. Expand Configurations on the left and click Asset Configuration.
5. Click Select New in the Asset Configuration section, search for and select an asset.
6. Click Save.

Update or Delete a Configuration Record

CA APM lets you update or delete a configuration record.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click Model or Asset.
2. Search for the model or asset for which you want to update or delete the configuration record.
3. Click the model or asset in the search results list.
4. Expand Configurations on the left and click the appropriate configuration option. For example, click Asset Configuration or Model Configuration.
5. Perform the steps for one of the following actions.
6. Update the configuration record.
    a. Click the Edit Record icon next to the configuration record.
    b. Select the new information for the configuration record.
    c. Click Save.

7. Delete the configuration record.
    a. Click the Mark for Deletion icon next to the configuration record.
    b. Click Save.

View the Configuration When an Asset is a Component

CA APM lets you view the configuration when an asset is a component.

Follow these steps:

1. Click Asset.
2. Search for the asset for which you want to view the configuration.
3. Click the asset in the search results list.
4. Expand Configurations on the left and click Asset Configuration.
   The list of assets in the specific configuration appears.

Costs and Payments

This article contains the following topics:

CA APM lets you track financial information that is associated with assets and legal documents. Tracking costs and payments helps reduce the risk of overpaying or underpaying vendors and suppliers. This information is also useful when deciding about future equipment purchases and deployment.

In addition to tracking cost-related information for assets and legal documents, use cost records with payments to create *payment schedules.* The schedules can help you make timely payments and reduce the risk of overpayment. The information that you provide on the Cost page is used to calculate the payment schedules. If you define the cost as a recurring cost, the schedule includes multiple payment records. For example, if you enter a cost that recurs monthly for one year, the product automatically creates 12 payment records. If the cost is a one-time cost (not a recurring cost), the schedule includes only a single payment record.

Cost records store information about costs and billing, payees, recurring charges, and one time charges. Payment records maintain information about individual payments that are related to a specific cost. A payment record also calculates and displays the total scheduled payment amount, total paid amount, and the balance due for a given cost. A payment record can represent a single payment of the full cost or multiple partial payments.

Define the Parts and Pricing for a Model

You can define the parts and pricing details for a model to identify the individual component costs that comprise the total cost for a model. For example, you have a model named Dell Precision Workstation 410. You can define the parts and pricing for the internal drives, video connectors, USB connectors, SCSI port connectors, and power supply.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Model.
2. Search to find the list of available models.
3. Click the model for which you want to define the parts and pricing.
4. In the Parts and Pricing area of the page, click New and enter the parts and pricing details.
5. Click Save.

Define the Cost for an Asset or Legal Document

Defining asset costs helps you track and manage the financial information that is related to a specific asset or legal document. You can add multiple cost records for an asset or legal document. You can also add cost information to multiple assets or legal documents and update multiple payment records.

Follow these steps:

1. Click Asset or Legal Document.
2. Search to find the list of available items.
3. Click the asset or legal document that you want to update.
4. On the left, click Costs.
5. Click New and enter the cost information.
   The following fields require explanation:

   - **Unit Amount**
     Specifies the cost per unit.
   - **Total Amount**
     Displays the total cost for the total quantity of the selected asset. This amount is calculated automatically by multiplying the Unit Amount on the Costs page by the Quantity on the Asset Details page.

- **Recurring Period**
  Specifies the number of Recurring Period Units (days, months, or years) after which the cost recurs. For example, if you enter 1 for the Recurring Period and select Month for the Recurring Period Units, the cost recurs every month.

  Note: If you specify a value other than zero, select the Recurring Period Units and Termination Date.

- **Recurring Period Units**
  Specifies the unit (days, months, or years) for the Recurring Period.

- **Termination Date**
  Specifies the last date for the recurring schedule.

6. Click Save.

   Note: If you specify recurring period information for an asset cost, a payment schedule with multiple payments is automatically created. If you do not specify recurring period information, the payment schedule includes only one payment.

7. (Optional) View the payment schedule for the cost that you defined using the following steps:

   a. Click the Edit Record icon for the cost record.

   b. Click Show Payments on the right.

      Note: You can record payments that you made for this cost.

Add Cost Records to Multiple Assets

CA APM lets you add a cost record to multiple assets at a time. For example, you procured 20 new laptops and want to enter cost records for these laptops.

You can choose to update individual asset cost record or make changes to all the records at a time. For example, all the laptops that you procured have the same Unit Amount. You enter the Unit Amount and apply the value to all the asset cost records.

Follow these steps:

1. Click the Asset tab.

2. Click Add Asset Cost under Mass Change utilities on the left.

3. Search for the list of the available assets.

> **Note**: You can only add new cost records to the assets. To update existing cost records, you must open the respective asset cost record and must update it.

4. To make cost record changes to multiple assets at the same time, complete the following steps:
    a. Under Search Results, select the assets that have common cost record fields.
    b. Click Fill All Values in a Column.
    c. Click New.
    d. In the Select Column drop-down list, select the cost record field name that you want to fill for the assets.
    e. In the Value text box, enter the data that you want to update.
    f. Click the Check button.
    The selected field column is updated with the value you entered.
5. Under Search Results, enter the appropriate values in the cost record fields.
6. Click Submit.
    The cost records are added to the assets.

Delete a Cost Record

You can delete the cost record of an asset or legal document. The payment records that are associated with the deleted cost record are also deleted.

> **Important!** When you delete a cost record, you can no longer view the audit history for the record.

Follow these steps:

1. Click Asset or Legal Document.
2. Search for and select the asset or legal document for which you want to delete the cost record.
3. On the left, click Costs.
4. Click the Mark for Deletion icon for the records you want to delete.

Note: To reverse the Mark for Deletion selection, click the Undo Record Deletion icon.

5. Click Save.

Payment Schedules and Recalculation

The Payment Schedule is a list of the payments due, based on the cost information you provide on a cost record. CA APM automatically generates the payment schedule in the form of a table when you define and save a cost record. The schedule generated depends on whether the cost is a one-time cost or a recurring cost.

For a one-time cost, the schedule assumes that you will pay the entire amount on the date you incurred the cost. One payment record is scheduled.

For a recurring charge, the schedule assumes that you will make payments of equal amounts for each recurring period. One payment record for each recurring period is scheduled.

Each row in the payment schedule represents a payment that you expect to make. If a payment is done, you can manually enter the date and amount paid details in the respective columns.

By default, every schedule is system-maintained as CA APM creates schedules when you create and save cost records. However, when you manually change information in a payment schedule, it becomes user-maintained.

System-Maintained Payment Schedules

A system-maintained payment schedule is a schedule that CA APM creates and automatically calculates the payments and dynamically updates whenever the cost record is modified. CA APM recalculates payment schedule based on the criteria you provide.

For example, you expect costs to escalate 3% a year and specify an escalation percentage. CA APM creates a payment schedule on this data. Later, if you change the escalation percentage to 3.5%, CA APM automatically recalculates the schedule. This helps you adjust cost information affecting the payment schedule to meet your requirements.

Payments are calculated automatically when you change the following values of the cost record:

- Unit Amount
- Recurring Period
- Recurring Period Units
- Escalation Percent
- Begin Date
- Termination Date
- Asset Quantity

User-Maintained Payment Schedule

The system-maintained payment schedule becomes user-maintained when you manually change the information on the payment schedule.

For example, to change the escalation percentage, you perform one of the following tasks:

- Recalculate each payment manually and update the amount due in each row.
- Specify the cost information and Save. CA APM automatically recalculates and updates the payments.

Events and Notifications

This article contains the following topics:

An *event* represents an activity related to a field (default or extended) for an object. When you define an event, you specify the criteria that must be met before the event occurs. For example, you want to know when the data in a particular field changes. You can define an event that detects the data change. An event works in combination with a *notification*, which the workflow provider (for example, CA Process Automation) creates to alert your team members that an important event has occurred for a specific field or object. By using events and notifications, you alert people about upcoming events and help ensure that the appropriate tasks are performed in the correct order at the right time.

A notification is triggered when an event that you define occurs. For example, you define a date event on the Termination Date field for a legal document to notify the contract manager 15 days before a legal contract expires. The contract manager uses the 15 days to review and possibly negotiate a better contract. When the date arrives (that is, 15 days before the contract expires), the event occurs and the notification process is triggered through the workflow provider. The workflow provider constructs, issues, and manages the notification based on the configuration that you provided in the workflow provider and in CA APM.

The default notification method in CA APM supports email notifications using a workflow provider. You can send an email notification to any user or distribution list that is defined in your internal email system, even if the user is not a CA APM user. In addition, you can send an email to any external email address, if permitted by your email system.

You can also configure the notification process in the workflow provider to trigger any type of process. For example, you can set up the notification process to perform certain actions in another application when an event occurs in CA APM. For information about setting up different notification processes, see your workflow provider documentation.

You can define the following types of events to track and manage important changes to fields or objects:

- Date events. Monitor a date field for an object and have the workflow provider notify you that an important date is approaching or has passed.
- Change events. Monitor a field for an object and have the workflow provider notify you that the field value has changed.
- Watch events. Monitor a field for an object and have the workflow provider notify you about a potential obstruction to completing a task.

Escalation of Notifications

When an event occurs, the workflow provider sends an email notification to the recipients that you specified when you defined the event. CA APM lets you send email notifications to different levels of recipients.

- *Initial recipients* are the primary recipients of the notification. They are the first users to receive the notification and to respond and acknowledge the notification. The notification contains information about the event that you specified when you defined the event. The recipient receives a reminder email before the acknowledgment due date arrives. If the recipient still does not acknowledge the notification by the due date, the notification is escalated if you selected a workflow process with escalation.
- *Escalation recipients* are secondary recipients of the notification. If the initial recipients do not acknowledge the notification within a specified time frame, the product escalates the notification to the escalation recipients if you selected a workflow process with escalation. Escalations help ensure that someone is notified about an important date or event when the initial recipient is not available to acknowledge the notification. The product includes the following workflow processes and escalations:

- Notification and One Escalation - Sends a notification to the initial recipient and sends a reminder email. If the recipient acknowledges the notification, the process marks the event as completed. If the recipient does not acknowledge in the specified time frame, the process escalates the notification to the escalation recipient. If the escalation recipient responds, the process marks the event as completed. If the escalation recipient does not respond, the process marks the event as failed.

- Notification without ACK - Sends a notification to the initial recipient and marks the event as completed. The recipient does not need to respond and the process does not escalate the notification.

- Notification without Escalation - Sends a notification to the initial recipient and sends a reminder email. If the recipient does not respond, the process marks the event as failed. If the recipient responds in the specified time frame, the process marks the event as completed.

The notification levels let you notify one or more users about an event and provide separate instructions to each user. You define the recipients and the notification escalation levels when you specify the workflow provider process parameters (see page 2393) for an event.

Acknowledgements

An email notification is acknowledged when the recipient opens the email, clicks the link to CA Process Automation, logs in to CA Process Automation, and acknowledges receipt of the notification. You acknowledge an email notification in the workflow provider.

The email that is sent to the initial recipient contains the message that you specified when you defined the event. If a user does not acknowledge receipt of the email, the notification is escalated to the next responsible recipient if the selected workflow process includes escalations. When a notification is acknowledged, the product does not perform any future escalations for the same event notification.

Email Notification Process Selection

When a date, change, or watch event occurs, the email notification process is started in the workflow provider (for example, CA Process Automation). You define and set up the email notification process in the workflow provider and in CA APM (for example, you define the email recipients, levels of escalation, and notification text). CA APM lets you define different types of notification processes in the workflow provider. For example, you can have an email notification process (provided with the product) and another user-defined process that initiates actions in an external application, such as an asset management dashboard. You select the notification process that you want to use with a specific event when you define the event.

Note: For more information about defining notification processes in the workflow provider, see your workflow provider documentation.

The type of email notification process that is started after an event occurs depends on the process that you selected when you defined the event. The following email notification processes are provided with the product and apply to the CA Process Automation workflow provider:

- Notification and One Escalation - Notifies the initial recipient and sends a reminder email. If the recipient acknowledges the notification, the process marks the event as completed. If the recipient does not acknowledge in the specified time frame, the process escalates the notification to the escalation recipient. If the escalation recipient responds, the process marks the event as completed. If the escalation recipient does not respond, the process marks the event as failed.

- Notification without ACK - Notifies the initial recipient and marks the event as completed. The recipient does not need to acknowledge the notification.

- Notification without Escalation - Notifies the initial recipient and sends a reminder email. If the recipient does not acknowledge the notification within the specified time frame, the process marks the event as failed. If the recipient acknowledges within the specified time frame, the process marks the event as completed.

You can define additional notification processes in the workflow provider that perform other actions (in addition to email notifications) when events occur. You can then select one of your own defined processes when you define an event.

How to Manage Events and Notifications

Events work in combination with notifications, which the workflow provider (for example, CA Process Automation) creates, to communicate information to your team members about important events and activity. To manage events and notifications, complete the following steps:

1. Administrators grant permissions to users to manage events.

   For more information about the permissions to manage events, see Grant Permissions to Manage Events (see page 1523).

2. Open an existing local or global configuration and define any of the following events:

   - Date event (see page 2379)
   - Change event (see page 2384)
   - Watch event (see page 2388)

3. When defining an event, map all required workflow provider notification parameters to a CA APM object attribute (see page 2393).

4. The workflow provider initiates the email notification process.

5. View an audit history of events.

6. (Optional) The notification recipient acknowledges the notification (see page 2378).

Date Events

Use a *date event* to monitor a date field for an object and have the workflow provider (for example, CA Process Automation) notify you that an important date is approaching or has passed. Date events are based on the value that is stored in a specific date field (default and extended fields), and the

notification from the workflow provider provides an advanced warning to alert someone to complete a follow-up task. The date on which a user is notified about the upcoming or passed event is based on the field value for the object and the information that you specify when you define the event, including the Days After value.

CA APM lets you define one or more date events for a single field.

Note: As a rule, events are not triggered (and notifications are not sent) for field changes that happened before the event was defined. An exception to this rule occurs for date events. If the notification date occurs *after* the event was defined, an event is triggered (and a notification is sent) even if the field change happened *before* the event was defined.

Example: Define a Date Event to Terminate a Legal Document

In this example, a contract negotiator must review contracts thirty days before they expire. You define a date event on the Terminate Date field for a legal document. For example, when the contract manager adds a legal document for which the termination date is 3/31/2010, a notification is sent to the appropriate person on 3/1/2010.

Define a Date Event

CA APM lets you define a date event to monitor a date field and have the workflow provider (for example, CA Process Automation) notify you that an important date is approaching or has passed. For example, you can define a date event on the Terminate Date field for a legal document. You can define one or more date events for a single field.

Note: If your administrator has granted you the correct permissions, you can complete this task.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled. In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

The Events page for the selected field appears.

2. Click New.

3. Specify the information for the date event.
   The following fields require explanation:

   - **Event Type**
     Select the type of event as a date event. After you select the event type and save the event, you cannot change the event type. If you select the incorrect event type when defining an event, delete the event and define it again using the correct event type.

   - **Days After**
     Specify a positive or negative number to indicate how many days before or after a field change occurs to create a date event.

     - A positive number indicates how many days after the original value has passed to create a date event.

     - A negative number indicates how many days before the original value approaches to create a date event.

   - **Inactive**
     Select this check box to indicate that the date event is inactive. When you make a date event inactive, no new notifications are created for the event. However, pending notifications are processed.

   - **Event Provider**
     Select the workflow provider to notify users that the date event has occurred (for example, CA IT Process Automation Manager). When you select a provider, all available workflow processes for the selected provider appear in the Workflow Process field.

   - **Workflow Process**
     Identifies the workflow process for the workflow provider. When you select a workflow process, all available process parameters for the workflow provider appear.

     - Notification and One Escalation - Notifies the initial recipient and sends a reminder email. If the recipient acknowledges the notification, the process marks the event as completed. If the recipient does not acknowledge in the specified time frame, the process escalates the notification to the escalation recipient. If the escalation recipient responds, the process marks the event as completed. If the escalation recipient does not respond, the process marks the event as failed.

     - Notification without ACK - Notifies the initial recipient and marks the event as completed. The recipient does not need to acknowledge the notification.

     - Notification without Escalation - Notifies the initial recipient and sends a reminder email. If the recipient does not acknowledge the notification within the specified time period, the process marks the event as failed. If the recipient acknowledges within the specified time period, the process marks the event as completed.

     - (Optional) Additional Process Types - Uses processes you defined in the workflow provider.

- **Notification Parameters**
  Specify each process parameter for the workflow provider by doing one of the following in each field:
  - Enter an actual (hard-coded) value.
  - Click Map Fields to map the parameter to a CA APM object attribute (see page 2393).
  - Enter an actual (hard-coded) value and, in the same field, click Map Fields to map the parameter.

  Note: Refer to the field tooltips for specific information about the format and content of each parameter field.

4. Click Save.
5. Click CONFIGURE: OFF.
   The configuration of the date event is complete.

Update a Date Event

CA APM lets you update the information for an existing date event. For example, you can change the event name and description, and you can make the event inactive.

Note: If your administrator has granted you the correct permissions, you can complete this task.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled.

   In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

2. Click the Edit Record icon next to the date event that you want to update.

3. Enter the new information for the date event.

   Note: After you define and save an event, you cannot change the Event Type, Event Cause, Value Changed From, and Value Changed To. If you enter the incorrect information, delete the event and define it again using the correct information.

4. Click the Complete Record Edit icon.

5. Click Save.

6. Click CONFIGURE: OFF.
   The configuration of the date event is complete.

Delete a Date Event

CA APM lets you delete a date event that you do not need. For example, when you do not want to be notified about a change to the Terminate Date field for a legal document, you can delete the associated date event. If your administrator has granted you the correct permissions, you can complete this task.

Note: Any pending notifications from the workflow provider (for example, CA Process Automation) about the event are sent before the event is deleted. When you delete an event, all historical information about the event is deleted. We recommend that instead of deleting the event, you make the event inactive. That way, if you need the event in the future, you do not have to redefine it.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure.

   On the left, click CONFIGURE: ON. The configuration of the event is enabled.

   In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

Next to the field, click the Event Configuration icon. The Events page for the selected field appears.

2. Click the Mark for Deletion icon next to the date event that you want to delete.

3. Click Save.

4. Click CONFIGURE: OFF.
   The configuration of the date event is complete.

Change Events

Use a *change event* to monitor a field for an object and have the workflow provider (for example, CA Process Automation) notify you that the field value has changed. Change events are based on the value that is stored in a specific field (default and extended fields), and the notification from the workflow provider provides a warning to alert someone when the value of a field is set or changes.

CA APM lets you define one or more change events for a single field.

Example: Define a Change Event to Find Equipment for a New Employee

In this example, asset technicians provide the appropriate equipment when an employee is hired or transferred to a different department. You define a change event that issues a notification to a member of the asset technician team when the Department field value for the contact is set or changes. This notification alerts the technician to find equipment for the new or transferred employee.

Define a Change Event

CA APM lets you define a change event to monitor a field and have the workflow provider (for example, CA Process Automation) notify you that the field value has changed. For example, you can define a change event on the Department field for a contact. You can define one or more change events for a single field.

Note: If your administrator has granted you the correct permissions, you can complete this task.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure.

   On the left, click CONFIGURE: ON. The configuration of the event is enabled.

   In the Configuration Information area of the page, select an existing global or local configuration.

Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

Next to the field, click the Event Configuration icon.

The Events page for the selected field appears.

2. Click New.

3. Specify the information for the change event.
The following fields require explanation:

   - **Event Type**
     Select the type of event as a change event. After you select the event type and save the event, you cannot change the event type. If you select the incorrect event type when defining an event, delete the event and define it again using the correct event type.

   - **Event Cause**
     Select the type of action that must happen to the field for the change event to occur. Supported event causes include when a field is changed, a record is added, and a record is deleted.

   - **Value Changed From**
     Select the initial state of the field value for the change event to occur. Supported field value changes include the following options:

     - **Any value**. Any field value sets the initial state.
     - **Blank**. A blank field value sets the initial state.
     - **Old value**. A specific value sets the initial state.

   - **Value**
     Available when you select *Old value* in the Value Changed From field. Enter a specific value to set the initial state.

   - **Value Changed To**
     Select the final state of the field value for the change event to occur. Supported field value changes include the following options:

     - **Any value**. Any field value, except a blank value, sets the final state.
     - **Blank**. A blank field value sets the final state.
     - **New value**. A specific value sets the final state.

   - **Value**
     Available when you select *New value* in the Value Changed To field. Enter a specific value to set the final state.

- **Inactive**
  Select this check box to indicate that the change event is inactive. When you make a change event inactive, no new notifications are created for the event. However, pending notifications are processed.

- **Event Provider**
  Select the workflow provider to notify users that the change event has occurred (for example, CA IT Process Automation Manager). When you select a provider, all available workflow processes for the selected provider appear in the Workflow Process field.

- **Workflow Process**
  Identifies the workflow process for the workflow provider. When you select a workflow process, all available process parameters for the workflow provider appear.

  - Notification and One Escalation - Notifies the initial recipient and sends a reminder email. If the recipient acknowledges the notification, the process marks the event as completed. If the recipient does not acknowledge in the specified time frame, the process escalates the notification to the escalation recipient. If the escalation recipient responds, the process marks the event as completed. If the escalation recipient does not respond, the process marks the event as failed.

  - Notification without ACK - Notifies the initial recipient and marks the event as completed. The recipient does not need to acknowledge the notification.

  - Notification without Escalation - Notifies the initial recipient and sends a reminder email. If the recipient does not acknowledge the notification within the specified time period, the process marks the event as failed. If the recipient acknowledges within the specified time period, the process marks the event as completed.

  - (Optional) Additional Process Types - Uses processes you defined in the workflow provider.

- **Notification Parameters**
  Specify each process parameter for the workflow provider by doing one of the following in each field:

  - Enter an actual (hard-coded) value.

  - Click Map Fields to map the parameter to a CA APM object attribute (see page 2393).

  - Enter an actual (hard-coded) value and, in the same field, click Map Fields to map the parameter.

  Note: Refer to the field tooltips for specific information about the format and content of each parameter field.

4. Click Save.

5. Click CONFIGURE: OFF.
   The configuration of the event is complete.

Update a Change Event

CA APM lets you update the information for an existing change event. For example, you can change the event name and description, and you can make the event inactive.

Note: If your administrator has granted you the correct permissions, you can complete this task.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.
   The configuration of the event is enabled.

2. In the Configuration Information area of the page, select an existing global or local configuration. Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

   Note: Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration

3. Click the Edit Record icon next to the change event that you want to update.

4. Enter the new information for the change event.

   Note: After you define and save an event, you cannot change the Event Type, Event Cause, Value Changed From, and Value Changed To. If you enter the incorrect information, delete the event and define it again using the correct information.

5. Click the Complete Record Edit icon.

6. Click Save.

7. Click CONFIGURE: OFF.
   The configuration of the change event is complete.

Delete a Change Event

CA APM lets you delete a change event that you do not need. For example, when you do not want to be notified about a change to the Department field for a contact, you can delete the associated change event. If your administrator has granted you the correct permissions, you can complete this task.

Note: Any pending notifications from the workflow provider (for example, CA Process Automation) about the event are sent before the event is deleted. When you delete an event, all historical information about the event is deleted. We recommend that instead of deleting the event, you make the event inactive. That way, if you need the event in the future, you do not have to redefine it.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled. In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

2. Click the Mark for Deletion icon next to the change event that you want to delete.

3. Click Save.

4. Click CONFIGURE: OFF.
   The configuration of the change event is complete.

Watch Events

Use a *watch event* to monitor a field for an object and have the workflow provider (for example, CA Process Automation) notify you about a potential obstruction to completing a task. Watch events are based on inactivity on a particular field (default and extended fields) within a specified time period, and the notification from the workflow provider provides an advanced warning to alert someone about a potential obstruction. If the field value changes within the time period, the workflow provider does not send a notification.

CA APM lets you define one or more watch events for a single field.

Example: Define a Watch Event to Configure and Deploy New Laptops

In this example, you require that asset technicians configure and deploy all new laptops to employees within five days of receiving the laptop. To meet this requirement, you define a watch event that creates an event when an asset is assigned a status (Lifecycle Status field) of received. If the status remains received for more than five days, a notification is sent to an asset technician.

Define a Watch Event

CA APM lets you define a watch event to monitor a field and have the workflow provider (for example, CA Process Automation) notify you about inactivity on a particular field. For example, you can define a watch event on the Lifecycle Status field for an asset. You can define one or more watch events for a single field.

Note: If your administrator has granted you the correct permissions, you can complete this task.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled. In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

2. Click New.

3. Specify the information for the watch event.

Important! The Value Changed From and Value fields work together to start the timer for the watch event. The timer continues for the duration that you specify in the Days After field. The Value Changed To and Value fields work together to indicate the value that you want to achieve and stop the timer. If the value that you want to achieve does not occur in the specified time period after the timer starts, the watch event occurs and indicates that the defined workflow did not happen.

The following fields require explanation:

- **Event Type**
  Select the type of event as a watch event. After you select the event type and save the event, you cannot change the event type. If you select the incorrect event type when defining an event, delete the event and define it again using the correct event type.

- **Event Cause**
  Select the type of action that must happen to the field for the watch event to occur. A supported event cause is when a field is changed.

- **Days After**
  Specify a positive number to indicate how many days to wait after the Value Changed From field value to start the watch timer.

  Note: If the Value Change To field value does not occur, the watch timer expires after the number of days that you specify. After the watch timer expires, the watch event is created. However, the watch timer will stop when the Value Change To field value changes to the specified value and no watch event is created.

- **Value Changed From**
  Select the initial field value to start the timer to create the watch event. Supported field value changes include the following options:

  - **Any value**. Any field value starts the timer for the watch event.
  - **Blank**. A blank field value starts the timer for the watch event.
  - **Old value**. A specific initial value starts the timer for the watch event.

- **Value**
  Available when you select *Old value* in the Value Changed From field. Enter a specific value to start the timer for the watch event.

- **Value Changed To**
  Select the final state of the field value that stops the timer for the watch event and prevents the watch event from occurring. Supported field value changes include the following options:

  - **Any value**. Any field value stops the timer for the watch event and prevents the watch event from occurring.

- **Blank**. A blank field value stops the timer for the watch event and prevents the watch event from occurring.

- **New value**. A specific field value stops the timer for the watch event and prevents the watch event from occurring.

- **Value**
  Available when you select *New value* in the Value Changed To field. Enter a specific value to stop the timer for the watch event and prevent the watch event from occurring.

- **Inactive**
  Select this check box to indicate that the watch event is inactive. When you make a watch event inactive, no new notifications are created for the event. However, pending notifications are processed.

- **Event Provider**
  Select the workflow provider to notify users that the watch event has occurred (for example, CA IT Process Automation Manager). When you select a provider, all available workflow processes for the selected provider appear in the Workflow Process field.

- **Workflow Process**
  Identifies the workflow process for the workflow provider. When you select a workflow process, all available process parameters for the workflow provider appear.

  - Notification and One Escalation - Notifies the initial recipient and sends a reminder email. If the recipient acknowledges the notification, the process marks the event as completed. If the recipient does not acknowledge in the specified time frame, the process escalates the notification to the escalation recipient. If the escalation recipient responds, the process marks the event as completed. If the escalation recipient does not respond, the process marks the event as failed.

  - Notification without ACK - Notifies the initial recipient and marks the event as completed. The recipient does not need to acknowledge the notification.

  - Notification without Escalation - Notifies the initial recipient and sends a reminder email. If the recipient does not acknowledge the notification within the specified time period, the process marks the event as failed. If the recipient acknowledges within the specified time period, the process marks the event as completed.

  - (Optional) Additional Process Types - Uses processes you defined in the workflow provider.

- **Notification Parameters**
  Specify each process parameter for the workflow provider by doing one of the following in each field:

  - Enter an actual (hard-coded) value.

  - Click Map Fields to map the parameter to a CA APM object attribute (see page 2393).

  - Enter an actual (hard-coded) value and, in the same field, click Map Fields to map the parameter.

Note: Refer to the field tooltips for specific information about the format and content of each parameter field.

4. Click Save.

5. Click CONFIGURE: OFF.
   The configuration of the watch event is complete.

Update a Watch Event

CA APM lets you update the information for an existing watch event. For example, you can change the event name and description, and you can make the event inactive.

Note: If your administrator has granted you the correct permissions, you can complete this task.

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled. In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

2. Click the Edit Record icon next to the watch event that you want to update.

3. Enter the new information for the watch event.

   Note: After you define and save an event, you cannot change the Event Type, Event Cause, Value Changed From, and Value Changed To. If you enter the incorrect information, delete the event and define it again using the correct information.

4. Click the Complete Record Edit icon.

5. Click Save.

6. Click CONFIGURE: OFF.
   The configuration of the watch event is complete.

Delete a Watch Event

CA APM lets you delete a watch event that you do not need. For example, when you do not want to be notified about a change to the Lifecycle Status field for an asset, you can delete the associated watch event. If your administrator has granted you the correct permissions, you can complete this task.

Note: Any pending notifications from the workflow provider (for example, CA Process Automation) about the event are sent before the event is deleted. When you delete an event, all historical information about the event is deleted. We recommend that instead of deleting the event, you make the event inactive. That way, if you need the event in the future, you do not have to redefine

Follow these steps:

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled. In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

2. Click the Mark for Deletion icon next to the watch event that you want to delete.

3. Click Save.

4. Click CONFIGURE: OFF.
   The configuration of the watch event is complete.

Workflow Provider Process Parameters

You perform some of the setup and configuration of the email notification process in the workflow provider. However, you also specify the process parameters for the workflow provider when you define an event in CA APM. The process parameters include items such as user IDs, email addresses, email subject, content of email, and other items. The workflow provider uses this information to construct, issue, and manage the email notification.

Note: For information about workflow provider process parameters that you must specify in CA Process Automation, see Integrate with CA Process Automation Integration for a Notification Process Manually (see page 3489). For information about setting up a notification process, see your workflow provider documentation.

You can provide actual (hard-coded) values when you specify the process parameters. If you use an actual value for an email address (or another parameter), you must verify that the address (or other data) is valid.

You can also map the process parameters to CA APM object attributes. If you map a process parameter to a CA APM object attribute, the workflow provider accesses CA APM to find the current value of the mapped attribute and uses that value to construct and manage the notification. For example, you map the process parameter Initial Email Addresses to the CA APM attribute Contact Email Address when you define an event. When that event occurs, the workflow provider determines the current value of the CA APM Contact Email Address and uses that value for the Email ID.

Important! To map CA Process Automation process parameters to CA APM objects successfully, you must understand the CA APM data objects and the CA Process Automation parameters. You need to determine which CA APM object is an appropriate match for each CA Process Automation parameter.

Notification and One Escalation Process Parameters

The process parameters that appear when you define an event depend on the workflow provider process type that you select. The Notification and One Escalation process is an email notification process that is included with the product. This process sends an email notification to the initial recipient when an event occurs and, if the initial recipient does not respond, escalates the email to the first escalation level recipients. When you select this process as the workflow process for an event, a list of parameters appears.

Important! CA APM and CA Process Automation do not validate the information that you enter for the parameters. You must verify that your input is valid and that you entered the data in the correct format.

The following fields require explanation:

- **Initial User IDs**
  CA Process Automation user ID (CA APM or non-CA APM user) for acknowledging the initial notification. You can specify more than one user ID, separated with colons. Do not enter spaces between entries.
  Example: This example contains a user ID (John) that is a text entry value and the mapped field {legaldoc.owner.userid}. The two items are separated with a colon. The mapped field {legaldoc.owner.userid} represents the user ID of the user in the Owner field of the Legal Document. To obtain the mapped field {legaldoc.owner.userid}, click the Map Fields button, select the Owner link in the Add Fields dialog, and select User ID from the list of attributes.

```
John:{legaldoc.owner.userid}
```

- **Initial Groups**
  CA Process Automation group name for acknowledging the initial notification. You can specify more than one group name, separated with colons. Do not enter spaces between entries.
  Example: This example contains a CA Process Automation group name (ITAM) that is a text entry value.

```
ITAM
```

- **Initial Email Addresses**
  Email address (or distribution list) of the initial recipient of the email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (john.doe@company.com) that is a text entry value and the mapped field {legaldoc.owner.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.owner.emailid} represents the email address of the user in the Owner field of the Legal Document. To obtain the mapped field {legaldoc.owner.emailid}, click the Map Fields button, select the Owner link in the Add Fields dialog, and select Email Address from the list of attributes.

```
john.doe@company.com;{legaldoc.owner.emailid}
```

- **Initial Email Copy Addresses**
  Email address (or distribution list) of the initial copy recipient of the email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (jane.doe@company.com) that is a text entry value and the mapped field {legaldoc.requestor.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.requestor.emailid} represents the email address of the user in the Requestor field of the Legal Document. To obtain the mapped field {legaldoc.requestor.emailid}, click the Map Fields button, select the Requestor link in the Add Fields dialog, and select Email Address from the list of attributes.

```
jane.doe@company.com;{legaldoc.requestor.emailid}
```

- **Initial Email Subject**
  Subject of the email message for the initial recipient. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Acknowledgement required for) and the mapped field {legaldoc.documentidentifier}.

```
Acknowledgment required for {legaldoc.documentidentifier}
```

- **Initial Email Message**
  Message of the email for the initial recipient. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier), the mapped field {legaldoc.documentidentifier}, and more text entry content.

```
The Legal Document Document Identifier {legaldoc.documentidentifier} requires your acknowledgment using the link in
the Subject of this email.
```

- **Acknowledgment Title**
  Title that appears on the acknowledgment task that the user accesses in CA Process Automation to acknowledge receipt of the notification. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier) only.

```
The Legal Document Document Identifier
```

- **Acknowledgment Description**
  Description that appears on the acknowledgment task that the user accesses in CA Process Automation to acknowledge receipt of the notification. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier) and the mapped field {legaldoc.documentidentifier}.

```
The Legal Document Document Identifier {legaldoc.documentidentifier}
```

- **Escalation User IDs**
  CA Process Automation user ID (CA APM or non-CA APM user) for acknowledging the escalation notification. You can specify more than one user ID, separated with colons. Do not enter spaces between entries.
  Example: This example contains a user ID (Mary) that is a text entry value and the mapped field {legaldoc.owner.supervisor.userid}. The two items are separated with a colon. The mapped field {legaldoc.owner.supervisor.userid} represents the user ID of the supervisor of the user in the Owner field of the Legal Document. To obtain the mapped field {legaldoc.owner.supervisor.userid}, click the Map Fields button, select the Owner link in the Add Fields dialog, select the Supervisor link, and select User ID from the list of attributes.

```
Mary:{legaldoc.owner.supervisor.userid}
```

- **Escalation Groups**
  CA Process Automation group name for acknowledging the escalation notification. You can specify more than one group name, separated with colons. Do not enter spaces between entries.
  Example: This example contains a CA Process Automation group name (ITAM) that is a text entry value.

```
ITAM
```

- **Escalation Email Addresses**
  Email address (or distribution list) of the recipient of the escalation email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (mary.doe@company.com) that is a text entry value and the mapped field {legaldoc.owner.supervisor.emailid}. The two items are separated with a semicolon. To obtain the mapped field {legaldoc.owner.supervisor.emailid}, click the Map Fields button, select the Owner link in the Add Fields dialog, select the Supervisor link, and select Email Address from the list of attributes.

```
mary.doe@company.com;{legaldoc.owner.supervisor.emailid}
```

- **Escalation Email Copy Addresses**
  Email address (or distribution list) of the copy recipients of the escalation email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (jane.doe@company.com) that is a text entry value and the mapped field {legaldoc.requestor.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.requestor.emailid} represents the email address of the user in the Requestor field of the Legal Document. To obtain the mapped field {legaldoc. requestor.emailid}, click the Map Fields button, select the Requestor link in the Add Fields dialog, and select Email Address from the list of attributes.

```
jane.doe@company.com;{legaldoc.requestor.emailid}
```

- **Escalation Email Subject**
  Subject of the escalation email. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Escalation for), the mapped field {legaldoc. documentidentifier}, and additional text entry content.

```
Escalation for {legaldoc.documentidentifier}. Acknowledgment required
```

- **Escalation Email Message**
  Message of the escalation email. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier), the mapped field {legaldoc.documentidentifier}, and more text entry content.

```
The Legal Document Document Identifier {legaldoc.documentidentifier} requires your acknowledgment using the link in
the Subject of this email.
```

- **Reminder Email Subject**
  Subject of the reminder email message for initial and escalation recipients. The product sends a reminder when half of the Acknowledgment Time-out period has passed. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Reminder for), the mapped field {legaldoc. documentidentifier}, and additional text entry content.

```
Reminder for {legaldoc.documentidentifier}. Acknowledgment required.
```

- **Reminder Email Message**
  Message of the reminder email for initial and escalation recipients. The product sends a reminder when half of the Acknowledgment Time-out period has passed. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Reminder: The Legal Document Document Identifier), the mapped field {legaldoc.documentidentifier}, and more text entry content.

```
Reminder: The Legal Document Document Identifier {legaldoc.documentidentifier} requires your acknowledgment using the
link in the Subject of this email.
```

- **Acknowledgment Time-out (Days:Hours:Minutes)**
  The amount of time that is allowed for acknowledgment after the email notification is sent before the escalation process begins. This time-out applies to initial and escalation notifications. Days, hours, and minutes can be any numeric value. The format must be *days*:*hours*:*minutes* (separated with colons).
  Example: This example specifies a time-out period of exactly four days.

```
4:00:00
```

Notification without ACK Process Parameters

The process parameters that appear when you define an event depend on the workflow provider process type that you select. The Notification without ACK process is an email notification process that is included with the product. This process sends an email notification to the specified recipient when an event occurs. The recipient does not need to acknowledge the notification, and the product does not escalate the notification. When you select this process as the workflow process for an event, a list of parameters appears.

Important! CA APM and CA Process Automation do not validate the information that you enter for the parameters. You must verify that your input is valid and that you entered the data in the correct format.

The following fields require explanation:

- **Email Address**
  Email address (or distribution list) of the recipient of the email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (john.doe@company.com) that is a text entry value and the mapped field {legaldoc.owner.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.owner.emailid} represents the email address of the user in the Owner field of the Legal Document. To obtain the mapped field {legaldoc.owner.emailid}, click the Map Fields button, select the Owner link in the Add Fields dialog, and select Email Address from the list of attributes.

```
john.doe@company.com;{legaldoc.owner.emailid}
```

- **Email Copy Address**
  Email address (or distribution list) of the copy recipient of the email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (jane.doe@company.com) that is a text entry value and the mapped field {legaldoc.requestor.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.requestor.emailid} represents the email address of the user in the Requestor field of the Legal Document. To obtain the mapped field {legaldoc. requestor.emailid}, click the Map Fields button, select the Requestor link in the Add Fields dialog, and select Email Address from the list of attributes.

```
jane.doe@company.com;{legaldoc.requestor.emailid}
```

- **Email Subject**
  Subject of the email message for the recipient. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Acknowledgment required for) and the mapped field {legaldoc.documentidentifier}.

```
Acknowledgment required for {legaldoc.documentidentifier}
```

- **Email Message**
  Message of the email for the recipient. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier), the mapped field {legaldoc.documentidentifier}, and more text entry content.

```
The Legal Document Document Identifier {legaldoc.documentidentifier} requires your acknowledgment using the link in
the Subject of this email.
```

Notification without Escalation Process Parameters

The process parameters that appear when you define an event depend on the workflow provider process type that you select. The Notification without Escalation process is an email notification process that is included with the product. This process sends an email notification to the specified recipient when an event occurs. If the recipient does not respond in the specified time period, the process does not escalate the notification. However, the process marks the associated event as failed. When you select this process as the workflow process for an event, a list of parameters appears.

Important! CA APM and CA Process Automation do not validate the information that you enter for the parameters. You must verify that your input is valid and that you entered the data in the correct format.

The following fields require explanation:

- **User IDs**
  CA Process Automation user ID (CA APM or non-CA APM user) for acknowledging the notification. You can specify more than one user ID, separated with colons. Do not enter spaces between entries.
  Example: This example contains a user ID (John) that is a text entry value and the mapped field {legaldoc.owner.userid}. The two items are separated with a colon. The mapped field {legaldoc.owner.userid} represents the user ID of the user in the Owner field of the Legal Document. To obtain the mapped field {legaldoc.owner.userid}, click the Map Fields button, select the Owner link in the Add Fields dialog, and select User ID from the list of attributes.

```
John:{legaldoc.owner.userid}
```

- **Groups**
  CA Process Automation group name for acknowledging the notification. You can specify more than one group name, separated with colons. Do not enter spaces between entries.
  Example: This example contains a CA Process Automation group name (ITAM) that is a text entry value.

```
ITAM
```

- **Email Addresses**
  Email address (or distribution list) of the recipient of the email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (john.doe@company.com) that is a text entry value and the mapped field {legaldoc.owner.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.owner.emailid} represents the email address of the user in the Owner field of the Legal Document. To obtain the mapped field {legaldoc.owner.emailid}, click the Map Fields button, select the Owner link in the Add Fields dialog, and select Email Address from the list of attributes.

```
john.doe@company.com;{legaldoc.owner.emailid}
```

- **Email Copy Addresses**
  Email address (or distribution list) of the copy recipient of the email. You can specify more than one address, separated with semicolons. You can enter spaces between entries.
  Example: This example contains an email address (jane.doe@company.com) that is a text entry value and the mapped field {legaldoc.requestor.emailid}. The two items are separated with a semicolon. The mapped field {legaldoc.requestor.emailid} represents the email address of the user in the Requestor field of the Legal Document. To obtain the mapped field {legaldoc.requestor.emailid}, click the Map Fields button, select the Requestor link in the Add Fields dialog, and select Email Address from the list of attributes.

```
jane.doe@company.com;{legaldoc.requestor.emailid}
```

- **Email Subject**
  Subject of the email message for the recipient. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Acknowledgment required for) and the mapped field {legaldoc.documentidentifier}.

```
Acknowledgment required for {legaldoc.documentidentifier}
```

- **Email Message**
  Message of the email for the recipient. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier), the mapped field {legaldoc.documentidentifier}, and more text entry content.

```
The Legal Document Document Identifier {legaldoc.documentidentifier} requires your acknowledgment using the link in
the Subject of this email.
```

- **Acknowledgment Title**
  Title that appears on the acknowledgment task that the user accesses in CA Process Automation to acknowledge receipt of the notification. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier) only.

```
The Legal Document Document Identifier
```

- **Acknowledgment Description**
  Description that appears on the acknowledgment task that the user accesses in CA Process Automation to acknowledge receipt of the notification. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (The Legal Document Document Identifier) and the mapped field {legaldoc.documentidentifier}.

```
The Legal Document Document Identifier {legaldoc.documentidentifier}
```

- **Acknowledgment Time-out (Days:Hours:Minutes)**
  The amount of time that is allowed for acknowledgment after the email notification is sent. Days, hours, and minutes can be any numeric value. The format must be *days*:*hours*:*minutes* (separated with colons).
  Example: This example specifies a time-out period of exactly four days.

```
4:00:00
```

- **Reminder Email Subject**
  Subject of the reminder email message. The product sends a reminder when half of the Acknowledgment Time-out period has passed. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Reminder for), the mapped field {legaldoc.documentidentifier}, and additional text entry content.

```
Reminder for {legaldoc.documentidentifier}. Acknowledgment required.
```

- **Reminder Email Message**
  Message of the reminder email. The product sends a reminder when half of the Acknowledgment Time-out period has passed. Enter text or combine text entry with mapped fields. You do not need to enter colons or semicolons to separate entries.
  Example: This example contains text entry content (Reminder: The Legal Document Document Identifier), the mapped field {legaldoc.documentidentifier}, and more text entry content.

```
Reminder: The Legal Document Document Identifier {legaldoc.documentidentifier} requires your acknowledgment using the
link in the Subject of this email.
```

Make an Event Inactive

CA APM lets you make an event inactive so that the workflow provider (for example, CA Process Automation) does not send future notifications for the event. The history about important dates and events is retained.

Note: If your administrator has granted you the correct permissions, you can complete this task.

To make an event inactive

1. Click the tab and optional subtab for the event definition that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the event is enabled. In the Configuration Information area of the page, select an existing global or local configuration.

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

   Next to the field, click the Event Configuration icon.

   The Events page for the selected field appears.

2. Click the Edit Record icon next to the event that you want to make inactive.
3. Select the Inactive check box.
4. Click the Complete Record Edit icon.
5. Click Save.
6. Click CONFIGURE: OFF.
   The configuration of the event is complete.

Notes

This article contains the following topics:

Notes are free-form explanatory text that you associate with any object, and supplement the information for an object. Notes are categorized by a *type* that you specify when you attach a note to an object. Use this information to search for objects that have a particular type of note assigned to them. For example, if another company acquires one of your primary suppliers, you can attach a company acquisition note to the company record for that supplier.

Default note types are provided for the following objects. Your administrator can define additional types.

- Models

- Assets
- Legal Documents
- Contacts
- Companies
- Organizations
- Locations
- Sites

Attach a Note

CA APM lets you attach a note to supplement the information for an object. For example, if another company acquires one of your primary suppliers, you can attach a company acquisition note to the company record for that supplier.

Follow these steps:

1. Click the object for which you want to attach a note. For example, click Model, Asset, Legal Document, Contact, Company, Organization, or Location.
2. Search for the list of available objects.
3. Click the object record for which you want to attach a note.
4. Click Notes on the left.
5. Click New and enter the note.
6. Click Save.

Update or Delete a Note

CA APM lets you update or delete a note that is attached to an object record.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click the object for which you want to update a note. For example, click Model, Asset, Legal Document, Contact, Company, Organization, or Location.
2. Search for the list of available objects.

3. Click the object record for which you want to update or delete a note.
4. Click Notes on the left.
5. Perform one of the following actions.
6. Update a note.
    a. Click the Edit Record icon for the note you want to update.
    b. Update the note information.
    c. Click Save.
7. Delete a note.
    a. Click the Mark for Deletion icon next to the note you want to delete.
    b. Click Save.

Hardware Asset Management

This section contains the following articles:

Hardware Reconciliation

This article contains the following topics:

The hardware reconciliation process matches *discovered assets* to corresponding *owned assets* from different logical repositories so that you can manage the assets based on your business practices. Use this process to identify the discrepancies between your owned and discovered assets. Hardware reconciliation identifies unauthorized, missing, under-utilized, and over-utilized assets, which helps you to optimize your hardware asset base.

- Owned assets provide IT asset information from a financial and ownership perspective. The product supports the entire lifecycle of an owned asset from procurement, acquisition, allocation, use, and disposal, including legal and cost information. Owned assets have purchase records, including a purchase order number, invoice number, associated costs (lease, payment schedule, maintenance), associated contracts (terms and conditions), and vendor information. The owned-asset data is entered and imported using the CA APM user interface, Administration tab, Data Importer.

- Discovered assets provide information about the assets that an enterprise is using or has deployed. External discovery products and the discovery component of CA Client Automation scan the assets on a network and store them as discovered assets in the CA MDB. Discovered assets contain evidence about the following information:

  - The asset is deployed and can be found on your network.

  - The asset is being used and has metrics.

  - The asset contains up-to-date configuration information for inventory.

The CA APM hardware reconciliation process matches the discovered asset data and the owned asset data that are stored in the CA MDB. The hardware reconciliation process may detect assets that cannot be reconciled with any of your owned assets. You can decide to add the unreconciled assets to your repository so that you can track and manage all assets in your network.

Hardware reconciliation automates the synchronization of ownership and discovered data. Hardware reconciliation supports the discovery component of CA Client Automation and third-party discovery products. These components and products are supported through the combination of the CA Asset Converter and the asset collector component of CA Client Automation. When CA SAM is installed, discovery connectors load the discovery data into the CA SAM repository. The discovery data is then synchronized with CA APM.

Hardware Reconciliation Engine

The *Hardware Reconciliation Engine* is a continuously processing Windows service that is responsible for the following tasks during the reconciliation process:

- Synchronizes discovered assets with ownership assets using reconciliation rules.

- Reconciles owned and discovered assets based on asset matching criteria (see page 2419).

- Maps discovery data to ownership data based on normalization rules (see page 2407).

- Updates selected asset fields in the product based on changes to the corresponding discovered assets.

- Completes the actions that are defined in the reconciliation rule that is being executed.

How Reconciliation Engines Process Reconciliation Rules

The date and time at which a reconciliation rule was last executed determines when the rule will be processed again. Hardware Reconciliation Engines process reconciliation rules in the following sequence, which allows for multiple tenant support as well as multiple Hardware Engines:

1. Each Hardware Reconciliation Engine searches for reconciliation rules that are not being processed by another engine and selects the rule that has the oldest processing date and time.

2. A Hardware Reconciliation Engine locks the reconciliation rule so it cannot be accessed by another engine, executes the rule, updates the rule date-and-time value, and then unlocks the rule. The Hardware Reconciliation Engine searches for the next available reconciliation rule with the oldest date-and-time value and repeats the process.

3. The process continues with all engines continuously operating and searching for and executing the next available reconciliation rule with the oldest date-and-time value.

How to Reconcile

The reconciliation process compares data from discovery products with CA APM ownership data in the CA MDB. This process reconciles discovered and owned assets, tracks changes to critical fields, and tracks discrepancies as the result of missing or deleted assets. To reconcile, complete the following steps:

1. Establish data normalization rules (see page 2407) to map data values between discovery repositories and the product.

2. Define a reconciliation rule to specify how to limit the data being processed and how to process the records found.

3. (Optional) Define reconciliation update options to specify the owned-asset fields that you want the Hardware Reconciliation Engine to update automatically with changes found in the corresponding discovered assets.

4. Define asset matching criteria (see page 2419) to match owned and discovered assets for a reconciliation rule.

5. (Optional) Exclude an ownership asset from the reconciliation process.

6. (Optional) Exclude an asset family from the reconciliation process.

7. View the reconciliation results in the message queue.

8. (Optional) Add unreconciled assets to your repository so that you can track and manage all assets in your network.

Note: You can generate reports to view information about your reconciliation results and environment. For more information about generating reports, see Reconciliation Reports (see page 2428).

Data Normalization

This article contains the following topics:

Data normalization is a step in the reconciliation process where you establish a list of rules to standardize, organize, and consolidate data between the product and discovery repositories. Normalization reduces, eliminates, and consolidates redundant data that is imported into the product from multiple sources, such as purchase order products, human resource products, procurement products, the Data Importer, and so forth.

When you normalize data, you reduce the time and effort necessary to manage the data. You also reduce the possibility of the user selecting the incorrect information when defining assets, models, and other objects, and when generating reports. The product guides you through the normalization process, enabling you to perform it much more efficiently and accurately. The consolidated discovery data is then reconciled with your owned assets during the reconciliation process and can be reported on using the reconciliation reports.

You normalize three of the fields that can be used as asset matching criteria (see page 2419): company, operating system, and system model. These fields are normalized because they often have multiple values that represent one normalized value. For example, the discovery tool may find many variations for the name of one company. You normalize all the variations to one value for the company name and include the normalized company name in asset matching criteria. These fields are normalized so that you can include them in asset matching criteria.

The Hardware Reconciliation Engine normalizes the data that is imported into the product by referencing the following normalization rules, which you define:

- Company normalization rules (see page 2408)
- Operating System normalization rules (see page 2411)
- System Model normalization rules (see page 2413)

Example: Normalize Company Data

In this example, when you import company data into the product using CA Client Automation, multiple variations of Document Management Company are discovered in various formats, including the following values:

- Document Management Company
- Document Management Co
- Doc Management Company
- Doc Management Co

To help users select the correct company when defining an asset and model and when generating reconciliation reports, you define company normalization rules to map all variations to Document Management Company. During the reconciliation process, the normalization rules map the values as follows, before an asset is updated in the CA MDB:

Note: A collected company that is mapped to an authoritative company affects Hardware Reconciliation only if the collected company is a discovered company.

Collected (Nonauthoritative Value)	Normalized (Authoritative Value)
Document Management Co	Document Management Company
Doc Management Company	Document Management Company
Doc Management Co	Document Management Company

Company Normalization Rules

Company normalization rules are intended for key organizations with which you have a business relationship, for example, Microsoft, Adobe, Lenovo, and so forth.

- **Collected Company**
  A *collected company* is either a discovered company or a *product-defined company*. Product-defined companies are collected from user input and other products that share the CA MDB. Hardware reconciliation reconciles only *discovered* companies. Collected companies have a *nonauthoritative* status. You map nonauthoritative collected companies to normalized *authoritative* companies.

Important! Only *discovered* collected companies that are mapped to normalized companies are reconciled during Hardware Reconciliation.

- **Normalized Company**
  A normalized company is either a *CA-content company* or a product-defined company. CA-content companies are provided with CA APM and have an *authoritative status*. Authoritative

status allows a company to have a normalization rule. You define a normalization rule for an authoritative normalized company when you map one or more collected companies to the authoritative company.
Product-defined companies initially have a nonauthoritative status. You can change the status of a product-defined company from nonauthoritative to authoritative. You can then map a collected company to the authoritative product-defined company to define a normalization rule. Only company normalization rules for discovered collected companies affect Hardware Reconciliation.

- **Subordinate Company**
  When you map a collected nonauthoritative company to a normalized authoritative company, the nonauthoritative company becomes *subordinate* to the authoritative company in the normalization rule.

Define Company Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can define company normalization rules that are applied during the matching process whenever the reconciliation rule contains asset matching criteria (see page 2419). Any asset matching criterion that contains company information automatically applies the company normalization rules.

When you map a collected nonauthoritative company to a normalized authoritative company, the nonauthoritative company becomes *subordinate* to the authoritative company in the normalization rule. The subordinate company no longer appears in the Collected Company list or the Normalized Company list. If you delete the normalization rule that contains the subordinate company, the subordinate company returns to nonauthoritative status and appears in the Collected Company list and, if it was a product-defined company, also in the Normalized Company list.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Normalization and select Company Normalization.
   The discovered collected company values and the normalized company values appear.
3. If the term you want to use as the normalized value does not appear in the Normalized Company list or the Collected Company list, click New Company to add the company, and then repeat the previous steps.
4. (Optional) Change a nonauthoritative company to an authoritative normalized company.
5. Map the Collected Company list discovered values to a Normalized Company value.
   The list of company normalization rules is defined and is referenced during the reconciliation process.

Update Company Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You update a company normalization rule when you want to change how a discovered company is normalized. This update may affect the reconciliation process. To update a normalization rule for a company, you delete the rule and define a new rule.

The product monitors updates to normalization rules. If you change a normalization rule, the Hardware Reconciliation Engine processes the asset matching so that the assets are matched using the new rule. Any assets that are matched as a result of a previous Hardware Reconciliation Engine process are evaluated again to determine if their matching should change based on the new normalization rule.

When you delete a company normalization rule, the subordinate company returns to nonauthoritative status and appears in the Collected Company list. If the subordinate company was a product-defined company, it also appears in the Normalized Company list on the Normalization Rule page.

Follow these steps:

1. Click Directory, List Management, Company Rules.
2. Delete the normalization rule that you want to change.
3. Define the new company normalization rule.

Change a Nonauthoritative Company to an Authoritative Normalized Company

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can map collected companies to only authoritative companies in the Normalized Company list on the Company Normalization page. Product-defined companies in the Normalized Company list initially have a nonauthoritative status. You can change a product-defined company that is in the Normalized Company list to an authoritative normalized company, to which you can map collected companies.

Note: Only company normalization rules for discovered collected companies affect Hardware Reconciliation.

Follow these steps:

1. Click Directory, List Management.

2. On the left, expand Normalization and select the normalization type.
   The discovered collected values and the normalized values appear.

3. Clear the Show only Authoritative records check box in the Normalized Company section.

4. Click Go in the Normalized Company section.
   The collected product-defined companies that are nonauthoritative and not yet mapped to an authoritative company appear in the normalized list with an Override icon next to the company name.

5. Click the Override icon to the left of the nonauthoritative company that you want to change to an authoritative company, in the *normalized* list.
   The nonauthoritative company changes to an authoritative normalized company.

6. Map a collected company to the new authoritative normalized company before performing any other action in the Normalized Company section.

   Note: The company is not saved as an authoritative company until at least one collected company is mapped to the new authoritative company.

   The new authoritative normalized company and its normalization rule are saved.

Operating System Normalization Rules

Operating system normalization rules are intended for operating systems managing your computers, for example, Windows XP Professional, Windows Server 2008 Enterprise Edition, Windows Vista Enterprise Edition, and so forth.

- **Collected Operating System**
  A collected operating system is always a discovered operating system. Collected operating systems have a nonauthoritative status. You map nonauthoritative collected operating systems to normalized authoritative operating systems.

- **Normalized Operating System**
  A normalized operating system is always a *product-defined operating system*. Product-defined operating systems are collected from user input and other products that share the CA MDB. Product-defined operating systems always have an authoritative status. Authoritative status allows an operating system to have a normalization rule. You define a normalization rule for an authoritative normalized operating system when you map one or more collected operating systems to the authoritative operating system.

- **Subordinate Operating System**
  When you map a collected nonauthoritative operating system to a normalized authoritative operating system, the nonauthoritative operating system becomes subordinate to the authoritative operating system in the normalization rule.

Define Operating System Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can define operating system normalization rules that are applied during the matching process whenever the reconciliation rule contains asset matching criteria (see page 2419). Any asset matching criterion that contains operating system information automatically applies the operating system normalization rules.

When you map a collected nonauthoritative operating system to a normalized authoritative operating system, the nonauthoritative operating system becomes subordinate to the authoritative operating system in the normalization rule. The subordinate operating system no longer appears in the Collected Operating System list. If you delete the normalization rule that contains the subordinate operating system, the subordinate operating system returns to nonauthoritative status and appears in the Collected Operating System list.

Follow these steps:

1. Click Directory, List Management.

2. On the left, expand Normalization and select Operating System Normalization.
   The discovered Collected Operating System values and the Normalized Operating System values appear.

3. If the term you want to use as the normalized value does not appear in the Normalized Operating System list or the Collected Operating System list, click New Operating System to add the operating system, and then repeat the previous steps.

4. Map the Collected Operating System list discovered values to a Normalized Operating System value.
   The list of operating system normalization rules is defined and is referenced during the reconciliation process.

Update Operating System Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You update an operating system normalization rule when you want to change how a discovered operating system is normalized. This update may affect the value of the operating system in a matching asset. To update a normalization rule for an operating system, you delete the rule and define a new rule.

The product monitors updates to normalization rules. If you change an operating system normalization rule and the reconciliation rule update option for operating system is enabled, the Hardware Reconciliation Engine changes the value of the operating system to the new normalized name in matching assets.

Important! If you change a normalization rule for an operating system that applies to public tenant data, the change may affect discovered assets for all tenants, depending on whether they use the specific operating system.

When you delete an operating system normalization rule, the subordinate operating system returns to nonauthoritative status and appears in the Collected Operating System list on the Normalization Rule page.

Follow these steps:

1. Click Directory, List Management, Operating System Rules.
2. Delete the normalization rule that you want to change.
3. Define the new operating system normalization rule.

System Model Normalization Rules

System model normalization rules are intended for hardware devices such as a computer, for example, Lenovo ThinkPad T400, Lenovo ThinkCentre M58, and so forth.

- **Collected System Model**
  A collected system model is always a discovered system model. Collected system models have a nonauthoritative status. You map nonauthoritative collected system models to normalized authoritative system models.

- **Normalized System Model**
  A normalized system model is always a *product-defined system model*. Product-defined system models are collected from user input and other products that share the CA MDB. Product-defined system models always have an authoritative status. Authoritative status allows a system model to have a normalization rule. You define a normalization rule for an authoritative normalized system model when you map one or more collected system models to the authoritative system model.

- **Subordinate System Model**
  When you map a collected nonauthoritative system model to a normalized authoritative system model, the nonauthoritative system model becomes subordinate to the authoritative system model in the normalization rule.

Define System Model Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can define system model normalization rules that are applied during the matching process whenever the reconciliation rule contains asset matching criteria (see page 2419). Any asset matching criterion that contains system model information automatically applies the system model normalization rules.

When you map a collected nonauthoritative system model to a normalized authoritative system model, the nonauthoritative system model becomes subordinate to the authoritative system model in the normalization rule. The subordinate system model no longer appears in the Collected System Model list. If you delete the normalization rule that contains the subordinate system model, the subordinate system model returns to nonauthoritative status and appears in the Collected System Model list.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Normalization and select System Model Normalization.
   The discovered collected system model name and manufacturer name values and the normalized system model name and manufacturer name values appear.
3. If the term you want to use as the normalized value does not appear in the Normalized System Model list or the Collected System Model list, click New System Model to add the system model, and then repeat the previous steps.
4. Map the Collected System Model list discovered values to a Normalized System Model value.
   The list of system model normalization rules is defined and is referenced during the reconciliation process.

Update System Model Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You update a system model normalization rule when you want to change how a discovered system model is normalized. This update may affect the reconciliation process. To update a normalization rule for a system model, you delete the rule and define a new rule.

The product monitors updates to normalization rules. If you change a normalization rule, the Hardware Reconciliation Engine processes assets so that the assets are matched using the new rule. Any assets that are matched as a result of a previous operation of the Hardware Reconciliation Engine are evaluated again to determine if their matching should change based on the new normalization rule.

When you delete a system model normalization rule, the subordinate system model returns to nonauthoritative status and appears in the Collected System Model list on the Normalization Rule page.

Follow these steps:

1. Click Directory, List Management, System Model Rules.
2. Delete the normalization rule that you want to change.
3. Define the new system model normalization rule.

View Normalization Rules

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can search for and view the normalization rules to see the mapping between collected values and the normalized values. This information is used during the hardware reconciliation process.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Normalization and select the normalization rule type that you want to view.
3. Search for the normalized value or the collected value for which you want to view the normalization mapping rules.
   For each normalization rule, the collected value and its corresponding normalized value appear in the Search Results section.

Delete a Normalization Rule

Important! Normalization rules apply to all tenants and public data that are associated with a service provider. Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You delete a normalization rule when you no longer want asset matching criteria to apply the normalization rule during the reconciliation process or when you want to change a normalization rule. To change a normalization rule for a company, operating system, or system model, you delete the rule and define a new rule.

When you delete a company normalization rule, the subordinate company returns to nonauthoritative status and appears in the Collected Company list. If the subordinate company was a product-defined company, it also appears in the Normalized Company list on the normalization rule page. When you delete an operating system normalization rule, the subordinate operating system returns to nonauthoritative status and appears in the Collected Operating System list on the normalization rule page. When you delete a system model normalization rule, the subordinate system model returns to nonauthoritative status and appears in the Collected System Model list on the normalization rule page.

Follow these steps:

1. Click Directory, List Management.

2. On the left, expand Normalization and select the normalization rule type for the rule that you want to delete.

3. Search for the normalized value or the collected value for which you want to delete a normalization rule.
   For each normalization rule, the collected value and its corresponding normalized value appear in the Search Results section.

4. Select the rule that you want to delete.

5. Click Delete Rule.
   The normalization rule is deleted. Asset matching criteria do not apply the rule during the reconciliation process.

Updates to Normalization Rules

You update a system model or company normalization rule when you want to change how a discovered system model or company is normalized. This update may affect the reconciliation process. You update an operating system normalization rule when you want to change how a discovered operating system is normalized. This update may affect the value of the operating system in a matching asset. To update a normalization rule, you delete the rule and define a new rule.

The product monitors updates to normalization rules. If you change a system model or company normalization rule, the Hardware Reconciliation Engine performs the asset matching process so that the assets are matched using the new rule. Any assets that are matched as a result of a previous operation are evaluated again to determine if their matching should change based on the new normalization rule. If you change an operating system normalization rule, the Hardware Reconciliation Engine changes the value of the operating system to the new normalized name in matching assets if the reconciliation rule update option for operating system is enabled.

When you delete a company normalization rule, the subordinate company returns to nonauthoritative status and appears in the Collected Company list. If the subordinate company was a product-defined company, it also appears in the Normalized Company list on the Normalization Rule page. When you delete an operating system normalization rule, the subordinate operating system returns to nonauthoritative status and appears in the Collected Operating System list on the

Normalization Rule page. When you delete a system model normalization rule, the subordinate system model returns to nonauthoritative status and appears in the Collected System Model list on the Normalization Rule page.

Define a Reconciliation Rule

Note: Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

Use a reconciliation rule to define the processing options and actions that the Hardware Reconciliation Engine performs. You can define one reconciliation rule for each tenant.

Note: Each tenant can have only one reconciliation rule. Therefore, if you make a rule inactive, the inactive rule is the only reconciliation rule that is associated with the tenant. If you want to change the reconciliation rule for a tenant, you can update the current reconciliation rule or delete the current reconciliation rule and define a new rule. If you delete a rule, all asset matching links between discovered and owned assets that are associated with the rule are also deleted.

Follow these steps:

1. Click Administration, Reconciliation Management.
2. On the left, click New Reconciliation Rule.
3. If applicable, select the tenant that is associated with the reconciliation rule that you are defining.
4. Enter the reconciliation rule information and click Save.

   Note: Select the Inactive check box if you want to suspend reconciliation processing for an individual tenant. If you select the Inactive check box, the Hardware Reconciliation Engine does not process the rule (no asset matching or data updates occur for the rule). For example, you can make a rule inactive temporarily while you define normalization rules or troubleshoot asset matching errors. If you make an existing rule inactive and the discovered and owned assets were already matched, the matching links are saved.

5. (Optional) Select the Monitor Asset Updates check box to define the reconciliation update options that you want the Hardware Reconciliation Engine to update automatically.
6. (Optional) Select the Match Assets check box to define the asset matching criteria (see page 2419) that you want the Hardware Reconciliation Engine to apply.

Note: If you do not define matching criteria, the Hardware Reconciliation Engine uses the default asset matching criterion, which matches the owned serial number to the discovered serial number.

7. Click Save.
   The new reconciliation rule is defined.

Define Reconciliation Update Options

Note: Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can apply changes to selected, critical owned-asset fields when the Hardware Reconciliation Engine detects new values in the corresponding discovered-asset fields. The Hardware Reconciliation Engine monitors the critical fields that you select and updates the owned-asset fields when changes are detected in the corresponding discovered assets. You specify the owned-asset fields that you want to be automatically updated with changes that are found in the corresponding discovered assets.

Follow these steps:

1. Click Administration, Reconciliation Management.
2. On the left, click Reconciliation Rule Search.
3. Search to find the list of available reconciliation rules.
4. Click the reconciliation rule for which you want to define reconciliation update options.
5. Select the Monitor Asset Updates check box to have the Hardware Reconciliation Engine apply automatic updates.
6. Select the check boxes for the fields that you want to be automatically updated.

   Note: Select the Host Name check box to enable and select the Copy Host Name to Asset Name update option.

7. Click Save.
   The new reconciliation update options are defined.

Asset Matching Criteria

This article contains the following topics:

The Hardware Reconciliation Engine matches the owned and discovered assets based on the *asset matching criteria* that you define for a reconciliation rule. The criteria define the matching factors for owned and discovered assets based on a list of field values from both CA APM and the discovery products. The Hardware Reconciliation Engine identifies all assets being managed and provides the required data during the reconciliation process.

If you modify the asset matching criteria associated with a reconciliation rule, the Hardware Reconciliation Engine reprocesses reconciled assets using the new criteria the next time the engine processes the rule.

You can match the following asset field values:

Owned Asset Field	Discovered Asset Field
Alternate Host Name	Host Name
Alternate Host Name	Registry Asset Name
Alternate ID	BIOS Asset Tag
Asset Alias	BIOS Asset Tag
Asset Alias	Host Name
Asset Name	Host Name
Class	System Type
Host Name	Host Name
Host Name	Registry Asset Name
MAC Address	MAC Address
MAC Address and Host Name	MAC Address and Host Name
Manufacturer	System Vendor
Model Name	System Model
Previous Asset Tag	BIOS Asset Tag
Serial Number	Serial Number
Subclass	System Type

The product monitors the asset matching fields of owned and discovered assets. If you modify the value of an owned asset field that can be used for asset matching, the Hardware Reconciliation Engine reprocesses the modified owned asset using the new value, during the next reconciliation process.

Similarly, if the discovery component of CA Client Automation or a third-party discovery product modifies the value of a discovered asset field in the CA MDB that can be used for asset matching, the Hardware Reconciliation Engine reprocesses the modified discovered asset using the new value, during the next reconciliation process.

The product also monitors changes to normalization rules for companies and system models. These rules affect the asset matching of owned and discovered assets. If you change one of the normalization rules, the Hardware Reconciliation Engine runs the asset matching process so that assets are matched using the new rules. Any assets that are matched as a result of a previous run of the Hardware Reconciliation Engine are evaluated again to determine if their matching should change based on the new normalization rules.

Inactive Status Effect on Asset Matching

Hardware Reconciliation processes all active owned assets created by CA APM that are not excluded from reconciliation. An inactive asset, model, asset family, or company affects reconciliation links between owned and discovered assets as follows:

- Inactive owned asset
  - If an owned asset is inactive before the Hardware Reconciliation Engine matches the asset to a discovered asset, the owned asset is not matched.
  - If an owned asset is made inactive after asset matching, the Hardware Reconciliation Engine clears the matching link the next time the engine processes the reconciliation rule.
- Inactive Model
  - When a model is made inactive before the Hardware Reconciliation Engine matches a discovered asset to an owned asset that is based on that model, the owned asset is not matched.
  - When a model is made inactive after an owned asset that is based on that model is matched, the Hardware Reconciliation Engine clears the matching link for that asset and all others that are based on the inactive model the next time the engine processes the reconciliation rule.
- Inactive Asset Family
  - When an asset family, class, or subclass is made inactive before the Hardware Reconciliation Engine matches a discovered asset to an owned asset with that asset family, class, or subclass, the owned asset is not matched.
  - When an asset family, class, or subclass is made inactive after an owned asset with the asset family, class, or subclass is matched, the Hardware Reconciliation Engine clears the matching link for that asset and all others that belong to the inactive asset family, class, or subclass the next time the engine processes the reconciliation rule.
- Inactive Company
  - When a company is made inactive before the Hardware Reconciliation Engine matches a discovered asset to an owned asset with that company as the manufacturer, the owned asset is not matched.

- When a company is made inactive after an owned asset with that company as the manufacturer is matched, the Hardware Reconciliation Engine clears the matching link for that asset and all others that are associated with the inactive company the next time the engine processes the reconciliation rule.

Define Asset Matching Criteria

Note: Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

Based on the matching criteria that you define for a reconciliation rule, the product attempts to match the owned and discovered assets. The Hardware Reconciliation Engine performs the asset reconciliation when the ownership field value matches the discovered field value.

Follow these steps:

1. Click Administration, Reconciliation Management.
2. On the left, click Reconciliation Rule Search.
3. Search to find the list of available reconciliation rules.
4. Click the reconciliation rule for which you want to define an asset matching criterion.
5. Select the Match Assets check box to have the Hardware Reconciliation Engine apply asset matching criteria.
6. Select the owned and discovered fields that you want to match and click Add Criteria.
   A new asset matching criteria record is added to the Matching Criteria section and a new trimming record is added to the Trimming section.
7. Click the Edit Record icon next to the new criterion in the Matching Criteria section.
8. Select the matching criterion options.
9. (Optional) In the Trimming section, click the Edit Record icon and select trimming options for the asset matching criterion. For example, discovered computer names at one site have a three-character location code as a prefix, which is not in the owned asset computer name. You create a trimming record for the asset matching criterion that trims three characters from the left side of the discovered computer names.
10. (Optional) Continue to add matching criteria to the reconciliation rule.
11. Click Save.
    The new asset matching criteria are defined and the reconciliation rule is saved.

Note: After a reconciliation rule is saved, if you want to change the matched fields in an asset matching criterion to different fields, delete the criterion and create a new one.

Exclude an Ownership Asset from the Reconciliation Process

You can exclude individual owned assets from the reconciliation process. Some reasons for excluding assets from reconciliation include the following examples:

- An owned asset has no matching discovered asset and continues to be included in the list of unreconciled assets. For example, assets that are never attached to the network, like some laptops, or assets that are retired, but their ownership data is stored in CA APM.
- A company does not want to include a particular class of asset, for example, laptops, in reconciliation.

If an owned asset is excluded from the reconciliation process before the Hardware Reconciliation Engine matches the asset to a discovered asset, the owned asset is not available for matching. If an owned asset is excluded from the reconciliation process after asset matching, the Hardware Reconciliation Engine clears the matching link the next time the engine processes the reconciliation rule. The owned asset is not available for matching.

Note: If the asset family of an excluded asset is set to be included in the hardware reconciliation process, the asset continues to be excluded from the process. If an asset family is excluded from the hardware reconciliation process, all assets that belong to the excluded asset family are excluded.

Follow these steps:

1. Click Asset, Asset Search.
2. Search to find the list of available assets.
3. Click the asset that you want to exclude from the reconciliation process.
4. In the Basic Information section, select the Exclude Reconciliation check box.
5. Click Save.
   The ownership asset is not included in future reconciliations.

Exclude an Asset Family from the Reconciliation Process

You can exclude all owned assets in an asset family from the hardware reconciliation process. Some reasons for excluding asset families from reconciliation include the following examples:

- Assets in an asset family have no matching discovered assets and continue to be included in the list of unreconciled assets. For example, assets that are in the service asset family are not attached to the network, but their ownership data is stored in CA APM.
- The asset family is software. The product does not reconcile software.

- A company wants to make an asset family inactive. Hardware Reconciliation processes active owned assets created by CA APM.

If an asset family is excluded from the reconciliation process before the Hardware Reconciliation Engine matches owned assets in that asset family to discovered assets, the owned assets are not available for matching. If an asset family is excluded from the reconciliation process after owned assets in that asset family are matched, the Hardware Reconciliation Engine clears the matching links the next time the engine processes the reconciliation rule. The owned assets are not available for matching.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Asset Lists and click Asset Family.
3. Click the Edit Record icon for the asset family that you want to exclude from the reconciliation process.
4. Complete one of the following options:
   - Clear the Reconcile Hardware check box.
   - Select the Is Software check box.
   - Select the Inactive check box.
5. Select the Complete Record Edit icon for the asset family object.
6. Click Save.
   Assets in the excluded asset family are not included in future reconciliations.

Exclude an Asset Family Class or Subclass from the Reconciliation Process

You can exclude all owned assets in an asset family class or subclass from the hardware reconciliation process. For example, you can exclude assets because your company wants to make an asset family class or subclass inactive. Hardware Reconciliation processes active owned assets created by CA APM.

If an asset family class or subclass is excluded from the reconciliation process before the Hardware Reconciliation Engine matches discovered assets to owned assets in that asset family class or subclass, the owned assets are not available for matching. If an asset family class or subclass is excluded from the reconciliation process after owned assets in that asset family class or subclass are matched, the Hardware Reconciliation Engine clears the matching links the next time the engine processes the reconciliation rule. The owned assets are not available for matching.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Asset Lists and click Asset Family.
3. Click the Edit Record icon for the asset family with a class or subclass you want to exclude from the reconciliation process.

4. Click Class List.
5. Click the Edit Record icon for the class you want to exclude from the reconciliation process (or the class with a subclass you want to exclude).
6. Select the Inactive check box and click the Complete Record Edit icon for the asset family class if you want to exclude the entire class.

   Note: Skip this step if you want to exclude a subclass, but not the entire class, from the reconciliation process.

7. Click Subclass List if you want to exclude a subclass.
8. Click the Edit Record icon for the subclass you want to exclude from the reconciliation process.
9. Select the Inactive check box and click the Complete Record Edit icon for the asset family subclass.
10. Click Save.
    Assets in the excluded asset family class or subclass are not included in future reconciliations.

View the Reconciliation Results

Note: Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.\

When the Hardware Reconciliation Engine processes actions for a reconciliation rule, the engine writes records to the message queue in the database. You can search the message queue for reconciliation log messages. The message queue retains log messages for a configurable number of days.

Note: You can control the level of detail written to the message queue by changing the Hardware Reconciliation Engine logging level. You can also control the number of days that messages are retained in the message queue. For more information about logging level and message queue retention settings, see Hardware Reconciliation Engine Configuration Settings.

Follow these steps:

1. Click Administration, Reconciliation Management.

2. On the left, click Reconciliation Message Search.
   The message queue displays reconciliation log messages in the Search Results section.

3. (Optional) Search to find a message in the message queue.

Note: You can export the message queue to a comma-separated values (CSV) file for use in a spreadsheet application. You can also generate reports to view information about your environment relative to reconciliation. For more information about generating reports, see Reconciliation Reports (see page 2428).

Add Assets from Unreconciled Discovered Records

The hardware reconciliation process can detect assets that cannot be reconciled with any of your owned assets. You can decide to add the unreconciled assets to your repository so that you can track and manage all assets in your network.

You can add the assets to your repository in one of the following ways:

- Configure CA APM to automatically add unreconciled discovered assets to your ownership repository.
- Add the unreconciled assets by generating and exporting the results of a report and then importing the report results through the Data Importer.

Important! Before you import data into CA APM, review the data to ensure accuracy and uniqueness.

Follow these steps:

- **To add assets from unreconciled discovered assets to your ownership repository automatically, complete the following steps:**

  1. Click Administration, Reconciliation Management.
  2. Click New Reconciliation Rule or search and select a reconciliation rule you created.
  3. The Reconciliation Rule Details page opens.
  4. Check the Add Assets to Ownership Repository check box.
  5. Under Add Assets to Ownership Repository, select the contact update details and the asset status.
  6. Select Add Models to add model details to the repository.

Note: If you select Add Models, and the unreconciled asset has no model information, CA APM does not add the asset details to the repository.

7. Click Save.

- **To add assets from unreconciled discovered records assets to your ownership repository manually, complete the following steps:**

1. Log in to Business Intelligence Launch Pad.
   The Reports pane opens.
2. Click Document List.
3. Expand Public Folders, CA Reports.
4. Click CA ITAM.
5. Double-click the icon to the left of the report that identifies the discovered assets that are not matched to any owned assets.
6. Enter the search criteria for the report.

   Note: Select one tenant only when you generate the report. You can import data into only one tenant at a time.

7. Click Run Query.
8. Click the link for the flat file format that you can export.
   The report is converted to a document format that you can view and export.
9. Save the document as a CSV file.
10. Log in to CA APM as the administrator.
11. Navigate to Administration, Data Importer, New Import.
12. Specify the CSV file name in the Data File field.
13. Select the main destination object and the delimiter.

    Important! Select the same tenant that you selected when you generated the report.

14. In the Advanced Settings area, verify that the following options are selected:

    Insert or Update
    Create Secondary Lookup Object
    Update Secondary Lookup objects
    Error on Secondary Lookup Object Errors

15. Click Save.
16. Specify the column mapping.
17. Click Submit in the Schedule area to start the import process.
    The unreconciled assets are added to your data repository.

Manage Reconciliation Rules

Note: Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

You can manage reconciliation rules in the following ways:

- Update the information for a reconciliation rule.
  If you modify the asset matching criteria associated with a reconciliation rule, the Hardware Reconciliation Engine reprocesses reconciled assets using the new criteria the next time the engine processes the rule.
- Delete a defined reconciliation rule.
  If you delete a rule, all asset matching links between discovered and owned assets that are associated with the rule are also deleted. Each tenant can have only one reconciliation rule. If you want to change the reconciliation rule for a tenant, update the current reconciliation rule or delete the current rule and define a new reconciliation rule.

  Note: You can also make a rule inactive if you want to suspend reconciliation processing temporarily for an individual tenant. To make a rule inactive, update the rule and select the Inactive check box. If the discovered and owned assets were already matched for the rule, the matching links are saved.

Follow these steps:

1. Click Administration, Reconciliation Management.
2. On the left, click Reconciliation Rule Search.
3. Search to find the list of available reconciliation rules.
4. To update a reconciliation rule, complete the following steps
   a. Click the reconciliation rule that you want to update.
   b. Enter the new information for the reconciliation rule.

Note: Select the Inactive check box if you want to suspend reconciliation processing for an individual tenant. If you select the Inactive check box, the Hardware Reconciliation Engine does not process the rule (no asset matching or data updates occur for the rule). For example, you can make a rule inactive temporarily while you define normalization rules or troubleshoot asset matching errors. If you make an existing rule inactive and the discovered and owned assets were already matched, the matching links are saved.

c. Click Save.

Note: After a reconciliation rule is saved, if you want to change the matched fields in an asset matching criterion to different fields, delete the criterion and create a new one.

5. To delete a reconciliation rule, complete the following steps:

   a. Click the rule that you want to delete.

   b. Click Delete and confirm that you want to delete the reconciliation rule.

Export the Reconciliation Results

Note: Verify that the user completing this task belongs to a role in which reconciliation management access is enabled.

After you view the message queue, you can export the queue to a comma-separated value (CSV) file for use in a spreadsheet application.

Follow these steps:

1. Click Administration, Reconciliation Management.
2. On the left, click Reconciliation Message Search.
   The message queue displays reconciliation log messages in the Search Results section.
3. Search to find the reconciliation log messages that you want to export.
4. Click Export to CSV.
   The message queue search results are exported to a CSV file and a link to the CSV file appears.

Reconciliation Reports

This article contains the following topics:

Use the reconciliation reports to view the following information and help you manage your IT assets based on your business practices:

Your security permissions determine the tenant data you see when generating reports. If you have access to multiple tenants, you see the data for all tenants to which you have access. If you only have access to a single tenant, you only see the data for that tenant.

Important! On an Oracle database, when you generate a report for the first time, you may encounter a database error. To resolve this issue, restart the *Server Intelligence Agent* service in the Central Configuration Manager.

- Owned assets that have been reconciled to a discovered asset, including both discovered inventory and network discovery records.
- Billed assets (that is, an active or received asset having a valid bill code) not matched to a discovery record.
- Discovered assets not reconciled to an owned asset.
- Discovered assets not processed due to missing or invalid data.
- Owned assets matched to discovery records.
- Owned assets not matched to discovery records.
- Matches between network discovery data and agent discovery data.
- Potential lost revenue, including assets not being billed, but discovered. This report exposes revenue opportunities based on the number of assets being billed. Use the information in this report to provide proof that an asset is active and discovered.
- Network discovery records that have not been matched to a corresponding discovered inventory. Network discovery provides limited data to identify an asset on the network. Discovery provides detailed hardware and software information about an asset.

Generate a Report

CA APM reports provide you with a detailed view of your owned and discovery assets to help with reconciliation.

Important! If you plan to add to your repository using the Data Importer the discovered assets that are not matched to any of your owned assets, select only a single tenant when generating the appropriate report.

Follow these steps:

1. Log in to BusinessObjects Enterprise Launch Pad.
   The Reports pane opens.
2. Click Documents.
3. On the left pane, click Folders.
4. Expand Public Folders, CA Reports.
5. Click CA Asset Portfolio Management.
6. Double-click the icon to the left of the report you want to generate.
7. Enter the search criteria for the report.
8. Click Run Query.

Remove the Tenant Drop-Down List

Any user belonging to more than one tenant can select a tenant in a drop-down list when generating a report. You can remove the tenant drop-down list so that you are not asked to select a tenant when generating a report.

Follow these steps:

1. Log in to BusinessObjects Enterprise Launch Pad.
   The Reports pane opens.
2. Click Documents.
3. On the left pane, click Folders.
4. Expand Public Folders, CA Reports, CA Service Management.
5. Click CA Asset Portfolio Management.
   All CA APM reports appear.
6. Right-click the report for which you want to remove the tenant drop-down list and select Modify.
7. Click Cancel.
8. Click Edit.
9. In the Query Filters pane, select the “Tenant - Multi-Mandatory” filter and click the Remove icon on the top-right of the pane.
10. Repeat the previous step for all tabs. Query Tabs appear below the Query Filters area of the page.
11. Click the Apply Changes and Close.

12. Save the report in the same location from where the report is opened.

13. When prompted, click Yes to override the existing report.

14. Click the Close document icon.
    When you generate the report, you are not asked to select a tenant.

Searching

This section contains the following articles:

Object Searching

Contents

An *object* represents something that you record and track in your repository. The primary objects in CA APM are models, assets, legal documents, contacts, companies, organizations, locations, and sites. At any time, you can search to find objects in the repository to manage. You can also search the audit history to see all changes made to an object record over time.

For example, you can search for objects for the following reasons:

- Search for a model so that you can define an asset from the model.

- Search for an asset so that you can define a support contact for the asset.

- Search for an asset from an inventory request that you want to fulfill.

- Search for a legal contract so that you can define terms and conditions for the contract.

- Search the audit history so that you can see when the cost center for a laptop changed, and who changed the cost center.

Based on the search criteria that you specify, a list of matching objects appear in the search results.

Most of the time, the objects that you want to view or update appear with the default search provided for each object. This type of search is intended for when you want to locate a single record for update from a simple list of objects. For example, you can enter the serial number when searching for a laptop to find the laptop matching the serial number.

When you search, you can use search operators (see page 2435) and search connectors (see page 243
to make your searches more precise and get more useful results.

Search Tips

Use the following information and techniques to help make your searches more effective:

- **Keep it simple**. For example, if you are looking for a specific asset or model, and you have the name available, enter the name. If you have additional information to identify the object, such as the serial number for an asset, enter that number. This additional information increases the chance that your search returns the object you want.

- **Expand your search with a wildcard**. Use the asterisk (*) or percent sign (%) wildcard character as a substitute for any number of characters in your search string to return search results. Use as many wildcard characters in your search string as you want. For example, enter *S** or *S%* when searching for contacts by last name to find contacts having the last name Sanders, Shelley, Smith, Spencer, Solomon, and so forth. Enter *Dell *" Monitor* when searching for assets by name to find any size Dell monitor; Dell 19" Monitor, Dell 21" Monitor, Dell 30" Monitor, and so forth.

- **Searches are not case-sensitive**. You can ignore capitalization in your searches. For example, a company search for *Document Management Company* returns the same results for *document management company.*

- **Search titles are unique in a tenant**.
  When you save a search and specify a title, the title must be unique within a tenant. You cannot save a search with the same title in a single tenant.

- **If you receive too many, or too few, search results** and cannot find an object, try the following suggestions:

  - Use different search criteria. For example, instead of searching for a contact by last name, search for their first name, department, user ID, or location.

  - Use operators (see page 2435) and connectors (see page 2435) to increase or decrease the objects returned in the results.

  - Verify that you have spelled the name of the object correctly, and have entered any additional search criteria correctly.

- **Expand your search with check box criteria**. Include check box fields such as Inactive in your searches. For example, search for all inactive assets and generate a report for management analysis. You can also search for all inactive assets to make them active again.

- **Expand your search within multiple asset families and legal template types**. Search within one or more asset families and legal template types. For example, search for a specific model under both hardware and software, or search for a legal document under a service contract and software addition.

- **Invalid Searches**. You can use the Invalid drop-down list when you manage searches to display or hide invalid searches. A search becomes invalid when your CA APM administrator configures the user interface and restricts access to any field that a search uses, or deletes an extended field that a search uses. If you have a search that you cannot use because of security restrictions, contact your CA APM administrator for assistance.

- Sort the search results (see page 2436) to help make it easier to find information.

- Save a search (see page 2436) you frequently use so that you do not have to enter the search criteria each time you use the search.

- Copy a search (see page 2438) and use the search as a template for creating another search that is similar.

- Export search results (see page 2439) for use in spreadsheet applications or reports.

- Configure your searches (see page 2447).

Search Security

Default searches let you find objects in the repository. For example, use the default searches to find assets, models, contacts, and so forth. The security for the default searches makes them available to all users and configurations. You can use these searches to create additional *user-defined searches*.

Consider the following security information for user-defined searches:

- All users that are assigned to a role and configuration can access the default searches and the user-defined searches that are assigned to the role and configuration. However, the search results that you see for the default searches do not display information and fields that your CA APM administrator hides and secures.

- When you configure the user interface and restrict access to any field that a search uses, or delete an extended field that a search uses, the search is invalid. As a result, the search is not available to any user that is associated with the role and configuration.

- Invalid and active searches appear together when you manage searches. When you try to use an invalid search, you receive a message. You should contact your CA APM administrator to troubleshoot the invalid search and make the search valid again.

- When a search becomes invalid, you may have no default search. When attempting to search, you receive a message. You should contact your CA APM administrator to have a default search assigned, or you can save a new search and set the search as your default search.

Example: Limit Asset Searches by Cost Center and General Ledger Code

In this example, an asset in your organization is assigned to a particular cost center and general ledger code. This information is used to identify the department responsible for the expense, and to allocate costs on order releases, shipments, and payment invoices. This information is sensitive and should not be available to all users who search for assets in your repository.

You can copy the default asset search and configure the search by adding the cost center and general ledger code to both the search criteria and search results. When you save the new configured search, you assign the search to only those individuals in your finance and procurement department (that is, users assigned to the finance user role). Users in the finance user role can now search and find assets based on the cost center and general ledger code. Users not assigned to this role cannot search for an asset using that information.

Search for Objects

At any time, you can search to find objects in the repository to manage. For example, you can search for a model and define an asset from the model. Based on the search criteria that you specify, a list of matching models appear in the search results.

To search for objects

1. Click the tab and optional subtab for the object that you want to find.

   In the Search Criteria area, specify the search criteria.

2. (Optional) In the Search Criteria area, click Advanced.

3. Click the Edit icon to specify the search criteria:

   - **Left Parenthesis**
     Determines if left parentheses are used to group search criteria and control the logic of the search. For example, you can select this check box to search for assets in which the asset name is OE001 or both the asset family is Computer and the asset name is Dell.

   - **Operator**
     Determines the standard search operators (see page 2435) to use to find objects. For example, you can search for assets in which the asset name is greater than OE001 and the asset family is Computer.

   - **Value**
     Determines the specific field value that you want to find. For example, you can search for an asset in which the asset name is OE001.

     Note: When you enter a search value in combination with the Like or Not Like operators, you can use all supported wildcard characters to expand your search.

   - **Right Parenthesis**
     Determines if right parentheses are used to group search criteria and control the logic of the search. For example, you can search for assets in which the asset name is OE001 or both the asset family is Computer and the asset name is Dell.

- **Connector**
  Determines the standard connectors (see page 2435) to use to find objects. For example, you can search for assets in which the asset name is OE001 or both the asset family is Computer and the asset name is Dell.

4. Click the Complete icon to accept your search criteria changes.

5. Click Go.
   A list of matching objects appears in the search results.

Search Operators

When you search for objects, CA APM lets you use the following standard search operators to find objects in the repository:

Operator	Description
Equal	Search for objects having the exact value specified.
Not Equal	Search for objects not matching the value specified.
Greater Than	Search for objects greater than the value specified.
Greater Than or Equal	Search for objects greater than or equal to the value specified.
Less Than	Search for objects less than the value specified.
Less Than or Equal	Search for objects less than or equal to the value specified.
Like	(Similar) Search for objects that match the value specified. When you use the Like search operator, the % wildcard is added after the characters you enter and searches for all objects that start with the characters. You can also add the % wildcard before the characters to search for all objects that end with the specified characters.
Not Like	(Not Similar) Search for objects that do not match the value specified. When you use the Not Like search operator, the % wildcard is inserted after the characters you enter and searches for all objects that do not start with the characters. You can also insert the % wildcard before the characters to search for all objects that do not end with the specified characters.

Search Connectors

When you search for objects, CA APM lets you use the following standard AND/OR connectors to connect search strings and find objects in the repository.

- **AND**
  The search must satisfy the criteria for both the current search field and the following search field.

- **OR**
  The search must satisfy the criteria for either the current search field or the following search field.

Sort the Search Results

CA APM lets you sort the search results to help make it easier for you to find the information in your search results. For example, you can sort the results in ascending order by asset family to find assets in the hardware asset family first, followed by assets in the software family.

To sort the search results

1. Search for objects.
   The search results appear.

2. In the Search Results area, click the appropriate icon next to a column heading.
   The sort results appear in either ascending or descending order.

> **Note:** You can extend the default sort of a single column by adding sort fields.

Save a Search

CA APM lets you save a search that you frequently use so that you do not have to enter the search criteria each time you use the search. For example, you can save a search to find assets by asset name, asset family, model, cost center, and creation date.

To save a search

1. Click the tab and optional subtab for the object that you want to find.

2. On the left, click New Search.
   The Add Fields dialog appears.

3. Specify the fields to appear in the search criteria and results.

> **Note:** When you search within multiple asset families and legal template types, only the assets, models, and legal documents for the selected families and template types appear in the search results.

4. At the top of the page, click CONFIGURE SEARCH: OFF.
   The configuration of the search is complete.

5. In the Search Details area of the page, specify the information to uniquely identify the search.

Note: When you save a search and specify a title, the title must be unique within a tenant. You cannot save a search with the same title in a single tenant.

6. In the Search Security area of the page, select the user roles for which the search is available. Roles are helpful so you can make the search available to all users having the roles you select. Administrators can also select specific configurations for the search.

Note: If you do not select either a role or configuration, the search is available to the current user.

7. Click Save.
   The search is saved and is available for future searches.

Update a Search

CA APM lets you change the search criteria in a saved search. For example, you can add the contact ID to a saved asset search.

To update a saved search

1. Click the tab and optional subtab for the object that you want to find.

   On the left, click Manage Searches.

   A list of saved searches displays.

2. Click the search that you want to update.

3. Update the search criteria.

4. (Optional) In the Search Security area of the page, select the user roles for which the search is available. Roles are helpful so you can make the search available to all users having the roles you select. Administrators can also select specific configurations for the search.

Note: If you do not select either a role or configuration, the search is available to the current user.

5. Click Save.
   The updates to the search are saved and available for future searches.

Search for Objects Using a Saved Search

CA APM lets you search for objects using a saved search. For example, you can use a saved weekly asset search to find all assets that have been added during the past week.

To search for objects using a saved search

1. Click the tab and optional subtab for the object that you want to find.

   On the left, click Manage Searches.

   A list of saved searches displays.

2. Click the search that you want to use.

3. Click Go.
   A list of matching objects appears in the search results.

Copy a Search

CA APM lets you copy a saved search and use the search as a template for creating another search that is similar. For example, you can copy the default asset search and add the asset creation date and user ID of the person who created the asset.

To copy a search

1. Click the tab and optional subtab for the object that you want to find.

   On the left, click Manage Searches.

   A list of saved searches displays.

2. Click the search that you want to copy.

3. Click Copy.
   A new search is created based on the copied search.

4. Change the information for the new, copied search.

5. (Optional) In the Search Security area of the page, select the user roles for which the search is available. Roles are helpful so you can make the search available to all users having the roles you select. Administrators can also select specific configurations for the search.

Note: If you do not select either a role or configuration, the search is available to the current user.

6. Click Save.
   The search is saved and is available for future searches.

Delete a Search

CA APM lets you delete a saved search that you do not need. You cannot delete the default searches provided by the product.

To delete a saved search

1. Click the tab and optional subtab for the object that you want to find.

   On the left, click Manage Searches.

   A list of saved searches displays.

2. Click the search that you want to delete.

3. Click Delete and confirm that you want to delete the search.
   The search is deleted.

Search Results Export

Contents

CA APM lets you export the results of an object, asset fulfillment, and audit history search so that you can report on and analyze the search results. For example, the asset manager, purchasing manager, and facilities manager require a weekly report that lists all of the assets that have been added during the past week. Based on this requirement, the administrator configures the search to return the list of assets and schedules the search and export to process at 10 p.m. every Friday. After the search and export processes, the managers receive an email notification that includes a link to the weekly report.

You can export the results of a search to the following formats:

- CSV file (see page 2440)
- Database view (see page 2440)

You can schedule a search and export for a particular time and automatically notify contacts by email so that the contact can access the latest information.

CSV File Export

When you export search results to a CSV file, the export includes the current data found by the search. CA APM lets you use the following methods to export to a CSV file:

- On demand export from a real-time search. This type of search includes the current data.
- Scheduled export from a saved search. This type of search includes the current data found each time you use the search according to the schedule.

Example: Export a Search for New Assets to a CSV File

In this example, a company adds new assets to its repository every week. The asset manager, purchasing manager, and facilities manager require a weekly report that lists all of the assets that have been added during the past week. Based on this requirement, the administrator configures the search to return the list of assets and schedules the search and export to process at 10 p.m. every Friday. After the search and export processes, the managers receive an email notification that includes a link to the weekly report.

Database View Export

When you export search results to a database view, the export contains the SQL statement that defines the columns and data in the search. The view does not collect data until you (or an external application) access and use the view in the database.

You can schedule the export from a saved search to export to a database view.

Example: Export a Search for Expiring Assets to a Database View

In this example, a company develops an external dashboard application that monitors asset allocation. The asset manager views the dashboard daily to verify that expiring assets are allocated properly - reallocated, retired, or returned to vendor. The company wants to configure the dashboard application to display CA APM asset data.

Based on these requirements, the administrator configures the search to display the list of expiring assets and their status and exports the search results to a database view. The administrator schedules the search and export to process weekly. The external dashboard application accesses the database view to gather the asset data, and the asset manager views the data in the external dashboard.

How Exporting Search Results Works

When you export search results to a *CSV file*, the process uses the following general steps:

1. The user defines a new search and exports the results; or the user accesses an existing saved search and schedules the export.
2. The search processes and the results include the current data.

> **Note:** The results for a scheduled search and export only include the results found by the current search and export. If you change the search or any part of the export criteria, you will not see the new search results until the next time the search and export process runs. For example, if you change the Export Format from CSV File with Column Headers to Database View or you change the Frequency of the Export Schedule, you do not see those changes in the current search and export.

1. The search results data is saved to a CSV file. The column heading labels in the CSV file (if requested with the export) match the column heading labels from the search results. If the user configured the default column heading labels in the search results, the configured labels are included in the CSV file.

2. An email notification is sent to the users assigned to the search. The email includes a link to the CSV file.

When you export search results to a *database view*, the process uses the following general steps:

1. The user accesses an existing saved search and schedules the export.

2. The search processes and the database view is exported. The column heading labels in the database view match the column heading labels from the search results. If the user configured the default column heading labels in the search results, the configured labels are included in the database view.

> **Note:** The results for a scheduled search and export only include the results found by the current search and export. If you change the search or any part of the export criteria, you will not see the new search results until the next time the search and export process runs. For example, if you change the Export Format from CSV File with Column Headers to Database View or you change the Frequency of the Export Schedule, you do not see those changes in the current search and export.

3. An email notification is sent to the users assigned to the search. The email specifies the name of the database view.

Export Search Results to a CSV File (On Demand)

CA APM lets you export the results of a search to a CSV file by searching for objects and exporting the results on demand or by scheduling a saved search and exporting the results.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.

2. Search for objects by entering search criteria or by selecting a saved search.
   A list of matching objects appears in the search results.

3. Click Export to CSV.
   The search results are exported. The column heading labels in the CSV file match the column heading labels from the search results. An email notification with a link to the CSV file is sent to all contacts associated with the export request.

Export Search Results to a Database View

CA APM lets you export the results of a search to a database view by scheduling a saved search and exporting the results.

Follow these steps:

1. Click the tab and optional subtab for the object for which you want to schedule a search and export.

2. On the left, click Manage Searches.
   A list of saved searches appears. If there are no saved searches, define and save a search that you want to schedule and export.

3. Click the search that you want to schedule and export.

4. On the left, click New Export.

5. Enter the basic information, schedule information, and security information as described in the steps to schedule the search and export.
   The search is processed and the results are exported according to the schedule. The column heading labels in the database view match the column heading labels in the search results. An email notification specifying the database view name is sent to all contacts associated with the export request.

Note: The results for a scheduled search and export only include the results found by the current search and export. If you change the search or any part of the export criteria, you will not see the new search results until the next time the search and export process runs. For example, if you change the Export Format from CSV File with Column Headers to Database View or you change the Frequency of the Export Schedule, you do not see those changes in the current search and export.

Schedule Searches and Exports

CA APM lets you schedule searches to process periodically and export the search results to a CSV file or a database view. For example, you can schedule a search to process at the end of the week and export all updated assets during that week to a CSV file. You can schedule the following types of searches:

- **Predefined**. Specify a recurring time for the search. For example, you can process the search at 3:00 p.m. on the 21st of every month.

- **Calculated**. Specify the start time and frequency for the search. For example, you can process the search at 10:00 p.m. on the 21st of September and use the search every five days thereafter.

Follow these steps:

1. Click the tab and optional subtab for the object for which you want to schedule a search.
2. On the left, click Manage Searches.
   A list of saved searches appears. If there are no saved searches, define and save a search that you want to schedule and export.
3. Click the search that you want to schedule.
4. On the left, click New Export.
5. Enter the basic export information.
   The following fields require explanation:

   - **Export Name**
     Specify the export name.
   - **Export Format**
     Select the format for the exported search results.
   - **View Name**
     Specify the database view name.

     Note: The View Name is required if you select Database View for the Export Format. The name must be a valid database view name. See your database product documentation for information about database view name requirements.
   - **Description**
     Specify a description for the exported search results.
   - **Retention Days**
     Specify the number of days that the exported search results are retained before the results are purged.
   - **Folder Name**
     Specify the folder for the exported CSV file search results.
   - **Never Expires**
     Select this check box to specify that the number of days of the selected period (Period Type) that the CSV file or database view is stored before being deleted never expires (the CSV file or database view is never purged). When you select this check box, any previous value that you added to the Retention Days field is removed, and the Retention Days field is disabled.
6. Schedule the search.
   The following fields require explanation:

- **Run Time**
  Select the time of the day, in 24-hour format, to process the search. When you schedule searches, use the local time zone on the CA APM application server.

- **Interval Type**
  Select the type of interval for the search. For example, you can select Day, Month, Quarter, Week, or Year.

- **Interval Day**
  Specify the day during the Interval Type to process the search. For example, if the Interval Type is Month and the Interval Day is 1, the search is processed on the first day of the month.

- **First Run Date**
  Select the date when the first search starts to process.

- **Interval**
  Specify how often the search processes, based on the specified Interval Type. For example, if the Interval Type is Weekly and the Interval is 2, the search processes every two weeks.

- **Last Day of Interval**
  Select this check box to specify that the search processes on the last day of the selected Interval Type. When you select this check box, any previous value that you added to the Interval Day field is removed, and the Interval Day field is disabled.

7. Specify whether all roles and configurations assigned to the search receive the exported search results.

8. Click Save.
   The search is saved. The search processes at the scheduled time and the search results are exported.

Note: The results for a scheduled search and export only include the results found by the current search and export. If you change the search or any part of the export criteria, you will not see the new search results until the next time the search and export process runs. For example, if you change the Export Format from CSV File with Column Headers to Database View or you change the Frequency of the Export Schedule, you do not see those changes in the current search and export.

How Exported Search Results are Retained and Purged

All exported CSV file and database view search results are retained and purged based on configuration settings you specify when you schedule searches and exports. The exported search results that are no longer needed are purged to release disk space.

The following information describes how exported search results are retained and purged:

- You specify the retention days when you schedule searches and exports. After the retention days elapse, the exported search results (CSV files and database views) are considered expired and are purged.
- The Export Service processes the purge once a day (by default, 5:00 a.m. Universal Time) and purges exported search results based on the specified retention days. Your administrator can configure the purge start time.

  Note: For information about the Export Service configuration settings, see Export Service Configuration Settings (see page 1595).

- The retention period depends on the processing time of the export and the time at which the Export Service purges the search results.

Example: Purge Search Results

In this example, you schedule an asset search named Weekly Asset Search to process every Friday and export all updated assets during the week. You set the retention days to 1 and the export completes at 5:00 p.m. Eastern time. The Export Service is scheduled to purge search results at midnight, Eastern time. Because the search results are less than one day old, the Export Service does not purge them until the next scheduled time (in this example, shortly after midnight the following day).

Search Results Mass Change

Contents

You can perform the following mass changes on a search results list:

- Change the value of a specific field for all objects or for selected objects in the list.
- Add a value to a specific field for all objects or for selected objects in the list that have blank values in that field.

Note: The following restrictions can affect the mass change functions that you can perform:

Configuration restrictions for your user role. For example, if your configuration does not allow you to modify a particular field, you cannot perform mass changes on that field.

- Multi-tenancy. If you have a multi-tenanted environment, the tenant name can be a part of the search results list. However, you cannot perform a mass change on the tenant name.

Example: Perform a mass change on the cost center

A data center administrator wants to assign all assets in the London data center to cost center 3218. The administrator configures the search to return a list of all assets in the London data center. The administrator then performs a mass change to change the cost center assignment for the assets to 3218.

How the Search Results Mass Change Works

When you perform a mass change on a search results list, the process uses the following general steps:

1. The user defines a new search, selects an existing search, or uses the default search.
2. The search processes and the results appear.
3. The user defines the mass change settings for all fields or selected fields and executes the mass change.

   Note: The user must be assigned to a configuration that permits mass changes.

4. The mass change job is created and displayed in the Mass Change Jobs list.
5. The user verifies the status of the mass change job and performs the original search again when the job is completed.
6. The search results list data is updated to show the new field values.

Perform a Mass Change on a Search Results List

You can change specific field values for all or selected objects in a search results list.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.
2. Search for objects by entering search criteria or by selecting a saved search.
   A list of matching objects appears in the search results.
3. Leave all objects selected, or clear the Select All check box and select specific object check boxes.
4. Click Mass Change Settings.
5. Click New.
6. Enter the information to define the mass change. The following fields require explanation:

   - **Mass Change Field**
     Specifies the field in the search results that you want to change.

> **Note:** The fields that are included in the search results list are available for selection.

- **Value**
  Specifies the new value for the selected field.

  > **Note:** Leave the Value field blank to specify a null value for a field.

- **Update Only Blank Values**
  Specifies that only blank values in the selected field are updated with the new value for the selected objects.

7. Click the Complete Record Edit icon.
8. (Optional) Click New to define more mass change settings.
9. Click the Mass Change button above the search results list when you have defined all mass change settings.
   A mass change job is created.
10. Click Mass Change Jobs on the left to see the Mass Change Jobs list.

    > **Note:** You can click Go to update the jobs list.

11. Click Status Message for your mass change job to verify when the processing is completed.
12. Click View Log for your selected job in the Mass Change Jobs list after the job is completed.
    The log file provides more information about the mass change job activity.
13. Perform your original search again.
    The search results display the new field values.

How to Configure Searches

This article contains the following topics:

CA APM lets you configure object, asset fulfillment, and audit history searches to simplify how you search for information in the repository. To configure searches, complete the following steps:

- Set a search result limit.
- Make it easier to search by specifying a default search.
- Make it easier to specify search criteria by completing the following tasks:
  - Adding fields
  - Removing fields
  - Moving fields
  - Changing the field name
  - Replacing fields
- Make it easier to find information in the search results by completing the following tasks:
  - Adding columns
  - Moving columns
  - Changing the column label
  - Removing columns
  - Adding sort fields
  - Preventing duplicate records from appearing
  - Preventing the ability to open records

Set a Search Result Limit

When you search for an object and the results are difficult to manage because too many object records appear, you can set a limit. For example, when you search for assets, over 2,000 assets appear in the search results. The results are difficult to navigate, you cannot find the assets you want, and the performance is negatively impacted. Therefore, you set a maximum of 50 object records to return.

Follow these steps:

1. Click the tab and optional subtab for the search that you want to configure.
2. On the left, click Manage Searches.
   A list of saved searches displays.
3. Click a search in the list.

4. In the Additional Settings, Maximum Search Results Returning area, specify the total number of objects to appear.

   Note: For performance reasons, we recommend that you set this value to less than 500.

5. Click Go.
   The limited search results appear and help you see the impact on the results before you save the limit. All future search results are limited to the specified number or percentage.

Specify a Default Search

CA APM lets you specify a search that you frequently use as the default each time you click a tab or subtab. For example, to find the contact search you click Directory, Contact. You copy the contact search, rename it, and then set it as your default. The next time you access the Contact Search page, the default search appears instead of the previous search.

Note: You cannot specify a search as the default when the search does not have a selectable column in the results.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.
2. On the left, click Manage Searches.
   A list of saved searches appears.
3. Click a search in the list.
4. Click Set As Default.
5. Click Save.
   The search is saved as the default.

Manage Fields

CA APM lets extend or modify your new and saved searches by letting you manage fields in search criteria. Management of fields includes adding, removing, moving, and changing a field in your search criteria. As a result, you can extend or modify the information that appears in your search criteria and results.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.

2. On the left, click Manage Searches.
   A list of saved searches appears.

3. Click a search in the list.

4. At the top of the page, click CONFIGURE SEARCH: ON.

5. Complete the following steps to add a field.

   a. Click Add Fields.

   b. Select the fields to add to the search criteria, results, or both.

   > **Note:** You can add fields to a new and saved search. You cannot add fields to the default searches provided by the product.

6. (Optional) To move a field complete the following step:

   a. Drag-and-drop the field to a new location in the search criteria.
      The new location of the field is saved.

7. (Optional) To remove, replace, and change a field, complete the following steps:

   a. In the search criteria area of the page, click Advanced.

   b. Click the Mark for the Deletion icon next to the field you want to remove from the search criteria.
      The field is removed.

   c. Click the Search icon next to the field that you want to replace with a different field.

   d. Select the replacement field and click OK.
      The field is replaced.

   e. Click the Edit Record icon next to the field for which you want to change the label.
      Enter the new field label.

   f. Click the Complete Record Edit icon.
      The field name is changed.

8. At the top of the page, click CONFIGURE SEARCH: OFF.
   The configuration of the search is complete.

9. Click Save.
   The addition, movement, removal, replacement, and name change of a field is completed.

Manage Columns in Search Results

CA APM makes it easier for you to find the information you need in search results by letting you manage columns in search results. Management of columns includes adding, removing, moving, and changing a column in your search result. As a result, you can easily find the information in your search results.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.
2. On the left, click Manage Searches.
   A list of saved searches appears.
3. Click a search in the list.
4. At the top of the page, click CONFIGURE SEARCH: ON.
5. Complete the following steps to add a column.
   a. Click Add Fields.
   b. Select the fields to add to the search results.

   > **Note:** You can add columns to a new and saved search. You cannot add columns to the default searches provided by the product.

6. (Optional) To move a column complete the following step:
   a. In the search results list, drag-and-drop the column to a new location.
      The new location of the column is saved.
7. (Optional) To remove a column and change a column label, complete the following steps:
   a. In the search results, click the appropriate icon for the Deletion next to the column.
      The column is removed.
   b. In the search results, select the column heading and enter the new label.
8. At the top of the page, click CONFIGURE SEARCH: OFF.
   The configuration of the search is complete.
9. Click Save.
   The addition, movement, removal, and change of a column is completed.

Add a Sorting Field

CA APM lets you add sorting fields to the search results and extend the default sort of a single column using either ascending or descending order. For example, you currently sort assets by asset name. You can add asset family to the sorting so that you can sort on both asset name and asset family.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.
2. On the left, click Manage Searches.
   A list of saved searches displays.
3. Click a search in the list.
4. In the Additional Settings, Search Results Sorting area, add the additional field for sorting.
5. Click Go.
   The results appear with the extended sorting and help you see the impact on the results before you save the sorting. The new field is added and you can use the field to sort the search results.

Prevent Duplicate Object Records

CA APM lets you prevent duplicate object records from appearing in the search results. For example, you have several people in your enterprise with the name John Smith. Their first and last names are the same, but their additional contact information (email address, supervisor, department, and so forth) is different.

You have a saved contact search in which only the first and last name of the contact appears in the results. When you search using the saved contact search and specify *John* as the first name and *Smith* as the last name, two instances of John Smith appear in the search results. When you prevent duplicate records from appearing, only one instance of John Smith appears.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.
2. On the left, click Manage Searches.
   A list of saved searches displays.
3. Click the search for which you want to prevent duplicate records from appearing.
4. In the Additional Settings, Unique Search Characteristics area, select the Make Results Unique check box.
5. Click Go.
   The results appear without the duplicate records and help you see the impact on the results before you save your settings. The DISTINCT argument is added to the SQL statement, preventing duplicate records from appearing in the search results.

Prevent Opening Records

CA APM lets you disable the ability to open individual records from the search results. For example, you do not want users to open and display contact information from the contact search results.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to find.
2. On the left, click Manage Searches.
   A list of saved searches displays.
3. Click a search in the list.
4. In the Additional Settings, Unique Search Characteristics area, clear the Allow Selection of Results check box.
5. Click Save.
   A hyperlink does not appear in the search results to open the object.

Software Asset Management

This section contains the following articles:

Software License Management

CA APM provides visibility into the software environment in your organization by tracking detailed information about software licenses. This information includes internal allocations (locations, companies, contacts, and assets), payment history, purchasing information, and the location of hard copy license agreements or attachments of the relevant license and payment documents required by an audit.

Software license management in CA APM involves working with the following objects:

- Software internal allocations (see page 2454)
- Software assets (see page 2457)

Important! We do not recommend that you manage software assets in CA APM. To take advantage of the enhancements that this release provides, we recommend that you use CA SAM to manage your software assets and licenses.

For more information, see SAM Documentation (https://support.ca.com/irj/portal/newhome).

Software Internal Allocations

This article contains the following topics:

A *software internal allocation* describes how your organization is internally approved to use a software asset, as specified in your software license agreement. For example, a license can stipulate that the software can be used only on a particular computer, or that a limited number of users can use the software at one time.

You track and maintain allocations in CA APM using an allocation record. Define an allocation record for any software asset in your repository.

CA APM lets you record an allocation in the following ways:

- For a software asset, you can add, edit, or delete a relationship to a hardware asset on which the software is internally approved for use.
- For a hardware asset, you can edit or delete information about an allocation that is specific to that hardware asset.

Note: Internal allocations are not legal restrictions. Legal information, including software usage constraints, can be maintained in legal document records and in CA SAM.

Add a Location Allocation

CA APM lets you add a location allocation to list the places where your organization is internally approved to use a software asset, as specified in your software license agreement. For example, you are licensed to use 100 copies of version 4.0 of a software product in your North American office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Asset.
2. Search to find the list of available assets.

3. Click the software asset for which you want to add a location allocation.
4. On the left, expand Relationships and click Location Allocation.
5. Click Select New to search for and select a location.
6. Click the Edit Record icon and enter the location allocation details.
7. Click Save.
   The location where your organization is internally approved to use the software asset is added.

Add a Company Allocation

CA APM lets you add a company allocation to list the subsidiary companies where your organization is internally approved to use a software asset, as specified in your software license agreement. For example, you are licensed to use 25 copies of version 4.0 of a software product in a sales office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Asset.
2. Search to find the list of available assets.
3. Click the software asset for which you want to add a company allocation.
4. On the left, expand Relationships and click Company Allocation.
5. Click Select New to search for and select a company.
6. Click the Edit Record icon and enter the company allocation details.
7. Click Save.
   The company where your organization is internally approved to use the software asset is added.

Add a Contact Allocation

CA APM lets you add a contact allocation to list the people who are internally approved to use a software asset, as specified in your software license agreement. For example, the members of your IT department are licensed to use ten copies of version 4.0 of a software product in a development office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Asset.
2. Search to find the list of available assets.
3. Click the software asset for which you want to add a contact allocation.
4. On the left, expand Relationships and click Contact Allocation.
5. Click Select New to search for and select a contact.
6. Click the Edit Record icon and enter the contact allocation details.
7. Click Save.
   The contact who is internally approved to use the software asset is added.

Add an Asset Allocation

CA APM lets you add an asset allocation to list the hardware assets on which your organization is internally approved to use a software asset, as specified in your software license agreement. For example, the members of your IT department are licensed to use 10 copies of version 4.0 of a software product on their Dell Precision Workstation 410 computers.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Asset.
2. Search to find the list of available assets.
3. Click the software asset for which you want to add an asset allocation.
4. On the left, expand Relationships and click Asset Allocation.
5. Click Select New and select a different hardware asset, other than the asset previously selected.
6. Click the Edit Record icon and enter the asset allocation details.
7. Click Save.
   The hardware asset on which your organization is internally approved to use the software asset is added.

Delete an Allocation

CA APM lets you delete the details of an allocation record. For example, your organization purchases Adobe Acrobat Professional and internally allocates the licenses to 100 users. One user does not need the license. Therefore, you remove the software from the computer and delete the allocation. By completing these steps, you make the license available to another user in a new allocation record.

Follow these steps:

1. Click Asset.
2. Search to find the list of available assets.
3. Click the software asset for which you want to delete the allocation.
4. On the left, expand Relationships and click the appropriate allocation type.
   The allocation list appears.
5. Click the Mark for Deletion icon next to the allocation that you want to delete.
6. Click Save.
   The allocation record is deleted.

Software Assets

CA APM lets you track and manage licensing information for *software assets* that your company is entitled to use. The following fields on the Asset Details page represent the licensing information that you can manage for software assets:

- License Class
- License Count
- License Key
- License Duration
- License Duration Units

You can define and maintain this license information for software assets only.

Vendor Management

Take control of your vendor relationships by understanding their interdependencies between your organization and among one another. CA APM lets you track and manage detailed information about the vendors with whom you do business, including contact information and their relationships to other companies. You can gather complete information about the total amount of money spent and what you will spend with a vendor, allowing you to negotiate product prices and purchases with your vendors.

Vendor management in CA APM involves working with the following objects:

Directories

Directory information is maintained in the repository so that you can locate the contact, company, location, and organization information you need for your IT assets. Having a directory offers you consistency for all of your assets to help make analysis easier. In addition, the directory serves as a contact repository when you must contact someone associated with an asset.

Companies

This article contains the following topics:

A *company* buys, sells, services, manages, or uses your IT assets in CA APM. You define company records for key organizations with which you have a business relationship, such as the following examples:

- Your own company, its parent company, or subsidiaries.
- IT manufacturers, vendors, escrow agents, maintenance providers, and service providers.

Before you define a company record, you must define records for the parent company, if any, and the default location, such as the headquarters. This additional information makes it easier to enter the information when defining the company record.

You can have multiple associations between locations and companies. These associations are useful to track companies with worldwide offices. For example, to track the contact details of a large vendor with worldwide offices, define location records for each office and associate them with the company record of the vendor.

You can specify one of the locations as the default location. The default location can be the headquarters of the company or the location that you contact most frequently.

Note: Although associating locations is not mandatory, it is considered good practice. Location records must exist in your repository before you can select locations for any objects.

You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Manage Companies

You can define, update, and delete company records for key organizations with which you have a business relationship. For example, you can define a company as an IT manufacturer, vendor, escrow agent, maintenance provider, or service provider.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click Directory, Company.
2. Perform one of the following actions.
3. Define a company.
    a. Click New Company.
    b. Enter the new company information and click Save.

    Note: You can also define a company by copying an existing company, supplying a new name, changing the information, and saving the new company.

4. Update a company.
    a. Search for the list of available companies.
    b. Click the company that you want to update.
    c. Enter the new information for the company and click Save.

Note: You can also view the details for an object that is related to your company, if the related object has a Browse icon. When you click the Browse icon, you leave the company page and you navigate to the related object page. To keep the company page in view and preserve the company information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. Delete a company.
    a. Search for the list of available companies.
    b. Click the company that you want to delete.
    c. Click Delete and confirm that you want to delete the company.

Associate Locations to a Company

Associating multiple locations to a company is a recommended best practice to track companies with worldwide offices. For example, you can associate your company with the North America office, Latin America office, Asia Pacific office, and European office. Location records must exist before you can associate the location with a company.

Follow these steps:

1. Click Directory, Company.
2. Search for the list of available companies.
3. Click the company that you want to associate with multiple locations.
4. Click Locations on the left.
5. Click Select New to display the list of all available locations.
6. Select the company locations.
7. Click Save.

Add an Acquired Company

CA APM lets you maintain the details of the companies that you acquire and track acquisitions made by external companies. This information is useful when tracking the association between parent and subsidiary companies. For example, to understand the relationship between two companies, you can review the list of acquired companies.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Directory, Company.

2. Search for the list of available companies.
3. Click the company to which you want to add an acquired company.
4. Expand Relationships on the left and click Company Acquisition.
5. Click Select New and select a different company, other than the company previously selected.
6. Click Save.
   The acquired company is added to the list.

Add a Company Allocation

You can add a company allocation to list the software assets that your organization is internally approved to use, as specified in your software license agreement. For example, you are licensed to use 25 copies of version 4.0 of a software product in a sales office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Directory, Company.
2. Search for the list of available companies.
3. Click the company for which you want to add a company allocation.
4. Expand Relationships on the left and click Software Allocation.
5. Click Select New to search for and select an asset.
6. Click the Edit Record icon and enter the company allocation details.
7. Click Save.
   The software asset that your company is internally approved to use is added.

Contacts

This article contains the following topics:

A *contact* is a person or department who buys, sells, services, manages, or uses your IT assets in CA APM. Define contact records for key individuals and departments in which you have a business relationship, such as the following examples:

- Users, asset management staff, contract administrators, and IT staff.

- Representatives of other companies, such as manufacturers, vendors, escrow agents, maintenance, and service providers.

Before you define a contact record, define a company record (see page 2459) to associate with the contact. Having the company record available makes it easier to add the company information when you are defining the contact record.
You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Manage Contacts

You can define, update, and delete contact records for key people or departments in which you have a business relationship. For example, you can define contacts as asset management staff, contract administrators, IT staff, manufacturers, vendors, and service providers.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click Directory, Contact.
2. Perform one of the following actions.
3. Define a contact.
    a. Click New Contact.
    b. Enter the new contact information.
    c. Click Save.

    Note: You can also define a contact by copying an existing contact, supplying a new name, changing the information, and saving the new contact.

4. Update a contact.
    a. Search for the list of available contacts.
    b. Click the contact that you want to update.
    c. Enter the new information for the contact.
    d. Click Save.

Note: You can also view the details for an object that is related to your contact, if the related object has a Browse icon. When you click the Browse icon, you leave the contact page and you navigate to the related object page. To keep the contact page in view and preserve the contact information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. Delete a contact.
    a. Search for the list of available contacts.
    b. Click the contact that you want to delete.
    c. Click Delete and confirm that you want to delete the contact.

Add a Contact Allocation

You can add a contact allocation to list the software assets that people in your organization are internally approved to use, as specified in your software license agreement. For example, the members of your IT department are licensed to use ten copies of version 4.0 of a software product in a development office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Directory, Contact.
2. Search for the list of available contacts.
3. Click the contact for which you want to add a contact allocation.
4. Expand Relationships on the left and click Software Allocation.
5. Click Select New to search for and select an asset.
6. Click the Edit Record icon and enter the contact allocation details.
7. Click Save.

Organizations

This article contains the following topics:

An *organization* is an internal department. CA APM lets you assign organizations to assets, locations, and contacts. For example, use an organization to identify the department for which an employee works.

Note: Administrators or users with administrative privileges can manage organizations. In addition, if you are using CA Service Desk Manager, you do not have to create the organization. You can use the information from the service desk.

You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Manage Organizations

You can define, update, and delete an organization for an internal department, division, or external company. For example, you can define an organization for research and development, corporate finance, worldwide law, or global human resources.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click Directory, Organization.
2. Perform one of the following actions.
3. Define an organization.
    a. Click New Organization.
    b. Enter the new organization information.
    c. Click Save.

    Note: You can also define an organization by copying an existing organization, supplying a new name, changing the information, and saving the new organization.
4. Update an organization.
    a. Search for the list of available organizations.

b. Click the organization that you want to update.

c. Enter the new information for the organization.

d. Click Save.

Note: You can also view the details for an object that is related to your contact, if the related object has a Browse icon. When you click the Browse icon, you leave the contact page and you navigate to the related object page. To keep the contact page in view and preserve the contact information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. Delete an organization.

a. Search for the list of available organizations.

b. Click the organization that you want to delete.

c. Click Delete and confirm that you want to delete the organization.

Locations

This article contains the following topics:

A *location* is a place where assets, companies, contacts, and legal documents are placed or situated. CA APM lets you associate locations with assets, companies, and contacts. You can define locations for the following objects:

- Assets
- Company offices and other locations where you track IT assets.
- Manufacturing companies, vendors, escrow agents, maintenance, and service providers.
- Contacts within and outside the company.

You can define multiple associations between locations and companies. The associations are useful when you want to track a large vendor with worldwide offices. For example, to track the contact details of a large vendor with worldwide offices, you can define location records for each office and associate them with the company record of the vendor. You can define location records for each office and associate them with the vendor company record.

You can specify one of the locations as the default location. The default location can be the headquarters of the company, or the location that you contact most frequently.

Note: Although associating locations is not mandatory, it is considered a best practice. Location records must exist in your repository before you can select locations for any objects.

You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Manage Locations

You can define, update, or delete a location to manage the addresses of assets, contacts, and companies. For example, you can define the address for your North American office, Latin America office, and Asia Pacific office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Directory, Location.
2. Perform one of the following actions.
3. Define a location.
    a. Click New Location.
    b. Enter the new location information.
    c. Click Save.

    Note: You can also define a location by copying an existing location, supplying a new name, changing the information, and saving the new location.

4. Update a location.
    a. Search for the list of available locations.
    b. Click the location that you want to update.
    c. Enter the new information for the location.
    d. Click Save.

Note: You can also view the details for an object that is related to your location, if the related object has a Browse icon. When you click the Browse icon, you leave the location page and you navigate to the related object page. To keep the location page in view and preserve the location information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. Delete a location.
    a. Search for the list of available locations.
    b. Click the location that you want to delete.
    c. Click Delete and confirm that you want to delete the location.

Associate Companies to Locations

Associating companies to locations is a best practice to track companies with worldwide offices. For example, you can associate your company with the North America office, Latin America office, Asia Pacific office, and European office.

Follow these steps:

1. Click Directory, Location.
2. Search for the list of available locations.
3. Click the location that you want to associate with companies.
4. Click Companies.
5. Associate the new location with the company.
6. Click Save.

Add a Location Allocation

You can add a location allocation to list the software assets that the locations in your organization are internally approved to use, as specified in your software license agreement. For example, you are licensed to use 100 copies of version 4.0 of a software product in your North American office.

Note: You can view an audit history for this relationship.

Follow these steps:

1. Click Directory, Location.
2. Search for the list of available locations.

3. Click the location for which you want to add a location allocation.
4. Expand Relationships on the left and click Software Allocation.
5. Click Select New to search for and select an asset.
6. Click the Edit Record icon and enter the location allocation details.
7. Click Save.
   The software asset that the location is internally approved to use is added.

Sites

This article contains the following topics:

A *site* is a group of locations, which lets you use the new site in the location. For example, a site can be a city in which your enterprise has one or more physical locations, or a region in which you have customers that you support.

For more information about defining date-specific and non-date-specific terms and conditions for legal documents, see Define Legal Document Terms and Conditions (see page 1535).

You can retrieve information from the repository about any object by searching. You can then select, view, and manage individual object records from the search results.

Manage Sites

You can define, update, and delete sites. Sites specify groups of locations, such as a city in which your enterprise has one or more locations, or a region in which you have customers.

Important! When you delete an object, you can no longer view the audit history for the object. We recommend that instead of deleting the object, you make the object inactive. Then, you can still view the audit history for the object.

Follow these steps:

1. Click Directory, Site.
2. Perform one of the following actions.
3. Define a site.
   a. Click New Site.
   b. Enter the new site information.
   c. Click Save.

Note: You can also define a site by copying an existing site, supplying a new name, changing the information, and saving the new site.

4. Update a site.
    a. Search to find the list of available sites.
    b. Click the site that you want to update.
    c. Enter the new information for the site.
    d. Click Save.

Note: You can also view the details for an object that is related to your site, if the related object has a Browse icon. When you click the Browse icon, you leave the site page and you navigate to the related object page. To keep the site page in view and preserve the site information, right-click the Browse icon and select Open Link in New Window. Close the new window when you are finished viewing the related object details.

5. Delete a site.
    a. Search to find the list of available sites.
    b. Click the site that you want to delete.
    c. Click Delete and confirm that you want to delete the site.

Configuration Management

This section contains the following articles:

Configuration Items

Contents

Configuration items are the devices, software, and services that make up your business infrastructure. The information that is associated with a configuration item uniquely identifies the configuration item and indicates its precise location. Configuration items can be associated with contacts (private configuration items) and organizations (shared configuration items). Configuration items let you:

- Identify configuration items by name, class, and family.
- Specify inventory information.
- Specify additional properties to define the configuration item.
- Log and view comments that are associated with the configuration item.
- Specify location information for the configuration item.
- Specify service information, such as a service type, for the configuration item.
- View and define contacts and organizations that are assigned to the configuration item.**CMDB Attributes**
- Identify hierarchical and peer-to-peer relationships between configuration items.
- View tickets that are associated with the configuration item.

You are not required to define all this information for configuration items. Defining an optimal amount of configuration item information gives you a clearer picture when you perform impact analysis for the organization.

Important! You can attach configuration items only if they are Active. You cannot search for an Inactive CI when working on a ticket.

Important! Depending on your role, you do not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create new ones.

Depending on your role, you can perform user and administration tasks on configuration items (CIs) by using the following features:

- Scoreboards allow you to perform user tasks and manage CIs and CI relationships.
- The Administration tab lets you perform administration tasks with CIs and relationships.
- CMDB Visualizer lets you perform user and administration tasks for visualizing CIs and relationships.

Create a Configuration Item

You can create a configuration item to be linked to tickets. Configuration items give analysts information about the entities that tickets affect.

Follow these steps:

1. On the Scoreboard, select File, New Configuration Item on the menu bar.
2. Enter a name and class for the configuration item.
   The class is a unique identifier that categorizes the CI class you are adding to the database. You can enter a class directly into the field or click the search icon to search for a defined class.
3. Click Continue and complete the Configuration Item fields (see page) as appropriate.
4. Click Save.

   The configuration item definition is saved and the Configuration Item Detail page appears. After you create a CI, the CI Detail page does not display some identifying attributes in the following cases:

   - The attributes have no associated value.
   - The attributes do not apply to the CI family.

However, identifying attributes with non-blank values always display. Configuration Item Detail pages identify a CI and determine which type of page appears so that you can create or manage the CI. CI Name and the CI Class are required. An asterisk (*) identifies a field that is required. If you use change verification (see page 2643), informational messages appear at the top of the detail form.

When you assign the new CI to a CI class, the CI family is automatically assigned (because a class is already associated with a family). When you click Continue on the initial Create New Configuration Item page, the appropriate CI page appears, depending on the family.

Note: A notification appears for successful and unsuccessful changes. A warning message is displayed for an unsuccessful change indicating the policy, attribute, and the corresponding action that occurred.

The following buttons are available for viewing configuration item information:

Asset Viewer: Opens the Common Asset Viewer. The viewer displays a detailed view of the configuration item that includes all properties that are managed or discovered.

Affected Tenants: Displays the tenants that are affected by this CI, based on its associated contacts and organizations.

Note: This button only appears when multi-tenancy is installed.

CMDBf Viewer: Displays the Federated View, a side by side view of CI attributes across registered MDRs.

Visualizer: Opens the Visualizer, which displays a graphical representation of the configuration item showing its relationship to other resources.

Configuration Item Fields

The following fields are required to create or update or search for a CI:

- **Family**
  Categorizes the classes of CIs.
- **Standard CI**
  Configuration item that is used for comparison.
- **Host Name**
  Identifies the IP host name of the CI.
- **MAC Address**
  Identifies the Media Access Code for the device. This field is automatically filled when the system creates a record for a device it detects.

- **Alt CI ID**
  Specifies the alternate identifier for a CI; for example, a barcode.

- **DNS Name**
  Identifies the Domain Name System name of the CI.

- **Serial Number**
  Identifies the serial number for the CI. The serial number applies to devices or software.

- **Active?**
  Specifies whether the record is active in the database. The inactive CI records do not appear on display lists.

- **Asset?**
  Categorizes an asset for filtering purposes and to control display in CA CMDB or other products such as CA APM. You cannot change the Asset flag to NO when an asset is managed by CA APM.

- **CI?**
  Categorizes a CI for filtering purposes and to control display in CA CMDB or other products such as CA APM. By default, a CI created by CA CMDB is flagged as a CI but not as an Asset.

- **Superceded By**
  Indicates the CI that has rendered this CI inactive due to its ambiguity.

- **Action**
  Sets or resets the Actual Date/Time to the current date and time.

- **Target**
  Specifies the current Service Target.

- **Target Date/Time**
  Specifies date and time when this Service Target is due. If the ticket is in a Hold status, this value is blank.

- **Actual Date/Time**
  Specifies the time when the target condition was met. If no value appears, the target condition has not been met.\

- **Time Left**
  Specifies the amount of remaining time for the service target when the ticket is on hold. If the Service Target has been met, Time Left shows the unused time. A negative value indicates the time that elapsed since the missed target date.

- **Violation Cost**
  Specifies the incurred cost when the service type time limit is violated.

Note: The CI Detail page does not display identifying blank attributes and attributes that do not apply to the CI family. However, identifying attributes with non-blank values always display.

Configuration Item Tabs

The following tabs can be available on the Create New Configuration Item, Configuration Item Detail, and the Update Configuration Item pages:

CMDB Attributes

- **Attributes**
  Itemizes and manages CI attributes associated with the class that is assigned. The CI Family determines what appears on the Attributes tab.

- **CMDB Relationships**
  Displays the relationships for this CI. All links display the CI Relationship Detail page.

- **Versioning**
  Displays and manages the history of the CI (see page 2497), associated snapshots, milestones, and other views. Versioning also displays pending Change Specifications that are associated with Change Orders. For example, view details about the future state of a CI.

- **Reconciliation**
  Lists all active CIs that are ambiguous with this CI. You can select Exclude Ambiguity to remove this CI from ambiguity calculations and ambiguity management. For more information, see the Reconcile CI Ambiguities Using MDR. (see page 2556)

- **Inventory**
  Stores detailed inventory information about the CI.

- **Service**
  Stores detailed service information that is related to servicing a CI. The following sub-tabs are required for a Service:

  1. **Service Type**: The level of support service received for this configuration item. For example, some items may receive problem resolution within four hours, while problems with others may be resolved within 72 hours. Enter the service type directly, or click the search icon to select the desired type.

  2. **Cost Center**: The code to which expenses related to this configuration item are charged. Enter the cost center directly, or click the search icon to select the desired cost center.

  3. **Responsible Organization**: The organization that is responsible for this configuration item.

  4. **Maintenance Organization**: The organization responsible for the maintenance of this configuration item.

  5. **Priority**: The level of attention given to problems with this configuration item.

  6. **Supply Vendor**: The vendor responsible for maintaining supplies for this configuration item.

  7. **Responsible Vendor**: The vendor responsible for maintaining the service provided by this configuration item.

8. **Maintenance Vendor**: The vendor responsible for the maintenance of this configuration item.

9. **Service Impact**: The level of importance of this service to the business.

Contacts, Location, Organizations

- **Contacts**
  Stores detailed contact information about the contacts responsible for the CI. The following sub-tabs are required for Contacts:

  1. **Primary Contact**: The primary person or group in charge of the CI.
  2. **Phone Number**: The primary telephone number of the person or group in charge of the CI
  3. **Email Address**: The email address of the person or group in charge of the CI
  4. **Billing**: The address that is listed by room number and building
  5. **Support 1**: The first contact for support in charge of the CI
  6. **Support 2**: The second contact for support in charge of the CI
  7. **Support 3**: The third contact for support in charge of the CI
  8. **Disaster Recovery**: The contact for disaster recovery in charge of the CI
  9. **Backup Services**: The contact for backup services in charge of the CI
  10. **Network Operations**: The contact for network operations in charge of the CI

- **Location**
  Stores detailed information about the geographical location of the CI.

- **Organizations**
  Stores detailed organization information about the organizations responsible for the CI.

Related Tickets

Information about related CA SDM tickets is displayed through Incidents, problems, requests, change orders, change specifications, and verification log.

Additional Information

- **Maintenance Windows**
  Displays global maintenance windows that are associated with the CI.

- **Service Contracts**
  Displays information about service contracts that are associated with the CI, to identify the level of support the item receives.

- **Activities**
  Displays the activity log for the CI. You can display the analyst or activity details.

- **Attachments**

  Note: This feature will only be available if you apply a patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

  Enables you to attach documents or URLs with this CI. Depending on the requirement, click Attach Documents or Attach URL and follow the on-screen instructions. The URL or the document is added to the record and is listed on the Attachments tab of the Configuration Item Detail page. A notification is sent to the related contacts of the CI when the attachment is attached successfully. Similarly when an attachment is removed from the CI, a notification is sent.

  Note: CA SDM is integrated with CA IT Asset Management and this CI is also an asset in CA IT Asset Management. If you have added an attachment to this CI from CA SDM, it will not be visible when this CI is viewed in CA IT Asset Management.

Knowledge Management

- **Knowledge**
  Lists the Knowledge documents that are related to the CI.

Inactivate a Configuration Item

If a configuration item is no longer used, you can edit the configuration item details to make it inactive. An inactive status removes the configuration item from the Scoreboard Configuration Item List. You cannot delete a configuration item.

Edit a CI and select Inactive from the Active drop-down list. The configuration item continues to appear in any existing relationships until the relationships are inactivated.

Note: Inactivating a Family or Class does not affect existing CIs in that Family and Class. Inactivating only prevents new CIs from being created in that Family and Class.

Reactivate a Configuration Item

To use a configuration item that is inactive, you can reactivate it. Edit a CI and select Active from the Active drop-down list.

View CI Attributes in Other CA Products

You can use the Common Asset Viewer page to view configuration item attributes in other CA products.

Follow these steps:

1. Locate and open the configuration item.
2. Click Asset Viewer.
   The Common Asset Viewer page appears.
3. Click the links on the Owned Resources tab to locate attribute information from other CA products.
4. Click Close Window when you are done.
   You have viewed configuration item attributes in other CA products.

Add a Discovered Asset

You can change non-owned assets in the Management Database (MDB) into owned configuration items.

Follow these steps:

1. Click the Discovered Assets button on the Configuration Item List page.
   The Discovered Asset Search page appears.
2. Click Search to display the Discovered Asset List.
3. Select the asset from the list that you want to add as a configuration item.
4. Right-click the asset and select Create New Configuration Item from the pop-up menu that appears.
   The Create New Configuration Item page appears with information about the item populating some of the fields.
5. Complete any remaining fields that apply to the new configuration item and click Continue.
6. Enter data as required in the appropriate fields on the Attributes tab.
   The family of the class that you selected for the configuration item determines the attributes that appear on the tab. Your business processes and the information you want to store and view for a configuration item determines the information that you enter here.
7. Click Save.
   The discovered asset is added.

Asset and CI Flags

To categorize the type of CI/asset for filtering purposes and to control what entities are visible in CA SDM or other products such as CA APM, use the following flags:

- **CI? (YES/NO)**
  Identifies configuration items.

- **Asset? (YES/NO)**
  Identifies the assets.

By default, a CI created by CA CMDB is flagged as a CI and not as an Asset. You can override this behavior if necessary. A CI can also be an Asset. CA CMDB does not allow the Asset flag to be changed once it has been set to Yes. The Asset flag is typically set to Yes when CA APM creates an asset.

These flags appear on all CI detail forms and in the CI search facility. The values can be updated in the CI detail form, GRLoader, and CA CMDB web services. The Edit in List feature also supports updating the new flags in multiple records.

The object attribute name for the CI flag is **is_ci**. The object attribute name for the Asset flag is **is_asset**. These names are SREL attributes that reference bool. The attribute names can be used as GRLoader XML tags. For example, to change the default value of the Asset flag when creating a CI with GRLoader, add the following XML to define the new CI:

```
<is_asset>YES</is_asset>
```

Create a CI Company

The companies supply the hardware, software, and services associated with your system.

Follow these steps:

1. From the Administration tab, navigate to Service Desk, Application Data, Configuration Items, Companies.

2. Click Create New and fill in the field information as appropriate.

   - **Company Type**
     The company type assigned to this vendor. For example, a company type of Lessor can be assigned to suppliers leasing out products. A company type of Provider can be assigned to companies offering services. A company type of Vendor can be assigned to companies selling assets.

   - **Primary Contact**
     The name of the person primarily responsible for issues related to this company. This person must be a defined contact in your system.

   - **Alias**
     An alternate name for this company. For example, if the full company name is John Smith Company, Incorporated, you might enter an alias of Smith Company.

   - **Parent Company**
     If this company is part of or a subsidiary of a larger organization, enter the name of that larger organization. The parent company must be a defined company in your system. You can enter the company name directly into this field, or click the search icon to select the company.

A new company is created for CI use.

Create a Company Type

Company types are supplier classification for the hardware, software, and services that are associated with your system. Company Types classification helps to organize and select the vendor on the basis of services provided. From the Administration tab, navigate to Service Desk, Application Data, Configuration Items, Company Types.

Families and Classes

Families classify configuration items by type and assign meaningful attributes for each one. *Classes* identify general categories of configuration items that your enterprise supports. Families are broad categories of configuration items such as hardware, software, and services. Classes are more specific categories within the broader family category. For example, the family hardware could contain classes such as, modem, router, repeater, and bridge.

Organizing your configuration items into families and classes makes it easier to manage your configuration items. For example, you can generate a list of configuration items that belong to a particular family or class.

Create a Configuration Item Class

Configuration item classes are general categories of hardware, software, and services. For example, workstation, printer services. The configuration item classes are grouped into broader categories known as configuration item families.

When you assign the new CI to a CI class, the CI family is automatically assigned (because a class is already associated with a family). When you click Continue on the initial Create New Configuration Item page, the appropriate CI page appears, depending on the family.

Follow these steps:

1. From the Administration tab, navigate to Service Desk, Application Data, Configuration Items, Configuration Item Classes.
2. Click Create New.
3. Fill in the following fields:
   - **Family** -- The Configuration Item Family associated with this Configuration Item Class. Families are broader categories for configuration items than classes. The families include computers, other hardware, software, and services. This field is updated automatically and cannot be modified.
   - **Record Status** -- Status indicates whether the configuration item class is active or inactive.
4. Click Save.

Create a Configuration Item Families

Configuration item families are broad categories you can use to classify your network resources. You can assign configuration item classes to families. By doing this, individual configuration items are automatically assigned to families when they are assigned to classes. The configuration item family controls the kind of record displayed.

Follow these steps:

1. From the Administration tab, navigate to the Configuration Item Families List.

   The Configuration Item Family List page displays.

2. Click Create New.

   The Create New Configuration Item Family page displays.

3. Fill in the following fields:

   - **Record Status** -- Indicates whether the configuration item family is active or inactive.
   - **Extension Name** -- Specifies an extension value related to a physical table name in the database. When you select an extension name in the drop-down list, the Physical Table Name field appears in the read-only Physical Table Name field.

4. Click Save.

Create a Service Status

A service status indicates the disposition of a configuration item (for example, In Service, Discontinued, In Repair, and so on).

Follow these steps:

1. Select Service Desk, Application Data, Configuration Items, Service Status on the Administration tab.

2. Click Create New.

3. Fill in the following fields:

   - **Name**
     A unique identifier for the service status.
   - **Record Status**
     Status whether the service is active or inactive.
   - **Description**
     A detailed description of the service status.

4. Click Save.
   The service status definition is saved and the Service Status Detail page appears.

1. Specifies the contact for Backup Services in charge of the CI.

Configuration Item Events and Logs

Contents

View Configuration Item Event History

You can view a record of significant actions that occur regarding a CI. The event list contains a record of the events that are associated with the CI. You maintain events, or procedures the system follows after a certain amount of time has elapsed. For example, an event can send a notification to an analyst if a CI has been updated.

You can view historical events and the status of a configuration item.

Follow these steps:

1. On the Administration tab, select Service Desk, Application Data, Configuration Items, Configuration Item List.
   The Configuration Item Search page appears.

2. Search for a Configuration Item and select it.

3. Click the Event History button.
   The Event History page displays the events and their status. The following fields require explanation:

   - **Condition**
     Indicates the condition that is checked for by the event. CA SDM provides macros that verify standard conditions such as priorities and object status (open or closed).

   - **Check Time**
     Indicates the time that the event was checked, based on the time parameters that the event configuration specifies.

   - **Time Loaded**
     Indicates the time that the event was loaded, based on the time parameters that the event configuration specifies.

Add Configuration Item Log

You can add log entries to record activities for the configuration item.

Follow these steps:

1. On the Scoreboard, browse to Configuration Items, Active, or Inactive. Select the Priority, Warranty, and Ownership for the configuration item you want to edit.
   The Configuration Item List appears.

2. Select the Configuration Item.
   The Configuration Item Detail page appears.

3. Click Edit.
   The Update Configuration Item page appears.

4. Select the Log tab.
   A list of log entries for this configuration item appears.

5. Click Add Log.
   The Create New Configuration Item Log page appears.

6. Enter the information that you want to record in the log and click Save.
   The Configuration Item Detail page displays the new log entry that is listed on the Log tab.

View Log History

You can view the log entries to see a history of activity for the configuration item.

Follow these steps:

1. On the Scoreboard, browse to Configuration Items, Active, or Inactive. Select the Priority, Warranty, and Ownership for the configuration item you want to edit.
   The Configuration Item List appears.

2. Select the Configuration Item.
   The Configuration Item Detail page appears.

3. Click Edit.
   The Update Configuration Item page displays.

4. Select the Log tab.
   A list of log entries for this configuration item displays.

CI Naming Conventions and Restrictions

CIs have the following naming conventions and restrictions:

- CI Name
  The CI Name is the common or display name that is used in all CI lists. The total length of the name must not exceed 255 characters. The CI name does not need to be unique, but we recommend that it is globally unique. In addition, when MDR determines the name, we recommend that MDR administrators emphasize the human readability factor when populating this field.

- Software CIs
  For third-party software, follow the same naming convention as the names that you manually create using the Administration tab. Matching naming conventions lets CA Cohesion ACM-discovered CIs reconcile to the manually created ones. If you do not follow this convention, you can create multiple CIs with only one software instance.

Use of systemname Attribute
The systemname attribute uniquely associates a *single* CI with a particular host name.
If multiple CIs are imported and specify the same systemname as an existing CI, reconciliation results only one CI.

Example

The following output lines show the creation of a Server CI (provider), a Software CI (dependent), and a *runs* relationship between them:

```
CI:  Name: Server1     Class: Server   Systemname: Server1
CI:  Name: Apache1   ON Server1      Class: Software
Relationship:  Server1 runs Apache1   ON Server1
```

The resulting relationship represents a server that runs Apache software.

Add a Discovered Asset

CA SDM does not operate on the entire set of resources that are stored in any database. Only configuration items (CIs) registered by CA Service Desk Manager are immediately available. From a business process perspective, a help desk is only concerned about supporting *owned* resources that are part of the organization through a purchasing process. For example, if a visiting consultant from an outside company plugs his laptop computer into the network, should this device automatically be entered into the help desk's inventory of supported configuration items? Probably not. The collection of configuration items that are used by CA Service Desk Manager are represented in the owned resource table: (ca_owned_resource).

You may need to track issues with configuration items that are registered in the database, but do not yet exist as owned resources. The Discovered Asset Selector allows the users to browse non-owned configuration item resource records in the database and transform them into owned resource records that can be used by CA Service Desk Manager.

The information from the nonowned asset is merged with the CA Service Desk Manager information into the same master record. If you search for Discovered Assets again, you can see that the original record has been updated to include the CA Service Desk Manager information you entered.

Follow these steps:

1. From the Configuration Item List page, click the Discovered Assets button.
   The Discovered Asset Search page appears.

2. To display the Discovered Asset List, click Search.

3. Select the asset from the list that you want to add as a configuration item. Right-click the asset and select Create New Configuration Item.
   The Create New Configuration Item page appears with information about the item populating some of the fields.

4. Complete any remaining fields that apply to the new configuration item and click Continue.

Note: Only name and class are required values for creating a configuration item.

5. Enter data as required in the appropriate fields on the Attributes tab.
   The family of the class that you selected for the configuration item determines the attributes that appear on the tab. The information you enter here is determined by your business processes and the information you want to store and view for a configuration item.

6. Click Save.
   The discovered asset is added.

Configuration Item Search Fields

The following search fields are available for filtering searches of configuration items. All search fields that allow text entry support use of the % wildcard character.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

- See the Configuration Item Fields (see page 2472) to filter based on the field values.

(Optional) Click the first  link to display the following fields:

- **Contact**
  Identifies a contact that is associated with the configuration item.

- **Manufacturer**
  Specifies the manufacturer of the item. This field is automatically populated, based on the value of the Model field, and cannot be changed.

- **Model**
  Specifies the manufacturer model identifier.
  Priority
  Specifies the priority ranking of the record that determines the amount of attention it receives. The predefined priority levels are 1 (highest) through 5 (lowest).

- **Product Version**
  Specifies the version number of the item, typically used for software and hardware.

- **License Number**
  Specifies the license number of the service provider (if applicable).

- **Financial Reference**
  Indicates the association of the configuration item with your financial software.

(Optional) Click the second  link to display the following fields:

- **Supply Vendor**
  Specifies the vendor responsible for maintaining supplies for this configuration item.

- **Responsible Vendor**
  Specifies the vendor responsible for maintaining the service that this configuration item provides.

- **Maintenance Vendor**
  Specifies the vendor responsible for the maintenance of this configuration item.

- **Cost Center**
  Specifies the code to which expenses related to this configuration item are charged. Enter the cost center directly, or to select the desired cost center, click the magnifier.

- **Responsible Organization**
  Specifies the organization that is responsible for this configuration item.

- **Maintenance Organization**
  Specifies the organization responsible for the maintenance of this configuration item.

(Optional) Click the third  link to display the following fields:

- **Earliest Acquire Date**
  Specifies the start date and time range for filtering your search that is based on when configuration items were acquired.

- **Latest Acquire Date**
  Specifies the end date and time range for filtering your search that is based on when configuration items were acquired.

- **Earliest Installation Date**
  Specifies the start date and time range for filtering your search that is based on when configuration items were installed.

- **Latest Installation Date**
  Specifies the end date and time range for filtering your search that is based on when configuration items were installed.

- **Earliest Warranty Start Date**
  Specifies the start date and time range for filtering your search. The search is based on when warranty coverage for configuration items began.

- **Latest Warranty Start Date**
  Specifies the end date and time range for filtering your search. The search is based on when warranty coverage for configuration items began.

- **Earliest Warranty End Date**
  Specifies the start date and time range for filtering your search. The search is based on when warranty coverage for configuration items ends.

- **Latest Warranty End Date**
  Specifies the end date and time range for filtering your search. The search is based on when warranty coverage for configuration items ends.

- **Earliest Expiration Date**
  Specifies the start date and time range for filtering your search that is based on when configuration items expire.

- **Latest Expiration Date**
  Specifies the end date and time range for filtering your search that is based on when configuration items expire.

You can click the More icon to display the Additional Search Arguments field. This field is intended only for expert users who understand SQL and Majic. You can enter a SQL WHERE clause in this field to specify an additional search argument.

Define CI Details

This article contains the following topics:

Define Service Information

You can store detailed information that is related to servicing a configuration item.

Follow these steps:

1. On the Service Desk tab, browse to Configuration Items, Active or Inactive. Select the Priority, Warranty, and Ownership for the configuration item you want to edit.
   The Configuration Item List appears.

2. Select the Configuration Item.
   The Configuration Item Detail page displays.

3. Click Edit.
   The Update Configuration Item page displays.

4. Select the Service tab and fill in the fields as appropriate.

5. Click Save.
   The configuration item definition is saved and the Configuration Item Detail page appears.

The following buttons are available for viewing configuration item details:

- **Asset Viewer**

  Opens the Common Asset Viewer. The viewer displays a detailed view of the configuration item that includes all properties that are managed or discovered.

Affected Tenants

Displays the tenants that are affected by this CI, based on its associated contacts and organizations.

Note: This button only appears when multi-tenancy is installed.

CMDBf Viewer

Displays the Federated View, a side by side view of CI attributes across registered MDRs.

Visualizer

Opens the Visualizer, which displays a graphical representation of the configuration item showing its relationship to other resources.

Service Fields

- **Service Type** -- The level of support service that is received for this configuration item. For example, some items can receive the problem resolution within four hours, while others can take up to 72 hours. Enter the service type directly, or click the search icon to select the desired type.
- **Cost Center** -- The code to which expenses related to this configuration item are charged. Enter the cost center directly or select the desired cost center by clicking the search icon.
- **Responsible Organization** -- The organization that is responsible for this configuration item.
- **Maintenance Organization** -- The organization responsible for the maintenance of this configuration item.
- **Priority** -- The level of attention that is given to problems with this configuration item.
- **Supply Vendor** -- The vendor responsible for maintaining supplies for this configuration item.
- **Responsible Vendor** -- The vendor responsible for maintaining the service that this configuration item provides.
- **Maintenance Vendor** -- The vendor responsible for the maintenance of this configuration item.
- **Service Impact** -- The level of importance of this service to the business.

Define Contact Information

You can define detailed information about the contacts that are responsible for a configuration item.

Follow these steps:

1. On the Scoreboard, select Configuration Items, Active or Inactive.

2. Select the Priority, Warranty, and Ownership for the configuration item you want to edit.
   The Configuration Item List appears.

3. Select the Configuration Item that you want to edit.
   The Configuration Item Detail page appears.

4. Click Edit.
   The Update Configuration Item page appears.

5. Select the Contacts tab.

6. Complete the tab fields as appropriate.

7. (Optional) Click Update Contacts.
   The Contact Search page displays.

8. Complete one or more of the search fields, and click Search.
   The Contact List page displays the contacts that match your search criteria.

9. From the list on the left, select the contacts that you want to assign to this configuration item.
   To select multiple contacts, hold down the CTRL key while clicking the left mouse button.

10. When you have selected all the contacts that you want, click the move button (>>).
    The selected contacts move to the Assigned to CI list on the right.

11. Click OK.
    The Configuration Item Detail page displays the selected contacts that are listed on the Contacts tab.

Define Location Information

You can store detailed information about the location of a configuration item.

Follow these steps:

1. On the Scoreboard, browse to Configuration Items, Active or Inactive. Select the Priority, Warranty, and Ownership for the configuration item you want to edit.
   The Configuration Item List appears.

2. Select the Configuration Item.
   The Configuration Item Detail page displays.

3. Click Edit.
   The Update Configuration Item page displays.

4. Select the Location tab, and fill in the fields as appropriate for the configuration item.

Note: The Address fields are filled in automatically when you select a location from the drop-down list.

5. Click Save.
   The location information is stored in the configuration item record.

Define Organization Information

You can define detailed information about the organizations that are responsible for a configuration item.

Follow these steps:

1. On the Scoreboard, select Configuration Items, Active or Inactive. Select the Priority, Warranty, and Ownership for the configuration item you want to edit.
   The Configuration Item List appears.

2. Select the Configuration Item.
   The Configuration Item Detail page appears.

3. Click Edit.
   The Update Configuration Item page appears.

4. Select the Organizations tab and click Update Organizations.
   The Organization Search page displays.

5. Complete one or more of the search fields, and click Search.
   The Organization List page displays the organizations that match your search criteria.

6. From the list on the left, click an organization that you want to assign to this configuration item. To highlight multiple organizations, hold down the CTRL key while selecting.

7. When you have selected all the organizations that you want, click Move (>>).
   The selected organizations move to the Assigned to CI list on the right.

8. Click OK.
   The Configuration Item Detail page displays the selected organizations that are listed on the Organizations tab.

CI Relationships

Contents

CA SDM provides a list of predefined relationship types that help you describe a relationship, or an association between configuration items. How the relationship is expressed depends on which configuration item is the focus. For example, a provider supports a dependent configuration item, but the dependent is supported by the provider. These are different expressions of the same relationship. The relationship type label that you see depends on whether you are viewing a provider-to-dependent or a dependent-to-provider relationship.

CIs in the CMDB can be related to other CIs. For example, a computer as a configuration item can result in additional configuration items, such as a printer and a monitor. The CI Relationship List displays sets of related CIs. For information about the relationship types that CMDB provides, see *CMDB Technical Reference* (see page 4168).

The CI relationships have the following characteristics:

- The *relationship type* defines how two configuration items are related.
- Hierarchical relationship types are paired as *provider/dependent*. For example, A (provider) *hosts* B; B (dependent) *is hosted by* A.
- Nonhierarchical relationship types are defined as *peer-to-peer*. For example, *is connected to*, which is the same in either direction.

You can do the following relationship functions by using the CMDB Relationships tab:

- View Active or Inactive relationships by searching on the Active? field.
- From the CI Relationship List, click any link for a relationship to launch its CI Relationship Detail page.

Create a Relationship Type

You can create a relationship type, and can make it available to create or update relationships.

Follow these steps:

1. On the Administration tab, expand the CMDB folder from the left pane, click CI Relationship Types.
   The CI Relationship Type List appears in the right pane.
2. Click Create New.
   The Create New CI Relationship Type page appears.
3. Complete the following fields:
   - **Provider to Dependent Label**
     Describes the relationship from the provider to the dependent. This is the name that appears in the list of relationship types. For example, "services" or "manages" is a Provider to Dependent relationship.

- **Dependent to Provider Label**
  Describes the relationship from the dependent to the provider. This is the name that appears in the list of relationship types. For example, "is serviced by" or "is managed by" is a Dependent to Provider relationship.

- **Peer-to-Peer?**
  Specifies that the relationship does not have a provider CI and dependent CI but instead consists of two equal CIs. For example, "connects to" and "fails over" are Peer-to-Peer relationships.

- **Active?**
  Makes the relationship type available for selection in configuration item relationships and lists.

4. Click Save.
   The relationship type is created and you can use it to create or update relationships.

Create a CI Relationship

You can add a CI relationship by starting from a focal configuration item. To launch a CI Relationship Detail page from the list, click any link in a relationship row. The Create New button allows you to create a new relationship from the CI detail.

The Impact Explorer button lets you view related providers and dependents using a search. The default search retrieves immediate providers one level deep. The related CIs are listed with the Relationship type with these additional fields:

- Family
- Contact

Follow these steps:

1. Select Search, Configuration Items on the menu bar of the Scoreboard.
   The Configuration Item Search page appears.

2. (Optional) Complete the filter fields to limit the search to the configuration items of interest and click Search.
   The Configuration Item List page displays the items that match your search criteria.

3. Select the Configuration Item to edit.
   The Configuration Item Detail page appears.

4. Select the CMDB Relationships tab.
   The tab lists any existing relationships for this CI.

5. Click Create New.
   The Create New Relationship page appears.

6. Enter the required data for this relationship:

- **Tenant (if multi-tenancy is installed)**
  The tenant level for this relationship.

- **Provider/Peer CI**
  The configuration item that provides the relationship. Enter the configuration item name directly into this field. To select the configuration item from a list, click the search icon.

- **Relationship Type**
  Use the Relationship Type Search and List to select relationship type.

- **Dependent/Peer CI**
  The dependent configuration item in this relationship. Enter the configuration item name directly into this field. To select the configuration item from a list, click the search icon. This field is required.

- **Symbol**
  (Optional) The unique identifier for this relationship. Assign a symbol that makes the relationship easily recognizable from the list.

- **Description**
  (Optional) A detailed description of the relationship. You can also use this field to describe the repositories that are assigned in the relationship.

- **Source Repository**
  (Optional) A detailed description of the relationship. You can also use this field to describe the repositories that are assigned in the relationship.

- **Cost**
  (Optional) The dollar value of the relationship between the configuration items.

7. Click Save.
   The CI relationship is saved and the CMDB Relationships tab displays the new relationship.

Manage a CI Relationship

The Configuration Item Relationship page provides all necessary settings in one location to simplify the CI relationship process.

You can use the page to do the following functions:

- Toggle the provider/dependent relationship between two CIs.
  Click Reverse to switch the Provider CI and Dependent CI for the relationship. The focal CI changes. If the reversed relationship is not valid, clicking Reverse clears the Relationship field.

- Set the Optional fields such as Symbol, Description, and Cost.
  Click Optional to set optional fields.
  If a Symbol is not supplied, a unique Symbol is automatically generated with prefix **cmdb bmhier:** and a unique number when the relationship is created.

Note: If your installation is integrated with CA Network and Systems Management (CA NSM), you must specify the CA NSM repository and cost.

Inactivate a CI Relationship

There are two ways to inactive a relationship. Consider a process depending on your organization needs.

Process 1: By setting the CI relationship status to Inactive.

Follow these steps:

1. Navigate to the CI Detail page, click the CMDB Relationships tab, and click Edit.
   The CMDB Relationships tab displays in Edit mode.

2. Choose a relationship and click any link on its row.
   The CI Relationship Detail page displays.

3. Click Edit.

4. Set the Active? attribute to Inactive. Click Save.
   The relationship is made Inactive. On the CI Relationship Detail page, the “Active?” attribute displays the Inactive attribute value.

Process 2: Using GRLoader to submit XML

Follow these steps:

1. Write XML that uses a Relation tag to identify the following parameters:
   - Provider CI
   - Dependent CI
   - Relationship type

2. Set the delete_flag to true (or yes or 1).

3. Submit the XML.
   The CI Relationship is deleted.

For more information about GRLoader, see the General Resource Loader (see page 4289) topic.

Example: Delete a CI Relationship Using GRLoader

In the following XML example, the "connects to" relationship between ci_1 and ci_2 is deleted.

```
<GRLoader>
    <relation>
        <dependent>
            <name>ci_2</name>
```

```
        </dependent>
    <type>connects to</type>
        <provider>
            <name>ci_1</name>
        </provider>
    <delete_flag>true</delete_flag>
    </relation>
</GRLoader>
```

Reactivate a CI Relationship

There are two ways to reactivate a CI relationship. Consider a process depending on your organization needs.

Process 1: Reactivate a deleted CI relationship

Follow these steps:

1. Navigate to the CI Detail page.
   The CI Detail page displays in Read-Only mode.

2. Click Edit.
   The CI Detail page displays in Edit mode.

3. Click the CMDB Relationships tab.

4. To open a CI Relationship Detail page, click any link on a row.

5. Click Edit.
   The Update CI Relationship page appears.

6. Change the Active? attribute to “Active”. Click Save.
   The relationship is reactivated.

Process 2: Reactivate using GRLoader to submit XML

Follow these steps:

1. Write XML that uses a relation tag to identify the following parameters:

   - Relationship type
   - Dependent CI
   - Provider CI

2. Set the delete_flag to false (or no or 0).

3. Submit the XML.
   The CI Relationship is reactivated.

For more information about GRLoader, see the General Resource Loader (see page 4289) topic.

Example: Reactivate a CI Relationship

In the following XML example, the "connects to" relationship between ci_1 and ci_2 is reactivated.

```
<GRLoader>
        <relation>
                <dependent>
                        <name>ci_2</name>
                </dependent>
        <type>connects to</type>
                <provider>
                        <name>ci_1</name>
                </provider>
        <delete_flag>false</delete_flag>
        </relation>
</GRLoader>
```

CI Relationship History and Comparison

The Versioning tab displays CI relationships and lets you do the following actions:

- View the relationship history for any CI in the CMDB. Changes that are made to a relationship are logged automatically when the relationship is created, updated, or deleted. You can view all current and historical relationships for a CI.

  Note: Relationships that are created with previous versions of CMDB do not have audit history information.

- Compare the relationships at any snapshot or milestone.

Versioning

This article contains the following topics:

Versioning promotes control over the IT infrastructure. Use versions for tracking and managing the life cycles of the CIs that constitute the authorized state of the CMDB. Versioning also applies to auditing the history of an object. Versioning provides the following functions to control the IT infrastructure:

- **Snapshots**
  Recorded automatically for changes to the value of any update to an object, such as when you update a CI. Versioning creates a snapshot with the complete state of the hardware CI after the

memory size of a computer is modified. Versioning can display the snapshot and can indicate which CI attributes have changed. Versioning can also compare it against all other historical snapshots of that CI. You require this critical information to understand the impact of changes on the availability and performance of a CI.

- **Milestones**
  Recorded as special-purpose snapshots with a user-defined label, such as First Day of Production or January Baseline. These labels can help find specific snapshots more quickly.

  Note: Milestones do *not* apply to change specifications, verification policies, managed change states, and managed attributes.

- **Comparisons**
  Compare a CI to another CI that acts as a standard. You can use any CI as a standard for comparison, but we recommend that you dedicate specific CIs as *Standard CIs*. A Standard CI lets you define a standard configuration to which other operational CIs in the same family can be compared. For example, define Server Large as a Standard CI to define the attribute values of this type of server. The Standard CI for a family can be made an attribute of an operational CI in that family. This relationship enables you to compare the current state or any historical state of a CI to its associated standard configuration. Like other comparisons, you can print this information or can export it as a comma-delimited file. Milestones can act as unshared, unchangeable baselines, but Standard CIs provide shared, dynamic baselines for your CIs.

  Important! A Standard CI must never contain values for any attribute that is used for CI reconciliation.

- **Change Specifications**
  View pending scheduled or unscheduled change specifications that a user specified for Change Orders for the CI. You can compare the change specification with the current state of the CI. For example, compare a planned value to the current state of a CI. This comparison can show conflicts with changes, identify overlapping changes in the schedule, and so on.

Versioning helps you complete the following tasks:

- Automatic capture of all CI modifications
- Snapshots of a CI at any time that are based on date or attribute changes
- Various levels of display including detailed Log, Basic, and Advanced views
- Multiple attribute comparisons with other snapshots, user-defined milestones for CIs, or a Standard CI
- Automatic snapshots whenever CA SDM change tickets change states

  Note: The automatic snapshot does not apply to change specifications, verification policies, managed change states, and managed attributes.

- Advanced filtering and comparison with Print and CSV Export support

Uses of Versioning

Versioning includes the following uses:

- **Problem Determination**
  To correct a problem with a CI, identify what changed in the environment of the CI. Versioning shows its current defective state, and its state at any point in the past. To identify potential problems, compare the two states.

- **Performance and Capacity Planning**
  By reviewing the history of a CI, a performance or capacity planner can determine the causes of performance issues. The history also helps in planning for future system growth.

- **Compliance**
  You can compare the state of a CI to its family Standard CI. To verify CI compliance and to identify attributes that need corrections, compare the state at any point in its change management lifecycle.

- **Change Verification**
  You can view the audit history of the object. For example, see who modified a verification policy, the date of the request, and the attributes and values that were modified. You can compare and contrast the changes between specific dates.

CI Versioning and Future State

View change Specifications in the CI Detail form Versioning tab. Provide more information, identify Change Order and corresponding change specifications. This tab also shows the future state of the CI as if the changes were applied. View snapshots of the CI, as of the scheduled date of the Change Order. If the Change Order has not been scheduled yet, it shows as an unscheduled change.

Versioning enables the following functionality:

- Quickly identify overlapping or conflicting change specification.

- Launch directly to change specification and view the corresponding change details by clicking Change Order in the detail view.

- Snapshots showing an *Unscheduled Change* indicated a change that is scheduled for some unspecified time in the future.

- The Change Order number is displayed with each change specification shown on the right side of snapshot label.

- Informational text displays in the bottom pane providing the following information about the change specification as hover text:

  - Change Order number.

  - Date of the scheduled change, if the Change Order specifies a scheduled date.

- Date need by, only shown if Change Order specifies a need by date.

Shared Asset and CI Audit Trail Records

The Versioning feature includes audit trail changes made to CA APM. Versioning also supports launch in context from CMDB to CA APM directly. The launch can be from an attribute log entry that is associated with each CA APM change. The CA APM audit trail is only available for CI/Assets from the CMDB families with CA APM audit logging enabled.

The Versioning tab that includes the CA APM audit trail information supports all families for which logging is enabled.

By default, CA APM does not log Asset attribute changes. To use CMDB Versioning with a CA APM-managed Asset/CI, enable Store Audit Trail Data on each asset attribute that requires logging. For more information about how to enable auditing, see the CA APM documentation.

When asset attributes are modified in CA APM, the Versioning tab data on the CI Detail page can be updated before the Attributes tab data due to caching activity. To resynchronize the values, click Edit.

Sources of Versioning Data

Versioning data generates whenever you create or modify an object by any component that supports the Audit Log facility. Snapshots that are generated from multiple sources are indistinguishable from one another. In a properly configure environment, snapshots appear automatically whenever CIs and their relationships are changed.

All CMDB families are enabled for versioning. CIs in CA Service Desk base families must be converted to CMDB families to take advantage of versioning.

Versioning data includes the following sources:

- **CMDB CI updates** -- Updates to common CI attributes and family-specific CI attributes by using the user interface.

  Note: For more information, see *CMDB Technical Reference (see page 4168)*.

- **CMDB relationship updates** -- Updates to relationships on the Relationships tab and the CI Relationship List by using the Edit and Edit In List feature.

- **GRLoader** -- CI insert and attribute updates, relationship updates, Standard CI assignments, and Milestones imported by using GRLoader. When the updates from an MDR are sent using GRLoader, the MDR source is also recorded. Recording the source helps you track attribute changes directly to their source.

- **CA SDM Change History** -- A snapshot is automatically created for all CIs associated with a change ticket. Up to four snapshots are taken when the CI is opened, closed, active, or resolved.

- **CA Asset Portfolio Management (CA APM) CI changes** -- Changes that CA APM makes to CIs that have logging enabled.

- **Change Verification** -- Updates to change specifications, verification policies, managed change states, and managed attributes.

Note: CIs created in CA SDM or previous CMDB releases only contain modification changes. The initial attribute values such as name, family, and class were not logged and do not appear in snapshots. In addition, Relationships created with CA Service Desk or previous versions of CMDB do not have audit history information.

CA SDM Change Management Integration

Versioning data is generated for each CI that is associated with a CA SDM change ticket. As the change ticket moves from *open* to *active* to *resolved* to *closed*, a snapshot is taken for each of the associated CIs. Thus, snapshots are created for opened, closed, active, or resolved statuses. If no CIs are associated with a change request, no snapshots are taken.

Note: The versioning feature requires no special configuration and is supported automatically in integrated installations.

The versioning feature handles the change ticket as follows:

1. Compares the state of the CI at the time the ticket was opened with its current state.
2. Verifies that all the required changes have been properly executed and that no additional changes were introduced.
3. Closes the ticket after the changes have been validated.

For auditing purposes, you can readily compare the state of the CI before and after each change was made. The comparison information helps answer questions including the state of a CI before and after a change request, for example:

- Did the appropriate change occur as requested?
- What other changes occurred to the CI not related to the change ticket?
- What time did the changes occur?
- How does this CI compare against the standard configuration, both before and after the change?

CA APM Integration

Versioning displays changes that CA APM makes to its CIs. Versioning also supports launch in context from CMDB to CA APM directly. The launch can be from any attribute log entry that is associated with a CA APM change. CA APM audit information is only available for CIs from CMDB families when CA APM auditing logging is enabled.

Note: When the CI attributes are modified in CA APM, the Versioning tab on the CI Detail page can be updated before the Attributes tab. This is due to caching activity. To resynchronize the values, click Edit.

By default, CA APM does not log CI attribute changes. To use Versioning with a CA APM-managed CI, enable Store Audit Trail Data on each asset attribute that requires logging.

By default, a 10-minute delay exists from the time a CI is updated in CA APM and the time it becomes available to versioning in the CMDB. You can modify this delay by changing the @NX_DBMONITOR_TIMER_MINUTES variable in an integrated installation.

Note: For information about how to enable attribute logging for assets, see the CA APM documentation.

CA SDM provides the following integration capabilities with CA APM:

- Shared records and audit log that differentiate between CA APM CIs and assets
- CMDB and CA APM launch in context to CI/asset information
- Shared extension table fields
- A CA SDM contact updates when CA APM changes a primary contact
- CA APM asset type modification to use CI families

CI Versioning Management

Contents

You can display and manage the history of the CI, associated snapshots, milestones, unscheduled changes, and other views. You use the left pane to navigate and the right pane to display CI details and the audit log.

Note: Versioning works similarly for managed attribute history and managed change state history. For example, the Managed Attribute History tab displays versioning information about a managed attribute.

To identify change specifications and the associated Change Orders, use versioning information. Versioning identifies unscheduled changes in the change specifications in the snapshot view. These changes correspond to Change Orders with no scheduled start date. You can view the snapshot and log of a change specification in CACF.

Example: Unscheduled Change

In this example, a user tries to change the value of a managed attribute. You view the Versioning tab on the CI detail page that displays Unscheduled Change in the snapshot. This snapshot displays information about the change, such as the date, time, username, and attribute value.

Select a snapshot or milestone in the left pane. The right pane displays the attribute values of that CI state, event, or comparison. The left pane displays CI snapshots or milestones by date and time (Basic mode) or by CI characteristics (Advanced mode). The left pane also includes the following links to help you manage a CI:

- **Create Milestone**
  Labels the state of a CI.

- **Show Log**
  Displays unfiltered CI history.

- **Advanced/Basic**
  Toggles between snapshot views.

- **Hide Empty Values**
  Permits filtering of blank data fields. When not selected, all CI attributes appear.

- **Print and Export**
  Print or cut-and-paste to save the versioning data on display.

Configuration Item Log

The log lets you view configuration item history. The Filter option permits filtering of log rows. Print and Export allow you to print or cut-and-paste to save the versioning data on display.

The Versioning information pane displays the following fields:

- Category
- Date
- Log
- Attribute
- New Value
- Old Value
- Changed By
- MDR

Note: The log only displays attribute *updates* for CIs that were created in previous releases of CA SDM or CA CMDB. The log does not display their initial CI attribute values. Relationships that were created in previous releases of CA SDM or CA CMDB do not include audit history information and do not appear in the log.

Log Filtering

The log can be filtered by entering a simple string in the Filter field. The Filter is case insensitive. If the filter string appears anyplace in a log row, the row is displayed. No special characters or wildcards are used in the filter. Log rows matching the filter criteria are displayed hiding rows that do not match.

You do not need to press Enter or refresh to update the display. The log view is filtered as each keystroke is entered and applies to all fields, Date, Log, Attribute, Old value, New Value, MDR, and Name.

CSV Export Support

You can export the CA CMDB log content to a Comma Separated Value (CSV) format file. Third-party reporting tools or applications can import the CSV file. The export is based on what is currently displayed, which can be filtered or unfiltered.

Integrated CA SDM and CA APM Logs

In addition to changes that were made using CA CMDB facilities, the CI log also includes CA SDM change ticket update activities and CA APM updates.

MDR Launch-in-Context and Source Identification

CA CMDB provides a way to launch in context, directly from the log to the MDR data provider for a particular CI log entry. You can also launch in context to the change specification. This launching feature does the following tasks:

- Tracks the attribute changes back to the source MDR, when the MDR used the <mdr_name> <mdr_class> and <federated_asset_id> tags in the GRLoader input.
- Identifies when multiple MDRs update a CI attribute. This situation occurs when multiple MDRs contribute data independently to a CI definition.
- Identifies which MDR is acting as the authoritative source.

Note: Log entries that are created in CA SDM or previous CA CMDB releases do not contain MDR launch in context information. In addition, CA Configuration Automation provides MDR launch information for most but not all attributes or relationships.

Attribute Names

Attribute names that are displayed in the log match the attribute name that is shown in the user interface. The attribute name is not same as the internal object name. For example, CA CMDB displays “Maintenance Type” instead of “mtce_type”.

Logging Custom Families and Attributes

To enable logging for modified families and attributes, specify new MDR attributes and audit triggers. If you create new families or attributes, you also must create metadata files to specify human readable attribute names to display in the log; otherwise, the internal object name appears.

For more information, see the Extending CMDB (see page 2603) topic.

Create a Milestone

You can create a milestone from the user interface or by using GRLoader.

Follow these steps:

1. To create a milestone from the user interface, complete the following steps:
   a. Select a CI and click its Versioning tab.
   b. Click Create Milestone.
   c. Enter descriptive text for the milestone. Click Save.
      The Create Milestone page closes.

d. Select View, Refresh.
The Basic view displays a new snapshot with the current date and time that represents the milestone that you created. Switching to the Milestone view, displays only those snapshots with assigned names. Milestones are displayed in descending date/time sequence, with the most recent at the top.

2. To create a milestone using GRLoader, complete the following steps:

a. Add the <milestone> tag to the XML for that CI.

b. Apply the same reconciliation rules apply as when associating a milestone with a CI.

Note: The value of the milestone tag is the label that is associated with that milestone.

c. Save and close the XML for the CI.
The milestone is created.

Example: Use GRLoader to Create a Milestone

The following GRLoader sample creates the milestone **Fiscal year end 2008**.

```
<ci>
<name>server1 </name>
<milestone>Fiscal year end 2008</milestone>
</ci>
```

Create a Standard CI

You create a Standard CI like you create any other CI. Any CI can act as a Standard CI, but the following cautions apply:

- A Standard CI must follow a naming convention so that it is not confused with regular CIs.
- A Standard CI must only act as a baseline for CIs in the same family as the Standard CI.
- A Standard CI must *not* be assigned values for any attributes that are used in reconciliation. For example, MAC Address, Serial Number, Alt CI ID, DNS, and so on.
- Because standard CIs are indistinguishable from regular CIs, they appear in your Scoreboard and count in the total number of CIs.
- As a best practice, Standard CI must not represent any actual instance of a business object.

Follow these steps:

1. Select Create New Configuration Item from the File menu.

2. Select the family that you want to use for the new Standard CI.

3. Define the attributes, as with any regular CI.
   The Standard CI is created.

Assign a Standard CI to a CI

You can assign a Standard configuration item to a configuration item by using the CI Detail page. You can assign a Standard CI to a list of CIs or using Edit in List.

Follow these steps:

1. To assign a Standard CI to a CI using the CI Detail page, complete the following steps:

   a. Select a CI and click Edit.
      The Update Configuration Item page appears.

   b. Click the icon next to the Standard CI field.
      The CI List displays.

   c. Select a CI to serve as the Standard CI. Click Save.
      The Standard CI is assigned.

2. To assign a Standard CI to a list of CIs, using edit in list, complete the following steps:

   a. From the Scoreboard or Administration tab, specify the search filter and click Search.

   b. Click the Edit In List button at the top right of the list results.
      The CI Edit in List controls is displayed.

   c. Select a row containing CI to assign the Standard CI too.
      The row is shown in highlighted color.

   d. Click the icon next to the Standard CI field.
      The CI List displays.

   e. Select a CI to serve as the Standard CI. Click Save to update the single CI or Change All to update all CIs in the list.
      The Standard CI is assigned to the single CI (Save) or all CIs listed (Change All)

Note: Any CI can act as a Standard CI, but the following cautions apply:

- A Standard CI must follow a naming convention so that it is not confused with regular CIs.
- A Standard CI must only act as a baseline for CIs in the same family as the Standard CI.
- A Standard CI must *not* be assigned values for any attributes that are used in reconciliation. For example, MAC Address, Serial Number, Alt CI ID, DNS, and so on.
- Because standard CIs are indistinguishable from regular CIs, they appear in your Scoreboard and count in the total number of CIs.
- As a best practice, Standard CI must not represent any actual instance of a business object.

Assign a Standard CI to a CI Using GRLoader

To assign a Standard CI to a CI, include the <standard_ci> tag in the description of a CI.

Example: Assign a Standard CI to a CI

If you have a standard workstation configuration that is stored in a CI named **standard workstation configuration.** You can assign the Standard CI to Joe's Workstation by using GRLoader to load the following XML:

```
<ci>
        <name>Joe's Workstation</name>
        <class>Server</class>
        <standard_ci>standard workstation configuration</standard_ci>
</ci>
```

Use the Basic View

You can select snapshots in either Basic or Advanced view. The same kinds of versioning data can be displayed in either mode. The Basic view lets you easily view the state of a CI.

Follow these steps:

1. Open the CI in the user interface and click the Versioning tab.
   The existing snapshots are listed on the left side of the page.

2. Select a snapshot type from the Snapshot type drop-down list:

   Note: If you select a Standard CI for the focal CI, it displays at the top of the snapshot or milestone list. If you click a Standard CI, the attributes for the Standard CI appear and not the focal CI.

   - **Snapshot**
     Lists all CI snapshots identified based on date/time and the Standard CI. The Snapshot view is the default option.

   - **Milestone**
     Lists all user-defined Milestones and the Standard CI.

Note: You can select two or more snapshots, milestones, or Standard CIs to compare them.

Use the Advanced View

You can select snapshots in either Basic or Advanced view. The same versioning data can be displayed in either mode. The Advanced view lets you view snapshots that are based on the attribute type, value, and time stamp. The Advanced view also lets you compare any with attributes, milestones, or a Standard CI with each other. A tree hierarchy shows a folder for each attribute of the CI, and each attribute folder contains a history of the values of the attribute. The hierarchy is organized as follows:

```
Root
     Attribute name
          Attribute value1
          Attribute value2
```

This hierarchy lets you view history of unique values for any particular attribute at a glance.

Follow these steps:

1. Open the CI in the user interface and click the Versioning tab.
   The existing snapshots are listed on the left side of the page.

2. Click Advanced.
   Advanced Selection shows a folder hierarchy.

3. Navigate the folder hierarchy, and click the folder that includes the information you want to view:

   - **Date**
     Lists Snapshots that are based on date/time, which is identical to the Basic view. If there are 30 or more snapshots for the CI, the snapshots can be divided further based on year /month. If a Standard CI is assigned to the focal CI, it is also listed in this folder.

   - **Milestone**
     This folder lists all user-defined Milestones. This view is identical to the Basic view. If a standard CI is assigned to the focal CI, it also appears in this folder.
     Standard CI attributes are displayed as special tree leaf nodes with a "Standard CI".
     Standard CI values only appear for attributes for which there is a standard CI value. If the value for an attribute is not set, it does not appear.

   - **Relationship**
     Contains all the relationships (past and present) for the CI. The folder hierarchy conveys the following information:

     ```
     Relationship

          Relationship Type

               Partner CI

                    Status and Date
     ```

Relationship Type specifies the kind of relationship, such as “is contained by”, “hosts” or “communicates with”.
Partner CI is name of the CI associated with the relationship.
Status and Date specify the Status of the relationship at the specified Date and Time.
Status values include the following ones:

- Relationship Created -- The state of the CI when the Relationship was created.
- Relationship Terminated -- This CI is no longer involved in the relationship. The relationship still exists at the partner end of the relationship, but the focal CI is not involved.
- Relationship Deleted -- The relationship was marked as deleted.
- Relationship Changed -- The relationship was reactivated from deleted state.
- New Partner and Type -- The partner end of the relationship was assigned to a new CI, and the relationship type was changed simultaneously.
- New Relationship Type -- The relationship type between two CIs has changed.
- Partner CI Assigned -- The partner end of the relationship has changed.

4. Click an attribute value.
   The complete state of the CI at the time that the attribute value was set displays.

Example: Use Advanced View to Show Disk Space Attributes

In the following example, Advanced Selection shows that disk space increased from 10 to 20 to 100 GB.

```
Root
      Disk space
            10 GB
            20 GB
            100 GB
```

Click any value to see the following information:

- When the change occurred
- The state of the other attributes when the change occurred
- The change request number that was open when the disk space was changed

View Snapshot Details

You can view snapshot details in the Basic or Advanced view. For example, the basic view displays a snapshot of an unscheduled change to a CI.

Follow these steps:

1. Open the object in the user interface and click the Versioning tab.
   A list of existing snapshots appears on the left side of the page.

2. Click a snapshot.
   Details are displayed in the right pane of the Basic and Advanced views. When you select only a single item, the right pane shows information about the selected snapshot, milestone (only for CIs), or standard.
   The displayed data includes the following details and indicators:

   - **Hide Empty Values**
     Permits filtering of blank data fields. When unchecked, all CI attributes are displayed.

   - **Bolded Value field text**
     Indicates that an attribute or relationship has changed since the last snapshot was taken. When viewing details for a Standard CI, all values are bold.
     Value
     Shows the previous value of the attribute and the time of the last change.

   - **"(blank)" Value**
     Indicates whether a previous value was cleared.

   - **Relationship Category**
     Shows information about the relationship, including the type and partner CI information.

   - **MDR Launch in Context and Source Identification**
     Provides launch-in-context to a provider MDR from the CI detail entry.

     Note: CIs created in CA SDM or previous versions of CA CMDB can lack MDR and Changed-By information. In addition, CA Cohesion ACM provides MDR launch-in-context for most but not all attributes or relationships.

     Tracks the attribute changes back to the source MDR.
     Detects when multiple MDRs update a CI attribute. This situation occurs when multiple MDRs contribute data independently to a CI definition.
     Identifies which MDR acts as the authoritative source.

Launch the MDR That Set an Attribute

If the history for a CI references an MDR, you can launch an MDR to view CI details.

Follow these steps:

1. Select a CI and navigate to its CI Detail page.

2. Click the Versioning tab.

3. Click Show Log, or select the CI snapshot or milestone you want to view.

4. Select the attribute row that you want to investigate.

5. If the CI history references an MDR, click the MDR link.
   The provider MDR shows more CI details.

Export Data

The Versioning Export to CSV page lets you export the snapshot and log information in a Comma Separated Value (CSV) format. Data displays in an Export page. The formatted data corresponds to the view you obtained. The filtering and data comparison you select on the Versioning tab is what is formatted for export.

Follow these steps:

1. Select an object and click the Versioning tab.
   Click the view that you want of the CI.
   For example, click Show Log, a snapshot comparison, milestone (CIs only).

2. Click Export.
   The Export Log to CSV for CI page appears.

3. Use the Select All action (from either context menu or keyboard shortcut).

4. Use cut and paste to transfer the data from the formatted page to a CSV file or third-party application. For example, you can Export to an Excel spreadsheet.
   The data is exported.

CI Family Changes and Snapshots

Family changes can affect a snapshot of a CI.

A snapshot includes the following different kinds of attributes:

- Common attributes
- Family-specific attributes

When you change the family of a CI, the following snapshot changes occur:

- The Family-specific attributes that are associated with the CI change.
- The Snapshot details reflect the family at the time of the snapshot.

The family of a CI determines the attributes of the CI. If you first change a *family-specific* attribute and then the family of the CI, the resulting CI no longer possesses the *family-specific* attribute you changed. Changing the family of a CI has no impact on its *common* attributes.

Example: Change the Family Associated with a CI

This example shows how CI family changes affect a snapshot of a CI.

Time	Status/Changes

0	The CI is in Family1.
1	One Family1-specific attribute value is changed.
2	Several common attribute values are changed.
3	The family of the CI is changed from Family1 to Family2. When this occurs, all Family1-specific attributes become unavailable to this CI.
4	One Family2-specific attribute value is changed.
5	Several common attributes are changed.
6	The CI family is changed back to Family1. When this occurs, all Family2-specific attribute values become unavailable to this CI, but previous Family1-specific attribute values are restored.
7	Several common attributes are changed.
8	One Family1-specific attribute is changed.

In the example, a snapshot at Time=7 does not contain information from the changes that are made at Times 3 or 4. Those changes represent changes that are made to Family2-specific attributes.

Compare Snapshots (Basic View)

You can compare two or more snapshots, milestones, or Standard CIs.

Follow these steps:

1. Select a CI and navigate to its CI Detail page.
2. Click the Versioning tab.
3. Select a Milestone or Snapshot from the Snapshot type drop-down list.
   Milestones or snapshots are listed.
4. Select two or more snapshots, milestones, or Standard CIs.
   The comparison view displays the following results:
   - A column is displays how the snapshots or milestones differ.
   - Each row displays the attribute values for the selected snapshots.
   - Only the attributes with differences are displayed. Date is always displayed unless snapshots are identical.
   - Standard CI comparisons are not time-specific, so their Date fields are set to say **Standard CI**.
   - Comparison results can be printed or exported to a CSV file.

Compare Snapshots (Advanced View)

You can compare two or more snapshots, milestones, or Standard CIs.

Follow these steps:

1. Select a CI and navigate to its CI Detail page.

2. Click the Versioning tab, and click Advanced.
   Advanced Selection displays the CI.

3. Navigate the folder hierarchy to the value you want to use for the snapshot comparison.

4. Select a value for each snapshot comparison.
   The comparison for the CI displays; for example, snapshot comparison that is based on the folder values selected.
   The comparison view displays the following results:

   - A column is displays how the snapshots or milestones differ.
   - Each row displays the attribute values for the selected snapshots.
   - Only the attributes with differences are displayed. Date is always displayed unless snapshots are identical.
   - Standard CI comparisons are not time-specific, so their Date fields are set to say **Standard CI**.
   - The comparison results can be printed or exported to a CSV file.

Note: In Advanced view, two CIs can have a relationship with no relationship type assigned (for example, CIs created by CA NSM). Such relationship nodes are identified as (blank).

CA SDM Change Management

Versioning data is automatically generated for each CI that is associated with a CA Service Desk change ticket. As the change ticket moves from *open* to *active,* and from *resolved* to *closed*, a snapshot is taken for each of the associated CIs. Versioning lets you do the following tasks:

- Compare the state of the CI to its Standard CI at any point in a change management lifecycle.
- Help ensure that the CI is in compliance and help identify those attributes which need remediation.
- Perform comparisons between states of the CI at any point in lifecycle of the change order, and any date or time in-between.
- View progress at each stage of the change, including any milestones.

The integration between CA Service Desk and CA CMDB is illustrated by demonstrating how you can audit changes that are performed during the service management lifecycle of a CI. In this example, a change request is used to upgrade components of a hardware server.

Follow these steps:

1. To create a change order and associate it with a CI, complete the following steps:

a. Create a CA Service Desk change ticket by clicking File, New Change Order.

b. Enter the change request information and order summary, for example: Upgrade hard drive to 500 GB.

c. Click the Configuration Items tab, and then click Update CIs.

d. Specify CI search criteria (for example, the name of the hardware server) and click Search.
In the Affected Configuration Items Update form select the CIs associated with the change ticket (for example, the hardware server from Step 4). Add them to the Affected Configuration Items list and click OK.

e. Save the change request.

2. To perform the changes, complete the following steps:

a. Make the changes for the CI. For example, install the hard drive on the physical computer, and then update the Disk Capacity attribute for the hardware server CI.

b. Close the change request.

c. Ensure that the change was completed: View the CI, click the Versioning tab, and compare snapshots of the CI before and after the change.
Suppose that you compare the state of the CI between the times when the change order was opened and closed. You notice that the hardware server drive size was 100 GB before the change and 500 GB after the change was completed. You also see the date and times that the changes occurred. Any other attributes that were modified between the open and close times also display.

CA CMDB Versioning Terminology

This article contains the following topics:

Versioning is the practice of representing and tracking *service transitions*. Versioning typically uses a naming convention to identify the dates, sequences, and meanings of such transitions. These records can be used to identify and compare specific states of a configuration item (CI).

Example: Version Comparison

For a Payroll Application CI, a comparison of Version 3 against Version 2 indicates the enhanced features and other differences.

States

In the context of versioning, the *state* of a CI represents all the attribute values of that CI at a single point in time. The state of a CI can be the result of attribute changes from multiple MDRs.

Versions

A *version* is an identified instance of an object such as a CI within a product breakdown or configuration structure. Use versions for purposes of tracking and auditing change history.

Snapshots

A *snapshot* is a representation of the complete state of an object at a single point in time. For example, a typical CI has many snapshots that are associated with it. A snapshot consolidates all modification events that occur to an object during a one-minute time interval. For example, if you update a CI (edited and saved) several times within one minute, CA SDM creates a single snapshot and includes all the updates during that minute.

Snapshot is a general term that refers to time and date-based snapshots, and milestones or Standard CIs. To help you to locate meaningful points in time, CA SDM lets you label snapshots meaningfully. These named snapshots are named milestones.

Every time an object is changed, CA SDM creates a snapshot automatically. Versioning captures all changes to the object. For example, snapshots originating at an MDR and came to the CMDB through GRLoader or CMDB Web Services.

Categories

A *category* identifies a class of attributes. The category is typically the name of the tab that displays the attributes.

Note: Items such as name, serial number, active flag are assigned to a category that is not a tab name.

Examples: Tabs and Categories

The following examples show how categories correspond to tabs:

- Because the *disk space* appears on the Attributes tab, its category is *Attributes*.
- Because *IP address* appears on the Inventory tab, its category is *Inventory*.
- *Milestone* appears in the *General* category.
- A *Standard CI* appears in the Classification category.
- *Relationships* appear in the Relationship category.

Milestones

A *milestone* is an on-demand labeled snapshot of a CI. It is created to mark an event, a logical breakpoint, or an accumulation of changes. The milestone contains the actual state of the CI at the time that the snapshot was created. Milestones let you quickly identify and navigate to significant points in the history of a CI. Creating a milestone, creates an equivalent “date” snapshot.

Milestones are CI-specific, not shared. The subcomponents of a milestone for a high-level object such as a service do not automatically create milestones. To take a milestone for an object which is composed of several subcomponents, you can generate several independent milestones.

Milestones are static and can never be changed or be deleted. When you create a milestone, the snapshot is of the current state of the CI. Later, when displayed or used in a comparison, milestones always reference a point in the past. A good naming convention for your milestones helps you easily identify critical points in the life of a CI.

Important! Milestones do *not* apply to change specifications, verification policies, managed change states, and managed attributes.

Standard CIs

A *Standard CI* is an abstracted configuration for a CI family. It can be used for baseline comparisons to "real" CI instances in the same family. A Standard CI can be a real CI in the sense that it represents a physical object or it can exist only for comparison. Standard CIs can have the following associations:

- A Standard CI can be shared among several CIs.
- A CI can only have a single Standard CI associated with it at any given time. When the Standard CI is changed, the change is shown in any comparison between the associated CIs and the Standard CI.
- A family can have multiple Standard CIs. For example, one family might have standard CIs named “Standard Test Server,” “Standard Production Server,” “Standard Acceptance Server.” We recommend that you name Standard CIs in such a way that they can be easily searched for and identified.

Because a Standard CI is itself a CI, it can be managed. It has an audit trail, security, a history of changes, and so on, like any other CI. After you define a Standard CI for a particular CI, you can use it to verify compliance with corporate standards.

The concept of “date” or “time” does not apply when comparing a Standard CI with a snapshot or milestone. Only the Standard CI attribute values are used for comparison, snapshots and milestones specific to the Standard CI do not apply.

Example: Standard CI Use

A company defines an **Employee Workstation** configuration as a Standard CI to compare with its actual desktop computers in the Hardware.Workstation family. A comparison reveals that a specific computer has only 1 GB of RAM, instead of the Standard CI memory value of 2 GB.

Stage CI Transactions Before Loading into CMDB

CMDB provides a facility where you can store data before you load it into the CMDB. This "staged" data is stored as transactions in the transaction work area (TWA). A staged transaction is a unit of work that creates or updates a CI or Relationship. The TWA can contain many transactions for a given CI or relationship.

You can capture data being loaded into the CMDB before that data is committed so that you can:

- Clean up and standardize nonstandard data.
- Supplement incomplete data. For example, CI names starting with "NY" can have their location set to "New York".
- Modify data that does not match existing lookup tables (SRELs).
- Schedule transactions for implementing later.
- Reconcile transactions to existing CIs in the CMDB before you load the data.
- Validate the CI and relationship transactions. Validating prevents the creation of invalid data or creation of new CIs when a single or existing CI can be updated. View each transaction and the potential CIs that it can update. This helps you reconcile the transaction manually to the target CI.

You can use the TWA to help you proactively manage the reconciliation process. You can configure GRLoader to load the data into the TWA. When the data is loaded, CMDB lets you modify it to handle transactions that can potentially update or reference the wrong CI.

For more information, see Review and Modify Inbound Data Using Transaction Work Area (TWA) (see page 2566).

How To Load Transactions into the CMDB

This article contains the following topics:

Instead of creating CIs and relationships through XML, specify the following options to select the TWA as its input source:

- lftwa (load from TWA)

- lftwai (load from TWA and inactivate)

Note: Unlike other GRLoader modes that use an err.xml file, loading from the TWA returns error messages to the transaction Message field.

As the transactions are processed, GRLoader sets the transaction status to indicate success or failure of each TWA transaction. If GRLoader -lftwa is run multiple times continuously, set the status of the transaction to Ready between runs of GRLoader. GRLoader does not attempt to load data that is already loaded.

The transaction is executed from the TWA as if GRLoader were running using XML input. Transaction security is based on the user that loads from the TWA, not the user that loaded the TWA transaction originally.

Auditing occurs when the transactions are processed successfully.

Note: Before you load the transactions, you can predetermine whether a set of transactions will create new CIs or relationships. Use the simulation options (-simci and -simrel). See How to Simulate TWA Operations (see page 2525) for more information.

How To Prevent Data Regression

While transaction data for a CI is in the TWA, some other action can update that CI in the CMDB. The update can then cause the TWA transaction data to become invalid. To prevent unwanted data regression, GRLoader compares the TWA tran_dt (Transaction Date) field with the CI last_update_dt (Last Modified Date) or relationship last_mod_dt (Last Modified Date). If the last_update_dt is more recent, GRLoader rejects the TWA transaction and posts an error message to the tran_message column.

You can resolve this situation by completing one of the following actions:

- Use the web interface to edit the CI or relationship tran_dt (Transaction Date) field to a more appropriate value.
- Set the GRLoader option grloader.workarea.ignore_transaction_dates="yes" to ignore the transaction dates and insert the data.

Note: If GRLoader rejects a transaction as older than the target CI, you must verify that the transaction is running. Se t the transaction date to a current or recent date and rerun GRLoader.

The ignore transaction dates option can cause data back-leveling or regression. When a single CI or relationship is updated multiple times in the same GRLoader -lftwa run, the last_update date is set to the current time during the first update. To allow for multiple updates to the same CI or relationship, another verification is made to see if the CI or relationship was updated after GRLoader started. If it was, then the update is allowed. If it was, then the update is allowed.

Filter By Change Order Number

The GRLoader -chg option can be used to select only transactions that are associated with a change ticket. To filter by change number, set the Change Order attribute (tran_chg_ref_num) to the appropriate change request number.

Note: The Change Order string is not validated when loaded into the CMDB.

Example: Filter By Change Ticket

The following option loads only transactions that are related to Change Order 23434.

```
grloader -lftwa -chg 23434
```

How to Use the Web Interface to Update Data in the TWA

Content

You can stage CI and relationship transactions before execution, by copying data into TWA staging area. Once in the staging area, you can manipulate CIs and relationships by using the web interfaces.

You also can validate the CI and relationship transactions. Validating prevents the creation of invalid data or creation of new CIs when a single or existing CIs must be updated. In this approach, you view each transaction and the potential CIs that it can update. It helps you reconcile the transaction manually to the target CI.

To manage the transaction work area, select the Administration tab and navigate to the CA CMDB, Transaction Work Area node. From this node, you can manage the Transaction Work Area pages.

Manage CI Transactions

The CI Transaction Detail page displays all nonblank attributes in the transaction. If you clear the Hide Empty Values check box, all CI attributes are displayed. For more attribute information, point to the attribute name.

You can do the following actions:

- View a transaction
- Create a transaction
- Edit the transaction
- Save or Cancel transaction changes (Edit mode)
- Reset the original transaction data (Edit mode)
- Show or hide data (Attributes tab)

- Set the target CI (Reconciliation tab)

The TWA accepts free-form text as case sensitive by default unless you enable case insensitivity. Use the -I GRLoader option to enable case insensitivity. Attribute values are not validated until load-from-TWA run time, so values must be entered exactly as required. If you enter string values for nonstring MDB fields, GRLoader issues warnings when loading to the CMDB. You can also simulate loading the data to predetermine (-simci) whether a set of transactions can create new CIs or report errors in the data.

Restrictions:

- If tgt_id is defined for a transaction, it displays as a CI name in the Target CI field.
- If superseded_by is defined for a transaction, it displays as a CI name in the Superseded By field.
- TWA entries are not logged.

Important! Data that you enter using this web interface must have the same format as native SQL or XML. For example, when you enter data for a lookup field, refer to the section on XML Input. When you want to specify an owner to look up by userid, use braces { } to specify the lookup field. For example, to find the name that is associated with the userid "admin", enter admin{userid} in the owner column.

After you save a single transaction, click the Reconciliation tab for that transaction. Verify whether any ambiguity exists in its intended target CI. If there is any ambiguity, you can specify a target CI (see page 2562). When all data entry is complete, you can simulate loading the data (see page 2525) to validate the data and verify reconciliation.

Important! Data that you enter into the TWA using this interface must follow certain rules. For more information about the rules, see the "How to load data into the TWA Using GRLoader (see page)" section.

The web UI does not validate case-sensitive data in the TWA. Verify that the values you enter exactly match the lookup values. Alternately, when you run GRLoader, you can specify the - I option to enable case insensitive lookups.

Note: Although tgt_id or superseded_by are stored as UUIDs in the transaction, they are displayed as CI names in the web interface.

Manage Ambiguous CI Transactions

Review and modify transactions that have ambiguous CI targets before loading the transaction data. Resolve CI transactions that do not have a target CI, but have identifying attributes for one or more existing CIs. This resolution ensures that the appropriate CI is updated and prevents incorrect or inconsistent data from being created.

After you save a single transaction, click the Reconciliation tab for that transaction. Verify whether any ambiguity exists in its intended target CI. If there is any ambiguity, you can specify a target CI (see page 2562). When all data entry is complete, you can simulate loading the data (see page 2525) to validate the data and verify reconciliation.

For more information about reconciling the data in the TWA, see Review and Modify Inbound Data Using Transaction Work Area (TWA) (see page 2566).

Manual Reconciliation

To reconcile a CI transaction manually, determine the target CI that matches the identifying attributes of the transaction. Set the tgt_id of that transaction to the UUID of the target CI.

When GRLoader processes a transaction with a tgt id, it updates the target CI with the transaction information. GRLoader registers that CI again when its identifying attributes have changed.

You can specify the target CI explicitly in the transaction. You also can use the Reconciliation tab to select a target CI.

For more information, see Review and Modify Inbound Data Using Transaction Work Area (TWA) (see page 2566).

Specify a Target CI for an Ambiguous CI Transaction

You can specify a CI for an ambiguous transaction so that its data is directed to a specific target CI regardless of the values of the identifying attributes specified in the transaction.

Follow these steps:

1. Select a CI transaction from the Ambiguous Transaction List page.
   The Configuration Item Transaction Detail page appears.

2. Click Edit.
   The Update Configuration Item Transaction page appears.

3. On the Reconciliation tab, select a CI from the list to designate the CI as the Target CI for the transaction. Click Set Target and then click Save.
   The selected CI becomes the target CI for the transaction.

Populating the TWA

This article contains the following topics:

Input data can come from a number of sources, including the following sources:

- CA products such as CA Configuration Automation, CA Wily CEM, CA Introscope, and CA Spectrum that import data by using GRLoader
- Any other MDR that imports data by using GRLoader
- Another CMDB
- Microsoft Excel spreadsheets
- Database tables
- An ETL tool that a vendor chooses

See Database Limitations (see page 2534) for more information.

How to Load Data into the TWA Using GRLoader

The following GRLoader options support the uses of the TWA:

- **-lttwa**
  Loads XML data to TWA in initial state.
- **-lttwar**
  Loads XML data to TWA in ready state.
- **-lftwa**
  Loads transactions to the CMDB from TWA.
- **-lftwai**
  Loads transactions to the CMDB from TWA and inactivates successful transactions.

GRLoader input XML documents can be loaded into the CMDB or the TWA without modification.

Loading data into the transaction work area can be accomplished by using GRLoader with the - lttwa (load to TWA) option. In the GRLoader configuration file:

```
grloader.loadtotwa=yes
```

In TWA mode, instead of creating CIs and relationships directly, GRLoader inserts the information into the transaction work area tables. Data that has been loaded into the TWA can be edited, changed, and verified. After the data modification process is complete, individual transactions can be loaded into the CMDB by using - lftwa or -lftwai.

When loading CI data into the CMDB, CIs undergo automatic reconciliation. Successful reconciliation results in data from a single business object updating a single CI in the CMDB. When loading *CI transactions* into the TWA, no automatic reconciliation occurs. Multiple transactions with identifying attributes targeting a single CI can appear in the TWA. The existing rows in the TWA are not updated when new rows are added in load to TWA mode, despite an identical match to an existing CI. Even identical CI definitions can appear many times in the TWA.

GRLoader validates data values when running in load from TWA mode (-lftwa or -lftwai) to create objects in the CMDB. Or, when running using the simulation mode (-simci or - simrel). See How to Simulate TWA Operations (see page 2525) for more details. The data values are not validated when GRLoader is run in load to TWA (-lttwa or -lttwar) mode.

The -lttwai parameter (or configuration option grloader.loadtotwa.inactivate) inactivates successfully loaded TWA transactions. After a successfully loaded transaction has been marked inactive, it can be permanently purged from the TWA by using Archive/Purge.

Example: Load to CMDB

The following command loads data directly into the CMDB:

```
grloader ... -i mydata.xml  - a  - n
```

The XML file mydata.xml contains:

```
<GRLoader>
  <ci>
     <name>server1</name>
     <class>Server</name>
   </ci>
</GRLoader>
```

Example: Load to TWA

The following command loads the data into the TWA, so that it can be manipulated before loading into the CMDB:

```
grloader ... -i mydata.xml -lttwa
```

XML Input

GRLoader uses XML input data. When loading to TWA, conflicts may occur when the column names overlap with the standard column names in the database. To prevent the conflict, the following XML columns are mapped:

FROM XML Name	TO Database Column
tenant	tgt_tenant
id	tgt_id

delete_flag	tgt_delete_flag

For relationships, the following mapping applies:

FROM XML Name	TO Database Column
name	provider_name or dependent_name
dns_name	provider_dns_name or dependent_dns_name
delete_flag	tgt_delete_flag

Mappings are reversed when loading from the TWA database tables.

lookup

When you specify data for lookup (SREL) attributes in the TWA, maintain the same format as specified in native XML for GRLoader. Lookup attributes accept only a specific set of values that must be defined in related tables in CA SDM. These attributes also can have more restrictions and exceptions that must be met for the assignment to occur. The specified values are the same whether specified using XML, SQL, or the TWA web interface.

To determine whether an attribute is an SREL, refer to the following *CMDB Technical Reference* sections:

- Families and Classes (SREL attributes are identified)
- Contact and Other Lookup Fields
- Fields Validated Against Data in Existing Tables (SREL)

Example: lookup XML

In the following example, the alternate SREL column is set by specifying the lookup parameter:

```
<ci>
<name>server1</name>
<owner lookup="userid">mckpe99</owner>
</ci>
```

In the TWA, the same thing can be accomplished by suffixing the alternate SREL column to the data value, which is included between delimiters. For more information, see the grloader.workarea. delimiters configuration given later. The equivalent transaction is represented in the transaction work area as:

ID	Name	Owner
100	server1	mckpe99 {userid}

You also can set the delimiter character that is used previously in the GRLoader configuration file:

```
grloader.workarea.delimiters=xy
```

x and y are different characters that typically do not appear in the work area.

Date Format

GRLoader supports the following date format options in XML:

- datefmt=UTC
- datefmt=localtime (the default)

Examples: datefmt XML

```
<ci>
<name>server1</name>
<purchase_date datefmt="UTC"> 1241197235</purchase_date>
</ci>
<ci>
<name>server3</name>
<purchase_date> 2009/05/01</purchase_date>
</ci>
```

The equivalent transaction is represented in the transaction work area as:

ID	Name	purchase_date
101	server1	1241197235
102	server2	2009/05/01

Note: If a date contains a special character such as a slash (/), then the format is assumed to be "localtime". If a date contains no special characters, the date is assumed to be UTC.

EMPTY

GRLoader supports the update_if_null option in the XML, which clears a field in the CMDB. The following example clears the owner field for server1. Without that attribute, the owner field is not affected. When using the TWA, you can use the keyword EMPTY instead.

Example: update_if_null XML

```
<ci>
<name>server1</name>
<owner update_if_null="yes"></owner>
</ci>
```

In the TWA, the database value is cleared by specifying the keyword EMPTY as the string value. The equivalent transaction in the work area is:

ID	Name	Owner
102	server1	EMPTY

The keyword value can be set by using the grloader.emptyvalue configuration option:

```
grloader.emptyvalue=xxxx
```

xxxx represents any string that typically does not appear in the work area data.

How To Simulate TWA Operations

You can predetermine whether a set of transactions can create new CIs or relationships and therefore create new ambiguities for other CIs. Use the following options:

- **- simci**
  Simulates processing CI transactions only. The option can be used to determine whether transactions create or update CIs. When the -simci option is used, GRLoader performs data validation.

- **- simrel**
  Simulates processing relationship transactions only. The option can be used to determine whether relationship transactions create or update relationships. The - simrel option checks relationships for the existence of the provider and dependent CIs, validates relationship types, and so on.

The output from simulation mode is directed to the TWA or to the _err.xml file. In normal load mode, the _err.xml file contains the CI input and a comment indicating whether the CI was inserted or updated. When a simulation is used, the GRLoader message on the CI Transaction List indicates whether the CI or relationship was inserted or updated. The transaction state remains unchanged.

Simulation can also be enabled in a configuration file by using the **grloader.simulateloadci** and **grloader.simulateloadrelation** options.

Note: If the GRLoader input creates CIs and relationships simultaneously, the - simrel option can only process actual CIs. The option cannot process CIs that are scheduled to be created. Because of this limitation, -simci and - simrel are mutually exclusive.

How to Use SQL to Update Data into the TWA

The TWA is stored in the MDB and you can update it directly with SQL queries.

TWA Tables

Transaction Work Area (TWA) tables include:

- **ci_twa_ci**
  A single table that contains all attributes across all CI families. The table stores data in a de-normalized form to enable customers and services to understand and manipulate the content.

- **ci_twa_relation**
  Complements the ci_twa_ci table. This table contains CI relationship information.

TWA column names correspond to the attributes that are used with GRLoader, with some exceptions.

TWA SQL Column Names

Column names in the ci_twa_ci and ci_twa_relation tables match the CI and Relationship attribute names with some exceptions.

TWA fields common to ci_twa_ci and ci_twa_relation

- **apply_after_dt (Apply After Date)**
  GRLoader executes the transaction only if the current date is after the Apply After Date. Measured in number of seconds since the epoch. If the value is zero (0), this field is ignored.

- **tran_chg_ref_num (Change Order)**
  Specifies the change order identifier that is associated with this transaction. The GRLoader - chg option uses this attribute to select only transactions with the specific change order number.

  Note: For more information about using the - chg option option, see Filter By Change Order Number (see page 2518).

- **tran_status (Transaction Status)**
  Specifies the status of the transaction. The tran_status must be one of the following values. Only the transactions with tran_status=1 are executed.

Value	Short Description	Long Description
0	Initial	Default value. Requires intervention to move to "Ready" for GRLoader to act upon this transaction.
1	Ready	The transaction is ready to be loaded into either the appropriate CI or relationship tables.
2	Successful	Transaction that is processed successfully.
3	Warning	Warning that is detected during load into ca_owned_resource/bmhier.
4	Error	Error that is detected during load into ca_owned_resource/bmhier.
40000+	For customer use	

- **tran_message (Message)**
  GRLoader message showing results of the load or simulation.

- **tran_dt (Transaction Date)**
  Prevents accidental overlaying of current information by old transaction data. The transaction date is compared with the last modification date of the CI. GRLoader rejects the transaction if the CI is more recent.
  If GRLoader rejects a transaction as older than the target CI, verify that the transaction is still applicable. Set the transaction date manually to be more current. Run GRLoader again.

- **tgt_delete_flag (Active?)**
  Inactivates the target CI or relationship. Set this value to 1 (one). This setting is not the same as setting delete_flag to 1, which indicates that the transaction must be deleted.

ci_twa_ci columns

In addition to the following column names, you can specify CI attribute names as column names in your SQL statements:

- **tgt_id (Target CI)**
  Specifies the UUID of the target CI. Used when performing manual reconciliation.

- **superseded_by (Superseded By)**
  Specifies the UUID of the superseded CI.

- **tgt_tenant (Tenant)**
  Specifies the tenant name that is assigned to the target CI. Tenant can only be assigned at the time of creating CI if the GRLoader user has proper authorization. This setting applies only when multi-tenancy is enabled.

ci_twa_relation columns

In addition to the following column names, you can specify relationship attribute names as column names in your SQL statements:

When using SQL to define relationship transactions, use the following database column names:

provider_name (Provider Name)

provider_mac_address (Provider MAC Address)

provider_serial_number (Provider Serial Number)

provider_system_name (Provider Host Name)

provider_asset_num (Provider Asset Number)

provider_dns_name (Provider DNS Name)

provider_tenant (Provider Tenant)

AND

dependent_name (Dependent Name)

dependent _mac_address (Dependent MAC Address)

dependent _serial_number (Dependent Serial Number)

dependent _system_name (Dependent Host Name)

dependent _asset_num (Dependent Asset Number)

dependent _dns_name (Dependent DNS Name)

dependent_tenant (Dependent Tenant)

If provider or dependent CI UUIDs are known, you can use the following fields:

provider_id specifies the UUID of the provider CI

dependent_id specifies the UUID of the dependent CI

Note: provider_tenant and dependent_tenant only apply when multi-tenancy is enabled.

Insert New Records in the TWA

You can insert a new record into the ci_twa_ci and ci_twa_relation tables from outside of CA SDM.

To insert records into the ci_twa_ci and ci_twa_relation tables, specify 0 in the ID column as:

```
insert into ci_twa_ci values(id, name) values(0,'test-ci');
insert into ci_twa_relation values(id, type) values(0,'test-relation-type');
```

Caution: If multi-tenancy is enabled, provide the tenant, tgt_tenant, provider_tenant or dependent_tenant attributes as appropriate. If you create a TWA transaction without specifying a tenant, the Public tenant is assumed.

How to Use the ODBC Driver

You can use SQL instead of GRLoader to load the TWA. We recommend that you use the ODBC driver that is provided with CA SDM, instead of native SQL services. Using the ODBC driver provides the following benefits:

- Performance
- Security
- Database independence
- Data integrity when the database updates come from the CA SDM server and the bulk editing tool is running simultaneously

Cautions

- Only the CA SDM ODBC drivers honor security features such as multi-tenancy, data partitioning, and role access. SQL that is executed using the native DBMS drivers does not enforce security.
- Make frequent data backups when performing updates using native SQL.

CI Identifiers in the TWA

In the ci_twa_ci table, three identifiers are associated with a CI transaction: ID, tgt_id, and superseded_by, These attributes are:

- ID is the transaction sequence number. **Do not modify this field.** IDs 1-2,000,000,000 are reserved for use by systems that modify the TWA outside the CA SDM server. IDs from 2,000,000,001 to approximately 4 billion are reserved for use by CA SDM. When the system runs out of IDs, reinitialize the table.
- tgt_id, provider_id, or dependent_id are the UUID of the target CI. Set this field whenever you perform manual reconciliation.
- superseded_by is the UUID of the superseding CI. Set this field whenever you manually designate the superseding CI for the transaction.

How to Set Transaction Status

You can set the transaction status (tran_status) of each transaction in the TWA. For GRLoader to process a transaction, it must be set to Ready (tran_status=1).

Value	Short Description	Long Description
0	Initial	Default value. Requires intervention to move to "Ready" for GRLoader to act upon this transaction.
1	Ready	The transaction is ready to be loaded into either the appropriate CI or relationship tables.
2	Successful	Transaction that is processed successfully.
3	Warning	Warning was detected during load into ca_owned_resource/bmhier.
4	Error	Error was detected during load into ca_owned_resource/bmhier.
40000+	For customer use	

If GRLoader - lftwa is run multiple times, the status is updated after the first run and all subsequent runs do not find any transactions. Reset the status of the ready transactions before every GRLoader - lftwa execution.

For information about how to represent XML data in the TWA tables, see the XML examples in previous sections.

How to Share Tables with CA SDM

SQL Server Only

When using SQL to update the ci_twa_ci and ci_twa_relation tables, set the last_mod_dt column manually, as follows:

```
SET last_mod_dt = DATEDIFF(s,'19700101', GETUTCDATE())
```

Example: Set last_mod_dt

The following example sets the last_mod_dt:

```
UPDATE ci_twa_ci
    SET tran_status=1,
        last_mod_dt = DATEDIFF(s,'19700101', GETUTCDATE())
    WHERE tran_status=1
```

Note: TWA table updates can take several minutes to appear in the web interface or GRLoader. For more information about update timing, see the NX_DBMONITOR_TIMER_MINUTES option.

Transaction Work Area

Use the Transaction Work Area (TWA or work area) to inspect and modify CI and relationship data before loading the data into the CMDB.

The transaction work area is a data warehouse to store, review, and modify CI and relationship transaction information from multiple sources. In the TWA, you can modify incoming transaction data to conform to your CMDB requirements. You also can use the TWA to modify data input that could create false positives or false negatives during the reconciliation process. False positives are multiple CI representations of the same business object. False negatives are multiple business objects that are identified as the same CI.

Transaction information can apply to new objects or to objects that are already in the CMDB.

The TWA process works as follows:

1. Load the data (see page 2520) into the TWA. The content can include CI transactions or relationship transactions. The input process does not attempt to reconcile records. The process simply populates the work area with CI and relationship transaction records in one of the following ways:
   - GRLoader - Reads XML data and stores it in the TWA using the -lttwa or -lttwar options.
   - Native SQL - Places data into the TWA using standard SQL processing.
   - Create a CI transaction or relationship transaction using the web interface.
2. (Optional) Manually reconcile transactions to existing CIs in the CMDB before you load the data. You can also simulate loading the data (see page 2525) to predetermine whether a set of transactions can create new CIs or relationships. For more information, see Review and Modify Inbound Data Using Transaction Work Area (TWA) (see page 2566).
3. Modify the data. You can modify the TWA from the following sources:
   - **CA SDM user interface**
     The web-based user interface lets you view and modify transactions in the work area.

- **Native SQL**
  When performing many changes to multiple transactions, native SQL can modify the data in the TWA.

  Note: Changes that are made using native SQL can bypass all CA SDM security.

GRLoader loads the data from the TWA to the CMDB using the -lftwa or -lftwai options. Each TWA row is treated as a separate transaction.

a. If there is an error after a GRLoader run, the error code is populated into the transaction to indicate that it is incomplete (to facilitate future retries).

b. All other records are identified as completed transactions.

4. Review the transaction results and correct any errors using the web interface. Consider the following points:

   - If you want the columns of custom families or attributes to appear in the work area, modify the work area to include the modified columns. For more information, see Extend the TWA Object (see page 2532).
   - To take advantage of the TWA, use the latest version of GRLoader. If you are using a product that includes a previous release of GRLoader, upgrade GRLoader to the latest version.
   - Changes made to transactions in the TWA are not audited.

5. Repeat steps 3 as needed.

TWA Administration

This article contains the following topics:

The TWA may require the following administration:

- Extend the TWA - required when you extend any OOB families or when you define your own custom families.
- Archive and purge of the TWA
- How to use the TWA with CA Configuration Automation
- Database limitations

Extend the TWA Object

Any modifications to the CMDB family schema require parallel modifications to the TWA schema. If no custom families or attribute have been defined, the TWA requires no modifications.

To extend the TWA object:

1. Modify the user-defined families and attributes *using the procedures in Extending CMDB*. (see page 2603)

2. Add the new family attributes to the ci_twa_ci schema using Web Screen Painter Schema Designer.
   To add a new attribute to ci_twa_ci schema:

   a. Using Web Screen Painter Schema Designer, open the schema for the ci_twa_ci table.

   b. Add the desired family attribute to the extension table.

   c. Publish the modified ci_twa_ci schema.

   Note: The new attributes must be type STRING and must hold the longest possible text value.

3. Add the metadata for the custom family to the TWA as follows:

   a. Using Web Screen Painter, open the cmdb_metadata_site_families.htmpl file.

   b. Add an PDM_INCLUDE for the appropriate cmdb_metadata_*extension*.htmpl file that was created for the custom family.

Archive and Purge of the TWA

To maintain the TWA, CA SDM provides the following archive/purge rules:

- **CI Inactive Transactions**
  Archives and purges the CI transactions that are marked for deletion.

- **CI Successful Transactions**
  Archives and purges the CI transactions that have completed successfully.

- **Relationship Inactive Transactions**
  Archives and purges relationship transactions that are marked for deletion.

- **Relationship Successful Transactions**
  Archives and purges relationship transactions that have completed successfully.

You can select how often the rules run or whether they are enabled.

You can modify and enable the rules for enabling archive and purge of the TWA. If you are a heavy user of the TWA, be aware of the limitations on the number of records in the TWA imposed by the DBMS.

If you have to reinitialize the TWA to clear out all data in the TWA, complete the following tasks:

- Set all transactions to inactive
- Run archive purge

Important! Do not use SQL to delete all records in the TWA because it deletes required header records.

TWA GRLoader Command Options

CA SDM provides the following command options for use in GRLoader TWA processing:

- **-lttwa**
  Loads XML into the initial state.
- **-lttwar**
  Loads XML into the ready state.
- **-lftwa**
  Loads transactions from the TWA.
- **-lftwai**
  Loads transactions from the TWA and inactivates successful transactions.
- **-chg *nnnn***
  Used with - lftwa and -lftwar. Loads only those transactions that are associated with change order *nnnn*.
  Note: The Change Order string is not validated when loaded into the CMDB.
- **-I**
  Ignore case of lookup attributes. By default free-form text for lookup attributes is processed as case sensitive unless you use this option.
- **-simci**
  Determines whether the CI transactions can create or update CIs. When this option is used, GRLoader perform error checking against CIs only.
- **-simrel**
  Determines whether relationship transactions can create or update relationships. This option verifies relationships for the existence of the provider and dependent CIs, validates relationship types, and so on.

TWA GRLoader Configuration File Options

CMDB provides the following TWA options for the GRLoader configuration file:

grloader.emptyvalue=EMPTY

grloader.loadfromtwa=yes

grloader.loadfromtwa.inactivatesuccessful=yes/no

grloader.loadtotwa=yes

grloader.loadtotwa.ready=yes/no

grloader.workarea.delimiters={ }

grloader.workarea.ignore_transaction_dates=yes

grloader.simulateloadci=yes/no

grloader.simulateloadrelation=yes/no

How to Use the TWA with CA Configuration Automation

To use the TWA with CA Configuration Automation processing, apply patch RO08739 to CA Configuration Automation r5. This patch allows you to specify the - lttwa option in the Other Options field on the Export Options tab of the CMDB Export Report definition. Upgrade the GRLoader component. Contact CA support for questions.

Database Limitations

The TWA is subject to the data limitations of the underlying database, as follows:

- When using TWA and Microsoft SQL Server, the total length of one data transaction must not exceed 8060 bytes.
- When using the dbload and pdm_load utilities, a load operation is restricted to 512 columns.
- Oracle has a 1000-column limitation. If you modify CMDB, verify that the total number of attributes does not exceed 1000 across all families (both CA-supplied and user-defined).
- SQL Server 2005 limitations as described in the following table:

Limitation Type	Limit (32-bit and 64-bit)
Columns per wide table	30000
Columns per base table	1024
Columns per SELECT statement	4096
Bytes per row	8060
Rows per table	Limited by available storage

Manage Relationship Transactions

The Relationship Transaction List displays relationship transaction data input.

Using this page, you can search for relationship transactions.

On the list, you can do the following actions:

- Create a relationship transaction
- Edit in list (except for identifying attributes)

Update a Relationship Transaction

You can view and modify data for a single relationship transaction. On the Relationship Transaction Detail page, you can do the following actions:

- Create a relationship transaction
- View the transaction
- Edit the transaction
- Save or Cancel transaction changes (Edit mode)
- Reset the original transaction data (Edit mode)

To update a relationship transaction:

1. Click Edit.
   The Update Relationship Transaction page appears.
2. Modify and complete fields.
3. Select Active.
4. Click Save.
   The relationship transaction is saved.

When all data entry is complete, you can simulate loading the data to validate the data and verify reconciliation.

Important! Data that you enter into the TWA using this interface must follow certain rules. For more information about the rules, see the "How to load data into the TWA Using GRLoader (see page)" section.

The web UI does not validate case-sensitive data in the TWA. Verify that the values you enter exactly match the lookup values. Alternately, when you run GRLoader, you can specify the - I option to enable case insensitive lookups.

Note: The provider_id or dependent_id are stored as UUIDs in the transaction. However, they are displayed as CI names in the web interface.

Define the Business Infrastructure

Contents

Implement your service desk using CA SDM by defining your business infrastructure with the following objects:

- Configuration item families and classes
- Manufacturers and models
- Service statuses
- Vendors and vendor types

The following information provides a general description for each object and explains how the object is used in the product.

Object Definition Order

You start at the bottom levels of the object hierarchy when you define objects. Therefore, when you define objects at higher levels, you can select from existing objects at lower levels in the hierarchy. For example, because a class has (references) a family, you define families first, followed by classes. Define configuration objects last, after you define all the supporting objects, because they are the top of the hierarchy. Therefore, you define data objects in the following order:

Define First	Define Second	Define Third
Families	Classes	Configuration items
Manufacturers	Models	Configuration items
Service statuses	Configuration items	
Vendor types	Vendors	Configuration items

Manufacturer and Models

Manufacturers identify the manufacturers of the various configuration items of concern to your enterprise. *Models* contain specific information about the products that a particular manufacturer provides to your enterprise. For example, you might define as a manufacturer a particular software company. Then, you would define as models each one of the applications that the company provides for your enterprise.

Defining manufacturers and models makes it easier to manage your configuration items. For example, you can generate a list of models that are provided by a particular manufacturer. You can also generate a list of configuration items of a particular model.

You can enter information about the manufacturers and models of the hardware, software, and services that are associated with your system. You can also reference this information in configuration item records. To create a model. from the Administration tab, navigate to Service Desk, Application Data, Configuration Items, Models. Click Create New and enter the fields as appropriate.

Service Status

Service status identifies the readiness condition of configuration items. Examples of service status include: *in service*, *in repair*, or *discontinued*. Defining service status lets you track the availability and use of configuration items in your enterprise. For example, you can generate a list of configuration items that are currently in repair.

Vendor Types and Vendors

Vendor types are classifications for vendors that identify the type of company providing configuration items. For example, you could classify vendors that you lease configuration items from as leasers. You can classify vendors that provide service to you as providers.

Vendors identify the companies that supply your enterprise, including the type of company and a primary contact. You can also reference a vendor in a user's contact record.

Defining vendor types and vendors gives you a convenient way to organize your configuration items. For example, you can generate a list of vendors that fall under a particular vendor type. You can also generate a list of configuration items from a particular vendor.

External Asset Management Tools

You can integrate CA SDM with other asset management tools such as CA NSM, CA Client Automation, and CA APM. The asset management features of these tools from CA SDM include the following features:

- CA NSM provides the pdm_nsmimp utility (for Windows only) to add asset information to CA SDM.
- CA Client Automation provides a complete set of hardware and software inventory functions. When viewing a CI in the CA SDM client, click Asset Viewer to display more information about the asset.
  Integration between CA SDM and CA Asset Management is activated when the products are installed on the same MDB.

- CA Asset Portfolio Management provides a complete set of asset lifecycle functions. When viewing a CI in the CA SDM client, click Asset Viewer to display more financial information about the asset.
  Integration between CA SDM and CA Asset Portfolio Management is activated when the products are installed on the same MDB.

About MDR

This article contains the following topics:

The Configuration Management Database Federation (CMDBf) is a working group that is composed of representatives from CA, IBM, HP, Microsoft, and other companies. The CMDBf defines a Management Data Repository (MDR) as anything that collects information about configuration items (CIs).

To create the relationship between an MDR and its CIs when implementing MDR Launcher, complete the following tasks:

1. Define the MDR.

2. Define the CIs that reference that MDR.
   You cannot have a CI that references a non-existent MDR. You can define a CI without defining an MDR association. You can add the MDR information during an update or can edit to take advantage of the MDR Launcher capability.

Multiple MDRs can discover the same CI. After the CI is discovered, each MDR attempts to manage that CI, and an MDR can do the following actions:

- Discover detailed attributes about the CI.

- Attempt to modify the CI state.

Example: A CI Discovered by Multiple MDRs

Both Network Management software and an Asset Management software package discover a CI.

- The network management software maintains information about network configuration and network topology.

- The asset management software contains information regarding cost, depreciation, licensing, and maintenance contracts for that particular CI.

MDR Classes and MDR Names

An IT enterprise can include many MDRs. Each MDR has an identifier that is known as an *MDR name (mdr_name*). It is common for an MDR to use the host server name as the mdr_name. The server name is used to allow multiple MDRs to reside on the same host server. Therefore, an MDR class (mdr_class) is appended to the mdr_name to identify each MDR uniquely.

CA Configuration Automation is an enterprise discovery tool that integrates tightly with CMDB Each CA Configuration Automation MDR defined to the CMDB must have an *mdr_class* of **Cohesion**. For more information about CA Configuration Automation, see the CA Configuration Automation online help. For CA Configuration Automation-CMDB integration, see the *CA Configuration Automation Implementation documentation*.

How does an MDR Complement CA SDM?

An MDR typically contains more detailed CI information than CMDB. However, a single MDR is not typically aware of the existence of other MDRs. It does not focus on the relationships that a particular CI can have with other CIs, especially if they are contained in other MDRs. CMDB manages this type of environment well, because it focuses on managing CIs regardless of their MDR source.

CMDB is not intended to store all attributes for all CIs. CMDB is used to consolidate the most important attributes that must be managed centrally. Attributes that are under the control of change management are excellent candidates for inclusion in the CMDB. Attributes that CMDB does not manage can be accessed by using the MDR Launch capability. In addition, CMDB provides the CMDBf Viewer. CMDBf Viewer allows side by side comparison of CI attributes across multiple CMDBs and MDRs.

MDR Launcher

The MDR Launcher lets you view data from almost any MDR by using a web page, without any coding. MDR Launcher lets anyone viewing a CI to obtain more details about the CI, and to gain control over it (if the MDR supports such control).

Some uses of the MDR Launcher include the following ones:

- From the hardware.server detail page, launch CA Configuration Automation to verify a change.
- From an Air Conditioning CI detail, launch to a vendor web page for diagnostic information and incident reporting.
- From a Contract CI, launch a contracts management system to learn contract details.
- From an SLA CI, launch CA Service to review Service Level Agreements before modifying.
- From a Server CI, launch CA Remote Control to take over the server to diagnose and correct a problem.

Define a URL to Launch an MDR

CMDB uses a URL to start a web page session with the source MDR to operate the MDR Launcher. You define the URL that CMDB uses.

Follow these steps:

1. Click the Administration tab.

2. In the left pane, open the CMDB, MDR Management tree.

3. Click MDR List.
   The Management Data Repository (MDR) List page appears.

4. Click an existing MDR (or create and save a new one).
   The MDR Provider Definition page appears.

5. Click Edit.
   The Update MDR Definition page appears.

6. Complete the following parameters:

   - **Hostname**
     Specifies the Network address or DNS name of the web server that serves up web pages for the MDR.

   - **Port**
     Specifies the port number that the Hostname web server uses.

   - **Path**
     Specifies the path to the web page, including the page itself.
     Parameters
     Specifies any parameters that are used to identify the desired CI to the MDR. CMDB posts this information to the MDR.

   - **Userid**
     Specifies the userid, if a common userid is allowed access to the MDR.

   - **Shared Secret**
     Specifies information that is shared between CMDB and the MDR. For CA Cohesion MDRs, this value must match the value that is specified in the CA Cohesion properties file, for the com.cendura.security.oneclickauth.secret value.

   - **CMDBf Namespace**
     Specifies the federated_asset_id that is passed to the query as a local ID. For CA CMDB, the value is http://cmdb.ca.com/r1.

   - **CMDBf Timeout**
     (Optional) Specifies time limit for CMDBf endpoint query.
     Default: 10 seconds

   - **CMDBf Endpoint**
     Specifies the Query Service endpoint for the MDR. Required for CMDBf Viewer and retrieving updated MDR data. If you use CA CMDB as an MDR provider, the value is http://cmdb_hostname:cmdb_port/axis/services/QueryPort (http://cmdb_hostnamecmdb_port/).

7. Save the definition.

The URL is defined. In addition, the URL can contain the substitution variables to further qualify the CI to the MDR. For more information, see the Using the MDR Launcher (see page 2542) topic.

Set Up a CA APM MDR Provider

You can set up an MDR to be the CA APM provider.

Follow these steps:

1. On the Administration tab, click CMDB, MDR Management, MDR List.

2. Click Create New to specify the CA APM MDR.
   The MDR Provider definition appears.

3. Enter the following required MDR provider information:

   - Button Name -- Specify APM or any other valid button name. We recommend using a Button Name of APM.

   - MDR Name -- Specify APM for CA Asset Portfolio Management r11.3.4 or ITAM for CA APM r12.6

   - MDR Class -- Specify GLOBAL.

   - Hostname -- Specifies the CA APM server name by using the network address or the DNS name of the CA APM web server.

   - URL for Launch in Context -- Specifies http://{hostname}:{port}/{path}?{parameters} and must not be changed.

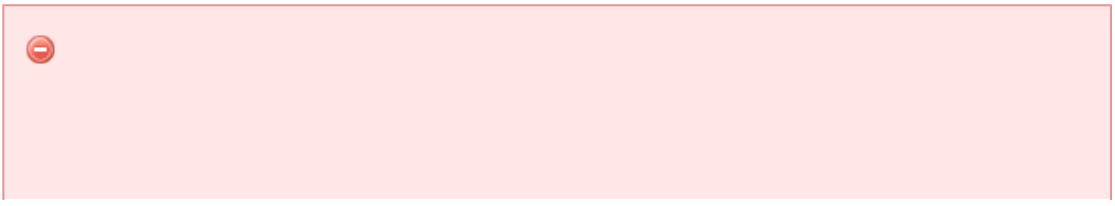
   The MDR provider form automatically populates the path and parameter values with the required CA APM launch in context information.

4. Click Save.
   The CA APM MDR provider is set up. For more information about the MDR launcher, see the MDR Launcher (see page 2542) topic.

Launch in Context from CMDB to CA APM

The CMDB MDR Launcher facility supports launch in context to CA APM when the tools share the same MDB. The CMDB UI provides a launch in context button on the Attributes tab in the CI detail form. The button appears when the user creates a special CA APM MDR provider definition.

The CA APM MDR definition has all the capabilities of a traditional MDR. The CMDB Versioning feature also supports launch in context directly from an attribute log entry that is associated with each CA APM change.



Important! Unlike other MDRs, the CA APM MDR is automatically associated with each CI or Asset. The MDR class of GLOBAL and MDR name of APM are used to identify the CA Asset Portfolio Management r11.3.4 MDR. The MDR class of GLOBAL and MDR name of ITAM are used to identify the CA APM r12.6 MDR. Use of the CA APM MDR is fully compatible with other MDRs, even for the same CI.

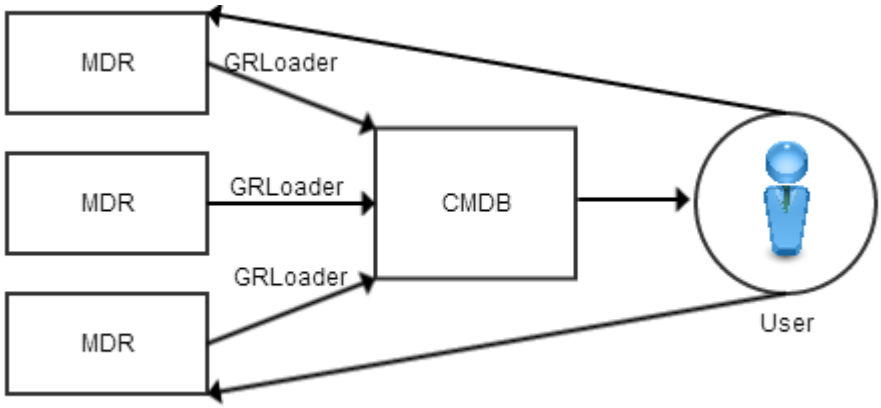
Using the MDR Launcher

This article contains the following topics:

The MDR Launcher

One of the main purposes for implementing CMDB is to aggregate data from multiple data sources (known as MDRs). However, a CI must always include a reference back to its MDR origin.

CMDB provides facilities for importing and loading CIs and also for associating the CIs with their origins. To view a CI in the CMDB, use the MDR Launcher. When you use the MDR Launcher for this purpose, you can return seamlessly to the CI-originating system. See the following diagram.



Using the MDR Launcher, it is possible to implement a “closed loop” change management process such as the following one:

1. Create a change record.
2. Implement the change.
3. Verify the change by checking the MDR source.
4. To indicate that the change has been made, update the CMDB.

From a Problem Management process perspective, you can use the MDR Launcher in the following way:

1. Detect a problem.
2. Determine the severity and pervasiveness of the problem. To determine what dependent CIs are affected, use the CI relationship data.
3. Determine possible causes of the problem by researching provider CIs.
4. Perform an in-depth analysis if necessary using the detailed information available in the MDR. To take corrective action, use the MDR.

MDR Terminology

The following terms are used in CMDB-MDR integration:

A management data repository (MDR) represents software or data that contains source information about a CI. An MDR generally contains more unrefined CI information than the CMDB, which contains a managed subset of that data.

An *MDR class* (MDR_CLASS) is used to group MDRs that CMDB processes similarly. Three special MDR classes include: **COHESION**, **GLOBAL**, and **cmdbf**.

An *MDR name* (MDR_NAME) is the name that an MDR uses to reference itself. Verify that the mdr_name and mdr_class value combination must be unique within your enterprise.

A Federated asset ID (FEDERATED_ASSET_ID) is a unique MDR identifier for a CI.

The different CI families typically use different respective MDRs as data providers. However, a single CI can have multiple MDR data providers. For example:

CI Family	MDR_CLASS
Contact	human resources system telephone directory single sign-on authentication system
Document	document management system
Air Conditioning	document management system contract management system air conditioning control system
Mainframe	tape management system DASD management system performance management system job scheduler
Storage	storage management system asset management system
Location	asset management system education calendar office directory
Network	network management systems problem management system

There can be multiple MDRs in each MDR class, and each MDR can contribute data to multiple CIs. A given CI can receive data from zero or more MDRs. A CI also can have data contributed to it independently. Consider the following example: One mainframe CI has data that Disk Management System 1 donated. Another mainframe CI has data that Disk Management System 2 and Job Scheduler 2 donated. CMDB manages the relationships among CIs and all their related MDRs.

MDR Mapping

Every MDR has a unique way of identifying the CIs that it manages. Those identifiers are seldom synchronized across MDRs. For example, when referencing a specific Contact CI, different MDRs can use different identifiers. A national identity number, telephone number, license number, or Employee ID can identify the same person. The process of associating these disparate identifiers with the same unique identifier (UUID) maintained in the MDB is named *mapping*. Mapping occurs automatically when data is imported using GRLoader when the CI contains the <mdr_name> <mdr_class> and <federated_asset_id> tags. Mapping can also be accomplished manually through the Administration functions in the user interface. A CI that has no mappings that are associated with it is named *unfederated*. Every CI is automatically mapped to global MDRs using the UUID as the federated_asset_id.

MDR Launching

When you view a CI with the CMDB user interface, click buttons to launch an MDR user interface directly. One button per MDR mapping exists for the focus CI. To verify that a change request has completed successfully, use this launching. To obtain more information about a CI than the CMDB has collected, use this launching.

CMDBf Viewer

CA SDM provides the CMDBf Viewer with the results of CI federation across MDRs. From a CI Detail page, click CMDBf Viewer to see CI attributes of federated CMDBs and MDRs in parallel. On the Federated View page, you can click Retrieve to update the information from any of the federated MDRs. For better readability, CMDB metadata files can reconcile MDR attribute names and CMDB attribute names.

Note: This feature requires MDRs that support Query. You configure the MDR CMDBf Endpoints to display their results on Federated View.

Define an MDR to CMDB

Before you use the CMDBf Viewer, define the MDR to CMDB.

Follow these steps:

1. On the Administration tab, navigate to CMDB, MDR Management, MDR List.

2. Click Create New.
   The Create New MDR Definition page appears.

3. Complete the following fields:

   - **Tenant**
     Identifies the tenant owner of this MDR (if multi-tenancy is installed).

   - **Button Name**
     Specifies the button label to appear on the CI Detail page. This name must be unique for each MDR. Required for “launch in context” and CMDBf Viewer.

   - **MDR Name**
     Specifies the string to match the XML data that is sent in the mdr_name field. While the MDR can use any string, the host name is used frequently. This name together with the mdr_class form a unique name for the MDR. Required for “launch in context” and CMDBf Viewer.

   - **MDR Class**
     Specifies the class that must match the data that is sent in the mdr_class field in the XML. While this name can be anything, it must together with the mdr_name field form a unique identifier for the MDR. Global MDRs are defined with an MDR Class of GLOBAL.

     - CA Configuration Automation MDRs must specify an MDR class of COHESION, which automatically sets the Path, Parameters and URL to be Launched fields to the required CA Configuration Automation launch-in-context values.

     - CA Asset Portfolio Management r11.3.4 MDRs must specify an MDR name of APM and MDR class of GLOBAL, which sets the Path, Parameters, and URL to be Launched fields to the required CA Asset Portfolio Management r11.3.4 launch-in-context values.

- CA APM r12.5 MDRs must specify an MDR name of ITAM and MDR class of GLOBAL, which sets the Path, Parameters, and URL to be Launched fields to the required CA APM 12.5 launch-in-context values.

- For CMDBf Viewer, MDR Class must be cmdbf.

- **Active**
  Denotes this MDR definition as active or inactive. The Inactive MDR definitions are logically deleted, but they can be made active again by using the Search utility.

- **Owner**
  Specifies the contact responsible for this MDR.

- **Description**
  Specifies a description in free-form text.

- **Hostname**
  Specifies the host name, DNS name, or IP address of the host, which contains the web server. The web server is the one that hosts the web page to be launched. Required for “launch in context”.

- **Port**
  Specifies the TCP/IP port that is used by the MDR web server to serve up web pages. Port 80 is the default. Required for “launch in context”.

- **Path**
  Specifies the portion of the URL that precedes the question mark (?) character. This information can be obtained from your MDR documentation.

  - For mdr_class of Cohesion, the value is set automatically to "CAisd/html /cmdb_cohesion.html" and cannot be changed.

  - For mdr_name of APM and mdr_class of GLOBAL, the value is set automatically to apm /frmObject.aspx and cannot be changed.

  - For mdr_name of ITAM and mdr_class of GLOBAL, the value is set automatically to ITAM/Pages/Asset.aspx and cannot be changed.

- **Parameters**
  Specifies the portion of the URL that follows the question mark (?) character. This information can be obtained from the MDR documentation.

  - For mdr_class of Cohesion, the value is set automatically to "hostname={hostname} +port={port}+family={family}+name={name}+secret={password}+federated_asset_id= {federated_asset_id}". The value cannot be changed.

  - For mdr_name of APM and mdr_class of GLOBAL, the value is set automatically to ObjectID={cmdb_asset_id}&obj=11&FUNCTION=1&WinID=OBFRASSET{cmdb_asset_id} &WinContainerID=. The value cannot be changed.

  - For mdr_name of ITAM and mdr_class of GLOBAL, the value is set automatically to ParentClass=Asset&assetid={cmdb_asset_id}&TicketID={itam_ticketid}. The value cannot be changed.

- **Userid**
  Specifies the MDR user logon, if necessary. This value is substituted into the URL wherever {userid} is found. If blank, userid defaults to whomever is signed on.
  For CA Configuration Automation, "Shared Secret" is the secret that is used to access CA Configuration Automation, if necessary. This value is substituted into the URL wherever {password} is found. For more information about defining the MDR, see the *CA Configuration Automation Implementation documentation*.

- **Shared Secret**
  Specifies information that is shared between CMDB and the MDR. This value is substituted into the URL wherever {password} is found. For CA Configuration Automation MDRs, the value must match the value of the “com.cendura.security.oneclickauth.secret”. For more information about creating a shared secret, see "Integrating with CA CMDB" in the *CA Configuration Automation Implementation documentation*. Required for CMDBf Viewer.

- **CMDBf Namespace**
  Specifies the federated_asset_id that is passed to the query as a local ID. For CMDB, the value is http://cmdb.ca.com/r1.

- **CMDBf Timeout**
  (Optional) Specifies time limit for CMDBf endpoint query. Default is ten (10) seconds.

- **URL to be Launched**
  Default value of http://{hostname}:{port}/{path}?{parameters}. For some MDRs, it can be overridden if necessary to accommodate MDR-specific requirements. Required for "launch in context".
  For mdr_name of APM and mdr_class of GLOBAL, the value is http://{hostname}:{port}/{path}?{parameters}
  For mdr_name of ITAM and mdr_class of GLOBAL, the value is http://{hostname}:{port}/{path}?{parameters}
  For mdr_class of Cohesion the default value is http://*cmdb_hostname*:*cmdb_port*/{path}?{parameters}
  where:
  cmdb_hostname is the host name, DNS name, or IP address of the CMDB web server. Defaults to the current hostname that is accessing the CMDB web server.
  cmdb_port is the TCP/IP port of the CMDB web server. Defaults to the current port number used to access the CMDB web server.

  > **Note:** If you have enabled SSL support for CA Configuration Automation, set the URL to: http://hostname:port/{path}?{parameters}+https=yes (http://hostnameport/)

  For information about enabling CA Configuration Automation HTTPS support, see the CA Configuration Automation online help topic Creating the HTTPS Certificate and Enabling HTTPS.

- **CMDBf Endpoint**

  Specifies the Query Service endpoint for the MDR. Required for CMDBf Viewer and retrieving updated MDR data. If you use CA CMDB as an MDR provider, the value is http://cmdb_hostname:cmdb_port/axis/services/QueryPort.

4. Click Save.

   The MDR is defined.

MDR URL Definitions

The URL to be launched has the default value of http://{hostname}:{port}/{path}?{parameters}. If necessary, you can modify this expression to accommodate any MDR-specific requirements. The URL is required for "launch in context".

For mdr_name of APM or ITAM and mdr_class of GLOBAL, the default value is:

```
http://{hostname}:{port}/{path}?{parameters}
```

For mdr_class of Cohesion, the default value is:

```
http://cmdb_hostname:cmdb_port/{path}?{parameters}
```

- ***cmdb_hostname***
  The cmdb_hostname variable specifies the hostname, dnsname, or IP address of the CMDB web server. The variable defaults to the current hostname currently accessing the CMDB web server.

- ***cmdb_port***
  The cmdb_port variable specifies the TCP/IP port of the CMDB web server. The variable defaults to the current port number that is used to access the CMDB web server.

Include http=yes when you set the URL if you have enabled SSL support for CA Configuration Automation. See the following example:

```
http://hostname:port/{path}?{parameters}+https=yes
```

For information about enabling CA Configuration Automation HTTPS support, see the CA Configuration Automation online help.

MDR Launch URL

The MDR launch URL has the following default value:

```
http://{hostname}:{port}/{path}?{parameters}
```

You can modify this expression to accommodate any MDR-specific requirements. The URL is required for "launch in context."

- For mdr_name of APM or ITAM and mdr_class of GLOBAL, the default value is:

  ```
  http://{hostname}:{port}/{path}?{parameters}
  ```

- For mdr_class of Cohesion, the default value is:

  ```
  http://cmdb_hostname:cmdb_port/{path}?{parameters}
  ```

- ***cmdb_hostname***
  The cmdb_hostname variable specifies the host name, DNS name, or IP address of the CMDB web server. The variable defaults to the host name currently accessing the CMDB web server.

- ***cmdb_port***
  The cmdb_port variable specifies the TCP/IP port of the CMDB web server. The variable defaults to the current port number that is used to access the CMDB web server.

Set the URL to include https=yes in the query string, if you have enabled SSL support for CA Configuration Automation. See the following example:

```
http://hostname:port/{path}?{parameters}+https=yes
```

For information about enabling CA Configuration Automation HTTPS support, see the Cohesion online help.

Defining Launch Parameters for URL Substitution

When defining an MDR, the following parameters can be used to construct its URL for display. These parameters are substituted with their appropriate values at run time. These variables must be specified in the fields that were described previously.

hostname is the MDR host name from the MDR definition.

alarm_id is the IP address of the selected CI.

federated_asset_ID is the unique identifier of the selected CI in the MDR.

cmdb_asset_id is the asset ID for the CI.

port is the MDR port number from the MDR definition.

userid is the user ID from the MDR definition. If blank, userid defaults to whomever is currently signed on.

password is the shared secret from the MDR definition.

mdr_name is the mdr_name from the MDR definition.

mdr_class is the mdr_class from the MDR definition.

class is the class of the selected CI.

family is the family of the selected CI.

path is the path as described in the MDR definition.

name is the name of the selected CI.

model is the model of the selected CI.

manufacturer is the manufacturer of the selected CI.

itam_ticketid is the ticket id to log in to CA APM.

Example: Launching an MDR

A CMDB user is looking at a Server CI named server1. Server1 has a map to an internally developed application that is named Comet. Comet uniquely identifies server1 as server:server1.

Comet is defined as an MDR with the following properties:

- Hostname: CometServer
- Port: 80
- Path: index.php
- Parameters: item={federated_asset_id}
- Launch_url: http://{hostname}:{port}/{path}?{parameters}

In CMDB, when the user clicks Comet on the Attributes tab of the server1 CI, a web browser opens the following URL:

http://CometServer:80/index.php?item=server:server1

Parameters for URL Substitution

When defining an MDR, you can use the following parameters to construct its URL for display. These parameters are substituted with their appropriate values at runtime. These variables must be specified in the MDR field definitions.

- **{hostname}**
  Specifies the MDR host name from the MDR definition.
- **{alarm_id}**
  Specifies the IP address of the selected CI.
- **{federated_asset_ID}**
  Specifies the unique identifier of the selected CI in the MDR.
- **{cmdb_asset_id}**
  Specifies the asset ID for the CI.
- **{port}**
  Specifies the MDR port number from the MDR definition.
- **{userid}**
  Specifies the user ID from the MDR definition. If blank, userid defaults to whomever is currently signed on.
- **{password}**
  Specifies the shared secret from the MDR definition.

- **{mdr_name}**
  Specifies the mdr_name from the MDR definition.
- **{mdr_class}**
  Specifies the mdr_class from the MDR definition.
- **{class}**
  Specifies the class of the selected CI.
- **{family}**
  Specifies the family of the selected CI.
- **{path}**
  Specifies the path as described in the MDR definition.
- **{name}**
  Specifies the name of the selected CI.
- **{model}**
  Specifies the model of the selected CI
- **{manufacturer}**
  Specifies the manufacturer of the selected CI

Example: Use Parameters for URL Substitution

A CMDB user is looking at a Server CI named server1. The Server CI has a map to an internally developed application that is known as Comet. Comet uniquely identifies server1 as server:server1.

Comet is defined as an MDR with the following properties:

- Hostname: CometServer
- Port: 80
- Path: index.php
- Parameters: item={federated_asset_id}
- Launch_url: http://{hostname}:{port}/{path}?{parameters}

In CMDB, when the user clicks Attributes, Comet in the server1 CI, a web browser opens the following URL:

```
http://CometServer:80/index.php?item=server:server1
```

Federation Using GRLoader

When using GRLoader, the following XML tags must be populated in every CI in the XML document. These tags apply to every MDR family.

- <mdr_name>

- <mdr_class>
- <federated_asset_id>

> **Note:** CA Configuration Automation automatically provides mdr_name, mdr_class and federated_asset_id.

if the XML tags are missing, “launch in context” is not possible. This is because, the origin of the CI cannot be determined.

To identify the source of a CI, you can modify the XML before it is input into GRLoader. You can use a text editor to modify the XML and make a global change. You can also program this task.

For more information about MDR identification and GRLoader, see the GRLoader XML (see page 4306) topic.

Federate a CI

If CIs are loaded into CMDB before their corresponding MDR is defined, they are unfederated. Unfederated means that the CIs are not yet connected to an MDR and they do not yet support “launch in context”.

Follow these steps:

1. Define the required MDR.
2. Do one of the following tasks:
   - Manually map the CI.
   - Rerun the CA Configuration Automation report which created the CI, specifying Allow update of existing CIs on the report. For more information about CA Configuration Automation Reports, see the *CA Configuration Automation Product documentation*.
3. Rerun GRLoader, specifying the same input file that was used to create the CIs.
   The CMDB reconciliation engine merges the MDR information into the existing CIs.
4. Create an XML document that describes the CI and its MDR and run GRLoader in Update mode.
   The CMDB reconciliation engine merges the new information into the existing CI. The existing CI is federated.

Example: Specify CI Location

To locate the CI you want to update, verify that the reconciliation engine is provided with enough information. In the following example, end tags are removed and spaces added for readability.

```
<ci>
   <name>         server3
   <mac_address>
```

```
   <serial_number>
   <asset_num>
   <dns_name>
   <mdr_name>     mdr_one
   <mdr_class>    Cohesion
</ci>
```

Define Multiple MDRs to a CI Using GRLoader

You can define multiple MDRs to a CI by using GRLoader.

To define multiple MDRs to a single CI, the XML document can repeat the <ci> node. With each duplicated <ci> mode, specify a different mdr_name and mdr_class. In other words, each MDR can contribute its attributes independently of any other MDR that contributes data to the CI.

Example: Define Multiple MDRs to a CI

If MDR1 and MDR2 both contribute data to the server2 CI, the XML document looks something like the following example. In the example, end tags are removed and spaces added for readability.

```
<ci>
   <name>      server2
   <mdr_name>  mdr1
   <mdr_class> Cohesion
   <diskspace> 500 gb
   <disktype>  SCSI-3
</ci>
<ci>
   <name>     server2
   <mdr_name> mdr2
   <mdr_class>Service Assure
   <sla>
</ci>
```

CMDB reconciles the two previous CIs to the same CI and associates each MDR to that single CI.

Note: The CIs can be imported in one or two runs of GRloader.

Map Between MDR CIs and CMDB CIs

After you define a CI manually using the File, New Configuration Item... option, manually define the mapping between this CI and the CI in the federated MDR. Associate a CI with an MDR in the following ways:

- Editing the CI.
- Using the Federated CI Mapping node on the CMDB Administration tab.

Follow these steps:

1. To create a mapping by editing the CI, complete the following steps:

    a. Display the CI Detail page of the CI that you want to associate with an MDR.

    b. Click Edit.

    c. Display the Attributes tab.

    d. Click Add MDR.
    The CI is associated with the MDR.

2. To create a mapping using the Federated CI Mapping page, complete the following steps:

    a. Click the CMDB Administration tab.

    b. Open the Management Data Repository node.

    c. Select the Federated CI Mapping node.
    The Federated CI Mapping List appears.

    d. Click Create New.
    The Create New Federated CI Mapping For page appears.

    e. Associate the CI with the MDR by completing the Federated CI Mapping fields:

    - **CI Name**
      Specifies the name to use to identify the configuration item.

    - **Federated Asset ID**
      Specifies the string identifier that is used by the source MDR to identify this CI. The MDR software determines the identifier.

    - **MDR Name**
      Specifies the name that identifies the MDR (and its MDR button).

    - **Active**
      Denotes whether this mapping is active or not. Mappings cannot be deleted, only inactivated.

    f. Click Save.
    The mapping between this CI and the CI in the federated MDR is defined.

How To Configure MDRs for CMDBf Viewer

To use the CMDBf Viewer, set up your federated MDR providers to point to the CMDBf query service, as follows:

- External MDRs must provide a query service that can handle InstanceIdConstraint query.
- Button Name, MDR Name, and MDR Class are required to show the CMDBf Viewer button on the CI Detail page.
- MDR Class must be defined as **cmdbf**

- For CMDB, CMDBf Namespace must be set to **http://cmdb.ca.com/r1**. For other CMDBs and MDRs, see the appropriate documentation.
- Timeout is optional. Default is ten (10) seconds.
- To display a working Retrieve button on the Federated View, define CMDBf Endpoint, Userid, and Shared Secret.

Note: An existing CMDB system can be set up as a CMDBf provider by specifying an CMDBf Endpoint of "http://servername:port/axis/services/QueryPort" where:

- hostname is the computer where CMDB is installed (localhost or computer name).
- port is the port where CMDB is configured.

Launching the MDR Web Browser Interface

After a mapping between a CI and an MDR is created, a button is placed automatically on the Attributes tab. If multiple MDRs are associated with this CI, multiple buttons appear.

When you click an MDR button, a new page opens. The fully substituted MDR URL that is defined in the MDR definition appears on the page.

Example: Launch CA Cohesion

When a CI has been correctly associated with its MDR, a Cohesion button appears on the Attributes tab. If a button does not appear on the Attributes tab, review the mapping for the displayed CI. Verify that there is a mapping for this CI. Also verify that the target MDR has a URL that can be launched. Clicking the button to launch the MDR causes a new window to open. The window opens to the target URL to launch CA Cohesion.

CA Cohesion Integration

Consider the following items when integrating CA Configuration Automation with CMDB:

- Integrating Cohesion with CMDB

  Note: For information about Cohesion-CMDB integration, see the *CA Configuration Automation Implementation documentation*.

- Importing CIs from a Cohesion MDR

  For information about how to import CIs from a Cohesion MDR, see the help in the CA Configuration Automation Report Templates tab.

- Launch-in-Context for Cohesion MDRs
  For launch-in-context integration to work best with CA Configuration Automation, we recommend that you define the Cohesion MDR *before* running the Cohesion CMDB Report. You can define Cohesion MDR in the CMDB Administration tab.

  Note: CA Configuration Automation does not support a unique Federated asset ID for NIC or File System CIs. Therefore, Cohesion does not support MDR Launcher for NIC or File System CIs. As a result, a Cohesion-based NIC or a File System CI does not display an MDR launch button even when it was imported successfully.

Reconcile CI Ambiguities Using MDR

Reconciliation ensures that updates from multiple data sources that refer to the same business object only update a single CI. A single CI is updated even if the data sources possess different identifying information.

Ambiguity represents the possibility that a CI is not unique. CIs are *ambiguous* when they represent the same real business object. The CI transactions are ambiguous when they have more than one possible target CI.

Ambiguous CIs can lead to incorrect data in the CMDB, which negates the value of the CMDB. A negated value can lead to incorrect business actions.

Automatic CI reconciliation is a key CMDB advantage that saves significant time, when compared with manual data maintenance. The process of reconciling CIs uses several specific identifying attributes. However, automatic reconciliation can result in the following matches:

- False positive matches
  Existing CIs are updated instead of creating a CI.

- False negative matches
  New CIs are created instead of updating an existing CI. The set of CIs with similar identifying attributes are ambiguous, because they resemble the same real business object with similar identifying attributes.

CA Service Desk Manager supports the following reconciliation approaches:

- **MDR-Based Reconciliation (Passive)**
  Allow the CMDB to reconcile any ambiguous data based on the MDR-Based Reconciliation process.

- **Identify and Resolve ambiguous CIs (Reactive)**
  Identify and resolve ambiguous CIs through identification and management of existing CIs in the CMDB.

- **Review and modify inbound data using a transaction work area (Proactive)**
  Review and modify inbound data before loading into the CMDB using a transaction work area (TWA).

How to Identify and Resolve Ambiguous CIs

Contents

We recommend managing the ambiguity for a CI by reviewing each CI. In each case, the Configuration Administrator must detect when the ambiguity exists and must determine the optimal approach. CA SDM takes a broad approach to identify and manage ambiguous CIs that are already in the CMDB.

The ambiguity index is an operational measure of the potential nonuniqueness of a configuration item (CI) or a CI transaction item, which is based on its identifying attributes. The ambiguity index measures the probability of one or more CIs representing the same real business object. Or, it measures the probability that a CI transaction has more than one possible target CI.

Important! If you manually delete CIs with database queries, errors can occur for CIs ambiguity indexes. To avoid these errors, execute the cmdb_update_ambiguity utility and set the -full parameter to 1. This parameter ensures that you receive the accurate ambiguity indexes when you execute cmdb_update_ambiguity.bat or the shell script.

CI Ambiguity Example

Data from four different data sources is loaded into the CMDB. Each data source uses its own subset of identifying characteristics. Because of this inconsistency, more CIs exist in the CMDB than are desired.

Example: Ambiguous CIs

The following four CIs reside in the CMDB:

- Name(Server1) DNS Name(dns1) Serial Number(serial1)
- Name(Server1) DNS Name(dns1)

- Name(Server2) DNS Name(dns1) Serial Number(serial1)
- Name(Server3) MAC Address(mac1)

Due to shared identifying characteristics, the two instances of Server1 and Server2 are ambiguous with each other. Server3 is not ambiguous.

Every CI has an ambiguity index that is associated with it. The ambiguity index is approximately the number of existing CIs that match on any of the identifying attributes. The greater the index, the more CIs that match on the identifiers. Therefore, the greater the probability that CI data was entered inconsistently and that more CIs are incorrectly created. CIs with an ambiguity index of zero are unique across all identifiers and are therefore unambiguous.

The ambiguity index of each of the previous CIs is

- First Instance for Server1: Count of other CIs matching name + dnsname + serial number = 1+2+1=4
- Second Instance of Server1: Count of other CIs matching name + dnsname = 1+2 = 3
- Server2: Count of other CIs matching name + dnsname + serial number = 0 +2+1 = 3
- Server3; Count of other CIs matching name + mac address = 0+0 = 0

Follow these steps:

1. Identify ambiguous CIs (see page 2558).
   - Calculate the ambiguity index for all CIs.
   - Review the list of ambiguous CIs from the Scoreboard.
2. Determine if the identifying attributes for each CI are valid.
3. Resolve the ambiguous CI (see page 2563) with one of the following actions:
   - Modify the identifying attributes.
   - Exclude a CI from ambiguity management.
   - Reject a CI Update by inactivating the CI.
   - Supersede a CI.

Identify Ambiguous CIs

Investigate any CI with a nonzero ambiguity index to determine if it is unique or it was inadvertently created. Ambiguous CIs can be created because of incorrect reconciliation. CIs are not ambiguous by themselves, they are ambiguous with other CIs. A system can have many sets of ambiguous CIs, each set containing CIs with common values for the identifying attributes.

When you research the ambiguity of a CI, you also research the ambiguity of other CIs in the same set. When you resolve the ambiguity of a single CI, you reduce the ambiguity of other CIs in that set.

CA SDM has reconciliation management tools, which enable you to find ambiguous CIs. The tools also help you find the set of CIs of which the ambiguous CI is a member. You can research the underlying cause of the ambiguity and can resolve it.

When managing ambiguity, follow these steps:

1. Calculate the ambiguity index for all CIs.
2. To view the list of ambiguous CIs, use the scoreboard. The scoreboard lists all CIs that are ambiguous, in descending order of ambiguity.
3. Starting with the CI that has the highest level of ambiguity in the scoreboard, inspect all CIs in its ambiguity set. The reconciliation tab on CI detail form of a single CI lists all other CIs in the ambiguity set.
    a. Determine if all CIs in the set are legitimate or if an error was made in reconciliation. Review the identifying attributes. Determine if the CIs in the set are created correctly or are created due to a false negative reconciliation match.
    b. Determine which CIs in the set, if any, are false negatives.
    When you determine that a false negative reconciliation match has occurred, and more CIs are created, determine the valid CIs and the incorrectly-created CIs. Consider factors such as identifying attributes and attributes such as last update date, related problems, and issues.

Calculate the Ambiguity Index

Before you can begin managing ambiguity, update the ambiguity index for the existing CIs and CI Transactions. You update the ambiguity index for CIs and CI transactions by running the cmdb_update_ambiguity command.

Important! Run cmdb_update_ambiguity at least once to measure CI or CI transaction ambiguity. If you do not run the command, all ambiguity indexes are 0 (zero). An ambiguity index of zero implies no ambiguity.

You can run the utility before and during ambiguity management. Schedule the utility to run periodically, so the ambiguity indexes reflect the current state of your system.

Follow these steps:

1. Determine the necessary parameters to run the utility.
2. Run the utility.
3. Start the CA SDM Web Client and navigate to the Ambiguous CI or Ambiguous CI Transaction Lists.

cmdb_update_ambiguity Command

You can calculate CI and CI transaction ambiguity indexes by entering command syntax similar to the following command:

```
cmdb_update_ambiguity [parameters]  - m { ci | twa | all }
```

For command parameters, see cmdb_update_ambiguity Parameters (see page 2561).

By default, the CI scan is done from the last scan date. If "-full 1" is specified, a complete scan is performed.

Example: Calculate CI ambiguity on a Microsoft SQL Server database

The following command calculates the ambiguity index for all existing CIs and Transactions in the TWA:

```
cmdb_update_ambiguity  - m all  - d MSSQL  - u servicedesk  - p dbpassword -s
dbserver1
```

Example: Calculate CI ambiguity on an Oracle database

The following command calculates the ambiguity index for CIs and specifies database information.

```
cmdb_update_ambiguity  - m ci  - d Oracle  - u mdbadmin  - p dbpassword -s server1 -
port 1521  - SID orcl
```

Use a Configuration File

You can specify many cmdb_update_ambiguity parameters in a configuration file. You can use the configuration file to secure parameter settings in an encrypted form using operating system tools. The valid keywords and the corresponding command-line options are listed in the parameter table.

Note: If you specify a parameter both on the command line and in a configuration file, the command-line value overrides the configuration file value.

Example: Use a configuration file to specify the parameters for a Microsoft SQL Server database

The following command runs the configuration file ambiguity_mssql.cfg.

```
cmdb_update_ambiguity  - m all -c ambiguity_mssql.cfg
```

Configuration File Format

Configuration file options are specified as *keyword=value*. On Windows, the directory separator can be a double backslash (\\) or a single forward slash (/). The path name must not be enclosed in double quotation marks ("").

The valid keywords and the corresponding command-line options are listed in the parameter table.

Note: A hash mark (#) in column 1 starts a comment line.

Example: Microsoft SQL Server configuration settings

```
#Sample configuration file for Microsoft SQL Server
DBType=MSSQL
DBUser=servicedesk
DBPassword=dbpassword
DBHost=dbserver1
LogLocation=C:\\Program Files\\CA\\Service Desk Manager\\log
LogLevel=ERROR
SchemaName=dbo
```

Example: Oracle configuration settings

```
#Sample configuration file for Oracle
DBType=Oracle
DBUser=mdbadmin
DBPassword=dbpassword
DBHost=dbserver1
LogLocation=/tmp/ambiguity/log
LogLevel=INFO
DBPort=1521
DBSID=orcl
SchemaName=mdbadmin
```

cmdb_update_ambiguity Parameters

You can specify parameters on the command line or in a configuration file (some parameters are command-line only). On the command line, use quotation marks ("") to enclose any path name with spaces. In the configuration file, do not use quotation marks. If any parameter is specified on the command line and in the configuration file, the command-line value overrides the configuration file value.

The cmdb_update_ambiguity command takes the following parameters:

Option	Configuration File Keyword	Values	Notes
-m	(none)	twa, ci, all	(Required) Command line only twa = compute ambiguity on TWA only. ci = compute ambiguity for CIs only. all = compute ambiguity for CIs and TWA.
-d	DBType	MSSQL or Oracle	(Required. Windows only.) Database type. On Linux/UNIX, only Oracle is supported and this option is not needed.
-u	DBUser	<db user name>	

			(Required) Database user name. A user name with spaces must be enclosed in double quotation marks (for example: -u "sys as sysdba"). The quotation marks are not required in the configuration file.
-p	DBPassword	<db password>	(Required) Password for database user. A password with spaces must be enclosed in double quotation marks (for example: -p "secret code"). The quotation marks are not required in the configuration file.
-c	(none)	<configuration file>	(Optional) Command line only The full pathname of the configuration file. The pathname must be enclosed in double quotes if there is a space in the pathname.
-log	LogLocation	<directory to place log file>	(Optional) Log file directory. The Default is the NX_ROOT\log directory.
-level	LogLevel	INFO, ERROR, DEBUG	(Optional) Level of detail to write to the log file. Default value is ERROR.
-s	DBHost	<server name>	(Required) Database server host name. To use a Microsoft SQL Server named instance, specify *server**instance* on the command line, or *server**instance* in the configuration file.
-CI	CI	<CI uuid>	(Optional) Compute ambiguity for the specified CI and all CIs that are ambiguous with it.
-full	(none)	0,1	(Optional) Command line only Optimizes the performance of the scan by only considering those CIs updated since the last time the utility was run. If set to 1, forces a full scan of all CIs in the computation of the ambiguity index. The default is 0. This parameter does not apply to the calculation of transaction ambiguity. The utility always evaluates all transactions in the TWA.
-port	DBPort	<port number>	(Required. Oracle only) Oracle port number
-SID	DBSID	<SID name>	(Required. Oracle only) Oracle SID name
-h	(none)		(Optional) Prints help usage message.
-schema	SchemaName	<db schema name>	(Optional) Default is mdbadmin for Oracle; or dbo for Microsoft SQL Server.

Resolve Ambiguous CIs

After you identify ambiguous CIs and determine if their identifying attributes are valid, resolve the ambiguity among the CIs in the ambiguity set. Use one or more of the following ways:

- **Modify the identifying attributes**
  If the identifying attributes are not complete or invalid, set the CI identifying attributes so that the CI is unique. Use either the Web interface, GRLoader, or CMDBf.

  Note: When the MDR updates the CI, the MDR can undo the manual reconciliation changes.

- **Exclude a CI from ambiguity management**
  If the CIs identifying characteristics are correct and represent a known, valid ambiguity, remove the CI from the ambiguity management lists and the ambiguity calculation of other CIs. You can mark the CI as not ambiguous (exclude ambiguity).

- **Reject a CI Update by inactivating the CI**
  When you determine that the identifying attributes of a CI are incorrect and that updates using those attributes cause data corruption, you can inactivate the CI and prevent further updates. The user or MDR generating the information receives an error and the entire transaction is rejected.

- **Supersede a CI**
  Sometimes the updates to the CMDB are beyond the control of the administrator. Invalid identifying data must be in the system with valid nonidentifying attribute data. The incoming transaction attribute data can be transparently redirected to a superseding CI.

  Note: The transparent redirection of attribute data from one CI to another can cause confusion. This is because transaction data may not be stored in the same CI as the transactions identifying attributes would lead you to believe. Use this method with discretion, when the previous methods cannot be used.

Exclude CIs from Ambiguity Management

Sometimes you recognize that although a particular CI receives an ambiguity index greater than zero, it must be left as is. Any CI with its Exclude Ambiguity check box selected is not considered part of the ambiguity index or ambiguity management features.

Exclude Ambiguity for a CI

You can update the exclude ambiguity option for a CI from the web interface.

Follow these steps:

1. Select the CI that you want to remove from ambiguity management from the Ambiguous CI List page.
   The Configuration Item Detail page appears.

2. Click Edit.
   The Update Configuration Item page appears.

3. Select the Exclude Ambiguity check box on the Reconciliation tab, and click Save.
   The CI is excluded from the ambiguity index calculation and other ambiguity management features.

Exclude Ambiguity Using GRLoader

You can update the exclude ambiguity option for a CI by using GRLoader to set the not_ambiguous flag.

not_ambiguous values are as follows:

- **YES (1)**
  Removes the CI from ambiguity management. The CI is identified as unique regardless of the identifying attributes of other CIs. The ambiguity index of the CI remains zero.

- **NO (0) (default)**
  This CI is eligible for ambiguity management. The uniqueness of the CIs identifying attributes determines the ambiguity index of this CI. The identifying attributes of this CI are considered when evaluating the ambiguity index of other CIs.

Note: For more information about GR Loader, see the *CMDB Technical Reference* (see page 4168).

Reject Updates

When a CI is marked as Inactive, no updates can be performed on it. Set the CI to Inactive if you want CA CMDB to reject data for a given CI and you want the MDR to know of the rejection.

In this way, you can reject problematic data immediately and can reflect it back to the source. The MDR can correct the rejected input at the source.

To set a CI to Inactive in the web interface, edit the CI, set it to Inactive, and click Save. You also can set a CI to Inactive by using GRLoader or CMDBf web services. Inactivated CIs can also be reactivated.

Supersede Ambiguous CIs

You can supersede an ambiguous CI to redirect data to a specific target CI. You can display superseded CIs, which are Inactive and all web interface updates to them are ignored.

Note: Updates that are sent to superseded CIs by GRLoader or CMDBf web services are redirected to the superseding CI. However, updates to identifying attributes are ignored.

Follow these steps:

1. Select the CI that you want to be the focal (superseding) CI from the Ambiguous CI List page.
   The Configuration Item Detail page appears.

2. Click Edit.
   The Update Configuration Item page appears.

3. Click the Reconciliation tab.
   All CIs that are ambiguous with the focal CI display.
   Determine which CIs you want to supersede by the focal CI. Inspect each CI in the list by clicking each CI to launch its Configuration Item Detail page.

4. Select one or more ambiguous CIs that you want to supersede with the focal CI and click Supersede.
   The focal CI supersedes the selected CIs.

MDR-Based Reconciliation

This article contains the following topics:

MDR-based reconciliation is performed at the management data repository. This helps reduce the occurrence of multiple CIs that refer to the same object in the physical world.

MDR-based reconciliation treats the MDR as a trusted source that always uses the same federated asset ID when it communicates information about a single CI. All updates from a given MDR to a given federated asset ID always update the same CI, even when identifying attributes are changed.

MDR-based reconciliation, reconciliation management, and the Transaction Work Area (TWA) described in these sections help you take control of the reconciliation process. However, to use reconciliation management and the TWA successfully, first understand how CA SDM uses reconciliation attributes.

Important: If you reinstall or reinitialize any external data provider, inactivate and reactivate its MDR definition in the CMDB. If the MDR reuses its federated asset IDs, inadvertent CI data overlay can occur.

How MDR Reconciliation Matches CIs

MDR-based reconciliation uses the following process to identify the appropriate matching CI:

1. If the transaction specifies an ID, the CI is identified and reconciliation is complete.

2. If the transaction does not specify an ID, CA SDM checks whether federated identification attributes are specified and match a CI. If there is a match, the transaction reconciles to the matching CI.

3. If the transaction does not specify an ID or federated identifying attributes, the CI transaction uses the identification attributes (see page 2566).

How MDR Reconciliation Identifies CIs

MDR-based reconciliation uses the following precedence to identify a CI:

1. ID (if a transaction specifies an ID, reconciliation is successful)
2. Federated identification attributes
   - Federated asset ID
   - MDR name
   - MDR class
3. CI identifying attributes
   - Tenant (if multi-tenancy is installed)
   - Name
   - Serial number
   - MAC address
   - System name
   - Alternate asset ID
   - DNS name

Review and Modify Inbound Data Using Transaction Work Area (TWA)

You can stage CI and relationship transactions before execution, by copying data into the TWA staging area. Once in the staging area, you can manipulate CIs and relationships by using the web interface or native SQL.

You also can validate the CI transactions to prevent the creation of new CIs when you update existing CIs. In this approach, you view each transaction and the potential CIs that it can update. This helps you reconcile the transaction manually to the target CI. Likewise, relationship transactions can be validated to reference the correct CIs.

For more information, see How to Identify and Resolve Ambiguous CIs (see page 2557).

CI Transaction Ambiguity Example

Transaction data from different data sources is loaded into CMDB. Each data source uses its own subset of identifying characteristics and may not fully identify the target CIs for the transactions. Because of this inconsistency, more CI Transactions may exist in CMDB than are valid.

Example: Ambiguous CI Transactions

The following CI transaction resides in the TWA:

- Name(Server1) DNS Name(dns1), Serial Number(serial1)

The following CIs reside in CMDB:

- Name(Server2) DNS Name(dns1)
- Name(Server3) DNS Name(dns1), Serial Number(serial1)
- Name(Server4) MAC Address(mac1), Serial Number(serial1)

Due to shared identifying characteristics, Server1 transaction is ambiguous with Server2, Server3, and Server4 in CMDB.

Every CI Transaction has an ambiguity index that is associated with it. The ambiguity index is approximately the number of existing CIs that match on any of the identifying attributes, minus one, specified in the CI transaction. The greater the index, the greater the number of other CIs that match on the transaction identifiers. Therefore the greater the probability that CI data was entered inconsistently and the possibility that more CIs are incorrectly created. CI Transactions with an ambiguity index of zero have identifying attributes that are unique across all CIs. Or, they have a target CI specified and are therefore unambiguous.

Example: Calculate the Ambiguity Index

The following CI transactions reside in the TWA:

- Name(Server1) DNS Name(dns1), Serial Number(serial1)
- Name(Server2) DNS Name(dns1), Serial Number(serial1)

The following CIs reside in CMDB:

- Name(Server1) DNS Name(dns1), Serial Number(serial1)
- Name(Server2) DNS Name(dns1), Serial Number(serial1), Mac Address(mac1)

The first transaction (Server1) ambiguity is 0 because there is an exact match with the Server1 CIs identifying attributes. The only possible target CI to this transaction is Server1 CI.

The second transaction (Server2) is ambiguous with Server1 CI and Server2 CI.

The ambiguity index for Server2 transaction consists of the following components:

- Number of matching CIs with Name (Server2) = 1
- Number of matching CIs with DNS Name(dns1) = 2
- Number of matching CIs with Serial Number (serial1) = 2

Based on shared CI identifying characteristics, the ambiguity index for server2 transaction is (1-1) + (2-1) + (2-1) = 2.

CI Properties that Support MDR Federation

This article contains the following topics:

Configuration item properties (attributes) identify assets for MDR federation purposes.

Federated Asset ID

People are known to different organizations by different identifiers. You may have the following identifiers:

- A unique nickname to your close friends
- Driver license (unique ID associated with you)
- A national service ID (for example, a selective service card)
- A health insurance number
- A national tax identification number

Each of these unique identifiers refers to you. However, the identifier is only valid when used to describe you to the appropriate repository.

Similarly, a CI can have multiple identifiers to associate it with its source MDRs. Each CI is known to an MDR by only a single identifier. We call this identifier the *federated asset ID*. The process of associating a CI with one or more MDRs is *mapping the CI*.

Mapping occurs when CIs are loaded into the MDB in one of two ways:

- Defining the CI mapping using the Administration user interface
- Loading CIs using the GRLoader utility

MDR Name and Class

The MDR name identifies the MDR to CMDB when exporting data using XML and GRLoader. The MDR typically has its own naming convention for how it identifies itself: a combination of host server name plus an identifying instance name or number. Because only one MDR exists on a particular host, the MDR name is often set to the host server name. **Required for CMDBf Viewer.**

Note: The MDR Name for CA Asset Portfolio Management release 11.3.4 is APM and the MDR Name for CA APM r12.6 is ITAM. Both products are supported. However, we recommend that you verify product availability at CA Support Online (http://support.ca.com/) before implementing the products

The customer defines the MDR class to group MDRs.

Note: An MDR Class of CMDBf is required for CMDBf viewing.

Important! The MDR Name plus the MDR Class must be unique within your enterprise.

MDR Definition with CA Configuration Automation Installation

CA Configuration Automation MDRs have the following requirements:

- The mdr_name specified in the MDR definition on the CMDB server must match exactly the value of the attribute com.cendura.installation.name in the cendura.properties file on the target CA Configuration Automation server.
- CA Configuration Automation MDRs must have an MDR class of Cohesion.
- The MDR must specify the hostname and port number of the CA Configuration Automation server.

To run MDR Launcher, edit the following portion of the cendura.properties file:

```
# -- Configure One-Click Authentication --
com.cendura.security.oneclickauth.secret=shared_secret
com.cendura.security.oneclickauth.scheme=
com.cendura.security.oneclickauth.user=userid
```

Important! The secret that is specified in the cendura.properties file must match the *shared secret* in the MDR definition.

The MDR Launcher logs in as the *userid* specified in the properties file and inherits its security attributes. To use functionality such as Refresh for CI attributes, verify that this user has sufficient privileges. For more information about creating a user, setting security options, and modifying the properties file, see the *CA Configuration Automation Implementation documentation.*

CA Configuration Automation MDRs

This article contains the following topics:

- MDR Definition Administration (see page 2572)
- CA Configuration Automation Report (see page 2573)

CA Configuration Automation MDRs must be defined before importing data from a CA Configuration Automation server. A CA Configuration Automation MDR must specify an MDR Class of Cohesion.

Example: Cohesion1 MDR Definition

In the following Cohesion1 MDR definition, the XML specifies an MDR Name of cohesion_server and an MDR Class of Cohesion. These values are required for the CIs to be imported.

- **Button Name**
  Cohesion1
- **MDR Name**
  cohesion_server
- **MDR Class**
  Cohesion
- **Active?**
  Active
- **Owner**
  CMDBAdmin
- **Description**
  CA Configuration Automation server in Chicago
- **Hostname**
  cohesion_server
- **Port**
  8090
- **Path**
  CAisd/html/cmdb_cohesion.html
- **Parameters**
  hostname={hostname}+port={port}+family={family}+name={name}+secret={password}
  +federated_asset_id={federated_asset_id}
- **userid**
  cohesion_userid
- **Shared Secret**
  Chicago01
- **URL to launch in Context**
  http://cmdb_hostname:8080/{path}?{parameters}

In addition, because this is a Cendura server, the values that are listed previously must match the values in the cendura.properties file on that server. See the following example:

```
com.cendura.security.oneclickauth.secret=Chicago01
com.cendura.installation.name=cohesion_server
```

You can modify the URL syntax to handle special requirements.

How to Associate an MDR to a CI Manually

You can associate MDRs with a CI manually. Use the Federated CI Mapping facility in the CMDB Administration tab, in the MDR Management branch of the tree.

Before you associate a CI to an MDR, complete the following tasks:

1. Create the MDR definition (if it does not exist).
2. Create the CI definition (if it does not exist).
3. Identify the unique Federated Asset ID of the CI that you want to connect to the MDR. This ID is MDR-specific, so it is beyond the scope of this document.

Note: To identify Federated Asset ID, consult your MDR documentation.

CA Cohesion Automatic Import

You can import CIs directly from CA Configuration Automation. Run a CA Configuration Automation report specifying the host name, port, user ID, and password to a CMDB server. If the MDR is defined in CMDB, CA Configuration Automation automatically generates the XML. The XML includes CIs and relationships, with the information necessary to perform the MDR Launch on a CI. The report automatically imports the CIs into CMDB. For more information about exporting CIs from CA Configuration Automation, see the online help from the Reports, Report Templates tab.

CI to MDR Mapping

Because each MDR uses a federated_asset_id to identify a CI, one CI can be related to multiple MDRs. A federated_asset_id does not have to be unique across MDRs, but a federated_asset_id must be unique within an MDR. Each MDR must have a unique MDR class and MDR name.

Important: Whenever a CI or an MDR provider is made Inactive, all Federated CI Mappings that are associated with the CI or the MDR provider are also made Inactive.

After you create an MDR Data Provider definition, complete the following tasks:

1. Create a CI in the CMDB that references an MDR.
2. Verify that the MDR definition works.
   Because you can only launch from within the context of a CI, it is not possible to test directly from the MDR definition, which has no CI context.

You can view the Federated CI Mapping List in the Administration tab, in the Federated CI Mapping node.

To view the CI in a particular MDR context, click an MDR Launch button.

The target MDR is launched in the context of the CI that was opened.

Example: CI Mapping

1. Click the Administration tab.

2. Navigate to MDR Management, Federated CI Mapping.
   The Federated CI Mapping List appears.

3. Enter server1 in the CI Name field.
   The following columns show the values:

   - **Federated Asset ID**
     1000234
     1000235

   - **CI Name**
     server1
     server1

   - **MDR Provider**
     Cohesion1
     Cohesion2

   - **Active**
     Active
     Active

   The Cohesion1 MDR Provider and the Cohesion2 MDR Provider know the existence of server1. The example shows that they each have independently assigned the server a unique ID.

4. Click the CI Name server1.
   The server1 Configuration Item Detail page appears that includes launch buttons would be named Cohesion1 and Cohesion2.

5. Click either MDR Provider launch button.
   More details about the CI appear.

MDR Definition Administration

Administering the MDR definitions is a flexible process. You can modify the parameters in an MDR definition even when CIs reference it. For example, you can modify the button name, host name, user ID, and shared secret, after the MDR is defined and the CIs are loaded.

CA Configuration Automation Report

CA Configuration Automation provides a facility for scheduling recurring reports. Use this facility to simplify the process of keeping the CMDB synchronized with the data in the CA Configuration Automation MDR. Common errors such as an invalid password (due to password change or expiration) can prevent successful importing of data. You can choose to receive notification of any errors that occur during background data execution of the data import. Enable the Notification option in the CMDB Export report in CA Configuration Automation. You will receive an email when an import error occurs. If you run the Cohesion report in the background as a scheduled task, we recommend that you enable the Notification option. For information about scheduling execution of the CMDB Export report regularly, see the *CA Configuration Automation Product Documentation*.

How to Deploy CMDBf Web Services

After you install CA SDM, you can deploy CMDBf web services.

Follow these steps:

1. Verify that the web server is up and running.
2. Navigate to the CMDBHOME\sdk\websvc\CMDBF directory.
3. Run deploy_cmdbws.bat.
   The CMDBf web services are deployed and started. For more information about CMDBf web services deployment, see the Web Services Deployment (see page 4362) topic.

Using GRLoader

When using GRLoader to load a CI, populate the following fields in the XML for the MDR Launch to operate:

- <mdr_class>
- <mdr_name>
- <federated_asset_id>

The values that you provide for <mdr_name> and <mdr_class> in the XML must match the values in the MDR definition exactly.

Important! The MDR name and class must be defined using the Administration interface before importing the CIs that reference the MDR. If the MDR specified in the XML is not defined, the CI is not imported.

The GRLoader supports importing CIs and CI relationships from spreadsheets in the XLS and XLSX formats. To load CI data into CA SDM, format the source data into XML or Microsoft Excel spreadsheets. For more information about using GRLoader to load spreadsheet data, see the How to Prepare for Loading Spreadsheet Data (see page 4323) topic.

system_name Naming Convention

We recommend the following naming standards for software CIs and all MDRs. These naming standards facilitate the integration of MDRs with CA Configuration Automation and other MDRs. The standards are also helpful for reconciling CIs properly. CA Configuration Automation follows the same standards.

- **System_name**
  Identifies software CIs uniquely. When you define a relationship that involves a software CI, specify the same system_name as the one in that CI definition. If multiple instances of the same version of a software are installed on the same hostname, modify the system_name. Modifying the system_name enforces uniqueness. The total length of the system_name must not exceed 255 characters. If you ignore this restriction, data corruption can occur.
  System_name must be a unique identifier for this instance of the software on a single host.

Use the following syntax:

```
hostname | softwarename | version | business-application
```

- **pipe (|) character**
  Separates the various fields in the concatenation of the syntax to let the user use the search facility.

- ***hostname***
  Specifies the hostname that contains the software.

- ***softwarename***
  Specifies a common name for the software.

- ***version***
  Specifies the version number of the software if available.

- ***business-application***
  Specifies a unique identifier for this instance of the software on *hostname.* If the instance is associated with a business application or service, the name of that service is the qualifier. When you cannot determine *business-application*, you can use the installation directory to identify the software. If the total length of this field exceeds 255 characters, use ellipses (…) to shorten the total length of this field.

Examples: Use the UI Search Facility

You can use the UI search facility to search software CIs, as in the following examples:

Use case	Name	System_name
Find all software CIs on host	xxx	Xxx%

Use case	Name	System_name
Find all instances of software	yyy	yyy%
Find all instances of software	yyy version 123.0	yyy% %|%|123.0%

In the results list that the search returns, the user sees only the Name field.

```
mac_address     Null.  - Inappropriate for software
asset_num       Null   - Inappropriate for software
serial_number   Null   - Inappropriate for software
dns_name        Null   - Inappropriate for software
```

How to Update Metadata Files for CMDBf Mapping

This article contains the following topics:

Use CA CMDB metadata files to translate between MDR attribute names and CMDB attribute names. Using CMDB metadata files improves readability of attribute comparisons. For any MDR attribute without CMDB mapping, the Federated View displays the attribute name. The attribute name is sent by the MDR. Metadata can be defined for CMDBf data providers to do the following tasks:

- Display MDR attribute values using CMDB attribute names.
- Prevent MDR provider attributes from being displayed in Federated View.
- Define MDR provider attributes that do not have CMDB equivalents.

You define metadata using the cmdb_metadata_federation_viewer_site_attr.htmpl file. This file contains instructions on how to update the file. Metadata can apply to all CMDB families (common attributes) or family-specific attributes.

To map external MDR attribute names to CMDB labels, you update the respective cmdb_metadata_*extensiontable*.htmpl form. Use the following fields in the cmdbmetadata macro:

- mdr_attr - the name of the MDR attribute to be translated.
- mdr_name - the name of the MDR being translated. Regular expressions are supported.

Example: Attribute mapping

The code in this example defines metadata that equates the CMDB "phys_mem" attribute with the provider attribute "mdr_memory" for all providers named "myMdr" or starting with "MDR". In addition, "physical_memory" is equated to with "phys_mem" for all other providers.

```
<macro name=cmdbMetadata attr="phys_mem"  provider_attr="mdr_memory" provider_name="
myMdr">
<macro name=cmdbMetadata attr="phys_mem"  provider_attr="mdr_memory"
provider_name_regexp="MDR.*">
```

```
<macro name=cmdbMetadata attr="phys_mem" provider_attr="physical_memory"
provider_name_regexp=".*">
```

Example: Attribute hiding

The following statement hides the MDR provider "widget_cost" attribute for all providers named "myMdr".

<macro name=cmdbMetadata hide_provider_attr="YES" provider_attr="widget_cost" provider_name="myMdr">

Example: Setting an attribute label

The following statement defines an attribute name “ext_mem_capacity” using the label “External Memory Capacity” under the attributes category in the CMDBf Viewer.

```
<macro name=cmdbMetadata  attr="ext_mem_capacity" category="Attributes" heading="
External Memory Capacity" help="Total external memory">
```

How To Display MDR Attribute Values With CA CMDB Attribute Names

Metadata can create an association between MDR provider attributes and CMDB attributes. The association helps to display the attributes together to see differences and share labels. By default, MDR attributes that do not have a mapping are displayed as **Not in CMDB** in the viewer. cmdbMetadata macro arguments to equate a CMDB attribute with an MDR provider attribute include:

- attr - CMDB attribute name
- provider_attr - MDR provider attribute name
- provider_name - MDR provider name
- provider_name_regexp - MDR provider name regular expression

provider_name or provider_name_regexp are required.

Example: Associate MDR Attributes with CMDB Attribute Names

The following three metadata statements do these respective actions:

- Equate the CMDB "phys_mem" attribute with the provider attribute "mdr_memory" for all providers named "myMdr".
- Equate the CMDB "phys_mem" attribute with the provider attribute "mdr_memory" for all provider names starting with "MDR".
- Equate "physical_memory" with "phys_mem" for all other providers.

```
<macro name=cmdbMetadata attr="phys_mem"  provider_attr="mdr_memory" provider_name="
myMdr">
<macro name=cmdbMetadata attr="phys_mem"  provider_attr="mdr_memory"
provider_name_regexp="MDR.*">
```

```
<macro name=cmdbMetadata attr="phys_mem"  provider_attr="physical_memory"
provider_name_regexp=".*">
```

Hide MDR Provider Attributes

Some MDR provider attributes do not need to appear in the Federated View. You can hide metadata for a particular MDR provider. This option only applies for MDR provider attributes and does not apply for CMDB attributes.

cmdbMetadata macro arguments to hide a provider attribute include:

- hide_provider_attr - "YES" - hides the MDR provider attribute
- provider_attr - MDR provider attribute name
- provider_name - MDR provider name
- provider_name_regexp - MDR provider name regular expression

provider_name or provider_name_regexp are required.

Example: Hide an MDR-Only Attribute

To hide the MDR provider *widget_cost* attribute for all providers that are named *myMdr,* use the following metadata statement:

```
<macro name=cmdbMetadata  hide_provider_attr="YES" provider_attr="widget_cost"
provider_name="myMdr">
```

Define MDR Attributes Without CA CMDB Equivalents

You can define labels and help text for MDR provider attributes that do not correspond with any CMDB attributes. Attributes are labeled Not in Family in the Federated View.

cmdbMetadata macro arguments to define an MDR provider attribute include:

- attr - CMDB attribute name
- category - Category name where attribute is displayed
- heading - Heading label for attribute
- help - Brief description of the attribute

Example: Define an MDR-Only Attribute

The following statement defines an attribute name "ext_mem_capacity" using the label "External Memory Capacity" under the Attributes category in the Federated View .

```
<macro name=cmdbMetadata  attr="ext_mem_capacity" category="Attributes" heading="
External Memory Capacity" help="Total external memory">
```

Define CMDBf Data Provider Metadata

You can control how data is displayed in the Federated View.

To define metadata for CMDBf Viewer

1. To open the cmdb_metadata_federation_viewer_site_attr.htmpl file, use Web Screen Painter.
2. Determine which metadata changes are needed.

   Note: Sample templates are provided in the file.

3. Copy the appropriate template and substitute the required arguments according to the instructions in the file.
4. Save and publish the changes.

CMDB Management

Contents

Depending on your role, CMDB lets you manage configuration items and their relationships:

- The Configuration Administrator (CMDB Administrator) manages the tools in your CMDB, such as change verification. In addition to CI management, Configuration Administrator role includes administration of CI classes, CI families, and relationship types.
- The Configuration Manager plans and audits the type of information to store in the CMDB.
- The Configuration Analyst enters data into the CMDB by using approved methods and checks the accuracy of the data.
- The Change Manager helps ensure that users complete the following tasks:
  - Document the requests for change correctly.
  - Review the requests for change.
  - Execute the changes according to environment rules. The environment rules include priority, completeness, compliance, and signoffs.

Note: The Change Manager is not responsible for the CMDB, but servers as a major customer of the CMDB.

Create a CI from a Base Object

A CA CMDB installation can define CIs for *base objects*: Contacts, Locations, and Organizations. These CIs can be managed so, and they can establish relationships with other CIs as desired. For some customers, this approach supports the configuration management process better than employing base objects only as CI attributes.

Note: You cannot select a contact that is already represented by another CI in the Contact family.

The Scoreboard lets you create a configuration item from a base object.

Follow these steps:

1. Click File, New Configuration Item.
   The Create New Configuration Item page appears.

2. Complete the CI fields. Name and Class are required. Click Continue.

   Note: The common CI attributes Host Name, Serial Number, MAC Address, and DNS Name are not relevant to a CI for a base object.

   The Create New Configuration Item page appears.

3. Click the base object link to define the object that this CI represents.

4. Select the object. You can search for an existing object or click Create New to create an object. If you want to create an object, click Save to continue.
   The selected object appears at the top of the Configuration Item Detail page.

5. Click Save.
   The main attributes of the selected object appear on the Attributes tab of the Configuration Item Detail page.

Create a Base Object CI Using GRLoader

You can use GRLoader to create a base object CI from an existing base object.

Follow these steps:

1. Write XML that identifies the following parameters:

- CI name
- Family
- Class

2. Submit the XML.
   The base object is created and the GRLoader displays that one CI was read and inserted.

Example: Create a CI From an Existing Contact

The following example creates a CI from the existing contact **Gibbs, Keith**.

```
<GRLoader>
<ci>
    <name>Gibbs, Keith</name>
    <family>Contact</family>
    <class>Technical</class>
    <base_contact>Gibbs, Keith</base_contact>
</ci>
</GRLoader>
```

How to View a Federated CI

The Federated View page displays parallel CI attribute values from CMDB and CMDBf-registered MDRs. If no external MDRs are configured for CMDBf, only the CMDB attributes are displayed.

To update the fields from an MDR, click Retrieve.

Legend:

bold - Attribute value differences between CMDB and MDRs.

Not in Family - MDR-only attribute customized to display in a CMDB category.

Not in CMDB - Category for MDR-only attributes.

Note: To customize the way MDR attributes are displayed, see MDR documentation.

Note: To display federated CI attributes, the MDR class must be **cmdbf**.

Populating CMDB

This article contains the following topics:

Database Population

Populating the CMDB with the CIs and relationships in your IT infrastructure is a part of using the application efficiently. You can populate the CMDB with data manually by:

- Using the built-in Configuration Item Editor
- Using GRLoader
- Importing items from other asset management tools.

How GRLoader Populates the Database

T populate the database by loading CIs and relationships, complete the following tasks:

1. Convert input data containing information about CIs and their relationships to XML or in a spreadsheet.
2. The CA CMDB GRLoader program uses the XML data as input.
3. GRLoader loads the data into the database.For information about GRLoader parameters, see the GRLoader Command (see page 4289) topic.

Use GRLoader to Import the Data

Import data by using the GRLoader program that is provided with CA SDM. The program creates CIs based on the data in an XML file or a Microsoft Excel spreadsheet.

Follow these steps:

1. From the Start menu, select Run.
2. Enter **cmd**.
   A DOS command window appears.
   Enter the following command:

   ```
   Grloader -u <username> -p <password> -s http://<ca_sdm_servername>:8080
   -i <xml_document or spreadsheet>
   ```

   GRLoader creates CIs using the data in the XML file. If errors are found during this process, an error file is created. The error file lists the CIs that could not be imported and the reason. GRLoader import completes.
3. Start CA SDM and verify that the CI data has been correctly populated.
4. To verify that relationship data has been populated correctly, start the CMDB Visualizer.
   The data is imported and verified. For more information about GRLoader, see the General Resource Loader (see page 4289) topic.

Family and Class Assignments

Apply a classification scheme to each CI; this scheme involves assigning each CI the following attributes:

- Family -- A collection of configuration items having similar attributes
- Class -- A subset of configuration items within a family

You can create assignments in the following ways:

- Populate manufacturer data identifying family and class for each hardware asset.
- Include nonblank values for family and class in the respective columns in the input file.

GRLoader does not import an CI that cannot resolve family and class to an existing family and class.

How to Load CA APM Data

The primary input to the CA APM Loader program is a table or view that contains an extract of the CA APM import data. This data is contained in the CMDB_Export_Asset_Data database table or view. In some cases, the import data into the MDB is located in the same database as the target. However, in many circumstances, the import data resides in a different database, for example, when importing data across subsidiaries. In either case, create a view on the same database as the source data.

The CA APM data view does not contain the class and family attributes, and can come from a system with a different classification scheme. For example, if the source of the asset data is a different company, a different classification system can be in effect.

The CA_MODEL_DEF table contains a list of models, which are matched against the data in CMDB_Export_Asset_Data. If there is a match, the family and class from the model are assigned to the asset being imported. If there is no match, define a new model for the asset. Consider either copying entries from the source CA_MODEL_DEF table to the target MDB, or updating the CA_MODEL_DEF table with entries for all new hardware makes and model numbers.

CMDB Visualizer Overview

CA SDM lets you align your IT components (*configuration items*, or CIs) with your business services. CMDB defines *relationships* among CIs, as when a group of CIs work to provide a business service. CMDB Visualizer lets you see the entire picture of your CI relationships, and provides functions to manage the relationships. Working from a *focus CI*, you can use the Visualizer to display up to nine levels of related CIs.

(If you are using Advanced Availability configuration) If the visualizer makes a server request during the application server quiesce period, the following message is displayed:

You can hide the message box but the message is displayed on the top panel throughout the quiescing period. If the server quiescing is canceled, you receive a message about the cancellation.

```
This CMDB Visualizer server is scheduled to shut down for maintenance in xx:xx.
Please save your work and logout.
```

CA uses a provider/dependent model to define relationships among CIs. All CIs that contribute to a business service are *providers* to that business service (the *dependent*). In much the same way, providers can also be *dependents* that rely on other CIs. You can use Visualizer to perform the following provider/dependent analyses:

- **Browse**
  Displays unfiltered view of all CIs.
- **Impact Analysis**
  Starts with a focal CI (provider) and searches for its dependents.
- **Root Cause**
  Starts with a business service (dependent) and view all the CIs that are providers to that service.
- **Cause and Effect CIs**
  Combines impact analysis and root cause in one search.
- **Trace Relation**
  Displays all possible relationships that are based on levels. If you select only one CI, this filter displays the Browse view.
- **Shortest Path**
  Displays the shortest chain of relationships that are based on levels.

CMDB Visualizer lets you do the following actions:

- Visualize multiple levels of CIs from a configurable graphical view
- Monitor or cancel rendering progress
- Search using flexible criteria
- Filter based on CI families, relationship types, and other attributes
- Display CI relationships
- Trace a relationship between two CIs
- Visualize a dependency chain
- Invoke CMDB directly from Visualizer
- Display CI attributes and properties
- Save graph metadata
- Print the graph layout
- Find a specific CI on a displayed graph
- Create a CI (depending on role)

- Create new CI relationships (depending on role)
- Use the Scratchpad to store key CIs
- Display CI status
- Hide or reveal a CI in the Visualizer layout
- Role-based data security
- Launch external MDRs
- Obtain online help for Visualizer features

How To Use the Visualizer Interface

This article contains the following topics:

CA CMDB Visualizer provides a graphical interface with toolbars and a graphical canvas. You can click the button on the left side of the canvas to display the retractable Search pane.

Graphical Display Tasks

With the Visualizer graphical display, you can display the CIs and relationships that you select for analysis. You can also do the following tasks:

Note: Visualizer uses the space bar to select or confirm an operation. For example, if the focus is on a button, then instead of pressing Enter, press the space bar.

- Create, manage, and apply analysis filters.
- Change the graph layout and number of CI levels displayed.
- Select CIs for graphical viewing and right-click to provide various functions, including the ability to view and modify CI properties.
- Use the Toolbar icons to provide various functions.
- Zoom in to view areas of interest, or zoom out to see the larger context.

- Use Full Screen Mode display a larger work area.

> **Note:** When you enable Full Screen mode, you cannot use the keyboard functionality.

Search for CIs by Attributes

You can search for CI (and asset) attributes to locate and manage CIs.

> **Note:** If you only search for CIs, you can disable the Asset search. To disable the Asset search, clear the CA APM check box on the Visualizer administrative interface.

Follow these steps:

1. Open the retractable Search pane on the left side of the Visualizer graph.
2. Click the Search tab.
3. Expand the sets of search criteria that you want.
4. Complete one or more of the attribute fields on the search criteria areas.
   The search criteria is specified.

   > **Note:** Visualizer searches for both CIs and Assets by default. To restrict the search, change the CI or Asset general options.

5. Click Search.
   The Search Results tab displays all CIs/Assets that match your search criteria.

Primary

Primary fields focus your search that is based on the following basic CI attributes:

- CI Family
- CI Class
- CI Status
- Location
- Organization
- Department

- Asset
- CI

Network

Network fields search on the following common CI attributes for network addressing:

- IP Address
- DNS Name
- Host Name
- MAC Address

Asset

Asset fields search on the following basic CI/asset attributes:

- Manufacturer
- Model
- Serial Number
- Cost Center
- License
- Product Version

Maintenance

Maintenance fields provide searching on CI attributes for the following maintenance tasks:

- Service type
- Responsible Vendor
- Responsible Organization
- Maintenance Vendor
- Maintenance Organization
- Acquire Date
- Installation Date
- Expiration Date
- Warranty Start Date
- Warranty End Date

Filters and Layouts in Visualizer

This article contains the following topics:

Create a Filter

CA CMDB Visualizer provides built-in analysis filters, and you can create filters for your business needs.

Follow these steps:

1. Click the New Filter button.
   The Filter Wizard launches.

2. Name the filter and select one of the following filter types:

   - **Browse**
     Displays the unfiltered display of all related CIs.

   - **Impact Analysis**
     With the focal CI as provider, shows the CIs that are affected when any change occurs to the focal CI.

   - **Root Cause**
     With the focal CI as dependent, shows the CIs that could be the root cause for the focal CI to go down or can affect the focal CI's behavior.

   - **Cause and Effect CIs**
     Combination of Root Cause and Impact Analysis. From the focal CI, shows all the CIs that could be the root cause. Or shows the CIs that could be affected when a change occurs to the focal CI.

   - **Trace Relation**
     Displays all possible relationships among focal CIs, based on the Levels setting. If the graph has only one focal CI, applying this filter displays only the focal CI.

   - **Shortest Path**
     Displays the shortest chain of relationships among focal CIs, based on the Levels setting. If the graph has only one focal CI, applying this filter displays only the focal CI.

> **Note:** In addition to the predefined filters, any available administrator-defined and user-defined filters display.

3. Click Save & Finish.
   The filter is created.

Visualizer Filters

CA CMDB Visualizer provides built-in analysis filters, and you also can create filters.

Built-in filters include the following filters:

- **Browse**
  Displays the default unfiltered display.
- **Impact Analysis**
  With the focal CI as provider, shows all the CIs affected when any change occurs to the focal CI.
- **Root Cause**
  With the focal CI as dependent, shows all the CIs that could be the root cause for the focal CI to go down. Or, shows the CIs that can affect the focal CIs behavior.
- **Cause and Effect CIs**
  Combination of Root Cause and Impact Analysis. From the focal CI, shows all the CIs that could be the root cause. Or, shows the CIs that could be affected when a change occurs to the focal CI.
- **Trace Relation**
  Displays all possible relationships among focal CIs, based on the Levels setting. If the graph has only one focal CI, applying this filter displays only the focal CI.
- **Shortest Path**
  Displays the shortest chain of relationships among focal CIs, based on the Levels setting. If the graph has only one focal CI, applying this filter displays only the focal CI.

In addition to the built-in filters, any available administrator-defined and user-defined filters display.

Layout

The Layout drop-down list lets you switch your CI display between two different layout options, depending on your analysis needs. The following types of layouts are available:

- Hierarchical
- Circular

Hierarchical Layout

Use a hierarchical layout when you want to view related CIs that can be logically distant from the focal CI.

Circular Layout

You use a circular layout when you want to emphasize all relationships closest to a focal CI.

Change Levels

You can change the number of levels of CIs that are displayed relative to the focal CI. The maximum number of levels that are allowed is nine. The default value is two levels, which you can modify by using the Administration interface.

Follow these steps:

1. Click the Levels drop-down list.
   The numbered levels appear.

2. Select the number of levels that you want.
   The graph adjusts to reflect the new setting.

Working with CIs in Visualizer

This article contains the following topics:

Create CI

Use the Create CI button to launch CMDB to provide CI definition capability directly from Visualizer.

Note: This function is available to roles that have MODIFY permission for Configuration Items and VIEW permission or higher for Relationships.

Follow these steps:

1. Click Create New CI on the Visualizer toolbar.
   The CMDB Create New Configuration Item page launches in context.

2. Define the new CI and click Save.

The CI is created.

View CI Properties

The Properties button provides a CMDB launch in context capability to view and edit selected CI details. Other methods include the following options:

- Select CI on Search Results, right-click, and select Properties.

- Select CI on the graph, right-click, and select Properties.

Create Relation

Use the Create Relation button to launch CMDB to provide relationship definition capability directly from Visualizer.

Note: This function is available to roles that have MODIFY permission for Relationships and VIEW permission or higher for Configuration Items.

Follow these steps:

1. From the graph, select up to two CIs.
2. On the Visualizer graph, click Create Relation.
   The Create New Configuration Item Relationship page launches in context. If two CIs are selected, one is shown as Provider and the other one as Dependent.
3. Select the relationship type from the drop-down list.

   Note: Specify the Relationship Type to save the graph with the new relationship.
4. Click Save.
   The new relationship is saved and the Create Relationship page closes.

Set a Focal CI

You can set a focal CI to display relationships from its point of view.

Follow these steps:

1. Select a CI to serve as the focus of the analysis from Search or graph.
2. Make the focal CI in one of the following ways:
   - Select CI on Search Results and hit Enter.
   - Select CI on Search Results and click its Make Focal CI icon.
   - Select CI on Search Results, right-click, and select Make Focal CI.
   - Select CI on the graph, and click Make Focal CI on the toolbar.
   - Select CI on the graph, right-click, and select Make Focal CI.

   The graph is reorganized around the focal CI.

Scratchpad

You use the Visualizer Scratchpad like the Favorites or Bookmark feature of internet browsers. You can store some CIs in the Scratchpad for convenient use later. You can select one or more CIs from the Scratchpad to add them to the Visualizer graph. You also can use the Scratchpad to make a CI the focal CI.

Note: The Scratchpad is saved locally. If you launch the Visualizer from a different server later, a saved Scratchpad is not available.

The Scratchpad provides two different CI views: Tiles and Details.

Note: If you change a CI name or family in CMDB, refresh the Scratchpad to view the changes.

Hidden CI(s)

Use the Hidden CI(s) button to display the CIs that were hidden by using the Hide/Unhide commands. On the Hidden CI(s) list, you can select one or more CIs and can redisplay them. Perform one of the following actions:

Follow these steps:

- Click Unhide.
- Drag and drop the CIs on the graph canvas.
- Using the CI right-click menu to select Unhide.

Hidden CIs can display either the Tiles or Details view.

Show Configured Status

You use the Show Configured Status button to switch the CI status display. The status bar displays the current setting.

When Show Configured Status is on, each CI displays an icon on the graph to indicate its configured status. To define icons for each Configured Status, use the CI Status page in the Administrator interface.

Working with Graphs in Visualizer

This article contains the following topics:

Open Graph

Follow these steps:

1. Click Open Graph on the toolbar.
   The Open Graph list displays graphs with saved metadata.

2. From the list, complete one of the following actions:

   - Double-click a graph item.

   - Select a graph and click Open.

   The graph is rebuilt based on its saved metadata and its current CMDB data.

Follow these steps:

1. Click Open Graph on the toolbar.
   The Open Graph list displays graphs with saved metadata.

2. Select the graph from the Open Graph list.

3. Click Delete.
   The graph is deleted.

Invert Graph

By default, Visualizer displays Provider CIs at the top and Dependent CIs at the bottom, relative to the Focal CI.

Follow these steps:

1. Click the Invert Graph button to reverse this arrangement to a vertical axis.
   You can view the data from a different perspective.

Find CIs on the Graph

You can find specific CIs to display as nodes on the graphical display. Use the Find CIs button to open a new window over the graph to prompt for what string to match. The Find string is matched using graphical node attributes such as the CI name and family. Find shows the count of CIs which matched the users input criteria. The count is displayed in the bottom left corner.

Follow these steps:

1. Select the nodes to use from the Find CI results.

2. Click Select On Graph.
   The selected CIs display.

Show Graph for a Single CI

Follow these steps:

1. On the Visualizer graph, select a CI to serve as the focus of the analysis.
2. Right-click the CIs menu and select Make Focal CI.
   The selected CI becomes the *Focal CI* in the Visualizer. Its associated relations display, including the configured number of levels.

Add Multiple CIs to Graph

Follow these steps:

Make Focal CI, Add to Graph, or drag-and-drop CIs from the following sources:

- Search Results
- Scratchpad
- Saved graphs
- Hidden CI list

Note: The maximum number of CIs is ten (10).

Visualizer Procedures

This article contains the following topics:

The topic describes the Visualizer features that are available when the CA SDM server with Visualizer is running.

Note: (For Advanced availability configuration only) If the visualizer makes a server request during the application server quiesce period, the following message is displayed:

“This CMDB Visualizer server is scheduled to shut down for maintenance in xx:xx. Please save your work and logout.”.

You can hide the message box but the message is displayed on the top panel throughout the quiescing period. If the server quiescing is canceled, you receive a message about the cancellation.

Launch Visualizer in CI Context

Follow these steps:

1. In the CA SDM web interface, navigate to a CI List, or Search for the CIs to analyze.
   The CI List displays.

2. Click a CI of interest.
   The CI Detail page is displayed and the Visualizer button is available. If CA CMDB Visualizer was not installed, the Visualizer button is inactive.

3. Click Visualizer.
   Visualizer starts and the relationships for the focal CI display.

   Default: Cause and Effect CIs

Launch Visualizer with Applied Filter

Follow these steps:

1. Navigate to the CI List, or search for the CIs you want to analyze.
   The CI List displays.

2. Click a CI of interest.
   The Configuration Item Detail page displays.

3. On the Filters list, select a filter.

4. Click Visualizer.
   Visualizer starts and the graphical relationships for the focal CI display according to the selected filter. If CA CMDB Visualizer was not installed, the Visualizer button is inactive.

Trace Relation with Focal CIs

You can trace all relationships between the selected CI and any focal CIs on the graph.

Follow these steps:

1. Select a CI on the graph.

2. Right-click and select Trace Relations with Focal CIs.
   Any relationships are displayed.

> **Note:** If the selected CI is also the only focal CI, only that CI is displayed.

Launch MDRs

Follow these steps:

1. Right-click a CI on the Visualizer graphical display.
   A pop-up menu displays.

2. Select the Launch MDR option on the pop-up menu.
   All external data providers that are associated with the CI appear.

3. Select an application name and click Launch to start the associated application.
   Visualizer launches the external MDR application as it is defined in the CMDB.

> **Note:** Visualizer does not validate the external MDR applications credentials and URLs.

Hide/Display CIs

To promote clearer viewing, you can hide and then redisplay graphed CIs. Hidden CIs are available only for the current graph. When a new graph is generated, or when a Focal CI is set, the Hidden CIs List is cleared.

Follow these steps:

1. To select a CI, click it.

2. Right-click the CI and select Hide from the drop-down list.
   The graph updates so that the CI is hidden.

Follow these steps:

1. Click Hidden CIs on the toolbar or status bar.
   The Hidden CIs list displays.

2. Select one or more hidden CIs from the list and perform one of the following actions:

   - Click Unhide.
   - Drag to the graph canvas.
   - Right-click and select Unhide.

   The graph updates so that the CIs display.

View Change History for a CI

Follow these steps:

1. Select the CI you want to view.

2. Click Properties.
   CA CMDB is launched in context, displaying the CI Detail page.

3. Select the Versioning tab and click Show Log.
   The tab displays the details of the changes that were made to the CI.

Apply a Filter

Follow these steps:

1. Build the desired graphical display.

2. Click the Filter drop-down list.
   The Filter list is displayed.

3. Select a filter from the list.
   The filter is applied to the graph, which reorients to display the new perspective.

Use the Scratchpad

To view the Scratchpad, click the Scratchpad button on the Visualizer toolbar.

The Scratchpad displays.

Follow these steps:

1. Select one or more CIs on the Scratchpad.

2. Complete one of the following actions:

   - Click the Make Focal CI button on the Scratchpad toolbar.

   - Drag and drop one or more CIs from the Scratchpad to the graph.

   - Right-click on a CI and select Make Focal CI.

Follow these steps:

1. Select one or more CIs on the Scratchpad.

2. Complete one of the following actions:

   - Click the Add Focal CI button on the Scratchpad toolbar.

   - Right-click on the CI and select Add To Graph.

Follow these steps:

1. Select one or more CIs to delete.

2. Click the Delete button on the Scratchpad toolbar.
   The CI is deleted from Scratchpad.

To synchronize the Scratchpad to the Database, click Refresh. The Scratchpad removes all the CIs that were deleted from the database.

To save a CI on the Scratchpad, right-click the CI and select Add to Scratchpad.

The CI is added to the Scratchpad.

Visualizer Administration

Use the CMDB Visualizer administration interface to perform the following functions:

- Install and configure the Visualizer server.
- Modify the display of CI status and relationships.
- Create and manage administrative filters.
- Create and manage Visualizer CI graphics.
  You can use the Icon Configuration page to map family names to their respective icon images when you upgrade from CMDB Visualizer r11. To reset the family icon mapping, click Reconfigure. The icon image mapping file (\CMDBVisualizer\WEB-INF\classes\com\ca\cmdbvisualizer\config\clientsvgfamilyimagemap.properties) is recreated.

Note: These functions are only available to roles with administrator privileges.

How to Configure CMDB Visualizer

You can configure a CMDB Visualizer server as a primary or secondary server. The primary Visualizer server must reside on the same computer as the primary CA SDM server. All other Visualizer servers are treated as secondary servers. You cannot change a secondary Visualizer server to primary unless a CA SDM server on the same computer is changed to primary. The primary server address is required to reconfigure a secondary server.

You change some of the configuration values that were entered for the CMDB Visualizer during its initial configuration. To change some settings, you edit the properties files. If the CA SDM server has changed, you also most update the server name.

Visualizer configuration information is stored in the following file:

```
../CMDBVisualizer/WEB-INF/classes/com/ca/cmdbvisualizer/config/cmdbvisualizerconfig.properties
```

The following properties in the property file must be changed:

- USD_WEBSERVICE_URL

- PARENT_APPLICATION

To update entries for the web service URL and the Parent application URL, modify the following parameters:

```
USD_WEBSERVICE_URL=http://<cmdb-server-name>:<port no>/axis/services
/USD_R11_WebService>
PARENT_APPLICATION=http://<cmdb-server-name>:<port no>/CAisd/pdmweb.exe
```

This process must be repeated across all Visualizer installations.

You can update the timeout for SQL Queries in the SQL_QUERY_TIMEOUT property. For example, set SQL_QUERY_TIMEOUT = 30 sets the timeout as 30 seconds.

Managing CI Family Icons

CA CMDB Visualizer can represent CI families by using either SVG or JPEG graphics icons. By default, CA SDM provides SVG icons for CA-supplied CI families at installation. You can use either SVG or JPEG images for user-defined CI families.

You manage SVG and JPEG graphics using properties files in the following directory:

```
visualizer-install-dir\CMDBVisualizer\WEB-INF\classes\com\ca\cmdbvisualizer\config\
```

SVG graphics are defined as *key*=*value* pairs in the clientsvgfamilyimagemap.properties file.

- ***key***
  Specifies the family ID.

- ***value***
  Specifies the file name of the SVG graphic.

Example

400007=HARDWARE_MAINFRAME

> **Note:** SVG images cannot be previewed; they can only be viewed in the application.

You maintain JPEG graphics as *key*=*value* pairs in the serverjpegfamilyimagemap.properties file.

- ***key***
  Specifies the family ID.

- ***value***
  Specifies the file name of the JPEG graphic.

Example

400039=conx_32.jpg

Note: JPEG images reside in the following directory:

```
visualizer-install-dir\CMDBVisualizer\resource\
```

Important: When you create and maintain graphics in the .properties files, verify that no duplicate Family ID (key) occurs.

Visualizer displays an SVG or JPEG graphic for a CI Family that is based on the following priority:

- Family ID in the SVG.properties file
- Family ID in the JPEG.properties file
- JPEG image with key DEFAULT in the JPEG image map file

Example

DEFAULT=default_32.jpg

Built-In SVG Graphics

CA SDM supplies SVG graphics for the following families:

- CLUSTER
- CLUSTER_RESOURCE
- CLUSTER_RESOURCE_GROUP
- COMPUTER
- CONTACT
- DOCUMENT
- FACILITIES_AIR_CONDITIONING
- FACILITIES_FIRE_CONTROL
- FACILITIES_OTHER
- FACILITIES_UNINTERRUPTIBLE_POWER_SUPPLY
- HARDWARE
- HARDWARE_LOGICAL_PARTITION
- HARDWARE_MAINFRAME
- HARDWARE_MONITOR

- HARDWARE_OTHER
- HARDWARE_PRINTER
- HARDWARE_SERVER
- HARDWARE_STORAGE
- HARDWARE_VIRTUAL_MACHINE
- HARDWARE_WORKSTATION
- INVESTMENT_IDEA
- INVESTMENT_OTHER
- INVESTMENT_PROGRAM
- INVESTMENT_PROJECT
- LOCATION
- NETWORK_BRIDGE
- NETWORK_CONTROLLER
- NETWORK_HUB
- NETWORK_NETWORK_INTERFACE_CARD
- NETWORK_OTHER
- NETWORK_PORT
- NETWORK_ROUTER
- NETWORK_SWITCH
- ORGANIZATION
- OTHER
- PROJECT
- PROJECTS
- SAN_INTERFACE
- SAN_SWITCH
- SECURITY
- SERVICE

- SERVICE_LEVEL_AGREEMENT
- SOFTWARE
- SOFTWARE_APPLICATION
- SOFTWARE_BESPOKE
- SOFTWARE_COTS
- SOFTWARE_DATABASE
- SOFTWARE_IN_HOUSE
- SOFTWARE_OPERATING_SYSTEM
- TELECOM_CIRCUIT
- TELECOM_OTHER
- TELECOM_RADIO
- TELECOM_VOICE
- TELECOM_WIRELESS

How to Change the Icon of CI on the Visualizer

You can change the icon of a CI on the Visualizer. Complete the following:

Follow these steps:

1. Navigate to *$NX_ROOT\bopcfg\www\CATALINA_BASE_VIZ\webapps\CMDBVisualizer\WEB-INF\classes\com\ca\cmdbvisualizer\config* location.
2. Open the **clientsvgfamilyimagemap.properties** file and comment out the line (with a #) that corresponds to the family you would like to change the icon.
3. Navigate to *$NX_ROOT\bopcfg\www\CATALINA_BASE_VIZ\webapps\CMDBVisualizer\WEB-INF\classes\com\ca\cmdbvisualizer\config*.
4. Open the **serverjpegfamilyimagemap.properties** file and add the family class and image name (300002=new_hardware_server.jpg).
5. Create a resource subdirectory in *$NX_ROOT\bopcfg\www\CATALINA_BASE_VIZ\webapps\CMDBVisualizer* and place the image file mentioned in step 4 in the subdirectory.
6. Restart the CA Service Desk Manager service.
   You have successfully changed the icon of a CI on the Visualizer.

CMDB Data Maintenance

This article contains the following topics:

The tasks that you perform to maintain CMDB data require administrator privileges. The tasks include setting up the families, classes, and relationship types that are used to manage configuration items and relationship information.

CMDB Family/Class Structure

CMDB provides default configuration item families and the CI classes they contain.

The following Service Desk and CA APM base families do not have their own CA CMDB extension tables:

- Computer
- Contact (as base object)
- Hardware
- Location (as base object)
- Organization (as base object)
- Other
- Project
- Software

In CA CMDB, CIs in these base families receive CI Detail pages with some extraneous fields and without Attributes tab. Use the Change Family and Class capability of CA CMDB to convert these CIs to CA CMDB families. The advanced features include the ability to track family-specific attributes, versioning, snapshots, and baselines.

Change Family/Class of a Single CI

You can change the Family and Class for a single CI.

Follow these steps:

1. Select the CI that you want to change.
2. Click Edit.
   The Update Configuration Item page displays.
3. Change the Class value for the CI. Selecting the class also determines the family for the CI. You can enter a value directly or click the magnifying glass to select from a list of classes.

4. Click Save.
   The Family and Class of the single CI is changed.

Change CI Family/Class Using GRLoader

You can change the Family and Class for a CI by using GRLoader.

Follow these steps:

1. Create XML code to change the CI attribute.
2. Using GRLoader, open the CI you want to modify.
3. To change the CI attribute, run the XML through GRLoader.
   The Family and Class for a CI are changed.

Example: Set the Class of an Open CI to Document

The following example shows an XML fragment that sets the class of an open CI to *Document*.

```
<ci>
    <name>document number 1
    <class>Document
</ci>
```

Important! Do not attempt to update both the Family and Class attributes of a CI simultaneously. To change both, use two separate CI updates in two separate invocations of GRLoader.

Extending CMDB

This article contains the following topics:

CMDB is a highly flexible system that can be extended to include extra families, classes, and attributes according to your business needs. New attributes can be family-specific or *common* (applicable across all families). While CMDB provides predefined families with many classes and attributes based on industry standards, some business cases require one or more of the following activities:

- Extend one or more of the CI families by adding new attributes. For example, to add a GPS coordinate for every device on your office campus, you can define a gps_coordinate attribute to add to any family. If you only want to extend one family, use Web Screen Painter Schema Designer to define the new attributes in the existing extension table. In addition, whenever you add an attribute, you also must modify the Detail page, Attribute tab, and metadata forms that use the attribute. For more information, see Add Family Attributes (see page 2605).

- Extend all CI families by adding a common attribute. For more information, see Add Common Attributes (see page 2605).

- Add new classes to an existing family to support more classification detail in your system. For example, instead of the generic Server class, you can create a separate class for every model of server device. For more information, see Define a New CI Class (see page 2606).

- Add a new family by using an existing extension table and its attributes. A new family provides an alternative way of organizing or classifying CIs. For more information, see Define a New CI Family (see page 2607).

- If the existing class or family structure does not match your requirements, you can start over with a minimum set of attributes. To add a new family using a new extension table, define the new extension table and its attributes using Web Screen Painter Schema Designer. Also, create the forms that are required for display and update. For more information, see Constructing a New Attribute Framework (see page 2608).

Important: Extending CMDB requires specialized knowledge of CA SDM data structures and tables, and familiarity with Web Screen Painter (WSP). We recommend that you contact CA Services to help with this activity and also read and understand thoroughly the following sections before attempting to extend CMDB families and attributes.

Adding New CMDB Attributes

Adding a new CMDB attribute requires careful planning. CMDB already provides many attributes in its predefined families and classes, so determine whether they are sufficient for your needs before considering customization.

If you determine that a new attribute is necessary, we recommend proceeding conservatively by asking whether you must:

- add one or more new attributes to an existing family?
- add the new attribute(s) to more than one family?
- add a new common attribute, which applies across all families?

You can extend an existing family by adding new attributes. For example, if some devices on your office campus are assigned a GPS coordinate, you can add a gps_coordinate attribute to any applicable CI family. For more information, continue to Add Family Attributes (see page 2605).

After your attribute requirements are identified, if you determine that they require the use of new families and classes, see Adding a New CA CMDB Family or Class (see page).

Add Family Attributes

You can add a new attribute to one or more existing families by using the Web Screen Painter Schema Designer, which updates the database to include the new attribute and also updates the associated CA SDM tables and files. This method is preferred over updating the tables and file changes manually.

To add a new attribute to a family

1. Using Web Screen Painter Schema Designer, open the schema that corresponds to the family extension table.
2. Add the desired attribute to the extension table.
3. Publish the modified extension table.

Note: GRLoader and Versioning automatically pick up new attributes without further action. However, we also recommended that you enable logging. Logging is required for auditing purposes and Versioning enabled to record all snapshots.

To enable logging, verify that UI_INFO for the attribute is set to **AUDITLOG**.

After a new family attribute is created, it must be added to each display form so that users can see and update that attribute and to the metadata form specific to that extension table. For more information, go to Add Attributes to Forms (see page 2609).

In addition, Versioning requires metadata, including information about column headings and the related Standard CI attributes. You define new metadata for all new attributes that you create; for instructions, continue to Create Metadata (see page 2610).

Add Common Attributes

Common attributes are stored in the **ca_owned_resource** table in the **nr** object. This table provides the following customizable fields:

- smag_1
- smag_2
- smag_3
- smag_4
- smag_5
- smag_6

If you require less than seven modified attributes among all CI families, these fields provide a convenient solution.

As supplied, these custom fields do not display on any form. To allow CMDB users to view or update a smag_*n* field, use the Web Screen Painter (WSP) to add it to any display form. All logging and GRLoader functions are already enabled.

Note: For Web Screen Painter Schema Designer procedures, see How to Implement CA SDM and the Web Screen Painter online help.

Adding a New CMDB Family or Class

Adding a new CMDB family requires careful planning. CMDB provides many predefined families and classes, so determine whether these are sufficient for your needs before considering customization. If not, some new requirements can be met by one of the following actions:

- Defining a new class in an existing family
- Defining a new family that uses an existing extension table

If you determine that existing extension tables are insufficient for your needs, skip this section and continue to the section Constructing a New Attribute Framework (see page 2608) to create an extension table and the forms that it requires.

Define a New CI Class

You can add new classes to support higher levels of classification granularity. For example, instead of using any of the CMDB-provided classes in the Hardware.Server family, you can define more classes for different server devices.

Before you create a new configuration item class, determine whether a suitable class already exists in the Configuration Item Class List.

> **Note:** If you also require a new family to govern a new set of classes, skip this topic and proceed to Define a New CI Family (see page 2607). Then you can return and populate the new family with classes.

To define a CI class using the Administration interface

1. Navigate to the Configuration Item Class List.
2. Click Create New.
   The Create New Configuration Item Class page appears.
3. Enter a unique name for the new class.
4. Enter the appropriate family name in the Family field, or click the icon over the field to search for a family.
5. Verify that the Record Status field is set to Active.
6. Click Save.
   The new CI class is defined and ready for you to create new CIs.

Define a New CI Family

Before you create a configuration item family, determine whether a suitable family already exists in the Configuration Item Family List. If not, you can create new families as an alternative method of organizing or classifying CIs using existing attributes.

If the new family that you need cannot use an existing extension table (or the default table), complete all the additional preparations that are outlined in Constructing a New Attribute Framework (see page 2608). The new extension table can be used to define new families.

To define a CI family using the Administration interface

1. Navigate to the Configuration Item Family List.
2. Click Create New.
   The Create New Configuration Item Family page appears.
3. Enter a unique name for the new family.
4. Verify that the Record Status field is set to Active.
5. In the Extension Name field, select the extension table that identifies the type of family that you want to create. This may be a new extension table that you created recently.
   For example, if you are adding a family for an unspecified type of hardware, select ci_hardware_other. This type ensures that when you create configuration items whose classes use the new family, the appropriate attributes display on the Attributes tab. If you do not select a table name in the Extension Name field, the default table is used and only default attributes appear when you create a configuration item within the new family.

6. Type a description in the Description field.
   The description that you enter displays in the Configuration Item Family List for informational purposes.

7. Click Save.
   The configuration item family is defined.

Now that your new family is defined, you can add classes to it as described in Define a New CI Class (see page 2606).

Constructing a New Attribute Framework

If none of the existing class or family structures match your requirements, you can start over with a minimum set of new attributes. This requires construction of a new extension table and other supporting structures.

Before using the CMDB administration interface to define a new CI family that is based on a new extension table, use the Web Screen Painter Schema Designer to create the new extension table.

To use the new extension table, you must also create new HTMPL forms for:

- New CI Detail page
- New Attributes tab with its associated attributes
- New metadata form and metadata

CA CMDB supplies templates that you can use to build these HTMPL forms. The following sections provide more detailed information about what is required.

Note: For Web Screen Painter Schema Designer procedures, see How to Implement CA SDM and the Web Screen Painter online help.

To use the new framework in the CMDB user interface, define:

- One or more CI families that use the new extension table
- CI classes to classify your CIs by type

Create a New Extension Table

Before you can define a family that is based on a new extension table, update the database with the new table and also update the CMDB schema with information about that table.

To create an extension table

1. Using the Web Screen Painter Schema Designer, define the new extension table and extension name.

2. Save and publish the new extension table.

Note: WSP Schema Designer automatically creates the logging trigger in CMDB.

To create the CI Detail page, continue to the next section.

Create a CI Detail Page

A CI Detail page is required to support attribute display for CIs that are associated with a new extension table.

To create the CI detail page

1. Using the Web Screen Painter Schema Designer, click File, New, and create a form that is based on detail_extension.template.

2. Save this new form as **detail_***extension***.htmpl**, where *extension* is the name of the extension table.

3. Follow the instructions that are listed in the file, replacing the ***EXTENSION*** string with the name of the new extension table (defined previously).

4. Save the file with all changes.

The CI Detail page includes two attribute sections:

- Common attribute section named cmdb_detail.htmpl
- Family-specific section (the Attributes tab) named nr_cmdb_extension_tab.htmpl, where *extension* is the name of the new extension table.

Continue to the next section to Create the CI Attributes Tab (see page 2609).

Create a CI Attributes Tab

The Attributes tab displays the family-specific attributes for a CI.

To create the Attributes tab

1. Using the Web Screen Painter Visual Editor, click File, New, and create a form that is based on nr_cmdb_extension_tab.template.

2. Save this file as **nr_cmdb_***extension***_tab.htmpl**, where *extension* is the name of the new extension table.

3. Follow the instructions that are listed in the file, replacing the ***EXTENSION*** string with the name of the new extension table (defined previously).

4. Save and publish the file with all changes.

Continue to the next section to populate the Attributes tab.

Add Attributes to Forms

After Web Screen Painter Schema Designed has been used to create a new attribute in an extension table, that attribute must be added to any form that is used for display or update. For new family-specific attributes, the only form that must be changed is the Attributes tab that is named **nr_cmdb_***extension***_tab.htmpl**, where *extension* is the name of the extension table. This form must be edited to include any new attributes.

To edit an attribute form

1. Using Web Screen Painter Visual Editor, click File, Open to access the appropriate form.
2. Drag and drop the new attribute or attributes on the form.

   Note: CMDB-provided forms do not lend itself to editing using the Web Screen Painter Visual Editor, so use the Web Screen Painter text editor on the Source tab.

3. Save and publish the form.

If you have not yet created a metadata form, continue to the section Create a Metadata Form (see page 2610). To define metadata for a new attribute on the form, continue to the section Create Metadata (see page 2610).

Create a Metadata Form

A new extension table requires its own metadata form to define column headings and Standard CI information for Versioning.

To create the metadata form

1. Using the Web Screen Painter Visual Editor, click File, Open to access cmdb_metadata_extension.template.
2. Save the file as **cmdb_metadata_***extension***.htmpl**, where *extension* is the name of the new extension table.
3. Follow the instructions that are listed in the file, replacing the ***EXTENSION*** string with the name of the new extension table (defined previously).
4. Save and publish the form with all changes.

To populate the metadata form, continue to the next section.

Create Metadata

Metadata includes information about attribute column headings and Standard CI information that the Versioning feature requires.

Important: Metadata requires careful planning to ensure correct data in Snapshots, correct titles in Versioning, and successful Standard CI comparisons.

To create metadata

1. Using the Web Screen Painter Visual Editor, click File, Open to access **cmdb_metadata_** *extension*.**htmpl**, where *extension* is the name of the extension table.

2. Following the instructions that are listed in the form, copy and modify the indicated row for each attribute in the new extension table.

Note: The following attributes, although required, do not need metadata:

- ID
- Last_modified_by
- Etc (to be provided)

If you are adding metadata to an existing CMDB family, audit changes are displayed correctly on the Versioning tab. However, if you are defining metadata for a new extension table, you must have a new family and class for your attributes; for more information, see Adding a New CA CMDB Family or Class (see page).

The structures for your new extension table are now in place. To define a new family for your attributes, continue to Define a New CI Family (see page 2607).

Example

In this sample scenario, you create an **Automobile** family and a **Sedan** class in it for tracking inventory for manufacturing, shipping, rental transportation, or other purposes. You could also create many other automobile classes; this example is for demonstration purposes only.

Step 1 Create the New Extension Table

1. In Web Screen Painter Schema Designer, click Add Extension Table.

2. Enter a name for the new extension table. In this example, **vehicle**.
   The **zvehicle** extension table is created and its properties displayed.

Note: "z" is appended to the beginning of all new table names to distinguish them from application-provided tables.

3. In the Table Info tab, set the Function Group field to **inventory**. Other fields are populated with default values.

4. Add new columns and attribute information as desired.

5. Save and publish the new extension table.

Step 2 Create a New Family

To create a family

1. Navigate to the CI Family List.
2. Click Create New.
   The Create New Configuration Item Family page displays.
3. Enter a unique name for the new family. In this example, **Automobile**.
4. Verify that Record Status is set to Active.
5. Select the extension table name. In this example, **zvehicle**.
6. Click Save.
   The new CI family is created.

Step 3 Create a New Class

1. Navigate to the CI Class List.
2. Click Create New.
   The Create New Configuration Item Class page displays.
3. Enter a unique name for the new class. In this example, **Sedan**
4. Verify that Record Status is set to Active.
5. Select the Family. In this example, **Automobile**.
6. Click Save.
   The new CI class is created.

Step 4 Create the New CI Detail Form

To create the CI Detail form

1. In the Web Screen Painter Visual Editor, open the form detail_extension.template.
2. Save the template with the name **detail_zvehicle.htmpl**.
   The new form is saved under NX_ROOT\site\mods\wsp\project\web\analyst
3. In the new form, replace all instances of ***EXTENSION*** with **zvehicle**
4. Save and publish the new CI Detail form.

Step 5 Create the Attributes Tab

To create the Attributes tab form

1. In the Web Screen Painter Visual Editor, open the form nr_cmdb_extension_tab.template
2. Save the template with the name **nr_cmdb_zvehicle_tab.htmpl**
   The new form is saved under NX_ROOT\site\mods\wsp\project\web\analyst
3. In the new form, replace all instances of ***EXTENSION*** with **zvehicle**
4. Add attributes to the form as desired.
5. Save and publish the new Attributes tab form.

Step 6 Create the Metadata Form

To create the metadata form

1. In the Web Screen Painter Visual Editor, open the form cmdb_metadata_extension.template.
2. Save the template with the name **cmdb_metadata_zvehicle.htmpl**
   The new form is saved under NX_ROOT\site\mods\wsp\project\web\analyst
3. Replace all occurrences of ***EXTENSION*** with **zvehicle**
4. Using the heading and attribute placeholders, add metadata for all family-specific attributes.
5. Save and publish the new metadata form.

CMDB Visualizer

This article contains the following topics:

CA SDM lets you align your IT components (*configuration items*, or CIs) with your business services. CA CMDB defines *relationships* among CIs, as when a group of CIs work to provide a business service. CMDB Visualizer lets you see the entire picture of your CI relationships, and provides functions to manage the relationships. Working from a *focus CI*, you can use the Visualizer to display up to nine levels of related CIs.

Advanced Availability Configuration Only

Note: If the visualizer makes a server request during the application server quiesce period, the following message appears:

"This CMDB Visualizer server is scheduled to shut down for maintenance in xx:xx. Please save your work and logout.".

You can hide the message box but the message is displayed on the top panel throughout the quiescing period. If the server quiescing is canceled, you receive a message about the cancellation.

CA uses a provider/dependent model to define relationships among CIs. All CIs that contribute to a business service are *providers* to that business service (the *dependent*). In much the same way, providers can also be *dependents* that rely on other CIs. You can use Visualizer to perform the following provider/dependent analyses:

- **Browse**
  Displays an unfiltered view of all CIs.
- **Impact Analysis**
  Starts with a focal CI (provider) and searches for its dependents.
- **Root Cause**
  Starts with a business service (dependent) and view all the CIs that are providers to that service.
- **Cause and Effect CIs**
  Combines impact analysis and root cause in one search.
- **Trace Relation**
  Displays all possible relationships that are based on levels. If you select only one CI, this filter displays the Browse view.
- **Shortest Path**
  Displays the shortest chain of relationships that are based on levels.

CMDB Visualizer lets you do the following actions:

- Visualize multiple levels of CIs from a configurable graphical view.
- Monitor or cancel rendering progress.
- Search using flexible criteria.
- Filter based on CI families, relationship types, and other attributes.
- Display CI relationships.
- Trace a relationship between two CIs.
- Visualize a dependency chain.
- Invoke CA CMDB directly from Visualizer.
- Display CI attributes and properties.
- Save graph metadata.
- Print the graph layout.
- Find a specific CI on a displayed graph.
- Create a CI (depending on role).

- Create new CI relationships (depending on role).
- Use the Scratchpad to store key CIs.
- Display CI status.
- Hide or reveal a CI in the Visualizer layout.
- Role-based data security.
- Launch external MDRs.
- Obtain online help for Visualizer features.

Perform Root Cause Analysis

Using Visualizer with the CMDBf Viewer, you can perform a root cause analysis.

Follow these steps:

1. In Visualizer, locate a Service CI in a particular problem condition (for example, slow or unavailable).
2. Right-click the CI and select Make Focal CI.
3. Select a Root Cause filter using the following criteria:
   - Class Type: n/a
   - Dependent to Provider Relationship: All relationships to be displayed for the root-cause analysis.
4. Click View.
   In the resulting graph, all CIs that are related to the focal CI are displayed as specified in the filters. All paths between CIs include intermediary CIs to the default level.
5. Navigate to the CIs and inspect them for incidents, problems, or recent changes. These could be candidates for the root cause of the focal CI condition.
6. Launch CMDB in context for a particular CI.
7. Click CMDBf Viewer.
   The Federated View is displayed with the list of MDR providers for the CI.
8. To obtain the latest MDR attributes, click Retrieve.
   The MDR attributes are updated.

Visualizer Administration

The Visualizer administration interface can be used to edit CMDB Visualizer settings. These functions are only available to roles with administrator privileges.

The following tabs are disabled on the Visualizer running on secondary servers. These tabs are enabled on all the other CA SDM servers:

- **Visualizer Configuration Tab**
  Permits setting of the server and CI display information.
- **Relationship Style Tab**
  Defines relationship graphical characteristics.
- **CI Status Tab**
  Defines CI graphical characteristics.
- **Filters Tab**
  Creates, edits, and deletes filters for CI analysis.
- **Icon Configuration Tab**
  Maps a CI family to its respective icon image when CMDB Visualizer has been upgraded from r11.2 to Release 12.9. For more information about Visualizer definitions, see the Visualizer Administration (see page 2597) topic.

CA Business Service Insight Integration

When you integrate CA Business Service Insight and CA Service Desk Manager, the BSI Service tab displays Exceeds and Violations counts. The BSI Service by Metric and BSI Contract by Metric tabs display the Metric, Violation, Compliant, and Target attributes.

Note: These tabs only appear for CIs with Federated Asset mappings to the CA Business Service Insight MDR.

The integration provides the following reports:

- **Service Level Compliance**
  Displays information about CA Service Desk Manager Enterprise Service family CIs.
- **Modified Service Level by Metric vs. Target**
  Displays information about CA Service Desk Manager Enterprise Service family CIs.
- **Modified Service Level by Contract vs. Target**
  Displays information for CA Service Desk Manager Contract family CIs. Enter a valid CA Business Service Insight Contract Party and refresh the report.

Consider the following information to help you debug error messages:

- For an incorrect CA Business Service Insight MDR userID or SharedSecret, the error message displays Invalid username/org.name.
- For an incorrect CA Business Service Insight hostname, the error message displays BSI hostname is unknown.

- For an invalid Contract Party in the BSI Contract by Metric tab, the error message displays there is no metric data for the contract for the Reporting Period.
- If no CA Business Service Insight reports are associated with a particular Service or Contract, one of the following error messages is displayed:
  - For Services, there are no service details reports for federated service id.
  - For Contracts, there is no metric data for the contract for the Reporting Period.
- If CA Business Service Insight services are not available on the CA Business Service Insight computer, the error message displays that the CA Business Service Insight hostname is unknown.

Database Views

This article contains the following topics:

The CA SDM database is a repository for data entered and used to operate your service desk. CA SDM provides several database views and enables you to create customized reports of the database.

Basic Views

The basic views are based on CA SDM's tables. These views show data as long as the implementation makes use of Requests, Incidents, Problems, Change Orders, Issues, Assets, or Contacts / Groups.

Using the basic views, you can design and produce many reports, including:

- Detailed and summarized lists of open priority 1 requests sorted by request area.
- Detailed and summarized lists of change orders assigned to the level 1 group that have been open for more than 24 hours, sorted by priority.
- Counts of issues open for more than a specified number of days, sorted by priority, assigned group, or priority and assigned group.

The following basic views are provided:

View Name	Description
View_Contact_Full	All contacts, including their contact type, location, organizations, and service types
View_Contact_to_Environment	All contacts and their environment (assets)
View_Group	All the groups defined in the database
View_Group_To_Contact	All contacts (including managers) within their group assignments
View_Request	

View Name	Description
	All requests, including their service types, severities, urgencies, categories, assets, impact numbers, assignees by name, customers by name, groups, statuses, and priorities
View_Act_Log	The request activity log information, including activity type and analyst name
View_Request_to_Act_Log	All requests with their activity logs (this view joins View_Request and View_Act_Log)
View_Request_to_Properties	Requests and their properties (this may not include all requests, especially if no properties are assigned to them)
View_Change	All change orders, including their statuses, priorities, categories, organizations, affected end users by name, requesters by name, assignees by name, groups, service types, and impact numbers
View_Change_Act_Log	The change order activity log information
View_Change_to_Change_Act_Log	All change orders with their activity logs (this view joins View_Change and View_Change_Act_Log)
View_Change_to_Properties	Change orders and their properties (this may not include all change orders, especially if no properties are assigned to them)
View_Change_to_Change_WF	Change orders and their workflow tasks (this may not include all change orders, especially if no workflow tasks are assigned to them)
View_Change_to_Assets	Change orders and their assets (this may not include all change orders, especially if they have no assets)
View_Change_to_Requests	Change orders with basic information about attached requests (this view joins View_Change and the Call_Request table, which may not include all change orders -- especially if no requests are attached to them)
View_Issue	All issues, including their statuses, priorities, categories, organizations, affected end users by name, assignees by name, groups, service types, and so on
View_Issue_Act_Log	The issue activity log information
View_Issue_to_Issue_Act_Log	All issues with their activity logs (this view joins View_Issue and View_Issue_Act_Log)
View_Issue_to_Properties	Issues and their properties (this may not include all issues, especially if no properties are assigned to them)
View_Issue_to_Issue_WF	Issues and their workflow tasks (this may not include all issues, especially if no workflow tasks are assigned to them)
View_Issue_to_Assets	Issues and their assets (this may not include all issues, especially if they have no assets)

Advanced Views

The advanced views are based on CA SDM's audit_log table. Install the audit_ins and /or the audit_upd options in the Options Manager and restart the system before using these views.

Using the advanced views, you can report on the duration of a ticket (that is, request, change order, or issue) in a particular state. For example, you can report on the following:

- Show the length of time, between opening and assignment to L2 for requests opened since January 1, 2002
- Show the length of time, issues remained priority 3 before escalating to priority 2 for issues opened since January 1, 2002.

The following advanced views are provided, which are views of the audit_log table in the CA SDM database that specifically query for the status, priority, group, or assignee attributes:

View Name	Description
View_Audit_Status	All tickets sorted by the time in each status (does not include tickets that have no status)
View_Audit_Priority	All tickets sorted by the time in each priority
View_Audit_Group	All tickets sorted by the time in each group assignment (does not include tickets that have no group)
View_Audit_Assignee	All tickets sorted by the time in each individual assignment (does not include tickets that have no assignee)

Important! You must install audit logging options using the Options Manager, to view data in the advanced views. The descriptions for the Audit Options audit_ins and audit_upd in the Online Help provide more information.

Maintain Relationships

You can create and manage the relationships between configuration items.

To create a new relationship:

1. From the Administration tab, navigate to the CI Relationship List.
   The Configuration Item Relationship List page appears.
2. Click Create New.
   The Create New Configuration Item Relationship page appears.
3. Fill in the following fields:

- **Tenant (if multi-tenancy is installed)**
  The tenant level for this relationship.

- **Provider/Peer CI**
  The configuration item that provides the relationship. Enter the configuration item name directly into this field. To select the configuration item from a list, click the search icon.

- **Relationship Type**
  Use the Relationship Type Search and List to select relationship type.

- **Dependent/Peer CI**
  The dependent configuration item in this relationship. Enter the configuration item name directly into this field. To select the configuration item from a list, click the search icon. This field is required.

- **Symbol**
  (Optional) The unique identifier for this relationship. Assign a symbol that makes the relationship easily recognizable from the list.

- **Description**
  (Optional) A detailed description of the relationship. You can also use this field to describe the repositories that are assigned in the relationship.

- **Source Repository**
  (Optional) A detailed description of the relationship. You can also use this field to describe the repositories that are assigned in the relationship.

- **Cost**
  (Optional) The dollar value of the relationship between the configuration items.

4. Click Save.
   The relationship is created and assigned to the selected CIs.

CI Relationship Types

CA Service Desk Manager provides a list of predefined relationship types. Use these relationship types to describe a relationship or association between configuration items. How the relationship is expressed depends on which configuration item is the focus. For example, a provider *supports* a dependent configuration item, but the dependent *is supported by* the provider. These are different expressions of the same relationship. The relationship type label that you see depends on whether you are viewing a provider-to-dependent or a dependent-to-provider relationship. For information about the relationship types in CMDB, see the CI Relationships (see page 2489) topic.

Using Configuration Audit

The Configuration Audit node lets you perform the following actions:

- Manage Incidents that CACF (see page) created for rogue or improperly executed changes. For example, View which changes have failed verification and which changes require more investigation.

- Manage Changes Specifications (see page 2622).
  For example, view all Change Specifications that completed successfully or are pending verification.

- Manage open Change Orders (see page) with active Change Specifications.
  For example, view the changes orders that are still open with pending change specifications.

- View the Verification Log history (see page) that shows all verification activities that have occurred in the system.
  For example, view which MDR is responsible for rogue updates and the affected CIs.

Managing CACF Incidents

The Change Manager manages CACF incidents generated due to a rogue change or improperly executed Change Orders that require further attention.

CACF policies provide conditions under which Incidents are created, and can specify that Incidents close automatically after failed verification remediation.

Managing Change Orders

The Change Manager manages Change Orders with active specifications from this menu.

Verification Log

The Verification Log list lets you view all CACF change verification activity. CACF logs each attempted update to the CI, and if the update was allowed. This log helps you determine which policy allowed or disallowed a change to a CI.

For example, search for a log that specifies a specific CI where CACF detected a variance or unverifiable change. The results display information such as the previous and discovered value, the verify status, and associated Incident.

You access the verification log from the following locations:

- On the Administration tab, click CA CMDB, Configuration Audit, Verification Log.

- On the Scoreboard click CMDB, Configuration Audit, Rogue Inserts or Rogue Updates.

The Verification Log tab for the specific object shows detailed events only pertaining to the object in question. View the log for the following objects:

- Verification Policies

- Change Orders

- Change Specifications

- CIs

- Incidents

Note: Verification log entries highlighted in red indicate that the corresponding change specification is either Failed Verification or Manual Verification Active, and requires further attention by the user.

The Discovered Attribute History list displayed in the Change Specification form lists all attribute values for the currently selected managed attribute and CI that were recently discovered by an MDR, whetherthey were actually authorized or loaded into the CMDB.

Use this list to assist in defining the planned value for the change specification. In the list you can view the format, case sensitivity, and so on of the previously discovered values so that you can determine an appropriate planned value pattern.

Managing Change Specifications

This article contains the following topics:

The Change Manager manages change specifications in your CACF environment. Change Analysts create Change Specifications when they create Change Orders. The Change Analyst defines the change in terms of the specific CI and CI attribute being changed.

The Change Specifications list shows all verified and outstanding change specification verifications in your environment. The ability to modify a change specification depends on the status of the Change Order. By default, you can only modify change specifications in Change Orders with the RFC status. After CACF verifies this change, it considers all subsequent changes as rogue inserts or updates

If multiple discoveries occur during change specification verification, discovery data can invalidate a previously verified change. At the end of verification, the CI is in the state that all the change specifications desire. For example, a variance occurs for a CI with a change specification in the Verified state, but the status changes to Failed Verification.

A single CI can have many outstanding change specification verifications pending from many Change Orders. CACF evaluates each verification independently, and a single MDR update can update multiple pending change verifications.

The Final field on the Change Specification List indicates whether a change has been completed. The Change Order is eligible for to move to the next default state when all change specifications are final and the Promote Change Order After Verification option is enabled for the managed change state.

The following fields require explanation:

- **Verify Status**
  Specifies the status of the change specification, such as Verification Pending. For more information about change specification statuses, see Change Specification Statuses (see page 2627
  .

- **Change Order Status**
  Specifies the status of the Change Order.

- **Incident**
  Specifies the Incident that the verification policy creates optionally for an incorrectly implemented Change Order.
  If the Configuration Administrator specified the policy option to create Incidents, the Incident documents the expected and discovered values. If all discoveries result in failed verifications, the Incident receives log comments indicating that the incident represents multiple failures.

- **CI Name**
  Specifies the CI that you want to define the change specification.

  When you make several identical changes to a set of CIs, you can leave the CI Name field blank in the Change Specification. In this case, the Managed Attribute and Planned Value apply to all CIs attached to the Change Order. Change specifications for each CI are created when the Change Order moves to a status with Change Verification Active enabled for the managed change state.

- **Original Value**
  Specifies the value of the attribute at the time a user created change specification.
  The original value field shows the current attribute value for the CI when defining the change specification value for the first time.

- **Last Discovered Value**
  Specifies the last value that was discovered for the attribute during the implementation and verification active process. This field updates each time CACF discovers a new value for the attribute.

- **Last Verification Policy**
  Specifies the verification policy that was in effect during the last change verification for this change specification.

- **Verification Message**
  Shows the message associated with the last verification action such as the reason why a verification failed.

- **TWA**
  Link to the TWA record associated with this change specification and policy.

Create a Change Specification

Create a change specification for a Change Order. By default, you can only modify change specifications in the RFC state. The Configuration or Change Administrators can change the definition of the Change Order managed change state that allows modification of change specifications.

The Verification Log tab shows the change verification activity history for this change specification. The log shows details about the policy and actions that CACF takes when change verification was in effect for the change specification. Verification log entries highlighted in red indicate that the corresponding change specification is either Failed Verification or Manual Verification Active, and requires further attention by the user.

To help you set the planned value, the Discovered Attribute History tab lists all values that an MDR recently discovered, whether they were authorized or loaded into the CMDB. From this tab, you can see the format and case sensitivity of the values so that you can determine an appropriate planned value pattern.

The Change Specification History tab shows the audit history listing all previous modifications made to the change specification options with the time and the user that made the changes.

Follow these steps:

1. From a Change Order, click the Configuration Management tab and select the Change Specifications tab.

   You can also create change specifications from the Administration tab from CA CMDB, Configuration Audit, Change Specifications. You can also create them from a CI if you click the Related Tickets tab then select the Change Specifications tab.

   The Change Specifications List page appears.

2. Click Create New.
   The Create New Change Specification page appears.

3. Complete the following steps:

   a. Enter the Change Order number that requests the change (only required if created from a CI or the Administration tab).

   b. Enter the name of the CI associated with the Change Order.
   You can leave the CI name blank to imply that the change specification applies to all defined CIs (see page 2629) for the Change Order.

   c. Set the change specification as Active or Inactive.

   d. (Optional) Enter a description for the change specification.

e. Select the Managed Attribute for this change specification from the drop-down list.
Selecting Any Managed Attribute indicates that any managed attribute can be changed during the verification of the Change Order. In this case, multiple attributes can be updated, the planned value cannot be specified, and the planned change status is never updated.

f. Enter the planned value of the Managed Attribute.
Specify the expected value of the attribute after executing the change. After the Change Order moves into a verification state, and the CI updates through the web interface, GRLoader, or Web Services, CACF compares the planned value with the inbound data to determine a match.
You can embed special characters (see page 2626) in the planned value when the exact value is not known.

g. Select the appropriate verification state of the Change Specification from the drop-down list:

- Manual Verification will be required
  When CACF verifies the Change Order, manual verification will be required.
- Set after Change Verified
  Set the CI attribute to the planned value after verification completes. Use this option for setting CI attributes when the attribute is not discoverable.

  The set operation only occurs when the Change Order moves from a state with change verification active to a nonactive default state. For example, the set takes place when a Change Order moves from Verification in Progress to Closed. The set does not occur if the Change Order is canceled, demoted, or moved to another state.

- Use Discovered Value
  Copy the discovered value to the CI at verification time, used when the planned value is not known prior to verification.
- Verification Pending
  The change has not been verified and waits for a CI update (see page 2627).

4. Click Save.
   The change specification is saved.

Change Specification Considerations

Consider the following information about change specifications:

- The CI name can be left blank which implies the change specification applies to all CIs defined for the change order. This option is useful when all of the CIs for Change Order are using the same planned value. The change specification applies to all CIs that are attached to the Change Order (see page 2629) when the managed change state moves to a state with change verification active.

- You can create a Change Specification that requires manual verification. This action lets you verify managed attributes manually (see page 2629).
- Change Specification planned values for Lookup field managed attributes must be unique. For example, if you want to create a planned value for the Primary Contact (primary_contact), the contact specified in the planned value must be unique.
- You set case sensitivity only for comparisons made for change specification managed attribute planned values using the *Case Sensitive* option in the managed attribute. Specifying case-sensitive managed attributes do *not* affect the policy selection patterns.
- When the exact value is not known for the planned value, you can use wildcard (*), range (> or <) or negation (!) values (see page 2626).

Special Characters

You can embed special characters when you do not know the exact value. Use the asterisk wildcard character to match any number of characters. The pattern *must* match the discovered data in the same sequence, and spaces are significant.

For example, enter *10.*.*.** as the Planned Value to match any IP addresses that begins with *10.* and has two periods that follow any value between the periods.

For example, the inbound server_type value contains Windows 2003 (WIN32) 5.2.Service Pack 2 (Build 3790) Intel x86. To verify this value, specify a planned value of ** Service Pack 2 ** in the change specification.

A word at the beginning of the planned value indicates that the discovered value must start with that value. Similarly, an asterisk at the beginning of the planned value indicates that the discovered value can begin with any value and end with the value specified following the asterisk.

The following table provides examples about how to use the asterisk:

Planned Value	Discovered Value	Match or No Match
a	b	No Match
a	a	Match
a	aba	Match
a	bab	Match
a*	a	Match
a*	ab	Match
a*	ba	No Match
*a	a	Match
*a	ab	No Match
*a	ba	Match

A pattern that begins with an exclamation point results in the negation of the value. You can only use the exclamation point as the first character in the pattern. For example, you cannot use a pattern of 10.!*.*.*.

To compare numeric values contained within string values, use greater than (>) or less than (<) as the first character in the planned value. If there is a leading exclamation point, it must be the second character.

CACF ignores leading or trailing nonnumeric values in the discovered value and planned value patterns.

The following table provides examples about how to use the exclamation point, and the greater than and less than symbols:

Planned Value	Discovered Value	Match or No Match
>200	aaa 201 bbb	Match
>200GB	aaa 200 bbb	No Match
>200GB	300 GB	Match
!<200GB	200 Bytes	Match
!<200	200 Bits	Match

If you do not know the planned value in advance, but the value may change, you can set the status of the change specification to Use Discovered Value. This behavior requires discovery to update the CI before CACF considers the change specification as validated. You require this behavior for numeric fields and SRELs where an asterisk cannot be accepted as a planned value.

To help you with setting the planned value, the Discovered Attribute History tab lists all values that were recently discovered by an MDR, and whether were actually authorized, or loaded into the CMDB. This tab displays the format, case sensitivity, and other information about values so that you can determine an appropriate planned value pattern.

Change Specification Statuses

Change specifications use status to indicate the type of verification to perform and the current state of verification. The status values are also used in the verification log when recording change verification operations during the verification process.

- **Initial Statuses**
  Used when creating a Change Specification to specify the type of verification for CACF to perform. These statuses are non-final and the Change Order is not considered verified when change specifications are in either of these statuses.
  Verification Pending -- The change specification has not been verified, or the change is waiting for the CI update.
  Manual Verification will be required -- When the changes for a Change Order are verified, manual verification will be required.
  Use Discovered Value -- Copy the discovered value to the CI at verification time, and used when

the planned value is not known prior to verification.
Set After Change Executed -- Sets a CI attribute to the planned value after verification has completed. Use this status for setting CI attributes when the attribute is not discoverable. For example, set the CI Primary Contact to User1 after a change completes.

- **Final Statuses**
  Indicates a completed change specification and considered as final. When all change specifications enter either of these final states, the Change Orders are eligible for promotion to the next default state.
  Verified -- The change specification has been successfully verified.
  Was Manually Verified -- The change specification has been manually verified.
  Used Discovered Value -- The CI has been updated with the discovered value.
  Was Set To Planned Value -- The CI has been updated with the planned value after Change Order verification.
  Accepted Planned Value -- The CI has been updated with the planned value and overwritten during verification.
  Accepted Discovered Value -- The CI has been updated with the last discovered value and overwritten during verification.
  No Change -- The planned value matched the CI at verification time and no verification was required.
  Cancel -- The change specification was canceled (see page 2629) by the change manager.

- **Intervention Statuses**
  Indicates a change specification requires manual intervention for verification. CA SDM highlights these statuses in a red color on list forms. These statuses are not final and the Change Order is not considered verified when change specifications are in either of these statuses.
  Failed Verification -- Discovery found the value to be other than what was specified in the Change Order. The Change Analyst must determine if the change was correctly executed and the Change Order was incorrectly specified, or if the Change Order was correct and the change requires verification again. Depending on the definition of the Managed Change State and the current change order status, the Change Analyst can override, change, or cancel the failed change specification.
  Manual Verification Active -- Manual verification is required before the change specification can be marked final.

- **Action Override Statuses**
  Indicates an action to initiate during change verification. These statuses are not final and the Change Order is not considered verified when change specifications are in either of these statuses.
  Accept Planned Value -- Request to override the CI attribute with the planned value.
  Accept Discovered Value -- Request to override the CI attribute with the last discovered value.

- **Reporting Status**
  Indicates the result of policy operations that the verification log displays for logging purposes and not used by change specifications.
  Update Was Allowed -- A policy allowed a request to update a CI and did not match any change specifications.

Managing Failed Verifications

When a verification fails, the CMDB, Configuration Audit, Failed Verifications node in the scoreboard lists the number of failed verifications and change specifications that require manual intervention in a red color. The Change Specifications can also be viewed under the Change Specifications tab in the Change Order, CI or Administration tab with the verify status of "Failed Verification". When a verification fails, the Change Analyst can intervene or wait until the next discovery occurs.

If the managed change state allows the Show Change Specification Override Buttons action, the Change Analyst can open the change specification, review the data, and click one of the following options to close the verification by moving it to a final state:

- **Accept Discovered Value**
  The Analyst determines that the change specification is incorrect and that the discovery tool has discovered the correct value.

- **Accept Planned Value**
  The Analyst determines that the discovery tool is wrong or has not performed discovery, and to accept planned value, as if it was discovered correctly.

- **Cancel**
  This portion of the Change Order was not executed and this specification was canceled.

Managing Undiscoverable Attributes

When a Change Specification requires manual verification, the Configuration Analyst must manually verify the change. The CMDB, Configuration Audit, Manual Intervention node in the scoreboard shows the number of change specifications that require manual intervention in a red color. The Change Specifications can also be viewed under the Change Specifications tab in the Change Order, CI or Administration tab with the verify status of "Manual Verification Active."

If the managed change state allows the Show Change Specification Override Buttons action, the Change Analyst can open the change specification, review the data, and click one of the following options to close the verification by moving it to a final state:

- **Mark as Verified**
  Used when the attribute is not discoverable and manually verified.

- **Cancel**
  This portion of the change order was not executed and this specification was canceled.

Defining Bulk Changes

Creating identical changes to a large number of CIs, for example, when changing the location for a collection of CIs, with the following steps:

1. Create a Change Order.

2. Define a single change specification which describes the change and leave the CI name blank.

3. Attach all the CIs to the Change Order.

If you do not know the exact details of a change in advance of the implementation, for example, you acquire a new Server and you only know the CI Name, complete the following steps:

1. Create a Change Order.
2. Create a change specification that specifies Any Managed Attribute as the attribute name.
3. Leave the planned value empty, since it is unknown.
4. Move the ticket through the change management process.
5. When the Change Order is in a verification active state, and discovery runs, the inbound CI data loads into the CI (assuming that the policy allows it).
6. When all discoveries for the CI complete, the Change Manager must mark the change specification as verified manually.

Follow these steps when there are a large number of dissimilar changes to a large number of CIs. For example, when moving a collection of servers from one location to another, and also assigning each one a unique IP address.

1. Create a Change Order
2. Create a spreadsheet and list on each row the Change Order number, CI and, the new attribute values. Each row results in a distinct change specification.
3. Load the spreadsheet with GRLoader to create the required change specifications.
4. Promote the Change Order and its change specifications as usual.

For more information about using GRLoader, see CMDB Technical Reference (see page 4168)
.

Configuration Audit and Control Facility (CACF)

Configuration Audit and Control Facility (CACF) unifies three disciplines: Change Management, Configuration Management (CMDB), and Discovery Management. CACF verifies that changes are executed accurately and no unauthorized changes occur.

Change verification ensures that the CMDB reflects any changes accurately, and the Discovery Management tools verify the changes.

Change verification provides the following benefits:

- **Change Management**
  - Assurance that authorized changes execute correctly.

- Detection of incorrectly executed changes.
- Detection of unauthorized changes.
- Management reporting.
- Full auditing of all changes down the attribute level.
- Detection of overlapping or conflicting changes.

- **Configuration Management**
  - CMDB contains an accurate and current representation of all managed CIs.
  - Ability to view the future state of the CI with the proposed change specifications.
  - Full auditing of CIs.

CACF has two major sections: the CMDB administrative interface and the change management interface.

CACF Administration and Policy Definition

This article contains the following topics:

The CMDB Administrator defines CIs and attributes that are managed. The CMDB Administrator also defines the policy for updating those CIs and attributes. You administer the CACF components in the Configuration Control node in the CA CMDB section of the Administration tab. Define CACF change specifications from the Change Order, CI, Incident forms, or the Configuration Audit node on the Administration tab.

The administrator must consider allowing standard changes and whether to define the following items:

- Authoritative and trusted sources of data.
- CIs and the CI attributes that are under CACF management.

An incorrectly executed change or rogue change can occur (also referred to as a variance). In this case, CA SDM can respond in any of the following ways:

- accept the new value
- create an Incident
- copy the data to the TWA for later processing.

CA SDM can use any combination of these actions.

Important! The Configuration Administrator *must* establish a change verification strategy (see page 2658) for your environment. The default policy for CACF allows all changes to all CIs. This policy applies even if the change is rogue, or if the change does not match a change ticket.

You can implement change verification policies dynamically or scheduled in advance. You can define these policies as generic or highly specific. The change verification policy describes how CA SDM responds to the following events:

- **Updates from Unauthorized MDRs**
  Indicates that specific MDRs are authoritative for specific attributes. CI attribute updates from unauthorized MDRs can be selectively accepted or rejected.
  For example, define policies to prevent CA Application Configuration Manager from updating the IP address of a CI, even if a matching Change Order exists. Let updates to IP address only if the source MDR is Spectrum.

- **Rogue Changes**

Detects and manages updates to CIs when no corresponding Change Order exists. Specify a policy that manages rogue changes requesting inserts or updates of CI data. For example, you can define a policy that loads data into TWA and does not update the CI for the following conditions:

- A CI named similar to server* in New York changes

- The change does not have a matching Change Order

- **Incorrectly executed changes**
  Detects whenever a Change Order is not implemented (see page 2633) correctly.

Auditing facilities provide the Configuration Manager with capabilities to view changes to policies and CACF object definitions. CACF logs each attempted update to the CI, whether the update was allowed. This log helps you determine which policy allowed or disallowed a change to a CI.

The Configuration Administrator defines which Change Order statuses represent changes that can be edited, and which Change Order change states represent verification states. By default, you can edit change specifications for Change Orders in the *RFC* change state. In addition, you can edit when change verification occurs for a Change Order in the *Verification in Progress* state. Optionally, change tickets can be automatically promoted or closed when all associated change specifications execute successfully.

Important! Performance may be degraded if the Configuration Administrator enables the Create Incident option with more than one active verification policy.

Note: By default, CACF considers updates to attribute values to Change Orders with change verification active as non-rogue changes. The changes are effectively in the Verification in Progress status. The Configuration Administrator can modify this behavior (see page 2649).

How Change Analysts Define Change Specifications

The Change Management interface portion of change verification integrates into the change ticket order form. Change Analysts typically create change specifications when they create a Change Order. The Change Analyst defines the change in terms of the specific CI and CI attribute that they want to change.

The Change Analyst can describe the change specification using any of the following templates:

- Provide the exact CI, CI attribute, and value.
  For example, after the change has been implemented, the IP Address for server1 sets to 10.10.10.10.
- Provide the CI attribute and value, but omit the CI name.
  For example, after the change, all CIs attached to the Change Order upgrade to 8 GB of memory.
- Provide an attribute value to set when the attribute is not discoverable.
  For example: after the change, the CMDB reflects that all CIs are located in NY.
- Use the discovered value.
  For example, you do not know the new IP address in advance, but you know that the IP address will definitely change. Set the IP Address of the CI to whatever value the authoritative MDR discovers.

When the change order is approved, the change specifications are approved as part of the same approval process. The subsequent modifications to the specification can be prohibited and are fully audited.

Change Verification

Change verification ensures that Change Orders execute according to change specifications. A Change Order is verified when its state is Verification in Progress and when the CI is updated. Now, when data from any MDR or web client user imports into the CMDB, CACF compares the incoming attribute data with active change specifications. If the CI attribute data matches, CACF verifies the change. If the inbound data does not match the Change Order specifications, a corrective action can occur based on the policy.

The executed policies can perform any of the following actions:

- Reject a single attribute update from the transaction.
- Reject the entire transaction, including all attribute and value pairs.
- Load the entire transaction to the TWA for deferred processing after approval and verification of the transaction.
- Create an Incident that describes each variance.

Note: This action can trigger existing notification and automation. To prevent multiple incident creation, rogue change detection creates a single incident for all rogue changes to a single CI.

- Accept the transaction unconditionally when accepting data from authorized source MDRs.

For example, the CMDB Administrator can define a policy that creates an Incident when a change to a production server executes incorrectly. When imported data from an authorized MDR does not match a pending change specification, CACF creates an Incident. The policy can allow or reject a CI update by the nonmatching import data. In addition, the Change Manager may accept the newly discovered value, even if the value does not match the planned change specification exactly.

Note: If multiple discoveries occur during change specification verification, discovery data can invalidate a previously verified change. At the end of verification, the CI is in the state that all the change specifications want.

How Change Managers Use Change Specifications

The Change Manager can perform the following actions:

- View and modify the verification status of each change specification.
  For example, the Change Manager wants to know which change specifications are still pending for Change Order 12345. The change order is in *Pending Verification* status.

- Manage Incidents for rogue or improperly executed changes.
  For example, the Change Manager wants to see which changes have failed verification and which changes require more investigation.

- Manage the changes that require manual intervention.
  For example, a Change Order specifies that manual verification is required for a nondiscoverable change. The Change Analyst must complete the task.
  For example, the Change Manager investigates and determines that Change Order 12345 specifies ten different change specifications. Due to a typo, change specification number 9 was incorrect and can be canceled.

Auditing facilities provide the change capabilities to view the status of each update to the change specification and any overrides to the change specification. The scoreboard shows the status of the running system and any exceptional conditions that require intervention or investigation. CA Business Intelligence reports provide a longer term view of the efficiency of Configuration Manager policies to monitor the health of your environment.

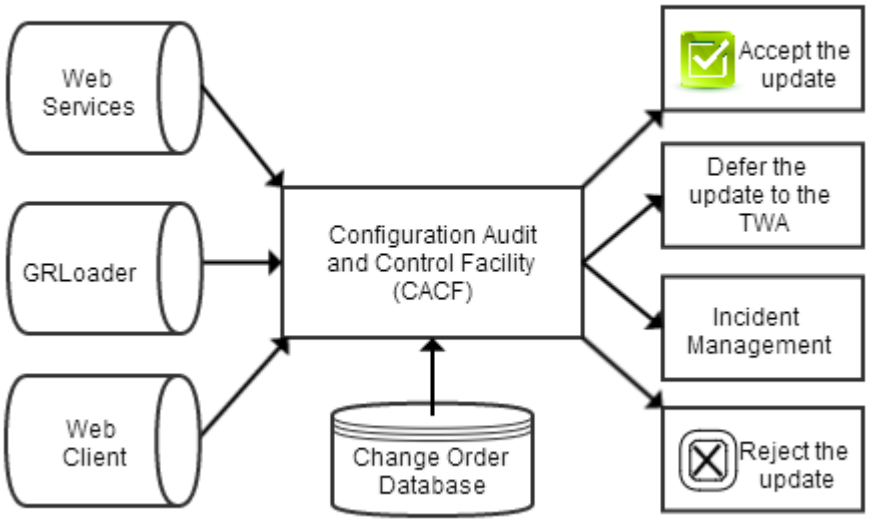
How Configuration Audit and Control Facility Works

This article contains the following topics:

CACF governs inbound CI data before loading the data into the CMDB. This verification ensures that each requested Change Order executes correctly, and detects and manages rogue changes automatically. The Configuration Administrator (CMDB Administrator) defines verification policies. The policies determine how CA SDM responds when any deviation or variance from the requested change occurs.

The following diagram shows how CACF works:

How Configuration Audit and Control Facility Works



1. Inbound CI data loads from Web Services, GRLoader, MDR, or the Web Interface to request an attribute update for a CI.

2. Based on the verification policies that your Configuration Administrator establishes, CACF completes one or more of the following actions:

   - CACF accepts the update and modifies the CI data in the CMDB.

   - CACF defers the update to the TWA for further processing.
     For example, your Change Manager handles transactions in the TWA.

   - CACF creates an Incident and lets you manage the ticket.
     For example, your Incident Management process requires managing the Incident for reporting purposes.

   - CACF rejects the update and the CI data is not changed in the database.

Verification Policy

First the Configuration Manager and the Change Manager agree on a change verification policy. Next, the decisions transcribe into a CA SDM change verification policy. A system can have many verification policies. When a CI update occurs, CACF selects a single verification policy for each updated attribute. The verification policy can update the CI, create a TWA entry, or create an Incident if a matching change specification exists.

Note: To monitor updates through the web client, specify the MDR Class Pattern as **Web Client** (case sensitive) in the policy. This pattern usage applies to English and localized versions of CA SDM when you want to monitor updates through the web client.

Important! Determining what policies you need in your environment requires significant thought into the goals of the organization and how you want to introduce those policies.

Verification Policy Selection

When an update occurs to a CI, CACF selects a policy for each updated attribute. This selection depends on the source of the update, the target CI, and whether matching change specification exists. When multiple policies match, CACF selects the single policy with the lowest sequence number to manage the attribute update.

Note: CACF can select multiple policies to manage a single transaction that updates multiple attributes. For example, updating a CI with a new description and new IP Address can trigger two different policies.

Each policy has four sections that CACF uses in policy selection:

- **Identification and Priority**
  Identifies a policy and specifies the order to evaluate the policy.
- **Change Order Alignment**
  Selects transactions that are based on how closely the attribute update matches an existing change specification.
- **Transaction Filter**
  Specifies the data sources to which this policy applies.
- **CI Filter**
  Specifies the CIs to which this policy applies.

A policy matches an attribute update when it passes each of these filters. If a policy does not match a transaction, CACF bypasses the policy. Next CACF evaluates other policies in the system. If CACF bypasses all policies, the default action lets the CI attribute update occur.

Verification Policy Filter Syntax

To help with establishing generic policies, the Change Order Alignment, Transaction Filter, and CI Filter accept an asterisk as a final pattern character as a wildcard. To indicate negation, use an exclamation point at the beginning of these filters.

Important! Policy pattern rules differ from change specification planned value rules. For policy filters, you cannot use embedded asterisks (*) or the greater than (>) and less than (<) special characters.

Policy filters are case-sensitive for verification policy selection patterns, such as CI Name or CI Class. The filters are case-sensitive even if you define those attributes as case insensitive.

Note: A blank "" (no value is specified in the field) policy filter matches only the blank value. A policy filter that uses an asterisk matches all values.

Consider the following information with the following example verification policies:

- Policy1 selects CIs name(prod*) attribute(IP Address) where a matching change specification exists.
- Policy2 selects CIs name(prod*) attribute(IP Address) where there is a rogue update.
- Policy3 selects CIs name(test*) attribute(Memory Installed) from mdr(Cohesion).
- Policy4 selects CIs name(“”) attribute(Memory Installed).

The following list describes the possible outcomes of these policies:

- When an update to CI(test2) attribute(Memory Installed) occurs, Policy3 manages the update. CACF ignores Policy1 and Policy2.
- When an update to CI(prod3) attribute(Memory Installed) occurs, and a matching change specification exists, Policy1 manages the update.
- When an update to CI(development4) attribute(IP Address) occurs, CACF updates the CI with the new IP address as no matching policy exists.
- When an update to CI(prod1) attribute(Disk Capacity) occurs, no policies for attribute(Disk Capacity) exist. CACF updates the CI with the new value. In this example, CACF does *not* manage the Disk Capacity attribute.

- Policy4 only matches CIs with blank names. Because blank CI names are invalid, the change is never executed.

Verification Policy Prioritization by Sequence Number

When multiple policies match an attribute update, CACF chooses the policy with the lowest sequence number. Consider the following policies and their sequence numbers.

- Policy name(Policy1) sequence(1000) CI(prod*)
- Policy name(Policy2) sequence(2000) CI(prod-NY*)

When an update to CI(prod1) occurs, Policy1 manages the transaction. When an update to CI(prod-NY-1) occurs, Policy1 still manages the transaction as it has a lower sequence number. In this example, Policy2 never takes effect.

We recommend that you change the sequence numbers so that the most specific policy has the lower sequence number. Refer to the following sample policies:

- Policy name(Policy1) sequence(2000) CI(prod*)
- Policy name(Policy2) sequence(1000) CI(prod-NY*)

When an update to CI(prod1) occurs, Policy1 manages the transaction. When an update to CI(prod-NY-1) occurs, Policy2 manages the transaction as it has a lower sequence number.

Change Order Alignment

Policies filter on how closely a CI attribute update matches a change specification. After a CI update, CACF searches for a change specification that matches both the CI and the attribute name. This search can verify the change specification. This Change Order Alignment can occur as follows:

- Change specifications exist for this attribute and CI.
- Change Orders exist for this CI, and those Change Orders do *not* contain change specifications.
- A rogue insert transaction occurs which indicates and new CI. A Change Order does *not* exist with this CI attached to it.
- A rogue update transaction occurs which indicates an existing CI. A Change Order does not exist with this CI attached to it.

Only Change Orders in a state where *change verification is active* are considered when looking for a matching Change Order. Closed, unapproved, unscheduled, or otherwise nonexecuted Change Orders are not considered when searching for a matching Change Order.

After CACF determines the Change Order alignment of a transaction, it performs a search for a corresponding policy. A policy can manage one or more Change Order alignment types:

- **Change Order with Specifications**
  Indicates that a Change Order with a change specification which specifies the updating CI and attribute name exists.

- **Change Orders Without Specifications**
  Indicates Change Orders that specify this updating CI, and those Change Orders do not have any change specifications.

- **Rogue Insert**
  Indicates an inserted CI, by definition, the CI does not have any matching Change Order in a verification state.

  Important! Policies which prevent rogue inserts must specify a managed attribute of *Name* or *All Managed Attribute. Name* specifies an active managed attribute.

  CACF always allows rogue inserts and updates when a transaction only has unmanaged attributes.

- **Rogue Update**
  Indicates an updated CI that has no matching Change Orders in a verification state.

Example Change Order Alignment Policies

The following example policies specify Change Order Alignments:

- Policy name(legacy) filters CI(*) attribute(Any Managed Attribute) alignment(Change Orders Without Specifications) action(Allow Attribute Update)

- Policy name(new) filters CI(*) attribute(Any Managed Attribute) alignment(Change Orders with Specifications) action(Allow Update Only if Matches Change Specification)

- Policy name(no-rogue) filters CI(*) attribute(Any Managed Attribute) alignment(rogue insert or rogue update) action(Always Cancel Entire Transaction, create Incident)

These examples provide the following functionality:

- Policy(legacy) allows CA SDM r12.6 change orders without change specifications to update the CI as they did before a CACF implementation.

- Policy(new) enforces change verification for all new change orders which have matching change specifications.

- Policy(no-rogue) prevents updates to CIs when no Change Orders exist in a Verification Active state.

Transaction Filter

Policies filter transactions that are based on the source of the transaction. The source includes the attribute name, MDR name, MDR class, and role (see page 2637) of the user that performs the update.

Note: If you want to filter users logged on through the web interface only, specify the keyword **Web Client** for the MDR class. The userid of the contact specifies the MDR name. This method of identifying users applies only to verification policies. The method does not appear in any other part of the product.

Example: Transaction Filters

The following example policies specify Transaction Filters:

- Policy name(root_access) filters ci(*) attribute(All Managed Attributes) role(Administrator) action (Allow Attribute Update)
- Policy name (cohesion_not_authorized) filters ci(*) attribute(IP Address) MDRclass(Cohesion) action(Keep Old Attribute Value)
- Policy name(john) filters ci(user1*) attribute(All Managed Attributes) MDRName(user1) MDRClass (Web Client) action(Allow Attribute Update)

These examples provide the following functionality:

- Policy(root_access) lets any user with Administrator access update any value. We recommend this type of policy to have a low sequence number.
- Policy(cohesion_not_authorized) prevents any MDR of MDR class(Cohesion) from updating the IP Address of the filtered CI. This example shows how to prevent an unauthorized MDR from updating data.
- Policy(user1) lets user1 update the CIs that the contact owns, but only when using the web client. This example shows how to provide specific users full control over their data.

CI Filter

Policy filters transactions on the characteristics of the updated CI. This selection criteria includes CI Name, class, priority, service type, and location.

Important! The CI filter is based on the attribute value in the CI before the update occurs. The filter is not based on the value in the inbound transaction data.

Example: CI Filter Policies

The following example policies specify CI Filters:

- Policy name(priority1) filters Service Type(priority1 resolution) action(Allow Update Only if Matches Change Specification, Create Incident)
- Policy name(prod-NY) filters ci(prod*) location(NY) attribute(All Managed Attributes) action(Allow Update Only if Matches Change Specification)
- Policy name(prod-not-NY) filters ci(prod*) location(!NY) attribute(All Managed Attributes) action (Allow Attribute Update)

These examples provide the following functionality:

- Policy(priority1) requires CIs with a service type of *priority1 resolution* to have a matching Change Order. This policy is a best practice because it helps control the most important CIs in the CMDB. This policy also requires verification for all changes under change management to have change specifications. It also requires the changes to be verified and completed.

- Policy(prod-NY) requires CIs in the NY location to have matching Change Orders. Using location to filter policies can help gradually implement change verification on a site by site basis.

- Policy(prod-not-NY) illustrates using the exclamation point in the location pattern to indicate CIs not located in NY.

Policy Actions

After CACF selects a policy, the action section of the policy determines the outcome of the attribute update. This section identifies the most important part of the verification policy because it affects the integrity of the CMDB. This section also affects the change management workflow, related notifications, and created Incidents.

A policy can have one of the following Update Behaviors:

- **Allow Update Only if Matches Change Specification**
  If the CI matches a change specification, conditionally applies the inbound attribute update to the CI. This update occurs when the Change Order is in a Verification Active state. Selecting this option enables change verification.

- **Allow Attribute Update**
  Unconditionally applies the inbound attribute update to the CI. This option effectively disables all change verification. Use this behavior for standard changes, when you have a trusted data source, authoritative, and you do not require a Change Order.

- **Always Cancel Entire Transaction**
  Cancels the update and any other attribute update in this transaction, even if a matching change specification exists. To prevent MDRs from updating CIs where they are not authorized to update, use this behavior. If any policy cancels a transaction, the entire transaction is canceled. The transaction is canceled even if other policies would have allowed the change to occur.
  For example, specify this behavior to stop an unauthorized MDR from inserting a CI. In addition, specify a common attribute name such as *Name*.

- **Keep Old Attribute Value**
  Cancels the single attribute update, but allows other attributes in the transaction to update if their policy allows it. Use this behavior when an MDR is unauthoritative at the attribute level.

A verification policy can specify that Incidents close automatically when failed verifications are remediated. The policy can specify that the inbound transaction data copies to the TWA. This type of policy is useful when data from an unauthorized MDR requires review before updating the CMDB.

To let the Configuration Manager identify that CACF policies that created the TWA record, the Change Order field in TWA is set to the name of the policy that created it. Writing data to TWA is independent of updating the CI in the CMDB, so a policy can update the CI, write to the TWA, or both.

Policy Scheduling

You can specify activation and deactivation dates on verification policies, which let the Configuration Administrator schedule unattended policy changes.

Multiple Policies

As you introduce more verification policies into your environment and more attributes are managed, organizing the policies becomes increasingly complex. More overlaps exist between the policies. For example, you have one policy for Server CIs and another policy for CIs in NY. Consider the appropriate policy for Server CIs in NY. Use the policy sequence number to force one policy to take precedence when multiple policies can potentially control a single attribute. As you manage more attributes, the possibility that more policies manage a single transaction can increase.

Consider the following information when you have multiple active policies for a single transaction:

- If any selected policy requests writing data to the TWA, data also writes to the TWA.
- If any selected policy requests to cancel the transaction, CACF cancels the entire transaction.

Important! Facilities that use the createAsset web service (including GRLoader and CMDBf) break the transaction into three separate transactions. The transactions include two inserts, and an update. Updates to ca_owned_resource can be allowed, while updates to the CI extension table are canceled. Updates to CI family-specific attributes in the extension table may not be detected as inserts, but rather as updates.

Example Multiple Policies

The following examples specify multiple policies:

- Policy name(IP Address) attribute(IP Address) action(Allow Attribute Update)
- Policy name(Memory Installed) attribute(Memory Installed) action(cancel transaction)
- Policy name(Disk Capacity) attribute(Disk Capacity) action(Keep Old Attribute Value)

These examples provide the following functionality:

- If a transaction only updates IP Address, the update is performed.
- If a transaction only updates Memory Installed, the update is not performed.
- If a transaction updates both IP Address and Memory Installed, the transaction is canceled in the web interface.
- If a transaction updates both IP Address and Disk Capacity in the web interface, IP Address is updated, but Disk Capacity is not updated.
- If a transaction updates both IP Address and Memory Installed in the web interface, neither attribute is updated.

Incident Consolidation

When a verification policy requests to create an Incident, CACF can reduce the number of open Incidents as follows:

- CACF creates only one open Incident for a single CI for rogue changes. More rogue changes update the single open Incident for rogue changes.
- CACF creates only one open Incident for each change specification verification failure. More verification failures for the change specification update the open Incident.

How to Define Policies for Change Verification

Contents

To begin using CACF in your CA SDM environment, complete the following recommended steps:

1. Review the Managed Change States in the CA SDM environment. Update the default Managed Change States or add states as necessary to suit your change management strategy. Change verification initiates when the status of a Change Order changes to a Change State that CACF manages. For example, Verification in Progress.

2. Identify the available CI Managed Attributes that you want CACF to manage for change verification.

   - For example, you want to manage changes to Memory Installed (phys_mem) so that the attribute *must* have a matching Change Order for the test* server. You also consider changes to IP Address (alarm_id) as normal and always allowed.

   - For example, you want to manage changes to Memory Installed (phys_mem), MAC Address (mac_address), and IP Address (alarm_id) so that the attribute must have a matching Change Order for prod*. You do not want MDR1 to update IP Address and prefer MDR2 to complete this update. When you have a problem, create an Incident. Closing the Change Order also closes the Incidents automatically.

3. Determine what CIs or subset of the CIs in your system that you want to monitor.
   For example, you want to control all servers name test* and prod*. In addition, you control what CIs based on CI Class and CI Location.

4. Determine what MDRs and sources of data that you want to monitor.
   For example, you want to restrict data from MDR1 for the IP Address attribute from updating any CIs.

5. Determine the appropriate verification policy to manage the following types of change:
   - CI changes that match change orders.
   - CI changes that match the attributes in a Change Order, but do not match the value.
   - CI changes that you consider as rogue updates.
   - CI changes that you consider as rogue inserts.

6. Determine the appropriate update behavior that CACF takes when it detects a variance for a policy:
   - Always allow the attribute update request.
   - Allow the attribute update only when a corresponding change specification is specified for the update.
   - Always cancel the entire transaction.
   - Keep the existing attribute value.
   - Write data to the TWA.
   - Create an Incident when CACF detects a variance.
   - Automatically close any Incidents after Change Order verification.

For more information about change verification planning and implementation, see Planning and Implementing Change Verification (see page 2670).

Change Verification Best Practices

Consider the following best practices when implementing change verification:

- Define a small number of policies.
- Avoid the use of negative logic (exclamation point in a policy pattern).
- A single CI update save must match a small number of policies.
- Organize the policies in a numerically tiered structure.
- Use Log Only Mode policies before you implement a change verification policy.
- Minimize overlapping policies, where multiple policies manage a single attribute being updated.
- Limit the number of Incidents that CACF creates.

- Implement archive and purge of CACF data.

Organizing Policies

You can use several strategies to track policies. We recommend that you use a multi-tier approach. To allow for future inserts, use increments of 100 between policy numbers.

Consider the following example tiers for this strategy:

- **Fundamental Policies**
  100,000-199,999
  - Allow Change Administrators to perform inserts.
  - Disallow the inserts by MDR Class(xxxx).
  - Exclude all test CIs from incident creation.
- **Temporary or Transient Policies**
  200,000-299,999: Bulk loads this week
- Application-Specific Policies
  - 301,000-301,999: Exceptions to the following general application-specific policies:
    For example, server1 in NY policies
  - 311,000-311,999: Policies that relate to Service Type priority1 resolution.
  - 320,000-320,999: Policies that relate to NY.
  - 331,000-331,999: Policies that relate to Lisle.
- Technology-Specific Policies
  - 410,000-410,999: Policies that are related to Servers.
  - 411,000-411,999: Policies that are related to Network.
- **Default Policies**
  You can use these policies if the previous policies do not apply to your environment.
  900,000-999,999: Default policies, such as all updates to managed attributes (Any Managed Attribute) must have a change specification.

Multi-Tenancy Considerations

Consider the following information when using CACF in a multi-tenancy environment:

- Managed attributes, verification policies, Change Orders, and change specifications are tenanted.
- Tenants up their hierarchy can view all CACF objects.
  For example, if a tenant creates a managed attribute, this action may block a tenant in the hierarchy from creating a duplicate managed attribute. The hierarchy requires unique policy sequence numbers.

- To determine the policy that manages a change to an attribute, consider only policies from the tenant hierarchy of the object (CI).
- A subtenant can create a policy that overrides the supertenant by assigning a lower sequence number to their local policy.
- CACF only considers policies at the tenant level and its parents in the hierarchy.
- CACF does not consider the tenant of that contact that performs the change.

Note: Verification policies are specific to your system and do not vary by user or role.

CACF Roles and Functional Access

The following table describes the default roles that CACF uses:

Role/Functional Access	Administration	CI	Incident/Problem/Request	Change Order
Administrator	Modify	Modify	Modify	Modify
Configuration Administrator	Modify	Modify	Modify	Modify
Configuration Analyst	View	Modify	Modify	Modify
Configuration Viewer	None	View	Modify	View
Change Manager	View	Modify	Modify	Modify
Service Desk Administrator	Modify	Modify	Modify	Modify
Service Desk Manager	View	Modify	Modify	Modify
System Administrator	Modify	Modify	View	View
Level 1 Analyst	View	View	Modify	View
Level 2 Analyst	View	Modify	Modify	Modify
Incident Manager	View	View	Modify	Modify
Problem Manager	View	View	Modify	Modify

- **Administration**
  Indicates creating, updating, and viewing CACF administration, policies, and attribute management.
- **CI**
  Indicates creating, updating, and viewing CI and relationship attribute data.
- **Incident/Problem/Request**
  Indicates modifying and viewing outstanding CACF issues, including rogue changes and incorrect change execution variances.
- **Change Orders**
  Indicates creating, updating, and viewing change specifications.

For example, the Change Manager role can view CACF policies and can manage attributes, but cannot update them.

Important! Update access to the Change Order and its status determine who can edit change specifications. For example, the Change Administrator provides this access to the Change Manager.

Example Change Specification in the Pending Verification Status

In this example, the Configuration Administrator established a verification policy for the Memory Installed (phys_mem) attribute to Allow Update Only if Matches Change Specification. CACF monitors a change specification for this attribute with the Verification Pending status. It sets the Change Specification to the Verified or Failed Verification status.

The following steps describe the lifecycle of this change specification:

1. A Change Order requests an update to the Memory Installed (phys_mem) attribute of a CI.
2. You create a change specification for the Memory Installed (phys_mem) Managed Attribute with a Planned Value of 4 GB with the initial status as Verification Pending.
3. The Change Order moves to a status with change verification active such as Verification in Progress.
4. The change specification waits for a discovery tool to discover CI details and export the values to the CMDB.
5. One of the following actions occurs after the discovery tool exports the value to the CMDB:
   - The value for Memory Installed matches the 4gb value that you specified in the change specification. CACF sets the status from Verification Pending to Verified. CACF closes the Change Order.
   - The value for Memory Installed does not match the value that you specified. CACF sets the status from Verification Pending to Failed Verification.

Example Change Specification in the Set After Change Verified Status

In this example, CACF updates the CMDB with the value that you want to use after the Change Order exits a managed change state with change verification active. For example, your environment uses Verification in Progress as the managed change state with change verification active enabled.

The following steps describe the lifecycle of this change specification:

1. A Change Order requests an update to the Serial Number (serial_number) attribute of a CI.
2. You create a change specification, specify Serial Number, and enter a planned value for an attribute.

3. You set the Change Order state to from RFC to Verification in Progress to Closed.

4. The CI attribute value is updated with the planned value after the Change Order exits a state with Change Verification Active (Verification In Progress). The value is updated to a state that does not have change verification active (Closed).

5. The change specification sets to Was Set to Planned Value to indicate that the set was completed successfully.

Accept the Planned Value

In this example, the Change Analyst researches the correct attribute value for a CI and accepts the planned value.

Follow these steps:

1. Open a Change Specification that an end user created in your environment.

2. To see the planned value for the CI attribute that the Change Analyst modified, view the detail page.

3. Research the attribute value for the CI.
   For example, your research indicates that the Change Analyst entered the correct value.

4. To update the CI with the corresponding planned value, click Accept Planned Value.
   CACF sets the state of the Change Specification to Accepted Planned Value.

Accept the Discovered Value

In this example, the Change Analyst determines that the CI is updated to a correct attribute value for a CI and accepts the discovered value.

Follow these steps:

1. Open a Change Specification that a Change Analyst created in your environment.

2. To see the planned value for the CI attribute that the Change Analyst specified, view the detail page.

3. Research the attribute value for the CI.
   For example, discovery indicates that the Change Analyst entered the incorrect value.

4. Click Accept Discovered Value.
   The CI updates with the discovered value. CACF sets the status of the change specification from Verification Pending to Accepted Discovered Value.

5. If you configured the managed state to enable the Promote Change Order After Verification option, CACF closes the Change Order. The closure happens after all change specifications are in a final state.

Manage Changes from an Unauthorized MDR

In this example, the Configuration Administrator established a verification policy to manage changes from an unauthorized MDR named MDR1. The policy rejects all updates to CIs from MDR1.

The following steps describe the lifecycle of this verification policy:

1. You create a Verification Policy with an MDR Name pattern of MDR1 and an Update Behavior of Always Cancel Entire Transaction.
2. Enable all Change Order alignment options.
3. Specify Any Managed Attribute and an asterisk (*) for all filters.
4. When the discovery tool (MDR1) runs and exports the data to the CMDB, the verification policy rejects all the updates.

Managed Attributes

Managed attributes indicate those eligible CI attributes for change verification by CACF. By default, this list contains *CI Name* and *Any Managed Attribute*. You add the CI attributes that you want managed as part of your change verification strategy. Define managed attributes as part of your change verification strategy in the Configuration Control, **Managed Attributes** node in the CA CMDB section of the Administration tab.

CACF does not consider unmanaged attributes (attributes not listed) for change verification. These unmanaged attributes update as usual.

Important! Change verification ignores unmanaged attributes and lets them update the CI, unless a verification policy specifies the Always Cancel Entire Transaction behavior.

Note: Case sensitivity in the managed attribute definition only applies when CACF compares the change specification planned value with the inbound CI transaction data. Case sensitivity does not apply to the selection patterns in the policy, which are always case-sensitive.

For a list of CI attribute names, see *CMDB Technical Reference (see page 4168)*.

Managed Change States

This article contains the following topics:

CACF uses managed change states to indicate which Change Order statuses CACF manages. CACF uses managed change states to control how or when to apply change verification for CI updates made to the system. You can customize these change states to suit the needs of your organization.

You configure managed change states on the Administration tab in the CA CMDB, Configuration Control, Managed Change States node.

The following list describes the Managed Change States options:

- **Change Specifications Editable**
  Specifies whether you can edit the change specifications for a Change Order. Typically, after a change request receives approval, you cannot change the request, and updates are restricted to performing a small set of override options in the *Verification in Progress* state.

- **Change Verification Active**
  Specifies whether changes discovered for a CI while the Change Order is in this status are considered for change verification. Change orders and their related change specifications are compared with any inbound transactions to verify that they were executed successfully.
  CACF monitors all CIs for any changes to their managed attribute values. As CACF verifies each attribute level change to the CI, CACF compares it against a list of change specifications that are in a *change verification active* state.
  After a change specification enters this state, any change specification without a specific CI undergoes expansion. This expansion occurs where new change specifications are created using the list of CIs attached to the Change Order.
  After a change specification exits this state, the list of change specifications with a verify status of *Set After Change Executed* complete. This action updates the CI with the planned values, as specified in each change specification.

- **Implementation State**
  Specifies whether the state represents a state when the changes are being executed or implemented on the CI. When a Change Order enters this transitional state, it is understood that the attribute values in the CI are volatile and may be updated as requested by the pending change specifications. CACF cannot consider these changes rogue changes, but it also cannot consider the changes for final verification. Typically, the change verification process should only compare the inbound attribute data after the Change Order executes completely.

- **Show Change Specification Override Buttons**
  Specifies whether the Change Analyst can control change specifications, and what level of control is given. In some implementations, the Change Analyst can edit change specifications as necessary, while in other implementations, the Change Analyst can override (see page 2657) or cancel (see page 2657) the change specification.

- **Promote Change Order after Verification**
  Specifies whether a Change Order promotes to the next default state automatically after CACF verifies all the change specifications.

Default Managed Change States

You can define Change Order states during which change specifications are created, overwritten, verified, or ignored.

The following list describes the default managed change state definitions that are provided by CA SDM as an example:

- **RFC**
  Define the Change Order specifications in this state, but are not considered during change verification. Changes to the CI detected while the Change Order is in this state are typically considered as rogue.

- **Approval in Progress**
  Change specifications in this state have the same characteristics as RFC and are editable and not considered for verification.
  After Change Order approval, the change specifications are approved as part of the same approval process. CACF prohibits more modifications to the specification and provides full auditing.

- **Implementation in Progress**
  Changes to CIs can occur, but are not considered rogue or used for verification. You may want to change the definition of this change state to let verification occur for Change Orders in this state.

- **Verification in Progress**
  Change specifications cannot be edited, but an analyst can override them. Change verification is active (see page 2654) in this state.

Change Specifications

A Change Order contains change specifications that define the specific CI changes that are requested for a CI. CACF uses these change specifications when the Change Order enters a verification state to validate and confirm that the actual changes to the CI completed correctly. Create change specifications from a Change Order, CI, or the Configuration Control, Change Specifications node the CA CMDB section of the Administration tab.

The change specification contains the following main sections:

- **Change Order Number**
  Specifies the Change Order that requests the change.

- **CI Name**
  Contains the name of the CI that you want to update.
  You can leave the CI Name field blank to imply that the change specification applies to all CIs defined for the Change Order. Use this option when all the CIs for a Change Order use the same managed attribute and planned value. The change specification applies to all CIs that are attached to the Change Order when the change order status moves to a managed change state with change verification active, referred to as expansion.

- **Attribute Name**
  Specifies the name of the managed attribute that you want to update.
  Selecting Any Managed Attribute indicates that any managed attribute can change during the verification of the Change Order. Because you can update multiple attributes in this case, you cannot specify the planned value.

- **Planned Value**
  Indicates the expected value of the attribute after executing the change. After the Change Order moves into a verification state, and the CI updates through the web interface, GRLoader, or Web Services, CACF compares the planned value with the inbound data to determine a match.
  Special characters (see page 2652) can be embedded in the planned value when the exact value is not known.

- **Status**
  Specifies the status of the change specification (see page 2656), such as Verification Pending.

If you do not know the planned value in advance, but the value may change, you can set the status of the change specification to Use Discovered Value. This behavior requires discovery to update the CI before CACF considers the change specification as validated. You require this behavior for numeric fields and SRELs where an asterisk cannot be accepted as a planned value.

To help you with setting the planned value, the Discovered Attribute History tab lists all values that were recently discovered by an MDR, and whether were actually authorized, or loaded into the CMDB. This tab displays the format, case sensitivity, and other information about values so that you can determine an appropriate planned value pattern.

Special Characters

You can embed special characters when you do not know the exact value. Use the asterisk wildcard character to match any number of characters. The pattern *must* match the discovered data in the same sequence, and spaces are significant.

For example, enter *10.*.*.** as the Planned Value to match any IP addresses that begins with *10.* and has two periods that follow any value between the periods.

For example, the inbound server_type value contains Windows 2003 (WIN32) 5.2.Service Pack 2 (Build 3790) Intel x86. To verify this value, specify a planned value of ** Service Pack 2 ** in the change specification.

A word at the beginning of the planned value indicates that the discovered value must start with that value. Similarly, an asterisk at the beginning of the planned value indicates that the discovered value can begin with any value and end with the value specified following the asterisk.

The following table provides examples about how to use the asterisk:

Planned Value	Discovered Value	Match or No Match
a	b	No Match
a	a	Match
a	aba	Match
a	bab	Match
a*	a	Match

a*	ab	Match
a*	ba	No Match
*a	a	Match
*a	ab	No Match
*a	ba	Match

A pattern that begins with an exclamation point results in the negation of the value. You can only use the exclamation point as the first character in the pattern. For example, you cannot use a pattern of 10.!*.*.*.

To compare numeric values that are contained within string values, use greater than (>) or less than (<) as the first character in the planned value. If there is a leading exclamation point, it must be the second character.

Important! CACF ignores leading or trailing nonnumeric values in the discovered value and planned value patterns.

The following table provides examples about how to use the exclamation point, and the greater than and less than symbols:

Planned Value	Discovered Value	Match or No Match
>200	aaa 201 bbb	Match
>200GB	aaa 200 bbb	No Match
>200GB	300 GB	Match
!<200GB	200 Bytes	Match
!<200	200 Bits	Match

If you do not know the planned value in advance, but the value may change, you can set the status of the change specification to Use Discovered Value. This behavior requires discovery to update the CI before CACF considers the change specification as validated. You require this behavior for numeric fields and SRELs where an asterisk cannot be accepted as a planned value.

To help you with setting the planned value, the Discovered Attribute History tab lists all values that an MDR recently discovered, and whether they were authorized, or loaded into the CMDB. This tab displays the format, case sensitivity, and other information about values so that you can determine an appropriate planned value pattern.

Defining Bulk Load

Managing new CIs without first creating a Change Order that requires defining those CIs presents an issue within CMDB environments. Consider the following information when you define a large number of CIs

- Define a special bulk loading policy that allows rogue insert to complete successfully, restricted by userid, MDR, or role.

- Define a special bulk loading policy that reroutes all new CIs to the TWA for verification and later processing. This action also requires the previous special bulk loading policy.

Defining Bulk Changes

Creating identical changes to a large number of CIs, for example, when changing the location for a collection of CIs, with the following steps:

1. Create a Change Order.

2. Define a single change specification which describes the change and leave the CI name blank.

3. Attach all the CIs to the Change Order.

If you do not know the exact details of a change in advance of the implementation, for example, you acquire a new Server and you only know the CI Name, complete the following steps:

1. Create a Change Order.

2. Create a change specification that specifies Any Managed Attribute as the attribute name.

3. Leave the planned value empty, since it is unknown.

4. Move the ticket through the change management process.

5. When the Change Order is in a verification active state, and discovery runs, the inbound CI data loads into the CI (assuming that the policy allows it).

6. When all discoveries for the CI complete, the Change Manager must mark the change specification as verified manually.

Follow these steps when there are many dissimilar changes to many CIs. For example, when moving a collection of servers from one location to another, and also assigning each one a unique IP address.

1. Create a Change Order

2. Create a spreadsheet and list on each row the Change Order number, CI and, the new attribute values. Each row results in a distinct change specification.

3. To create the required change specifications, load the spreadsheet with GRLoader.

4. Promote the Change Order and its change specifications as usual.
   For more information about using GRLoader, see the General Resource Loader (see page 4289) topic.

How Change Verification Occurs

When a user requests a save to a CI, CA SDM searches for applicable change specifications as it searches for all matches. The following information describes an applicable change specification:

- The CI in the change specification is the same as the one that is being saved.
- The Change Order is in a managed change state that is defined with Change Verification Active.
- The attribute in the change specification is the same as the attribute being updated.
- The change specification is active.
- If there are no managed attributes being updated or policy in effect, the save proceeds uninhibited.

If the inbound data values match a change specification exactly, CACF considers the change specification as validated. Depending on the policy, verification closes any Incident that change verification created.

Verification takes place when information from web clients, web services, or GRLoader update the CI. At this time, the Change Order and all underlying change specifications are undergoing verification. After all verification for a Change Order complete, the Change Order can optionally promote to the next Change Order state automatically.

If the inbound data values do not match the values in the change specification, it is considered an incorrectly implemented or failed change. Incidents are created or appended to, depending on the policy.

For example, CA SDM does not find applicable change specifications, but Change Orders exist in a *change verification active* state. These Change Orders specify the target CI and have no change specifications. CACF manages this change by policies which handle *Change Orders without Specifications*.

- If there are no applicable change specifications or Change Orders without specifications, the save operation is considered rogue.
- After all attributes have been processed, any policy that requested the inbound data to write to the TWA triggers.

Managing Change Specifications

After a change is executed or implemented, the Change Order enters a change state that is managed by CACF. The change state is set to *change verification active*. When the Change Order is in this state, CACF reviews all related CI activity. CACF reports the status of each change specification to the scoreboard.

The Change Manager uses the scoreboard to verify that the required changes are correctly executed and to perform any manual verification that is required.

After all verification for a Change Order are complete, the Change Order may optionally be promoted to the next Change Order state (typically closed). In this state all change specifications are automatically marked inactive.

Change Specification Statuses

Change specifications use status to indicate the type of verification to perform and the current state of verification. The status values are also used in the verification log when recording change verification operations during the verification process.

- **Initial Statuses**
  Used when creating a Change Specification to specify the type of verification for CACF to perform. These statuses are not final. The Change Order is not considered verified when change specifications are in either of these statuses.
  Verification Pending -- The change specification has not been verified, or the change is waiting for the CI update.
  Manual Verification will be required -- When the changes for a Change Order are verified, manual verification is required.
  Use Discovered Value -- Copy the discovered value to the CI at verification time, and used when the planned value is not known before verification.
  Set After Change Executed -- Sets a CI attribute to the planned value after verification has completed. Use this status for setting CI attributes when the attribute is not discoverable. For example, set the CI Primary Contact to User1 after a change completes.

- **Final Statuses**
  Indicates a completed change specification and considered as final. When all change specifications enter either of these final states, they are eligible for promotion to the next default state.
  Verified -- The change specification has been successfully verified.
  Was Manually Verified -- The change specification has been manually verified.
  Used Discovered Value -- The CI has been updated with the discovered value.
  Was Set To Planned Value -- The CI has been updated with the planned value after Change Order verification.
  Accepted Planned Value -- The CI has been updated with the planned value and overwritten during verification.
  Accepted Discovered Value -- The CI has been updated with the last discovered value and overwritten during verification.
  No Change -- The planned value matched the CI at verification time and no verification was required.
  Cancel -- The change manager canceled the change specification.

- **Intervention Statuses**
  Indicates that a change specification requires manual intervention for verification. CA SDM highlights these statuses in a red color on list forms. These statuses are not final. The Change Order is not considered verified when change specifications are in either of these statuses.
  Failed Verification -- Discovery found the value to be other than what was specified in the Change Order. The Change Analyst must determine if the change was correctly executed and the Change Order was incorrectly specified. Or, if the Change Order was correct and the change requires verification again. Depending on the definition of the Managed Change State and the current change order status, the Change Analyst can override, change, or cancel the failed change specification.
  Manual Verification Active -- Manual verification is required before the change specification can be marked final.

- **Action Override Statuses**
  Indicates an action to initiate during change verification. These statuses are not final. The Change Order is not considered verified when change specifications are in either of these statuses.
  Accept Planned Value -- Request to override the CI attribute with the planned value.
  Accept Discovered Value -- Request to override the CI attribute with the last discovered value.

- **Reporting Status**
  Indicates the result of policy operations that the verification log displays for logging purposes and not used by change specifications.
  Update Was Allowed -- A policy allowed a request to update a CI and did not match any change specifications.

Managing Failed Verifications

When a verification fails, the CMDB, Configuration Audit, Failed Verifications node in the scoreboard lists the number of failed verifications. The scoreboard also lists the number of change specifications that require manual intervention in red. The Change Specifications can also be viewed under the Change Specifications tab in the Change Order, CI, or Administration tab. Failed verifications have the verify status of "Failed Verification". When a verification fails, the Change Analyst can intervene or wait until the next discovery occurs.

If the managed change state allows the Show Change Specification Override Buttons action, the Change Analyst can open the change specification and review the data. The Change Analyst can click one of the following options to close the verification by moving it to a final state:

- **Accept Discovered Value**
  The Analyst determines that the change specification is incorrect and that the discovery tool has discovered the correct value.

- **Accept Planned Value**
  The Analyst determines that the discovery tool is wrong or has not performed discovery. The Analyst decides to accept planned value, as if it was discovered correctly.

- **Cancel**
  This portion of the Change Order was not executed and this specification was canceled.

Managing Undiscoverable Attributes

When a Change Specification requires manual verification, the Configuration Analyst must manually verify the change. The CMDB, Configuration Audit, Manual Intervention node in the scoreboard shows the number of change specifications that require manual intervention in red. The Change Specifications can also be viewed under the Change Specifications tab in the Change Order, CI, or Administration tab with the verify status of "Manual Verification Active."

If the managed change state allows the Show Change Specification Override Buttons action, the Change Analyst can open the change specification and review the data. The Change Analyst can click one of the following options to close the verification by moving it to a final state:

- **Mark as Verified**
  Used when the attribute is cannot be discovered and manually verified.

- **Cancel**
  This portion of the change order was not executed and this specification was canceled.

How to Archive and Purge Audit Data

We recommend that you archive and purge obsolete Verification Log entries, CACF audit history, and CI audit history as part of database maintenance.

Important! The CACF reports typically present monthly reports with a yearly summary. The default archive purge time for the archive purge rules for the log, CACF audit history, and CI audit history tables is 30 days. Use the same value in the archive and purge rules for verification log entries, Incidents, and Change Orders. Using the same value ensures data consistency. You can probably change the 30-day default to something more in keeping with your reporting requirements.

To archive and purge audit data, complete the following actions:

1. To archive and purge inactive Incidents older than *nn* days, use the current incident rule.
   CA SDM archives and purges verification log entries only after archiving and purging associated Incidents. If you associate a Change order with an Incident, CA SDM does not verify whether the Change Order is active.

2. To archive and purge inactive Change Orders older than *nn* days, use the current Change Order rule.
   CA SDM archives and purges verification log entries and change specifications only after archiving and purging associated Change Orders. If you associated an Incident with a Change Order, CA SDM does not archive and purge the Change Order.

3. Use the Rogue Change Verification Log rule for rogue changes that did not create an Incident. To archive and purge verification log entries older than *nn* days, use this rule. By definition, rogue changes are not associated with Change Orders.

4. Use the CMDB Audit rule to archive information that is shown in the Change Specification History, Verification Policy History, Managed Change State History, and Managed Attribute History tabs. These tabs are shown in the respective Change Specifications, Verification Policy, Managed Change State, and Managed Attributes detail forms. CA SDM stores this information in the ci_audit table.

Implement a Change Verification Strategy

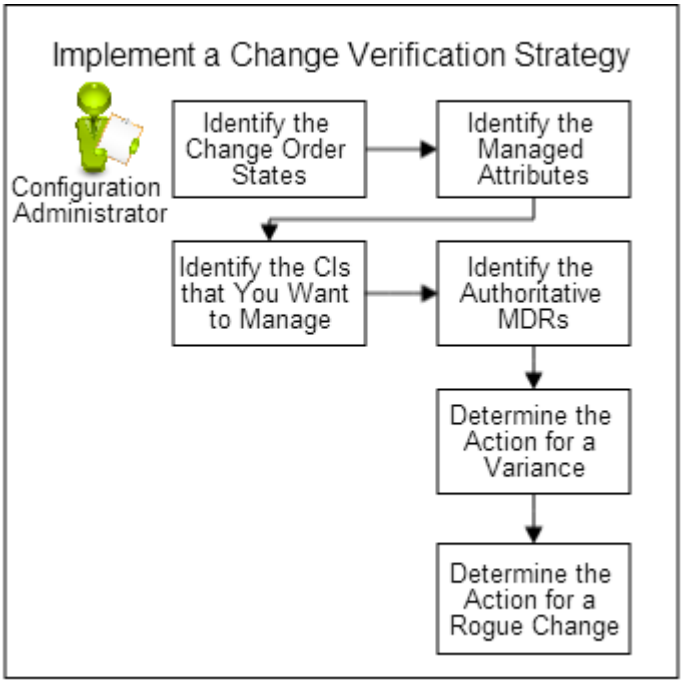
This article contains the following topics:

- Determine the Action for a Variance (see page 2662)
- Determine the Action for a Rogue Change (see page 2662)

The Configuration Administrator determines how aggressively to implement the change verification strategy for your CMDB environment. You identify areas of your Change Management process that require a change verification strategy. These areas include attributes under change control, the Change Order states that indicate that change verification are active, when you can modify change specification, and authoritative MDRs.

For example, you only want to allow updates to the IP Address attribute from MDR1. You also determine the appropriate actions when CACF detects a variance and rogue change.

The following diagram explains how a Configuration Administrator implements a change verification strategy:



1. Identify the Change Order States (see page 2660).
2. Identify the Managed Attributes (see page 2660).
3. Identify the CIs that You Want to Manage (see page 2661).
4. Identify the Authoritative MDRs (see page 2661).
5. Determine the Action for a Variance (see page 2662).
6. Determine the Action for a Rogue Change (see page 2662).

Identify the Change Order States

The Configuration Administrator identifies the Change Order states for when change verification is in effect. The verification happens after a change is executed. Change states help you determine specific conditions, such as if you can edit change specifications in a particular state. For example, you want to review the RFC change state for Change Orders that request updates to CIs.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Managed Change States.
2. To view the change state details or create a Change Order state that has not been already defined, click RFC.

   Note: By default, the RFC Change Order state lets you only edit change specifications. The Implementation in progress state does not let you edit change specifications. The Verification in progress state enables change verification and displays override buttons for the Change Manager or other authorized user.

3. Specify the CACF options and behavior for when a Change Order enters this state.
4. Click Save.

Identify the Managed Attributes

Identify which CI attributes you want to manage for the change verification strategy. For example, you want to manage the IP Address (alarm_id) attribute with change verification.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Managed Attributes.
2. Click Create New.
3. Complete the following steps:
   a. Enter **alarm_id** as the Attribute Name.
   b. Enter **IP Address** as the Attribute Label.
   c. Select an Initial Verify Status from the drop-down list.
      Default: Verification Pending
   d. (Optional) If you want to enforce case sensitivity for change specification planned value comparisons, select the Case Sensitive option.
      Default: Disabled
   e. Click Save.

Identify the CIs that You Want to Manage

Identify the CIs that you want to manage with a verification policy. For example, you want to manage the IP Address (alarm_id) for all high priority CIs with names beginning with NY_Server.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Verification Policies.
2. Click Create New.
3. Complete the following steps:
    a. Enter a sequence, such as **100**.
    b. Enter **NY Server IP Addresses** as the Policy Name.
    c. Select the appropriate Change Order Alignment options.
    For example, you want the verification policy for all options except Change Orders Without Specifications.
4. To specify the transaction and CI filters, complete the following steps:
    a. Select IP Address from the Managed Attribute drop-down list.
    b. Enter a Role Pattern or leave the asterisk to apply to all roles.
    c. Enter **NY** as the Location Pattern.
    d. Enter **NY_Server*** as the CI Name Pattern.
    For example, this filter verifies CIs named NY_Server1, NY_Server2.
5. Select *Allow Update Only if Matches Change Specification* from the Update Behavior drop-down list.
6. (Optional) Use Log Only Mode if you want to experiment with the policy. Also use this mode to view the results only in the standard log, and not affect the active CMDB environment.
7. Click Save.

Identify the Authoritative MDRs

Identify the authoritative MDRs in your CMDB environment. For example, you want to allow updates to CIs from CA Configuration Automation that you identified as MDR1. You consider updates from Web Services that you identified as MDR2 as unauthoritative. You want to send those requests to the TWA.

Follow these steps:

1. Open the NY Server IP Addresses policy, click Edit.

2. Enter **MDR1** as the MDR Name Pattern.
   Note: If you want to exclude an MDR named MDR2, but you want to allow MDR1, MDR3, and so on, enter **!MDR2** as the pattern.

3. Create a separate verification policy, such as MDR2 NY Server.

4. Enter the same information as in the previous policy except the following fields:

   a. Enter **MDR2** as the MDR Name Pattern.

   b. Select *Always Cancel the Entire Transaction* as the Update Behavior.

   c. Select Always from the Write Data to the TWA drop-down list.

5. Click Save.

Determine the Action for a Variance

Determine the action for a variance. For example, a change to a CI does not match the values that are specified in the Change Order. You want the verification policy to create an Incident for the variance.

Follow these steps:

1. Open the MDR2 NY Server policy that you created and click Edit.

2. Select Yes from the Create Incident drop-down list and assign a template.

3. Click Save.

4. An end user creates a Change Order with a change specification to update a CI from MDR2.

5. CACF creates an Incident if MDR2 requests a CI update with a value that does not match the planned value.

Determine the Action for a Rogue Change

Determine the action for a rogue change. For example, CACF detects a change to a CI that does not have any change specifications from any active Change Orders. The Configuration Administrator wants to reject these types of requests.

Follow these steps:

1. Create a verification policy and enter **Rogue NY Server** as the name.

2. Complete the appropriate pattern fields.

3. Verify that only Rogue Insert and Rogue Update are selected as the Change Order Alignment options.

4. Select *Allow Update Only If Matches Change Specification* from the Update Behavior drop-down list.

5. Select Yes from the Create Incident drop-down list and assign a template.

6. Click Save.

Change Verification Notification Messages

The CI detail form displays a notification message when a change is completed. The message indicates whether a change performed in the web interface was successful or unsuccessful. If a change does not complete successfully, a warning message displays with the policy, attribute, and corresponding action. For example, if a user attempts to update a CI but the change was not saved. The reason could be the policy rejected the change when the user attempted to update the CI.

The Verification Log tab also shows details corresponding to the message for future reference.

The notification message indicates the following information:

- Which policy was in effect and corresponding policy action
- Whether a rogue update was detected and if the changes do not match any change orders pending verification
- Whether an Incident was created, updated, or closed, and the corresponding reference number

Examples for Implementing Change Verification

This article contains the following topics:

For Implementing Change verification, consider the following examples:

Example Upgrade Laptops in Your Organization

In this example, an Asset Manager wants to upgrade all laptops from Windows XP to Windows 7 in your organization. The Configuration Administrator creates a verification policy for the Product Version attribute. The verification policy is to filter all laptops with the Windows XP operating system. The Configuration Administrator creates a Managed Attribute definition with the *Use Discovered Value* status, reviews Managed States, and creates a verification policy. CA SDM receives updates to the CMDB from CA Configuration Automation from laptops that require an operating system update. The Asset Management team completes the upgrades.

Follow these steps:

1. Create the following managed attribute:
   - Enter **product_version** as the Attribute Name.
   - Enter **Product Version** as the Attribute Label.
   - Select Use Discovered Value from the Initial Status drop-down list.
   - Enter a label and description for details about the managed attribute.
2. Create the following verification policy:
   - Enter a sequence that you base on other policies in your organization.
     For example, you enter **101**.
   - Enter **Windows* XP*** as the CI Name Pattern.
   - Enter **Workstation** as the Class Pattern.
   - (Optional) Enter a Location Pattern if you want to associate the policy with a specific office in your organization.
   - Select Allow Update Only if Matches Change Specification from the Update Behavior drop-down list.
   - Select Yes from the Create Incident drop-down list.
3. Create a Change Order and change specifications that specify Windows 7 for the Product Version managed attribute for each of the laptop CIs.
4. Move the Change Order to Implementation in Progress status and wait for your Asset Management team to start the upgrades.
5. When the implementations complete, move the Change Order to Verification in Progress.
   CA Configuration Automation discovers laptop information and imports the data in the CMDB.
6. View the open CACF Incidents list for any variances that CACF detected.
7. Select one of the Incidents and review the details about the laptop that CA Configuration Automation discovered.
8. Click Create Change Order and associate the CI with the ticket. Specify change specifications for Product Version for the outstanding changes.
   Wait until discovery verifies that all remaining changes completed.
9. Repeat Steps 6-8 as necessary for any new Incidents that CACF creates.

Example Lock Down Nonverified Change Orders

In this example, the Configuration Administrator wants to only allow a CI update for a matching Change Order. Only CIs in the Server class that is located in NY update for verified Change Orders. Any variance creates an Incident.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:
    a. Enter a sequence number.
    b. Select Any Managed Attribute as the Managed Attribute.
    c. Enter **NY** as the Location Pattern.
    d. Enter **Server** as the Class Pattern.
    e. Select Allow Update Only if Matches Change Specification as the Update Behavior.
    f. Select Yes from the Create Incident drop-down list.
3. Save the policy.

Example Allow a CI Update If No Matching Change Order Exists

In this example, the Configuration Administrator allows updates for all CIs named test*, even if no matching Change Order exists. This policy accepts updates from all users in an administrative role.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:
    a. Enter a sequence number.
    b. Select Any Managed Attribute as the Managed Attribute.
    c. Enter **test*** as the CI Name Pattern.
    d. Enter **Administrator*** as the Role Pattern.
    e. Select Allow Attribute Update as the Update Behavior.
3. Save the policy.
4. A user with an administrative role creates a change specification for a CI named test5. The CI updates successfully.

Example Defer All Updates from CA Configuration Automation to the TWA

In this example, the Configuration Administrator wants to defer all CI updates from CA Configuration Automation to the TWA. This policy does not update the CI in CMDB. It writes the data for all rogue changes to the TWA for further evaluation instead.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:
    a. Enter a sequence number.
    b. Select Any Managed Attribute as the Managed Attribute.
    c. Select Rogue Insert and Rogue Update as the Change Order Alignment.
    d. Enter **CCA** as the MDR Class Pattern.
    e. Select Always Cancel Entire Transaction as the Update Behavior.
    f. Select Always for the Write Data to TWA option.
3. Save the policy.

Example Only Log the Policy Results as a Test

In this example, the Configuration Administrator wants to test a new policy before implementing it in your CMDB environment. The Log Only option lets CACF write the potential CI impacts of the policy to the standard log file.

Follow these steps:

1. Create a verification policy.
2. Complete the information for the alignment, filters, and action.
3. Select the Log Only Mode option.
4. Save the policy.
5. To simulate executing the policy, view the standard log file after you perform CI updates that match the policy specifications and filter criteria.

Example Reject a CI Update

In this example, the Configuration Administrator rejects updates from an MDR named Cohesion for the IP Address (alarm_id) attribute only. This policy does not update the IP address of the CI in CMDB, while it may update other attributes. CACF writes all attributes to the TWA for further evaluation.

Follow these steps:

1. Add IP Address (alarm_id) to the managed attributes list.
2. Create a verification policy.
3. Complete the following steps:
    a. Enter a sequence number.
    b. Select IP Address as the Managed Attribute.
    c. Select Rogue Insert and Rogue Update as the Change Order Alignment.
    d. Enter **Cohesion** as the MDR Pattern.
    e. Select Keep Old Attribute Value as the Update Behavior.
    f. Select Always for the Write Data to TWA option.
4. Save the policy.

Example Allow Change Orders Created Without Specifications

In this example, the Configuration Administrator wants to trust Change Orders that users created without specifications. This policy assumes that the CI text describes all changes accurately and lets the CI update.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:
    a. Enter a sequence number.
    b. Select Any Managed Attribute as the Managed Attribute.
    c. Select Change Orders Without Specifications as the alignment.
    d. Select Allow Attribute Update as the Update Behavior.
3. Save the policy.

Example Do Not Allow Change Orders Created Without Specifications

In this example, the Configuration Administrator does *not* want to trust Change Orders that users created without specifications. This policy ignores Change Orders without specifications and creates Incidents.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:

a. Enter a sequence number.

b. Select Any Managed Attribute as the Managed Attribute.

c. Select Change Orders Without Specifications as the alignment.

d. Select Always Cancel Entire Transaction as the Update Behavior.

e. Select Yes from the Create Incident drop-down list and select an Incident template.

3. Save the policy.

Example Allow Rogue Inserts from Selected Sources

In this example, the Configuration Administrator wants to allow new CIs from selected sources. The z /OS MDRs can create CIs without requiring a Change Order.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:

   a. Enter a sequence number.

   b. Select Any Managed Attribute as the Managed Attribute.

   c. Select Rogue Insert as the alignment.

   d. Enter **z/OS** as the MDR Class Pattern.

   e. Select Allow Attribute Update as the Update Behavior.

3. Save the policy.

Example Allow a Rogue Update for a Nonproduction CI

In this example, the Configuration Administrator allows updates to the IP Address attribute from the Spectrum MDR, but the name cannot begin with *PROD*.

Follow these steps:

1. Create a verification policy.
2. Complete the following steps:

   a. Enter a sequence number.

   b. Select IP Address (alarm_id) as the Managed Attribute.

   c. Select Rogue Update as the alignment.

   d. Enter **!PROD*** as the CI Name Pattern.

e. Enter **Spectrum** as the MDR Class Pattern.

f. Select Allow Attribute Update as the Update Behavior.

3. Save the policy.

Example Allow Rogue Updates Only From a Specific Location

In this example, server CIs in your New York office require repair. The vendor that repairs your servers also resides in New York. The Asset Manager requires that your organization ships all defective servers to New York. The Configuration Administrator wants to allow rogue updates to the CIs when the hardware arrives in New York. The Configuration Administrator creates a verification policy for the Maintenance Vendor attribute. This policy lets a Service Desk Analyst in New York verify that the vendor receives the servers.

Follow these steps:

1. Create the following managed attribute:
   - Enter **vendor_repair** as the Attribute Name.
   - Select verification pending from the Initial Status drop-down list.
   - Enter **Maintenance** as the label and description for details about the managed attribute.
2. Create the following managed change status:
   - Enter **Vendor Hold** as the Change Order Status.
   - Enable the Change Verification Active option.
3. Create the following verification policy:
   - Select Rogue Insert and Rogue Update as the change order alignments.
   - Enter a sequence number for the policy.
     For example, you enter **201**.
   - Enter **server*** as the CI Name Pattern.
   - Enter **Server** as the Class Pattern.
   - Enter **New York** as the Location Pattern.
   - Select Allow Attribute Update from the Update Behavior drop-down list.
4. The Service Desk Analyst creates a Change Order and change specifications for the server CIs and specifies New York for the location.
5. The Service Desk Analyst sets the Change Order Status to Vendor-Hold.

6. The Service Desk Analyst updates the location for the server CIs as New York.
   For example, defective servers from the Chicago office ship to New York. The Service Desk Analyst verifies that the servers arrived in New York.

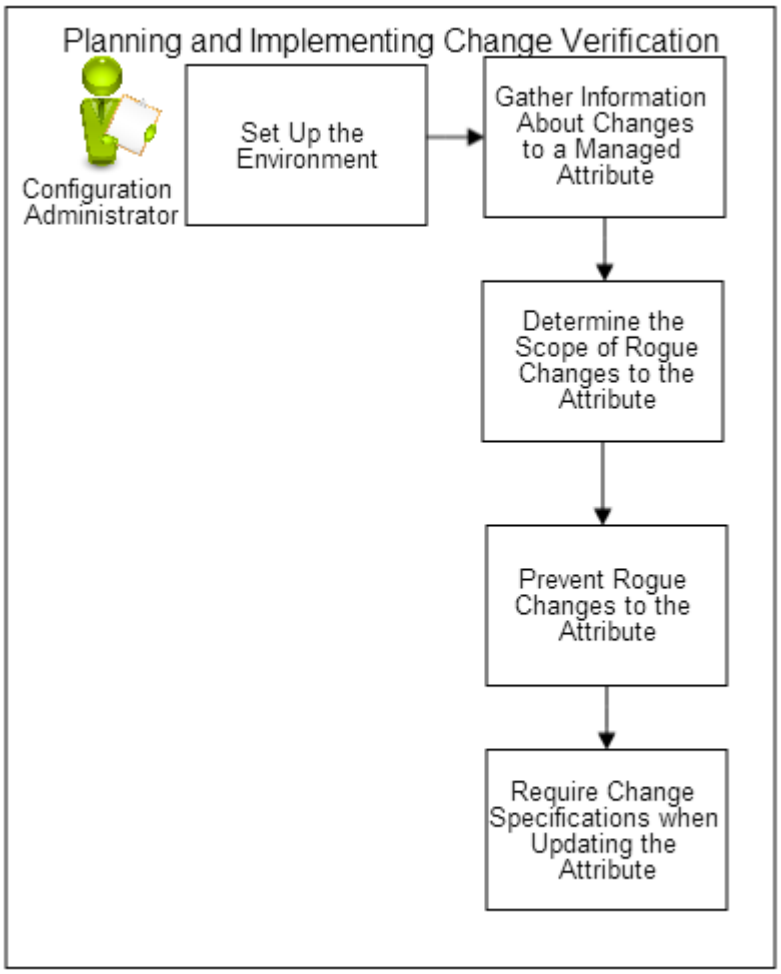
7. The Service Desk Analyst enters the vendor information in the CI.
   The Change Order closes after all the CI locations are set to New York and all the change specifications are verified.

Planning and Implementing Change Verification

The Configuration Manager wants to implement change verification so that the CMDB contains correct data. The Change Manager wants to ensure that changes execute correctly. The Change Manager wants to track the number of rogue changes that occur and their data sources. Both managers agree implementing change verification provides significant value to the organization. The Change Manager wants to ensure that changes do not harm the production environment.

The Configuration Manager and the Change Manager agree to a conservative-phased implementation. The Configuration Administrator implements policies for specific locations and specific CIs in those locations. This scenario describes example phases about completing the verification policy implementation to a broader audience for your organization.

The following diagram shows how a Configuration Administrator completes the example phases to implement change verification:



Follow these steps:

1. Set Up the Environment (see page 2671).
2. Gather Information About Changes to a Managed Attribute (see page 2672).
3. Determine the Scope of Rogue Changes to the Attribute (see page 2673).
4. Prevent Rogue Changes to the Attribute (see page 2674).
5. Require Change Specifications when Updating the Attribute (see page 2675).

Set Up the Environment

You set up the environment so that Configuration Administrators can always update CIs. The Configuration Administrator can create and update CIs in the CMDB as needed, without specifying a change order. The Configuration Administrator is trusted to provide correct CI data.

Follow these steps:

1. Create a verification policy that is named **Policy0.1** with the following information:
   - Enter **1** as the sequence.
   - Enter **Allow Administrator to Always Update CIs** as the description.
   - Select all Change Order Alignment options.
   - Enter **Configuration Administrator** as the Role Pattern.
   - Enter **Web Client** as the MDR Class Pattern.
   - Enter an asterisk (*****) as the CI Name and Class, and all other patterns.
   - Select Any Managed Attribute for the Managed Attribute.
2. Select Allow Attribute Update as the Update Behavior action.
3. Click Save.
   The policy is enabled to only allow Configuration Administrators to update CIs always.

Gather Information about Changes to a Managed Attribute

You want to gather information about changes to a specific CI-managed attribute. The change information helps you identify the CIs that are being updated, the source of the changes, and the specified values. This information helps when defining a verification strategy for the attribute and corresponding CIs. For example, you want to understand the scope of all changes to IP Address (alarm_id) and log this to the CA SDM standard log (stdlog). Gathering this information can take several weeks, depending on the number of changes to attributes that occur in your organization.

1. Define IP Address (alarm_id) as a Managed Attribute.
2. Define Implementation in Progress and Verification in Progress as Managed Change States in your environment. Enable Change Verification Active in both states.
3. Create a verification policy that is named Policy1.1with the following information:
   - Enter **3000** as the Sequence.
   - Enter **Log All Changes to IP Address** as the description.
   - Select all Change Order Alignment options.
   - Enter an asterisk as the CI Name and Class and all other patterns.
   - Enable Log Only Mode.
4. Click Save.
5. After a few weeks, review the stdlogs to view the sources of the updates.
   For example, the log displays rogue CI updates and updates with matching Change Orders.

6. You determine that users located in NY have been updating the IP Address of CIs without creating Change Orders.

7. After you complete your analysis, inactivate Policy1.1 by editing the policy and setting Active? to Inactive.

Determine the Scope of Rogue Changes to the Attribute

You want to determine the scope of rogue changes to the IP Address attribute. Knowing the scope of rogue changes helps you understand the impact of rogue changes on your organization. For example, based on your previous analysis using the Log Only option, you want to create Incidents whenever a change occurs to IP Address to CIs that begin with "test" located in NY without a Change Order. To ignore new Incidents that this process creates, communicate with Change Managers in your organization.

Follow these steps:

1. Complete the following initial implementation actions:

   - Define Implementation in Progress as a managed change state and enable the Implementation State option.
   - Define Verification in Progress as a managed changes state and disable the Promote Change Order After Verification option.
   - Define IP Address (alarm_id) as a Managed Attribute if not already defined.

2. Create a verification policy that is named Policy2.1 with the following information:

   - Enter 3001 as the Sequence.
   - Enter a description about this policy. For example, you enter **Rogue inserts and rogue updates cause Incidents to be created. All other changes are not impeded**.
   - Select Rogue Inserts and Rogue Updates as the alignments.
   - Select IP Address from the Managed Attribute drop-down list.
   - Enter **test*** as the CI Name and **NY** as the Location and an asterisk for all other Patterns.
   - Select Allow Attribute Update, Yes to Create Incident, and an Incident Template from the actions.

3. Click Save.
   After you complete this phase, CACF creates Incidents for all computers in NY. You discover the following information after reviewing the Incidents:

   - Several MDRs report different IP addresses for the same CI.
   - Some MDRs are authoritative, other MDRs are not authoritative.
   - Some CIs cannot be managed based on Location, Family, Name, Service Type, and so on.

4. The Change Manager meets with other IT Managers to review the CMDB, CI detail forms, verification logs, and filtering by attribute name to see the rogue data.

5. Your organization decides to update the CI filter in Policy 2.1 to manage Priority 1 Servers only.

Prevent Rogue Changes to the Attribute

You want to prevent rogue changes to the IP Address attribute to ensure CMDB data integrity. You want to require a Change Order for the update. The Change Order must specify the CI. However, a change specification is not required for the IP Address for the change to occur. Change verification occurs at the CI/Change Order level but not at the attribute level. For example, prevent any rogue updates to and use Incident creation to track the users that request these changes.

Follow these steps:

1. Set Policy1.1 and Policy2.1 to Inactive to disable these policies so that they are not in effect.

2. Create Policy 3.1 with the following information:

   - Enter **3100** as the Sequence.
   - Enter **Prevent rogue changes without any Change Order** as the description.
   - Select Rogue Update as the alignment.
   - Enter **test*** as the CI Name and **NY** as the Location and Any Managed Attribute. Enter an asterisk for all other patterns.
   - Select the Always Cancel Entire Transaction action.

3. Click Save.

4. Create Policy3.2 with the following information:

   - Enter **3200** as the Sequence.
   - Enter **Require a Change Order for IP address changes** as the description.
   - Select Change Orders Without Specifications as the alignment.
   - Enter **test*** as the CI Name and **NY** as the Location and an asterisk for all other patterns.
   - Select IP Address from the Managed Attribute drop-down list.
   - Select Allow Attribute Update as the action.

5. Click Save.
   This policy eliminates rogue changes, because Change Orders must accompany the change. With this policy, the Configuration Manager prevents data that is not defined in the Change

Order being updated. For example, requesting a change to increase Memory Installed while changing the IP Address simultaneously, would not be considered a rogue change because there is a Change Order. They also would like the Change Orders to be automatically verified and promoted and determine they want verification at the attribute level.

Require Change Specifications when Updating the Attribute

Your Configuration Manager may be concerned that the CMDB is updated multiple times although changes are not specified in the Change Order. For example, a user changes the value of Memory Installed (phys_mem) and IP Address (ip_address) simultaneously. In the previous phase, CACF does not consider this request as a rogue change because a Change Order exists.

The Configuration Manager wants to enforce change verification at the attribute level. The Configuration Administrator creates a policy with the following requirements:

- Use change specifications when updating IP Address.
- If no rogue update is attempted, create an Incident.

Follow these steps:

1. The Configuration Manager contacts Change Analysts that changes to IP Address must contain a change specification.
2. Set Policy3.1 and Policy3.2 to Inactive to disable these policies so they are not in effect.
3. Create Policy4.1 with the following information:
   - Enter **4000** as the Sequence.
   - Enter **Require Change Specifications for IP Address changes** as the description.
   - Select Rogue Insert, Rogue Update, and Change Orders Without Specifications as the alignment.
   - Enter **test*** as the CI name and **NY** as the Location, and an asterisk for all other patterns.
   - Select IP Address from the Managed Attribute drop-down list.
   - Select Always Cancel Entire Transaction as the action.
4. Click Save.
5. Create Policy4.2 with the following information:
   - Enter **4100** as the Sequence.
   - Enter **Require Change Specifications for IP Address changes** as the description.
   - Select Change Orders With Specifications as the alignment.
   - Enter **test*** as the CI Name and **NY** as the Location pattern.

- Select IP Address from the Managed Attribute drop-down list.
- Select Allow Update only if Matches Change Specification as the action.

6. Click Save.

You have successfully completed the appropriate example phases to implement change verification in your environment. You can expand the change verification strategy to include more attributes, CIs, MDRs, and tenants.

Verify a CI Attribute Value Update Manually

The Configuration Administrator determines that your CA SDM environment requires a verification policy for the Memory Installed (phys_mem) attribute. The Configuration Administrator creates a Managed Attribute definition with the *Manual Verification will be required* status. This status is appropriate because CA SDM does not have an MDR to discover the value. The Configuration Administrator reviews the managed states and creates a verification policy. The Change Manager views a Change Order that requests an update to the Memory Installed value of a CI. This change request requires manual verification.

Follow these steps:

1. Create a Managed Attribute definition (see page 2676).
2. Review the Managed Change states in your environment (see page 2677).
3. Create a Verification Policy for the Managed Attribute (see page 2677).
4. Review the Change Specifications list (see page 2678).
5. Accept the Planned Value (see page 2679).

Create a Managed Attribute Definition

The Configuration Administrator creates a Managed Attribute definition for the Memory Installed (phys_mem) attribute.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Managed Attributes.
2. Click Create New.
3. Enter **phys_mem** as the attribute name.
4. Enter **Memory Installed** as the Attribute Label.
5. Select *Manual Verification will be required* from the Initial Verify Status drop-down list.
6. (Optional) Select the Case Sensitive option to enforce case sensitivity for change specification planned value comparisons.
   Default: Disabled

7. Click Save.
   The Managed Attribute is saved.

Review the Managed Change States in Your Environment

The Configuration Administrator reviews the Managed Change States in the CA SDM environment. Change verification initiates when the status of a Change Order changes to a Change State that CACF manages. For example, Verification in Progress.

> **Note:** The Configuration Administrator can modify which state in the Change Order lifecycle initiates change verification. The administrator can also modify which states allow you to modify change specifications when implementation starts.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Managed Change States.
2. Click Implementation in Progress to open the managed status detail page.
3. Review the details about the managed status.
   For example, you make the Implementation in Progress status allow editing change specifications, and also enable Change Verification Active. This example indicates an active change verification process. It also indicates that you can edit values when the Change Order sets to the Implementation in Progress status.

Create a Verification Policy for the Managed Attribute

The Verification Policy specifies the CACF action when an MDR discovers an attribute value. The MDR attempts to update the CMDB with that data.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Verification Policies.
2. Click Create New to open the detail page.
3. Enter **1000** as the policy Sequence.

   > **Note:** You can enter a higher or lower number, which is based on other verification policy priorities in your environment.

4. Enter a Policy Name, such as **RAM Management** and a brief description of the policy.
5. Select Rogue Insert and Rogue Updates under Change Order Alignment.

6. You can configure the policy to prevent a specific MDR from updating the Memory Installed (phys_mem) attribute.
   Complete the following tasks:

   - Select Memory Installed as the Managed Attribute.
   - Enter a Role Pattern or use an asterisk to apply to all roles.
   - Enter a CI Name Pattern or use an asterisk to apply to all CIs.
   - Enter a Class Pattern or use an asterisk to apply to all classes.
   - Select Keep Old Attribute Value as the Update Behavior.

   - **Note:** To allow updates to this attribute from a web interface user, enter Web Client as the MDR Name Pattern.

7. Click Save.

Review the Change Specifications List

A Change Order with an RFC status wants to change the value of the Memory Installed (phys_mem) attribute in a CI named server1. The Change Manager sets the verification status of the Change Specification to *Manual Verification will be required*. The Change Manager can view the Change Specification in CA SDM.

Follow these steps:

1. The Change Manager moves the Change Order from RFC to Verification in Progress.
   All the change specifications with Manual Verification become Manual Verification Active.

2. From the Change Order, select the Change Specifications tab from the Configuration Management tab.
   The tab highlights all change specifications in red to indicate that manual verification is required.

   Note: You can also view change specifications from the Administration tab when you click CA CMDB, Configuration Audit, Change Specifications. Additionally, view change specifications from a CI after you select the Change Specifications tab from the Related Tickets tab.

3. Search for change specifications with *requires manual verification* as the Verify Status.
   For example, change specifications of Change Order 21 contain this status.

4. Research the appropriate value for the Memory Installed attribute for the server1 CI.

Note: Change specifications that failed verification also display in red to help show change specifications that require further attention.

Accept the Planned Value

The Change Manager researches the correct attribute value for the CI and makes the appropriate decision on the change request.

Follow these steps:

1. Open the Change Specification to view the detail page.
2. You research the specific Memory Installed (phys_mem) attribute for CI and confirm the planned value.
3. Verify that the Change Order of the Change Specification is in Verification in Progress State.
4. Click Accept Planned Value.
   The Verify Status changes to Accepted Planned Value.

Note: After you click Accept Planned Value, the CI updates with the Planned Value automatically.

MDR Management

This article contains the following topics:

The MDR Launcher is an open integration tool that lets you view data in a management data repository (MDR) from a CMDB web page. MDR Launcher lets you obtain additional details about a CI and to gain control over it (if the MDR supports such control).

Manage Federated CI Mappings

A single CI can be associated to multiple MDRs, with each MDR having a federated_asset_id that identifies the CI. While it is not necessary for the federated_asset_id to be unique among MDRs, a federated_asset_id must be unique within each MDR.

Each MDR is identified uniquely by its combination of MDR class and MDR name.

To view the CI in a particular MDR context, click Launch. The target MDR is launched in the context of the CI that was open.

View an MDR Location for a CI

You can display the MDR location for a CI.

- **CI Name**
  Identifies the configuration item.
- **Federated Asset ID**
  Specifies the string that the source MDR uses to identify this CI. The MDR software typically determines this identifier. CMDBf Viewer uses the UUID.
- **MDR Name**
  Identifies the MDR.
- **Active**
  Denotes whether this mapping is active or not. You can inactivate mappings but not delete them.

Create MDRs

Before you can associate a CI with an MDR, define the MDR to CA SDM.

Follow these steps:

1. Click Create New on the MDR List.
2. Enter the definition (see page)for the new MDR.
3. Click Save.

Note: When you associate a CI with an MDR, the Add MDR button does not appear until the CI is first saved and then edited.

MDR Defintion

You can create, view, and edit an MDR definition. The MDR Definition page provides the following settings:

- **Tenant**
  Identifies the tenant owner of this MDR (if multi-tenancy is installed).
- **Button Name**
  Defines the MDR button label that appears on the CI Detail page. This name is unique for each MDR. Required for “launch in context” and for CMDBf Viewer.

- **MDR Name**
  Specifies the data that is sent in the mdr_name field in XML. While this string can be anything that the MDR chooses to send to CMDB, typically it is the hostname of the source. This name together with the mdr_class create a unique name for the MDR. Note: CA APM MDRs must specify an MDR name of APM and MDR class of GLOBAL. Required for “launch in context", CMDBf Viewer and GRLoader.

- **MDR Class**
  Specifies the data that is sent in the mdr_class field in the XML. While this name can be anything, it must together with the mdr_name field create a unique identifier for the MDR. Global MDRs are defined with an MDR Class of “GLOBAL”. Note: Cohesion MDRs must specify an MDR class of COHESION, which automatically sets the Path, Parameters and "URL to be Launched" fields to the required Cohesion launch-in-context values. CA APM MDRs must specify an MDR class of "GLOBAL", which automatically sets the Path, Parameters and "URL to be Launched" fields to the required CA APM launch-in-context values. Required for CMDBf Viewer. CMDBf Endpoint sets to "cmdbf" for all federated MDRs.

- **Active**
  Denotes this MDR definition as active or inactive. Inactive MDR definitions are logically deleted, but they can be made active again by using the Search utility.

- **Owner**
  Denotes the contact responsible for this MDR.

- **Description**
  Specifies text field.

- **Hostname**
  Specifies the host name, DNS name or IP address of the host, which contains the web server which hosts the web page that is launched. Required for “launch in context”.

- **Port**
  Specifies the TCP/IP port used by the MDR web server to serve up web pages. Port 8080 is the default. Required for “launch in context”.

- **Path**
  Specifies the portion of the URL that precedes the question mark (?) character. This information can be obtained from the MDR documentation. For mdr_class of Cohesion, the value is set automatically to CAisd/html/cmdb_cohesion.html and cannot be changed. For mdr_name of UAPM and mdr_class of GLOBAL, the value is set automatically to apm/frmObject.aspx and cannot be changed.

- **Parameters**
  Specifies the portion of the URL that follows the question mark (?) character. This information can be obtained from the MDR documentation. For mdr_class of Cohesion, the value is set automatically to hostname={hostname}+port={port}+family={family}+name={name}+secret={password}+federated_asset_id={federated_asset_id} and cannot be changed. For mdr_name of UAPM and mdr_class of GLOBAL, the value is set automatically to ObjectID={cmdb_asset_id} &obj=11&FUNCTION=1&WinID=OBFRASSET{cmdb_asset_id}&WinContainerID= and cannot be changed.

- **Userid**
  Specifies the user ID to logon to the MDR (if necessary). This value is substituted into the URL wherever {userid} is found.

- **Shared Secret**
  Specifies information that is shared between CMDB and the MDR. This value is substituted into the URL wherever {password} is found. For Cohesion MDRs, the value must match the value of the “com.cendura.security.oneclickauth.secret”. Required for CMDBf Viewer.

- **CMDBf Namespace**
  Specifies the MDR namespace that is passed to the query by CMDBf Viewer. If you use CMDB as an MDR provider, the value is "http://cmdb.ca.com/r1". For external MDRs, consult the MDR documentation. Required if MDR Class is cmdbf.

- **CMDBf Timeout**
  (Optional) Specifies time limit for CMDBf endpoint query. Default is ten (10) seconds. Only applies when MDR Class is cmdbf.

- **URL to be Launched**
  Default value of *http:///{hostname}:{port}/{path}?{parameters}*. For some MDRs, it can be overridden if necessary to accommodate MDR-specific requirements. Required for "launch in context".
  For mdr_name of UAPM and mdr_class of GLOBAL, the value is *http:///{hostname}:{port}/{path}?{parameters}*
  For mdr_class of Cohesion the default value is: *http://cmdb_hostname:cmdb_port/{path}?{parameters}*

  where
  cmdb_hostname is the host name, DNS name or IP address of the CMDB web server. Defaults to the current hostname that is currently accessing the CMDB web server.cmdb_port is the TCP/IP port of the CMDB web server. Defaults to the current port number used to access the CMDB web server.If you have enabled SSL support for Cohesion, set the URL to:*http://hostname:port/{path}?{parameters}+https=yes*

- **CMDBf Endpoint**

  Specifies the MDR Query Service endpoint for CMDBf Viewer. Required if MDR Class is cmdbf.

Using the Configuration Control

Contents

Under the Configuration Control node in the Administration tab, view and manage CACF Managed Attributes, Managed Changes States, and Verification Policies. Change verification governs inbound CI data before loading the data into the CMDB. This verification ensures that each requested Change Order executes correctly, and detects and manages rogue changes automatically. Change verification lets you perform the following tasks:

- **Authoritative MDR Updates**
  Specifies that MDRs can only update authoritative attributes at the attribute level.
- **Rogue Change Detection**
  Detects and manages updates to CIs when no corresponding Change Order exists.
- **Change Verification**
  Provides automated verification that Change Orders executed correctly.

Change verification policies can be implemented dynamically or scheduled in advance. They can be generic or highly specific.

Managed Attributes

The managed attributes indicate those eligible CI attributes for change verification by CACF. By default, this list contains *CI name* and *Any Managed Attribute*. You add the CI attributes that you want managed as part of your change verification strategy. For more information about establishing a change verification strategy, see the Implement a Change Verification Strategy topic.

CACF does not consider unmanaged attributes (attributes not listed) for change verification. These unmanaged attributes update as usual. Selecting Any Managed Attribute as the Attribute Name in a verification policy or change specification applies to all managed attributes.

Case sensitivity in the managed attribute definition only applies when CACF compares the change specification planned value with the inbound CI transaction data. Case sensitivity does not apply to the selection patterns in the policy, which are always case-sensitive.

By default, CACF manages the CI *Name* attribute to enable rogue insert rejection. If you inactivate *Name* from the managed attributes list, executing a transaction that inserts a CI but does not update any managed attributes is considered an unmanaged change. So, inactivating may cause CACF verification policies to ignore rogue inserts.

For a list of CI attribute names, see the *CA CMDB Technical Reference Guide*.

Create a Managed Attribute

Add managed attributes to use change verification in your environment. For example, the Configuration Administrator wants to enable change verification for a specific CI attribute and requires to define change specifications when updating a CI.

The Managed Attribute History tab shows the audit history. The audit history lists all previous modifications to the managed attribute options with the time and user that changed.

Follow these steps:

1. On the Administration tab, click [set the cmdb value at the book level], Configuration Control, Managed Attributes.
   The Managed Attribute List page appears.

2. Click Create New.
   The Create New Managed Attribute page appears.

3. Enter a valid CI attribute name. For information about attribute names, see the *CA CMDB Technical Reference Guide*. You can also use grloader -sc xxxxx (where xxxx indicates the class name) to list attribute names for a particular class.

4. Enter an attribute label.

5. Select the default Initial Status from the drop-down list of the verification criterion. When you select a managed attribute when creating a change specification, this status is used as the initial default value.

   - **Manual Verification will be required**
     Indicates that this verification requires a Configuration Administrator to verify that the change completed successfully.

   - **Set After Change Executed**
     Indicates that the planned value from the change specification sets in the CI after CACF verifies and completes the Change Order. This set operation only occurs when the Change Order moves from a state with change verification active to nonactive. For example, the set takes place when a Change Order moves from Verification in Progress to Closed. The set does not occur if the Change Order is canceled, demoted, or moved to another state.

   - **Use Discovered Value**
     Indicates that the Configuration Administrator uses the discovered value regardless of the planned value in the change specification. The original value in the verification criterion remains unchanged, but updates the CI attribute with the new value.

   - **Verification Pending**
     Indicates a pending verification.

6. Set the managed attribute as Active or Inactive to remove the attribute from being considered by CACF.

7. Enter a description for the managed attribute.

8. Enable the Ignore Case option if you want the comparisons between the discovered and planned values to remain case insensitive.

9. Click Save.
   The managed attribute is saved.

Managed Change States

CACF uses managed change states to indicate which Change Order statuses CACF manages. CACF uses managed change states to control how or when to apply change verification for CI updates. You can customize these change states to suit the needs of your organization.

The Change Order statuses represent changes that can be edited. Similarly, Change Order change states represent verification states. By default, you can edit change specifications for a Change Order in the RFC change state. The change verification occurs for a Change Order in the Verification in Progress state. Optionally, change tickets can be automatically promoted or closed when all associated change specifications execute successfully.

The following list describes the Managed Change States options:

- **Change Specifications Editable**
  Specifies whether you can edit the change specifications for a Change Order. Typically, after a change request receives approval, you cannot change the request. The updates are restricted to performing a small set of override options in the *Verification in Progress* state.

- **Change Verification Active**
  Specifies whether changes discovered for a CI while the Change Order is in this status are considered for change verification. Change orders and their related change specifications are compared with any inbound transactions to verify that they were executed successfully.
  CACF monitors all CIs for any changes to their managed attribute values. As CACF verifies each attribute level change to the CI, CACF compares it against a list of change specifications which are in a *change verification active* state.
  After a change specification enters this state, any change specification without a specific CI undergoes expansion. This expansion occurs where new change specifications are created using the list of CIs attached to the Change Order.
  After a change specification exits this state, the change specifications with a verify status of *Set After Change Verified* execute. This action updates the CI with the planned values, as specified in each change specification.

- **Implementation State**
  Specifies whether the state represents a state when the changes are being executed or implemented on the CI. When a Change Order enters this transitional state, assume that the attribute values in the CI are volatile. CACF cannot consider these changes rogue changes, but it also cannot consider the changes for final verification. Typically, the change verification process only compares the inbound attribute data after the Change Order executes completely.

- **Show Change Specification Override Buttons**
  Specifies whether the Change Analyst can control change specifications, and what level of control is given. In some implementations, the Change Analyst can edit change specifications as necessary. In other implementations, the Change Analyst can override or cancel the change specification.

- **Promote Change Order after Verification**
  Specifies whether a Change Order promotes to the next default state automatically after CACF verifies all the change specifications.

Create a Managed Change State

Create a managed change state for your change verification environment. For example, the Change Administrator wants to create the Approval In Progress state and set the verification to active.

The Managed Change State History tab shows the audit history that lists all previous modifications to the managed change state options. The tab also shows any previous values and the users that specified them.

Follow these steps:

1. On the Administration tab, click CA CMDB, Configuration Control, Managed Change States.
   The Managed Change States List page appears.

2. Click Create New.
   The Create New Managed Change State page appears.

3. Enter a Change Order status, such as **Approval in Progress**.
   You can also click Change Order Status to search for a status.

4. Select the option to set the change state as Active or Inactive.

5. (Optional) Select any of the following change states:

   - **Change Verification Active**
     Enables change verification for this change state.

   - **Implementation State**
     Indicates that the Change Order is in an implementation phase.
     Use this option to prevent unwanted Incident creation for incomplete Change Orders. For example, CACF detects a rogue change where the change matches the CI and attribute names of a change specification. The verification policy states to only update if the change matches. You can reject this change because the Change Order is verified after fully implemented and moved to a verification state.

     You cannot use a managed change state as both as an active change verification and an implementation state.

   - **Change Specifications Editable**
     Indicates that you can edit change specifications in this state.

   - **Show Change Specification Override Buttons**
     Displays the override buttons when a change verification is active. However, editing such as Accept Discovered Value, Accept Planned Value, Mark As Verified, and Cancel is not allowed.

   - **Promote Change Order After Verification**
     Promotes the Change Order to the next state automatically after change specifications move to a verified or final state.

> Promotion only occurs when the Change Order is in a state with change verification active.

6. Click Save.
   The managed change state is created and saved.

Verification Policies

Verification policies specify the action that CACF takes when an MDR discovers an attribute value, and the MDR attempts to update the CMDB with that data. A variance occurs when the inbound data does not match the desired state information, as described in the change specification. A policy search executes to locate a policy that matches both the change order alignment and change specifications. Policies process in an ascending, sequential number order. By default, a compatibility policy lets all updates occur providing the behavior observed in previous releases of CA Service Desk Manager.

The change verification policy describes how CA Service Desk Manager responds to the following events:

- **Updates from Unauthorized MDRs**
  Specifies that specific MDRs are authoritative for specific attributes. CI attribute updates from unauthorized MDRs can be selectively accepted or rejected.
  For example, define policies to prevent CA Configuration Automation from updating the IP address of a CI, even if a matching Change Order exists. Allow updates to the IP address to occur only if the source MDR is Spectrum.

- **Rogue Changes**

Detects and manages updates to CIs when no corresponding Change Order exists. Specify a policy that manages rogue changes that request inserts or updates of CI data. For example, you can define a policy that loads data into TWA and does not update the CI for the following conditions:

- - A CI named similar to server* in New York changes
  - The change does not have a matching Change Order

- **Incorrectly executed changes**
  Detects whenever a Change Order is not implemented correctly.

The policy specifies any of the following actions with the discovered data inbound to the CMDB:

1. Accept the data into the CMDB even though a variance exists.
2. Reject the inbound attribute data.
3. Reject the entire inbound transaction.
4. Write the inbound data to the TWA.
5. Create an Incident.

6. Write to the standard log.

The Configuration and Change Administrators *must* establish a change verification strategy for your environment. The default policy allows all changes to all CIs, even if the change is rogue, or the change does not match a change ticket. For more information about implementing a strategy see the Implement a Change Verification Strategy topic.

Create a Verification Policy

The Configuration Administrator creates verification policies for change verification. For example, the policy can reject specific attributes and values from a transaction. Or, it can record the transaction to the TWA for deferred processing. For authorized source MDRs, the policy can accept the transaction unconditionally.

The Verification Policy History tab shows the audit history that displays all previous modifications that are made to the policy. The Verification Log tab shows all the CACF events that are associated with the policy. The Verification Log tab lists all events that have occurred for the policy. The log shows details on the affected change specifications, managed attributes, and actions when the policy was effect.

For example, the log displays the modified managed attribute and the policy history shows the category values that you specified in the policy. Verification log entries in red indicate that the change specification is either Failed Verification or Manual Verification Active and require further attention by the user.

Follow these steps:

1. Click Create New.
   The Create New Verification Policy page appears.

2. Complete the Policy Description:

   a. **Sequence**
   (Unique) Specifies the numbered order to process the policy.
   Note: CACF processes policies in ascending order.

3. On the Policy Settings tab, select the appropriate Change Order alignment:

   a. **Change Orders With Specifications**
   Active if a Change Order with selection criteria matches the inbound CI and the attribute. The inbound transaction data may not match the specified change specifications. If an exact match exists between the planned value and the inbound data, the policy determines whether to close any Incidents that change verification creates automatically.

   b. **Change Orders Without Specifications**
   Active for Change Orders that do not have any change specifications defined. Indicates that CACF cannot verify the variance for the inbound CI attribute data for Change Orders that do not have change specifications.

c. **Rogue Insert**
Indicates that the variance is found without a matching CI or change ticket.

d. **Rogue Update**
Indicates that the variance is found with a matching CI, but without a matching change ticket that updates the changed attribute.

4. Select a Managed Attribute.

5. Select Any Managed Attributes if the policy applies to all managed attributes.

6. Enter the appropriate patterns such as Role Pattern, MDR Name Pattern, MDR Class Pattern, CI Name Pattern, Class pattern, Location Pattern. Consider the following rules:

   - When you specify patterns, the MDR Name Pattern, MDR Class Patterns, and role patterns refer to the source of the data update. The other filters refer to the CI that a user updated.
   - Specify an exact string match for the inbound attribute value.
     For example, enter **COHESION** to return all string matching *COHESION*.
   - Specify an exact string matched suffixed with a wildcard (*) for the inbound attribute value. CACF only allows one asterisk at the end of the string.
     For example, enter **spectrum*** to match the string *spectrum*, and any string that starts with *spectrum*.
   - Specify the negative of an exact string match by prefixing the string with an exclamation point.
     For example, enter **!COHESION** to match any string that does not start with COHESION.
   - The MDR Name of Web Client indicates that the web interface created the source data.

   Note: Policy filters do not support embedded wildcards, such as spec*rum.

7. (Optional) Select a Priority level from the drop-down list to match the CI priority.

8. (Optional) Select a Service Type from the drop-down list to match the CI Service Type.

9. Select the appropriate Update Behavior from the drop-down list:

   a. **Allow Attribute Update**
   Updates to CI attribute values are always allowed.
   Use this value when you require no attribute verification, such as when you require logging and auditing.

   b. **Allow Update Only if Matches Change Specification**
   Updates the CI attribute value only if it matches the planned value of the change specification. Otherwise, CACF rejects the update, and the change specification status sets to Failed.
   Use this selection when you enable Change Order verification.

c. **Always Cancel Entire Transaction**
Cancels this update and all other updated attributes during this transaction. If any matching policy cancels the entire transaction, the transaction is canceled, even if other policies allow the change.
This value only triggers when an update occurs to a managed attribute.

d. **Keep Old Attribute Value**
Value rejects the inbound data.
This value is similar to canceling the entire transaction, but it only rejects a single attribute.

10. Select the appropriate Action:

a. **Write Data to TWA**
Select Always or Never. If you select Always, the incoming data is written to the TWA for later processing.

b. **Create Incident**
Select Yes or No to create Incidents that is based on this verification policy. If you select Yes, CACF creates an Incident for failed verification or a rogue update.

c. **Incident Template**
(Optional) Select an existing template to use if CACF creates an Incident.

d. **Close Incident after Verification**
Automatically closes any associated Incidents with this verification policy. The criteria for closing are that the data matches the Change Order and all change specifications are in a final state.

e. **Log Only Mode**
Adds a warning message to the stdlog whenever this policy would take effect.
Note: Any higher sequenced policy governs the transaction, as if this mode policy did not exist.

11. Specify the Activation and Deactivation dates when this policy is in effect, and click Save.
The verification policy is saved.

Knowledge Management

This section contains the following articles:

Knowledge Management Overview

This article contains the following topics:

Knowledge management refers to the concept of finding, organizing, and publishing knowledge. Knowledge management captures information quickly and efficiently and then delivers this information to a user or group. The information that is captured and made available for retrieval is referred to as a knowledge base.

Users access a knowledge base by using a search engine. Knowledge Management lets you create and manage content that resides in a knowledge base. You set category and document permissions to use groups or roles. Knowledge Management helps you provide customers with solutions to complex issues. Effective knowledge management quickly delivers solutions to customers through a process that is user-friendly and easy to navigate.

To manage knowledge effectively, you take the following actions:

- Create a meaningful hierarchy of content.
- Identify the gaps in existing knowledge.
- Perform the updates and maintenance to help ensure relevance of content.
- Measure the value of available content.

Key Features

Some of the key features of Knowledge Management are as follows:

- **Document Preferences**
  Users can define preferences that help them work with documents. For example, users can set preferences for the contents that display on the Knowledge Document List page. To view the Preferences Settings page:

  - Select Preferences from the View menu.
  - Click Edit on the Preferences Detail window.

- **Natural Language Search**
  Natural Language Search (NLS) lets the analyst specify a natural language string, such as "How do I install a network printer?" to query the knowledge base for solutions. NLS instantly pinpoints candidate solutions, ranking them in order of relevance. As NLS learns from every solution that is captured, it continuously and automatically refines the knowledge base.

- **Knowledge Categories**
  Knowledge categories allow the analyst to manage the content in the knowledge base. They provide a mechanism for building and editing knowledge underlying the retrieval tools. Knowledge categories also include the ability to assign ownership of a particular knowledge solution to an expert. Hence, they ensure that the solution for a given problem is kept current and accurate.

- **Knowledge Tree Designer**
  The Knowledge Tree Designer (see page) tool helps the analyst develop and deploy business policies and intelligence by mapping any reasoning process into a knowledge tree structure.

- **HTML Editor**
  The HTML Editor (see page 2740) lets the analyst define the layout and static content of a knowledge document template. The template defines the layout and content of the Resolution section of a knowledge document. In a knowledge tree document, it defines the layout and content of a node.

- **Knowledge Report Card**

  The Knowledge Report Card (see page 2819) provides feedback to analysts, knowledge engineers, knowledge managers, supervisors, category owners, and system administrators about which knowledge documents are most effective. You can use the report card to improve the processes of creating knowledge documents and providing the best support to customers.

- **Multi-Tenancy**
  Multi-Tenancy allows analysts to create and modify knowledge documents and knowledge categories publically, or for specific tenants. A tenant dropdown appears in the search filter, and the search can include or exclude Public data.

Types of Knowledge Documents

Knowledge documents can be of two types:

- Knowledge document
- Knowledge tree document

Knowledge Document

Knowledge documents are placed into categories that some organizations assign to owners. Under the Top category in the Knowledge Tree, many sub categories can exist. These sub categories can in turn have many sub categories.

A knowledge document contains the following components:

- **Template**
  Specifies the content and format of documents that are displayed in the defined user view. The following templates are available by default:
  - Knowledge Documents
  - Knowledge Tree Documents
  - Quick Editing
- **Document Fields**
  Provides a consistent structure to the content in a knowledge document. For example, the Title and Summary make the content easy to scan when viewed in a list of items. The Resolution field stores the body of the solution, in rich text, tables, graphical images, and much more. These fields and their associated attributes define properties such as categorization, ownership, permission, modification date, and a range of other metadata that can help with management and retrieval.

Links to Other Forms

Allows knowledge documents to link to other forms of knowledge, which is stored either within or outside of Knowledge Management, including unstructured content such as a text file. You can also add action content (a live URL) so that the user viewing the document can perform certain actions. For example, you can insert a link into the Resolution field, which creates a ticket or performs some other action.

Knowledge Tree Documents

A knowledge document and knowledge tree document share much of the same descriptive data (such as Title, Summary, Modify Date). However, a knowledge tree document prompts the user with a series of questions with a list of multiple choice answers. By responding to the questions, they are directed to the correct answer or to the information they require. This interaction is governed by a decision tree, which is designed by the creator of the Knowledge Tree document.

Knowledge Tree Documents is well-suited to the following situations:

- Common incidents that need decision-based diagnosis/process guidance.
- Highly structured content.
- Relatively unchanging content.

Knowledge Management Roles and Functions

Knowledge Management is designed for a wide variety of users, from administrators and knowledge managers, who manage the product. It is also for customers, and employees, who use the system to find solutions to their problems. Although one person can fill multiple roles, the following roles are the basic user roles in Knowledge Management:

- **Customer --** An external end user who performs basic self-service tasks.
- **Employee --** An internal end user who performs basic self-service tasks.
- **Knowledge Analyst --** A user that is responsible for one or more steps within the knowledge management process. This user interacts with service desk analysts to create and maintain a quality solution base.
- **Knowledge Manager --** A supervisor for the Knowledge Analyst. This role handles knowledge document reassignments and escalations, and manages day-to-day administrative aspects of the solution. For example, creating the category structure, defining the approval process, managing noise words, special terms, synonyms, and other settings and options that are more dynamic in nature than what the Knowledge Management Administrator controls.
- **Administrator --** The administrator who has access to all the functionality in CA SDM and Knowledge Management. This role is typically used when implementing CA SDM to help ensure that all users and roles are set up properly. This role is also applicable for a CA SDM environment that has a single person performing all administration tasks.
- **Knowledge Management Administrator --** An administrator who is responsible for configuring and monitoring the knowledge management process. This role includes creating the category structure, defining the approval process, and configuring default search and security settings.

Each role has a different level of access in the CA SDM environment. These levels help define the tasks that each role performs.

Knowledge Documents Lifecycle

Knowledge documents provide you with information about knowledge that is stored in the knowledge base. Creating quality knowledge requires input from several individuals. Each individual is responsible for performing specific tasks throughout various stages in the lifecycle of a knowledge document.

Knowledge documents reside in the knowledge base and are managed as part of the following ongoing process:

1. Identify content to include in the knowledge base.
2. Create a knowledge document.
   Knowledge documents are placed into categories that some organizations assign to owners. If the Incident/Request Area in CA SDM matches the knowledge categories in Knowledge Management, the category is automatically selected for the knowledge submission.

> **Note**: When a document is created or updated, it is placed in an owner Inbox. Until the items are published, the items in the Inbox do not appear as resolutions and are not added to the knowledge base.

3. Revise the document.
   After a document arrives in the inbox, users can modify the documents according to their assigned roles.
   All users with full (read/write) permission to the document can modify the document. The current owner has full permissions to the document, but not necessarily have explicit write permissions. Users can create versions or can roll back to a previous version when a problem with the document is found.

4. Submit the document.
   In addition to submission from the customer or employee self-service interface, knowledge can also be submitted from CA SDM. This option lets the analyst submit a new resolution from an existing ticket. This option also provides a link between a problem and its resolution, and can help other users with similar problems to find a resolution.

5. Publish the document.
   After a document has passed through the complete approval process cycle, it can be published. A document that has been published becomes part of the viewable knowledge base on the start date, which is the current date by default. The document is only viewable by groups that have been granted access rights to read it. A user with full permissions can edit a published document.

Evaluate and decide whether to perform the following tasks:

- **Unpublish the document --** When a knowledge document is published, the user is not permitted to modify the document unless it is unpublished first. During this time, the knowledge document is offline and unavailable to users. The owner of the document, a knowledge manager, or a system administrator can unpublish the document using the Rework button and the Unpublish check box. Unpublishing a document returns it to draft status. An administrative user can then select the next step in the workflow process.

- **Create a Rework Version --** Users with full editing permissions can create a rework-draft version of a published document while it remains online and available for viewing and searches. A rework version create a copy of the document. This document replaces the original document in the knowledge base after it is verified and republished.

- **Retire the document --** The owner of the document, a knowledge manager, or a system administrator can retire the document from the knowledge base.

You can define the tasks and the roles that perform each of these tasks to meet the approval process structure that exists in your organization.

Note: You can track knowledge activities from the Event Log tab on contact detail pages. For example, the event log records the actions that an user performed on the document and provides a link to the document.

Knowledge Management User Interfaces

The following user interfaces help you manage knowledge:

- **Self-Service --** In the self-service interface, customers and employees using CA SDM can access knowledge documents and can submit knowledge for further consideration. Customers can search, browse, or use bookmarks to locate and view knowledge documents.

- **Knowledge Documents --** The knowledge documents interface is accessed from the Knowledge Documents node on the CA SDM Scoreboard. All users of the system can view their Inbox and follow-up comments using this interface. The *administrator* manages their unassigned/unindexed documents, automated document lifecycle policies, and user forums.

- **Knowledge Management --** The knowledge management interface is accessed from the Knowledge tab in CA SDM. The *knowledge analyst* or *knowledge manager* can find, organize, and publish knowledge using this interface.. They can also filter the documents that are displayed using advanced options, and sort the results by relevance, modified date and much more.

- **Knowledge Administration --** The knowledge administration interface is accessed from the Knowledge node on the CA SDM Administration tab. The *administrator, knowledge manager, or knowledge management administrator* can set system options using this interface. Settings can help conform the functionality and use of Knowledge Management.

Knowledge Management Configuration and Management Functions

You can perform the following configuration and management functions in Knowledge Management:

- Create "action content" (a live action URL) that you can insert into the Resolution field of a document.

- Set up the approval process and define the knowledge document lifecycle process.

- Set up automated policies that automate certain tasks in the knowledge document approval process.

- Set up document options that are related to comments, submitting knowledge, templates, and document settings.

- Create the templates that control how a document displays information.

- Manage the default Knowledge Management search engine and configure noise words, special terms, and synonyms that are used to perform keyword and natural language searches.

- Create "recommended documents" that display in the self-service interface when users search for knowledge solutions.

- Manage the knowledge category structure to make document access easier.

- Set up the Knowledge Report Card and general system settings.

- Define the surveys that collect and analyze the customer feedback about knowledge document performance.

- Manage integration of Knowledge Management into CA SDM, including the field mapping and request and issue search configuration.

Web Services

Knowledge can be accessed through SOAP web services. Various methods are available, permitting the search, retrieval, creation, and updating of documents, and a range of other operations.

Note: For more information about SOAP web services, see Web Services Management (see page 1855).

Knowledge Base Monitoring

You can monitor the efficiency of the knowledge base using the following reporting tools. These tools let you view statistics on the usefulness of your documents and their effectiveness in solving problems.

- **Knowledge Report Card**
  Lists statistics for documents you have created. Each user has an individual Knowledge Report Card.

- **Web-Based Reports**
  Displays metrics that describe how knowledge is meeting user needs. Some of the most commonly used features include:

  - Listing the most frequently accessed documents.

  - Displaying user searches that did not return any results.

Getting Started with Knowledge Management

Effective knowledge management consists of more than the development of a large knowledge base. Knowledge management also involves the implementation of processes and procedures for maintaining relevant and accurate content.

To set up a knowledge base, do the following tasks:

1. Analyze how you plan to use the knowledge base and the scope of it.

2. Consider who the customers are and what information they are likely to need.

3. Develop a strategic plan that identifies the potential issues that can result in the need for customer support. The problems that you identify can guide you in determining what content must reside in your knowledge base.

4. Execute the development of your knowledge base. Create, organize, maintain, and secure this data. You can perform all these functions by using Knowledge Management.

Import Sample Knowledge Data

Sample Knowledge data from Knowledge Broker and Knowledge Accelerators is provided for your use. You can import the sample data to view example knowledge articles on How-to, knowledge broker, and so on.

Note: The sample files are not localized. Importing sample data does not work on localized environments.

For the advanced availability configuration, run ImportSampleData.bat or ImportSampleData.sh from the background server.

Windows

1. Go to $NX_ROOT\samples\data and unzip SampleData.zip into the same directory.
2. From the command window, go to $NX_ROOT/bin and run ImportSampleData.bat.

UNIX

1. Run the command tar -xvf SampleData.tar from $NX_ROOT/samples/data.
2. From the command window, go to $NX_ROOT/bin and run ImportSampleData.sh.

Setting Up the Knowledge Management System

This section includes the following articles:

Configure Knowledge Management Settings

Contents

You can configure certain role-specific and document-specific settings when you are setting up your knowledge management system. You can also change these settings later to suit your requirements.

How to Manage Role Privileges and Document Visibility

You can set up Knowledge Management security permissions by managing role privileges for users in your environment. Use these permissions to define the information that users can access in a knowledge document, when they view or create knowledge. You can also define how users are authenticated when they log in to the system.

Follow these steps:

1. From the Administration tab, select Security and Role Management, Role Management, Role List.
   The Role List page appears.

2. Select the role that you want. For example, Knowledge Manager.
   The Role Detail and Update Role pages display the following tabs:

   - **Knowledge Management**
     Specifies the Knowledge Management privileges for the role.

   - **KT Document Visibility**
     Specifies which document statuses the role is allowed to view, such as draft, retired, and published.

3. Complete the tab pages and save changes.
   Security and role privileges are defined.

Note: For more information about setting up security and defining roles, see Managing Roles (see page 1166).

Configure General Settings

You can set the default information to display on the Knowledge tab at logon. You can specify the format in which categories display in the Knowledge Categories pane on the Administration tab, and the number of documents to list in the Top Solutions list on the Knowledge Management home page.

Follow these steps:

1. Select **Knowledge, System, General Settings** on the **Administration** tab.
   The **General Settings** page opens.

2. Complete the following fields as appropriate:

   - **Search Tool Opening Screen**
     Specifies the information that is displayed by default on the **Knowledge** tab. You can select one of the following options:

     - **Open with FAQ / Search**
       Displays the **Category, Knowledge Search**, and **Knowledge Document List** panes.

- **Open with Knowledge Tree Document ID**

- Displays the knowledge tree with the document ID specified in the field provided. You can return to the knowledge tree document itself, and then to the **Category**, **Knowledge Search**, and **Knowledge Document List** panes. **Default:** Open with FAQ /Search

- **Category Viewing**
  Specifies the format in which document categories display in the **Knowledge Categories** pane on the **Administration** tab. You can select one of the following options:

  - **Display categories in tree view**
    Presents the categories in a hierarchical tree structure in the **Knowledge Categories** pane. Categories expand to reveal associated subcategories. In this manner, you can view all the categories in the tree simultaneously.

  - **Display categories in list view**
    Presents the categories in a list format in the **Knowledge Categories** pane. When you select a category, its subcategories display in a list. You can view only the current level of categories or subcategories at one time. Use the **Up One Level** link to return to the previous category level.

  Note: If you have more than 250 categories under the top category, or under any category, use the **Display Categories in List View** option and not the tree view.

- **Top Solutions**
  Specifies the number of documents to list in the **Top Solutions** list on the CA SDM home page.
  Default: 10

  Path for EBR Index Files

  Defines the location for storing EBR index files. CA SDM creates EBR index files when you save and publish any knowledge document. Depending on your configuration type, consider the following points while defining the EBR index file path:

  - Conventional: If you are upgrading from the CA SDM Release 12.9 from r11.2 or r12.X, you may choose not to use UNC shared path. If you have not created a UNC path, CA SDM uses the default path to store EBR index files. If you are using a UNC shared drive, manually copy the ebr/ebr_ADM folders from the default location ($NX_ROOT/site/) to the UNC shared path.

  - Advanced availability: If you are upgrading to the advanced availability configuration from CA SDM r11.2 or r12.X, you must create the UNC shared path and use it to store EBR index files. The UNC credentials are not required for the default path. After you create the UNC path, manually copy the ebr/ebr_ADM folders from the default location ($NX_ROOT/site/) to the UNC shared path.

    Important!EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

Default: $NX_ROOT/site/ebr

- **Path For Knowledge Import/Export Files**

Defines the location for storing KEIT import/export packages during an import/export operation. Depending on your configuration type, consider the following points while defining KEIT file path:

- Conventional: If you are upgrading to CA SDM Release 12.9 from r11.2 or r12.X, you may chose not to use UNC shared path. If you have not created a UNC path, CA SDM uses the default path to store the KEIT files. If you are using a UNC shared drive, manually copy the Import/Export package folders from the default location ($NX_ROOT/site/keit) to the UNC shared path.

- Advanced availability: If you are upgrading to the advanced availability configuration from CA SDM r11.2 or r12.X, you must create the UNC shared path and use it to store the KEIT files. The UNC credentials are not required for the default path. After you create the UNC path, manually copy the Import/Export package folders from the default location ($NX_ROOT/site/keit) to the UNC shared path.

  Important!EBR Index Files path & **KEIT Files path** must refer to the same UNC credentials and the path must reside on a same server to support this.

Default: $NX_ROOT/site/keit

- **UNC Credentials**

You can use this option to create UNC credentials to access the network shared drive to access EBR indexing files and import/export packages. Use the **UNC Credentials** link to create the UNC credentials.

Note: UNC paths and UNC credentials are required in case of the advanced availability configuration. Restart the CA SDM service when you change any of the UNC details (UNC paths or UNC credentials).

- **Document Indexing Notifications**

Sets a user to receive email notifications about status or when errors occur with document indexing. The user must have an email address in the ca_contacts table to receive these email notifications. Use the Notification Page for the assignee contact record for setting notification methods.

Important! You must set an **Assignee** to receive document indexing notifications in the **Document Indexing Notifications** section. A valid email address must be defined in the **Notification** tab of this contact to enable email notifications.

3. Click Save.
   General settings are configured.

Note: When migrating from an older CA SDM release to the advanced availability configuration, manually copy the import/export packages to UNC shared location (specified in **Path For Knowledge Import/Export Files** field). For EBR index files, you can manually move the EBR/ebr_ADM folders to the UNC shared location or execute the pdm_k_reindex command path.

Specify Document Settings

As a system administrator, you can specify settings that are related to comments, submitting knowledge, and viewing knowledge tree documents.

Follow these steps:

1. On the Administration tab, select Knowledge, Documents, Document Settings.
   The Document Settings page appears.

2. Complete the following fields:

   - **Knowledge Tree Document Viewing**
     Specifies the viewing mode in which knowledge tree documents open. Select Open in Tree Mode (default) to open the knowledge tree directly or Open in Document Mode to open the document in document view. If you open in Document Mode, click Display to show the knowledge tree.

   - **Comments**
     Specifies if users can submit comments for documents and view document comments. Select one of the following options:

     - **Allow comment submission and comment viewing (default)**
       Displays a Comment field at the bottom of an open document so users can submit comments for the document. Users can view comments that are already associated with the open document.

     - **Allow comment submission but not comment viewing**
       Displays a Comment field on the right of an open document so users can submit comments for the document. Users cannot view comments that are already associated with the open document.

     - **Allow neither comment submission nor comment viewing**
       Disallows the users from submitting or viewing comments. The Comment field does not display in an open document.

3. **Submit Knowledge**
   Defines the repository for user-submitted documents. The product populates the list with the names of repositories that are defined on the Attachment Library pane.
   Consider the following information:

- When an analyst creates a document in a category that has an owner and assigns the document to the category owner:
  Category owner becomes the assignee and owner of that document.
  Category owner must receive a document assigned notification.

- When an analyst creates a document in a category that has no owner and assigns the document to the category owner:
  No one becomes the assignee or owner of that document.
  Submit KD notification must send as defined in the administration.

- When an analyst creates a document and does assign the document to the category owner:
  That user becomes the assignee and owner.
  A notification does not send.

- When an employee or customer creates new documents, CA SDM takes the action as stated in the first two points.

4. **Maximum Resolution Size**
   Defines the maximum size (in characters) that the Resolution field in a document can contain.
   Limits: The maximum characters allowed is 256000.
   Default: 32768.

5. **Duplicate Document Avoidance**
   Forces a search for similar documents when the user creates a knowledge document.

6. **Notification before Expiration**
   Defines the number of days before the document expires and a notification is sent.
   Default: 7

   Note: This value only applies to documents that have been updated or created in CA SDM. If you migrate documents from CA SDM r11.2, and the expiration dates are set before the migration, this option applies only when you update the document after the migration.

7. Click Save.

   The changes apply when you open a knowledge document or a knowledge tree document.

Setting Up Self-Service Knowledge Options

Customers and employees using CA SDM have access to knowledge documents through the self-service interface. Customers can search, browse, or use bookmarks to locate and view knowledge documents. Giving the customers access to knowledge documents and services permits customers to find answers themselves and reduces the pressure on resources.

In the self-service user interface, employees, and customers can view the following knowledge solution options:

- **Search for Knowledge Solutions**
  Employees and customers can enter keywords and phrases in a search field that retrieves a list of knowledge solutions. You can configure this option in the following location: Administration, Knowledge, Search, Search Settings.

- **View Top Solutions**
  Employees and customers can display a list of top solutions in the self-service interface. The following Administrator setting: Administration, Knowledge, System, General Settings, Top Solutions -- Number of Documents to Display, determines the number of documents to display.

- **Prompt for Knowledge Survey**
  The users are prompted for a knowledge survey after they have read the document. The survey has a series of questions. One of these questions lets the customer indicate through a prompt whether they feel that their problem has been solved. You can configure this option in the following location: Administration, Knowledge, Solution Survey, Survey Settings.

- **Suggest Knowledge**
  Employees and customers can, where permitted, view a list of knowledge suggestions when they create a ticket in the self-service interface. You can configure this option in the following location: Administration, Knowledge, Service Desk Integration, Suggest Knowledge.

Define Document Preferences

You can define preferences that help you work with information in Knowledge Management. The Preferences Settings window opens when you do either of the following actions:

- Select Preferences from the View menu
- Click Edit on the Preferences Detail window

In General Settings, the following fields require explanation:

- **Avoid Popups**
  Specifies whether to reduce the number of new browser windows opened by displaying new forms in the main browser window whenever possible.

  - Select the check box to minimize the number of new browser windows opened.
  - Clear the check box to open new browser windows according to the properties set in the form definition.

  Default: Cleared.

  Note: If this option is selected, the Back to List button can be used to navigate from detail forms back to the previously displayed list window. The Back to List button appears in the upper right-hand side of the window.

- **Keep Log Reader Window**
  Specifies whether to keep the Log Reader window open when you select the Close All Popups command from the Window menu and after you log off of Knowledge Management. This setting has no effect when the Log Reader window is not open.

- Select the check box to keep the Log Reader window open.
- Clear the check box to close the Log Reader window when you select the Close All Popups command or log off of Knowledge Management.

Default: Selected.

- **Preserve Popup Size**
  Specifies whether to open new popup windows with the same dimensions as the most recently resized popup window.
  - Select the check box to use the new dimensions for new popup windows.
  - Clear the check box to open new popup windows with default dimensions.

  Default: Selected.

  Note: If you select Preserve Popup Size, maximizing a popup window will cause subsequent windows to cover any other open window. However, new popup windows appear slightly off the screen, to the right and down. As there is a 10 pixel (left and top) offset for popups, they do not completely overlay the currently displayed window. We recommended that you do not maximize popup windows when using the Preserve Popup Size option.

- **Using Screen Reader**
  Selecting this preference modifies behavior for optimal use with a screen reader for blind and limited vision users. Log off and log back in again after changing this preference. From the Help menu, select Screen Reader Usage for an overview of using CA SDM with a screen reader.

In Knowledge Search Document Settings, the following fields require explanation:

- **Attributes to be shown in list**
  Displays two lists with which you can define the properties that display for each document in the Knowledge Document List pane on the Knowledge Categories pane of the Administration tab.

  Note: Choosing the attributes different from the Preference default can impact performance. If you believe that extra display columns are needed, contact the system administration and ask them to use the Web Screen Painter utility to modify the default page columns for the Document List page.

Define a Document Approval Process

Contents

For the administrators who want to control the management of their knowledge base, the ability to modify the document editing and approval process is essential. You can design Approval Process templates that specify how, when, and by which an employee document can be modified and published to the public. Approval Process templates can designate different approval processes best suited to your business environment. The approval process that you implement can be modified over time to become simpler or more complex.

The Approval Process Manager lets you define Approval Process templates. By default, the Built-in Approval Process template is used. However, you can create a template or can edit an existing template. When creating an Approval Process template, you define statuses and you add tasks to the template. The approval process involves a series of tasks that are performed on a knowledge document. The owner that is assigned a task in the Approval Process template performs each task.

The following statuses are the various states that the document is associated with during the stages of the approval process:

- **Draft**
  Specifies a new document.
- **Published**
  Specifies a document that has passed through the complete approval cycle and becomes part of the viewable knowledge base.
- **Rework-Draft Version**
  Specifies a rework version of a copy of the document that is replaced in the knowledge base after it is verified and republished.
- **Retired**
  Specifies a document that has reached its expiration date. You can also create your own statuses, which you later associate with tasks.

Note: You can also create new document statuses. For more information, see Create a Document Status (see page 2708).

Approval Process Manager

Knowledge Administrators can use the Approval Process Manager to perform these actions:

- Determine which groups can read a knowledge document and which groups can write (or edit) the knowledge document.
- Identify the tasks in an approval process template that determine the lifecycle of documents that are created with the template.
- Define the various statuses that the document can be associated with during the approval process.

Important! When creating a knowledge document, verify that document permissions include users that can later be assigned to the document through the approval process. Users from that group do not necessarily have the permission to view the document. If the document is assigned to a specific user, default data partition constraints let the user view the document.

Define an Approval Process for Document Editing

Knowledge administrators can specify who can edit documents before the approval process and after publishing. Users with full (read/write) permissions can edit published documents.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Approval Process Manager, Approval Process Settings.
   The Approval Process Settings page appears.

2. Specify who can edit documents *before* the documents are published. Select one of the following options:

   - **Documents may be edited by a task assignee, an owner or users with the appropriate Access Type views**
     Specifies that the following contacts can edit documents:

     - A contact that is assigned to the current task
     - A contact that is specified as an owner of the document for the current task
     - A knowledge manager
     - A system administrator

   - **Documents may be edited by users with full permissions**
     Specifies that any user with write permissions to the document can edit it.

3. Specify who can edit documents *after* the documents are published. Select one of the following options:

   - **User with full permissions may edit documents after they have been published**
     Specifies that a user with full permissions can edit published documents.

   - **User with full permissions can change published document's attributes**
     Specifies that any user with write permissions to the document can change only attributes of published documents such as configuration items or products.

   - **Document must be unpublished before editing is allowed**
     Specifies that the user must unpublish a document before editing it.

   Click Save.
   The approval process is defined.

Create an Approval Process Template

The tasks in an approval process template define the lifecycle of documents that are created with the template.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. From the Administration tab, select Knowledge, Approval Process Manager, Approval Process Templates.
2. Click Create New.
3. Enter a name for the template and a description.
4. Click Save.
   The Approval Process Template Detail page displays more fields.
5. Select the task that you want to perform when you create a rework version of the document using this template.
6. Select the task that you want to perform when you unretire a document that was created using this template.
7. Click Insert Task to create a task to add to the template.
   The Create New Task page displays.
8. Complete the fields.
9. Click Save.
   The approval process template is created.

Create a Document Status

You can add and delete user-defined document statuses, and modify the names and descriptions of predefined document statuses.

Follow these steps:

1. From the Administration tab, select Knowledge, Approval Process Manager, Document Statuses.
   The Document Status List appears.
2. Click Create New.
3. Enter a name for the status and a description.

4. Click Save.
   The document status is created.

Define Comment Types

Contents

If the analyst notices a typo or problem with the content in a document, they can add a comment. The comment flags the document for correction and then assign the problem to another analyst for followup. Administrators can define the comment types that appear in various list views within the end-user interface.

Create a Comment Type

You can define the comment types that appear in various list views within the end-user interface.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration tab, select Knowledge, Documents, Comment Types.
   The Comment Type List page appears.

2. Click Create New.
   The Create New Comment Type page appears.

3. Complete the fields as appropriate. The following fields require explanation:

   - **Time to Complete (Days)**
     Defines the number of days by which the user must follow up on this type of comment.

   - **Show in User View**
     Displays the comment in various list views within the user interface.

   - **Follow-up Required**
     Specifies if the user is required to respond to this type of comment.

   Click Save.
   The new comment type appears on the Comment Types List page.

Set Up a Follow-Up Comment Notification

Several default activity notifications that are listed on the Activity Notification List page let you set up notifications to users when a follow-up comment is assigned to them.

The Follow-Up Comments queue on the scoreboard is the repository for assigned and unassigned follow-up comments.

Follow these steps:

1. On the Administration tab, browse to Notifications, Activity Notifications.
   The Activity Notification List page appears.
2. Select *one* of the following activity notifications:
   - Follow-Up Comment Assigned
   - Follow-Up Comment Closed

   The Activity Notification Detail page appears.
3. Click Edit.
4. Change the fields as appropriate.
5. Click Save.

Define Document Templates

You can use document templates to control the format and default content of knowledge documents. Every knowledge document uses a document template to define its properties and appearance when opened. By default, a built-in template is associated with new knowledge documents.

The Template Editor lets you do the following tasks:

- Design a document template that can later be associated with a document.
- Modify the built-in template and other templates.
  By editing templates, you can create templates to associate with documents. You can select the Properties options and can edit the Header and Body sections using the HTML Editor.
- Update document templates from a previous release to support knowledge relationships (see page), such as parent-child links.

A document template specifies the content and appearance of documents in the knowledge base. You can apply the default templates:

- Built In -- Knowledge Document
- Built In -- Knowledge Tree
- Built In -- Quick Editing

The knowledge documents and knowledge tree documents use the default templates unless you create document templates and you associate them with your documents.

Note: When you are creating a knowledge document, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Documents, Document Templates.
   The Document Templates List page appears.

2. Click Create New.
   The Create New Document Template page appears.

3. Complete the following fields:

   - **Template**
     (Required) Defines a unique name for the template.

   - **Detail**
     Displays the static content that appears in documents that are created using the current template. If you select the HTML Source option, you can edit HTML code for the body directly in the Body. Select the Quick View option to view the body content as it appears at run time.

4. (Optional) Click Set Default Values.
   The Default Values Template page appears.
   You can set default values when creating a document. If you change the template on an existing document, there is no impact.

5. (Optional) Hide the Title, Summary, Problem, or Resolution from appearing in your template.
   You can hide these fields when you want a simple document, such as a question and answer template.

6. Click Edit Detail.
   The HTML Editor page appears and you can specify the static content and layout of documents that use the template. You can edit the code using the toolbar to insert placeholder tags.

   Important! You can remove knowledge relationships, such as parent, child, and related links, by deleting the {TAG_PARENT} and {TAG_RELATED} tags from the template.

7. Click OK.
   The Detail field shows the updated content.

8. (Optional) Click Quick View.
   A quick view of the content as it appears in documents that are based on the template is displayed.

9. (Optional) Click HTML View.

> **Note:** You can update knowledge document templates from a previous release of CA SDM to display knowledge relationships. You modify the template by adding the {TAG_PARENT} and {TAG_RELATED} tags. The tags allows documents that are using the template to display document relationships, such as parent-child links and tenant. To do so, select *Select Template Placeholder* on the Edit Detail dropdown to add tags to the document template.

10. Click Save.

11. The Document Template Detail page appears.

12. Click Close Window.
    The new documents that use the template show the new content and layout.
    The name of the template appears in the Template List when you display the list again.

> **Note**: Changes to the document using the template display after starting a new session by logging in to the system.

Define FAQ and Solution Survey Settings

Contents

Solution Surveys let you collect and analyze customer feedback about Knowledge Document performance. You can modify the survey settings by selecting Knowledge, Solution Survey from the Administrative Interface. The survey appears on a published Knowledge Document. The customers, guests, and employees can take the survey and rate the effectiveness of the Knowledge Document.

This feature contains the following components:

- FAQ Settings
- Survey Settings

Define FAQ Settings

You can set the parameters by which the product calculates the FAQ rating that is assigned to each document. The product bases the FAQ rating on the following criteria:

- How frequently the document was accessed in the past?
- How helpful the document was to users?

- How the effectiveness of the document has decreased over time?

By default, the document list page displays documents that are sorted in the order of FAQ rating (in the order of usefulness). The most useful documents "bubble up" to the top of the document list. Over time, documents tend to move downward in the document list as users learn solutions to the problems.

Follow these steps:

1. Select Knowledge, Solution Survey, FAQ Settings from the Administration tab.
   The FAQ Settings page appears.

2. Complete the following fields as appropriate:

   - **Last Updated**
     Specifies whether to run the FAQ Rating Service and displays the date on which FAQ ratings were last updated.

     - Select the Run the FAQ Rating Service check box to run the FAQ calculation service using the settings on this window.

     - Clear the Run the FAQ Rating Service check box to turn off the FAQ calculation service.

   - **Schedule**
     Defines the frequency at which the product updates FAQ ratings. This field contains the following components:

   - **Perform the FAQ Calculation Every...**
     Specifies the time that elapses before the product updates the FAQ rating for documents.
     Default: 1 day

   - **From...**
     Specifies the time of day that the product must begin recalculating FAQ ratings.
     Default: 00:00 (12:00 A.M.)

   - **To...**
     Specifies the time of day that the product must stop recalculating FAQ ratings, regardless of whether the calculation is finished. This setting initially takes effect the day after product installation. For example, if you install the product on April 19, 2008, the FAQ server runs for the first time on April 20, 2008.
     Default: 07:00 (7:00 A.M.)

   - **Aging**
     Defines the number of times a document FAQ rating is recalculated before it reaches 0. Based on the specified value, the document FAQ rating decreases and eventually becomes 0. At this point it appears at the bottom of the document list (when the list is sorted by FAQ Rating).
     Default: 180
     For example, if the Aging value is 180 for a document with a rating of 4 (very helpful), the FAQ rating of the document is 0 (zero) when the product has recalculated the FAQ rating 180 times.

Note: By default, the FAQ bubble-up calculation requires bu_trans data for the last 180 days, where 180 is the aging factor. So, if you change the aging factor for FAQ to more than 365 days, you must extend the archive rules for the bu_trans table accordingly.

- **Days New**
  Specifies the number of days that a newly created or imported document displays in the New Documents folder on the Knowledge tab.
  Default: 5 days

- **Rating**
  Specifies the default rating (Not Helpful at All, Somewhat Helpful, or Very Helpful) for documents that users have opened but not rated.
  Default: Somewhat Helpful

Click Save.
The FAQ settings are defined.

Define Solution Survey Settings

You can configure the survey options that you want to show to the users when they access the document.

Follow these steps:

1. Select Knowledge, Solution Survey, Survey Settings from the Administration tab.
   The Survey Settings page appears.

2. Select the survey options that you want. Select the Display 'Voting Summary' option to display the number of votes that the document received and the average rating. The summary is displayed on the Employee interface.
   The solution survey settings are defined.

Create a Knowledge Category

Knowledge documents are arranged into *knowledge categories*. Knowledge engineers, knowledge managers, and administrators can manage the categories. Each of these individuals uses Knowledge Management to create, copy, and modify categories. However, only knowledge managers and administrators can delete categories. The category structure in Knowledge Categories helps you create a hierarchical structure that service desk employees, customers, and analysts use to navigate to relevant documents.

Assign each document to a primary category. For example, any knowledge that is related to Microsoft Word must be added to the Microsoft Word category. In addition, Knowledge Management lets you associate a document with multiple secondary categories and other documents. This feature allows a document to be classified under many different applicable categories and results in better search results.

The category structure performs the following functions:

- Organizes knowledge solutions into manageable groups.

- Makes it easier to assign access rights.
- Makes it possible to search for solutions using FAQ/Browse.
  To use category browse functionality from an incident, the incident area and the knowledge category must match. When you create an incident that is based on a knowledge document, the document category sets the incident area; therefore, the category and the area always match.
- Creates a document link -- A *see also* link appears when viewing either of the linked documents. The *see also* link lets you go directly from one linked document to the other.

For each category, you can define properties that identify attributes or qualities to be associated with the ticket. You can also create a workflow that identifies all the individual tasks that are required to fulfill the ticket.

You can use categories to specify default values for certain fields in tickets, or automatically associate a level of service to tickets by assigning a default service type to categories. Whenever an analyst assigns a category to a ticket, all the information you associate with the category is automatically associated with the ticket.

Note: If you are using multi-tenancy, a tenant drop-down list appears in the Knowledge Document search filter. If you select <empty> in this drop-down list, the search is public. A tenant column also appears on the list page.

Follow these steps:

1. On the Administration Tab, browse to Knowledge, Knowledge Categories.
   The Knowledge Categories page appears.
2. Right-click the category under which you want to create the category. Select New Category from the shortcut menu.
   The Create New Category page opens to the Content tab.
3. Complete the fields (see page 2716) as appropriate.
4. Click Permissions.
   The Permissions tab appears.
5. Select one of the following permissions options for the category:
   - **Inherit from Parent**
     Specifies that the new category has the same permission settings as its parent category.
     Note: The Inherit from Parent option is not available if you select the TOP category before opening the Create Category page.
   - **Control by Group**
     Specifies category permissions for groups to have read or write access to the category.
   - **Control by Role**
     Specifies category permissions for roles to have read or write access to the category.

Note: If you change controls, such as changing the category permission from group to role, a warning appears that previous permissions are deleted for that category.

- **Grant Write Permission to Everyone**
  Specifies that all users have write access to the category. Write access indicates that you can edit or delete this category.

  Note: The Grant Read Permission to Everyone check box is automatically selected if you select the Grant Write Permission to Everyone check box.

- **Grant Read Permission to Everyone**
  Specifies that all users have read access to the category. Read permission indicates that you can view the category, but you cannot edit or delete it. Users with administrative rights can edit a folder even if their associated permission group cannot. If a user belongs to multiple permission groups with varying levels of access to the category, the user gets the highest available access level (for example, if one group has read-only access and the other write access, the user gets write access).

  Note: The Grant Read Permission to Everyone check box is automatically selected if you select the Grant Write Permission to Everyone check box.

  Important: When you grant permissions for Everyone, the access by role or group is the same. If you selected Everyone and Control by Role, after you save the permissions, the Control by Group becomes selected.

6. (Optional) Specify the read-write permissions to specific groups or roles from the Available and Selected lists.
   You use this option to manage which groups or roles have read or write access to the category. You can select one or more permission groups or roles from the Available Groups /Roles list, and then use the Add and Remove buttons to move the selected groups or roles to the Groups/Roles with Write Permission and Groups/Roles with Read Permission lists.

7. Click Save.
   The Category Detail page appears.

8. Click Close Window.
   The Knowledge Categories pane refreshes to include the new category.

Category Fields

- **Title**
  Names the category.

- **Description**
  Describes the category.

- **Category Owner**
  Indicates the person responsible for the category. When a contact is defined as the owner of a category, the contact has a link on the Knowledge Report Card named "My Categories," from which they can view statistics for that category and the documents it contains. This person is also the default owner for new documents in the category when the user who creates the documents is not an analyst, or an analyst creates the documents with 'Assign to Category Owner' selected.

- **Documents Template**
  Defines the document template to use for all documents that are associated with this category. The <empty> option means that none have been defined, but by default, the predefined template is used.

- **Approval Process Template**
  Defines the default template to use for the approval process for all documents that are associated with this category. The approval process template defines the workflow steps a document must go through before it is published. The default is <empty>, which indicates the application default template is used.

- **Allow forums to be created in this category**
  Specifies whether analysts can create forums within this category.

- **Request/Incident/Problem Area**
  Designates a Request/Incident/Problem area that your administrator defines to designate an area of responsibility. You can click the search icon to select from the available areas.

- **Issue Category**
  Designates an Issue Category that your administrator defines to designate an area of responsibility. You can click the search icon to select from the available areas.

How to Set Up the KT Search Engine

The Search feature enables administrators to perform the following tasks:

- Manage the Knowledge Management search engine.

- Define the settings that are used to manage noise words, special terms, and synonyms that are excluded or included in searches.

- Define the settings that are used to parse documents.

- Define default search settings.

- Create "recommended documents" that display in the search results. Dynamic FAQ listing is used to push (bubble up) the recommended documents to users.

Note: A document can have different permissions than the attachments linked to the document.

KT Search Engine

Content:

After you install CA SDM, the KT search engine is configured as the default. Searches of the knowledge base are limited to knowledge documents. The search engine is on the Administration tab, Knowledge, Search, KT Search Engine node.

Note: You can define accessibility and defaults to all knowledge sources based on a user role. By default, knowledge documents are searchable for all user roles.

To configure the search engine, go to Options Manager, Search Engine from the Administration tab and edit the ebr_version as KT Search Engine. For more information about editing an option, see Install/Uninstall Options Manager Options (see page 2718) page.

Noise Words, Synonyms, and Special Terms

You can define words (synonyms, noise words, and special terms) that affect natural language and keyword searches that are performed in CA SDM. Adding or deleting the following terms has a significant effect on search results that are returned to the user:

- Noise Words
- Special Terms
- Synonyms

Create Noise Words

Specifies the words that do not generally contribute to the search process and can, therefore, be ignored. For example, prepositions such as a, an, the, or, and to are often identified as noise words. The search engine ignores the noise words in documents and queries without affecting search results.

Follow these steps:

1. On the Administration tab, select Knowledge, Search, KT Search Engine, Noise Words.
   The Noise Words List page appears.
2. Click Create New.
   The Create New Noise Word page appears.

3. Enter the word that you want to define as a noise word in the Noise Word FIELD.

   Note: You cannot define a noise word that exists as a synonym or keyword.

4. Click Save
   The new noise word appears on the Noise Words List page. You can click the Edit button to update the new noise word.
   Note: You cannot define a noise word that exists as a synonym or keyword.

Note: After you create, modify, or delete noise words, special terms, synonyms, or parse settings, use the Knowledge Re-Index utility that is provided with the product to re-index the knowledge base.

Create Special Term

Specifies a term that you want identified as a single word during the search process, although it can consist of several words or contain special characters. For example, words that have a nonalphanumeric character, such as the forward slash (/) in TCP/IP, the hyphen (-) in dial-up, or the underscore (_) in LOCAL_SERVER can be added as special terms. In your evaluation of which words to define, consider valid words that can be divided during the search process because they have a nonalphanumeric character.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Search, KT Search Engine, Special Terms.
   The Special Terms List page appears.

2. Click Create New.
   The Create New Special Term page appears.

3. Enter the word or phrase you want to define as a special term in the Special Term field.

4. Click Save.
   The Special Term Detail page opens so you can review the word or phrase you added. You can use the Edit button to update the new term. The new special term appears on the Special Terms List page.

Create a Synonym

Specifies a word that has the same meaning as another word. When a user searches for a particular word, and a corresponding synonym for that word exists in your knowledge base, the information can be found. You can define several synonyms for the same word. The system automatically creates reverse synonyms from the keywords you define. For example, if you define computer as a synonym for the word PC, PC automatically becomes a synonym for the word computer. Use the Synonyms List page to specify keyword/synonym pairs that the product uses interchangeably when parsing documents and queries. These keyword/synonym pairs can improve search results.

Note: After you create, modify, or delete noise words, special terms, synonyms, or parse settings, use the Knowledge Re-Index utility provided with the product to re-index the knowledge base.

If you define a new complex synonym (that is, a synonym containing multiple words that are separated by spaces or other delimiters), also create an identical special term so that the product can treat the synonym as a single entity. For example, if you define "Computer Associates" as a synonym for "CA", also define "Computer Associates" as a special term.

You cannot define a synonym or keyword that exists as a noise word.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Search, KT Search Engine, Synonyms.
   The Synonyms List page appears.

2. Click Create New.
   The Create New Synonyms page appears.

3. Enter the word or phrase you want to define as a synonym in the Synonyms field.

4. Click Save.
   The Synonyms Detail page opens so you can review the word or phrase you added. The new synonym appears on the Synonyms List page.

5. Right-click the synonym and select Edit if you want to edit the synonym,

Define Parse Settings

When you publish a document to the knowledge base, the product parses the information in the Title, Summary, Problem, and Resolution fields of the document into keywords. When a user searches the knowledge base, the product compares keywords from the user query with the keywords parsed from the knowledge base to produce a result list.

Use the Knowledge Re-Index utility to re-index the knowledge base after you change parse settings and when you add noise words, special terms, or synonyms. Re-indexing the knowledge base ensures that keyword searches are based on current and accurate information.

Note: Depending upon the size of your knowledge base, re-indexing may take a significant amount of time.

To re-index the knowledge base, see instructions on the pdm_k_reindex utility from the CA SDM PDM Database Commands (see page 3889) page.

Follow these steps:

1. Browse the Administration tab in Knowledge, Search, Parse Settings.
   The Parse Settings appears.

2. Use the following fields to define settings:

- **Maximum Search Keywords**
  Defines the maximum number of keywords to extract when the product parses the search text.
  Default: 20

  Note: The valid range is 1-100, so that a CA SDM Knowledge administrator can change the value within this range, which is based on search needs and parameters of a specific Knowledge database. Use a lower number of search keywords for faster performance.

- **Language**
  Specifies the language type to use for parse processing. Select one of the following settings:

  - **English**
    Performs certain types of processing specific to the English language (for example, de-pluralizing search terms) during a search, if applicable.

  - **Other European**
    Performs only European specific processing during the search.

  - **Korean**
    Performs only Korean specific processing during the search.

  - **Other Far East**
    Performs processing for other far east languages during the search.

    Note: When you are in a Chinese, Japanese, or Korean operating environment, verify that you understand the available parsing approaches, and limitations of Multi-Byte Character Set (MBCS) languages (see page 2723), before implementing your Knowledge Management system to help ensure that user expectations are set appropriately.

- **Valid Character Range**
  Defines the range of alphanumeric characters to consider valid when parsing the Title, Summary, Problem, and Resolution fields in a document. The product treats any other characters as separators.

  Note: When you select Yes from the Recognize Special Terms list, the product does not parse words and phrases defined as special terms.

Default: a-z, which indicate that the alphabetic characters a through z are valid characters for parsing.
The Valid Character Range field contains the appropriate letters that parsing uses. The letters that are not presented in the Valid Character Range are removed.
The recommended values for different languages are as follows:
Language Valid Character Range
German a-zäöüß
Spanish a-záéíóúüñ
French a-zàäâçéèêëîïôùû
Portuguese Brazil a-zàáãçéêíóúü
Italian a-zàèéìîïù
Simplified Chinese a-z
Japanese a-z
Traditional Chinese a-z
Korean a-z

Note: Japanese contains the "a-z" range plus a list of Katakana valid characters, excluding punctuation marks.

- **Remove Similar Words**
  Specifies whether the product removes structurally similar keywords from the groups that are used in a search. You can select one of the following settings:

  - **Yes**
    Removes structurally similar keywords from the search criteria.

    Note: When you select Yes, the product also removes similar words when you save or publish the document. This setting can impact whether a document is searchable if the Remove Similar Words field was set to Yes. The similar word may have not been indexed and used in the later search and retrieval of the document.

  - **No**
    Leaves structurally similar keywords in the search criteria.

  Default: No

- **Remove Noise Words**
  Specifies whether the product removes noise words when parsing the Title, Summary, Problem, and Resolution fields in a document. You can select one of the following settings:

  - **Yes**
    Removes noise words from the search criteria.

  - **No**
    Leaves noise words in the search criteria.

  Default: Yes

- **Recognize Special Terms**
  Specifies whether the product considers special terms as single entities or as multiple words when parsing the Title, Summary, Problem, and Resolution fields in a document. You can select one of the following settings:

  - **Yes**
    Processes special terms as single entities in the search criteria.

  - **No**
    Processes the words that comprise special terms as separate entities in the search criteria.

  Default: Yes

Multi-Byte Character Set Search Limitations

Make sure that you understand the available parsing approaches, and limitations of MBCS languages, before implementing your Knowledge Management system to help ensure that user expectations are set appropriately. This limitation of the product impacts search features using Japanese, Chinese, or Korean language text within the system. The word parsing mechanism used by the search mechanism is controlled on the Parse Settings (see page 2720) page.

For the English, Other European, and Korean settings, the product assumes that punctuation, “white space,” or both characters separates words. This assumption allows the document text to be broken into specific words, and allows noise words to be ignored and application of known synonyms and special terms to search terms.

Alternatively, when the Far East language setting is selected, the parsing routine uses a character-by-character parsing approach to accommodate some Far East language text approaches of not using white-space delimiters between words. This setting tells the parser to assume that each character is treated as a full word. The setting applies to all text to be searched. Because the language setting changes the way that the search parsing works, the entire search index must be recreated if the language setting is changed to or from Far East.

Create Recommended Documents

The CA SDM users can specify the criteria about an item of interest. The search engine then finds the matching knowledge documents and displays them on the search results page as a set of "recommended document" links. The search query can be expressed as a keyword or set of words (phrase) that identify the desired concept that one or more documents can contain.

The list of documents that meet the search criteria is sorted, and ranked (from highest to lowest) to place the most relevant documents first in the search results. Using recommended documents helps users reduce the time that is required to find the desired information.

To provide a set of matching documents that are sorted according to some criteria quickly, the search engine collects data through the condition type (phrase, keywords, or category), which the administrator configures on the Create Recommended Documents page.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Search, Recommended Documents.
   The Recommended Documents List appears.

2. Click Create New.
   The Create New Recommended Documents page appears.

3. Complete the following fields as appropriate.

   - **Knowledge Document**
     Specifies a knowledge document or click the search icon to open the Knowledge Document Search page.

   - **Condition Type**
     Specifies a condition type (see page 2724) by which the search engine sorts and matches the document.

     - If the condition type is Full Match, Exact Phrase, or Keywords, a text field appears. You can enter a phrase or keyword that identifies the concept you want for the document to contain.

     - If the condition type is Knowledge Category, the Knowledge Category link appears. You can specify a knowledge category to associate with this document.

   - **Status**
     Defines the status of this record as active or inactive.

   Click Save.
   The new recommended document is saved to the knowledge base and appears on the Recommended Documents List page.

Condition Type Field

The search engine locates documents by the following condition types:

- **Full Match**
  Searches for documents by the search phrase entered in the search text. A match occurs only when the search engine finds all the same words in a phrase.

- **Exact Phrase**
  Searches for documents by the exact phrase entered in the search text. A match occurs only when the search engine finds the exact set or sequence of words in a phrase.

- **Keywords**
  Searches for documents by the keywords entered in the search text. A match occurs only when the search engine finds all of the keywords.

- **Knowledge Category**
  Searches for documents by knowledge category. A match occurs only when a user navigates to a category configured for recommended documents.

Set Up Default Search Settings

You can set up default search options that appear when users search for knowledge using the search field.

Note: These search options are overwritten by any personal search settings users define in the Preferences window, or any additional search options that are specified in the following places:

- In the Knowledge Search pane on the Knowledge tab.
- In the Knowledge Categories pane on the Administration tab.

Follow these steps:

1. From the Administration tab, navigate to Knowledge, Search, Search Settings.
   The Search Options page displays.
2. Select the following options as appropriate:
   - **Recommended Results**
     Specifies the number of documents to display in the search results list.
   - **Default Search Fields**
     Specifies which document fields to include by default in keyword searches. The following document fields are available for searching:
     - Title
     - Summary
     - Problem
     - Resolution
     - Attachments
   - **Search Settings for All Sources**
     Specifies whether searches can include all knowledge sources. For example, knowledge categories and request areas.
   - **Search Settings in a Ticket Context**
     Specifies whether searches can include all fields that are defined in a service desk ticket (incident, problem, issue, change order, or request).
     For these options, select *one* of the following match types:
     - **Any of the words (OR)**
       Includes a document in the result set when it contains any of the words in the Search field. This option is the default selection.

- **All of the words (AND)**
  Includes a document in the result set only when it contains all the words in the Search field.

3. Click Save.
   The default search settings are set up.

How to Set Up Knowledge Management with Ticket Categories

This article contains the following topics:

Define the configuration options available for CA SDM Integration.

Define Field Mapping

Administrators can specify which fields to populate with Knowledge Management information, and whether to overwrite existing information.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Service Desk Integration, Field Mapping.
   The Field Mapping page appears.

2. Complete the following fields as appropriate:

   - **Populate Service Desk Values from Knowledge Management**
     Specifies whether to use information from Knowledge Management to populate fields in service desk issues or requests.

     - Select the check box to make fields in the Knowledge Management, Populate Empty Service Desk Values, and Overwrite Service Desk Values columns available so you can specify which Knowledge Management information to use to populate fields in service desk issues or requests.

     - Clear the check box to make fields in the Knowledge Management, Populate Empty Service Desk Values, and Overwrite Service Desk Values unavailable. In this case, users must manually populate service desk issues or requests that are created from Knowledge Management.

     Default: This check box is selected.

- **Service Desk**
  Identifies the fields in issues or requests that correspond to fields listed in the Knowledge Management column.
  For each check box selected in the Populate Empty Service Desk Values column, information from the corresponding field in the Knowledge Management column populates the issue or request.

- **Knowledge Management**
  Identifies the Knowledge Management fields that correspond to the service desk fields listed in the Service Desk column.
  For each check box selected in the Populate Empty Service Desk Values column, information from the corresponding field in the Knowledge Management column populates the issue or request.
  The Knowledge Management column contains two drop-down lists:

  - The first drop-down list corresponds to the Summary field in the Service Desk column. It also specifies the Knowledge Management field (Title, Summary, or Problem) with which to populate the Summary field in an issue or request.

  Default: Summary.

  - The second drop-down list corresponds to the Description field in the Service Desk column. It also specifies the Knowledge Management field (Title, Summary, or Problem) with which to populate the Description field in an issue or request.

  - **Default**: Problem.

- **Populate Empty Service Desk Values**
  Specifies which empty fields in a service desk issue or request to populate with information from Knowledge Management.

  - Select a check box to map information from the Knowledge Management field to the corresponding service desk field if that field currently contains no information.

  - Clear a check box if you do not want to map information from the Knowledge Management field to the corresponding service desk field.

  Default: The check boxes corresponding to the
  Summary, Description, Product, Asset, and Request Area fields in service desk are selected.

- **Overwrite Service Desk Values**
  Specifies which fields in a service desk issue or request to overwrite with information from Knowledge Management.

  - Select a check box to replace information in the service desk field with information from the corresponding Knowledge Management field.

  - Clear a check box if you do not want to replace information in the service desk field with information from the corresponding Knowledge Management field.

These check boxes are only available when the corresponding check boxes in the Populate Empty Service Desk Values column are selected.
Default: All Overwrite Service Desk Values check boxes are cleared.

3. Click Save.
   Field mapping is defined.

Define Issue Search Configuration

You can define the fields within an Issue to search in when you click the Search Knowledge button on a ticket. The fields that you select are copied to the corresponding fields in the Search Filter on the Knowledge tab of the Issue Detail window. The population of the Search Filter fields from the ticket occurs when the Knowledge tab is selected or the Reset Filter button (on the Knowledge tab) is clicked.

Follow these steps:

1. From the Administration tab, select Knowledge, CA SDM Integration, Issue Search Configuration.
   The CA SDM Integration page displays.

2. Select the fields that you want to be available for Knowledge Base searches.

   - Summary
   - Description
   - Configuration Item
   - Priority
   - Category
   - Root Cause
   - Product

   Note: You cannot select both the Summary and Description fields.

3. Select the "Automatically run search when the Knowledge tab of an issue is selected" option if you want to search the knowledge base automatically when the Knowledge tab on the detail page is selected.

4. Click Save.
   Issue search is configured.

Define Request/Incident/Problem Search Configuration

You can define the fields within a request, incident, or problem to search in when you click the Search Knowledge button on a ticket. The fields that you select are copied to the corresponding fields in the Search Filter on the Knowledge tab of the ticket detail page. The population of the Search Filter fields from the ticket occurs when the Knowledge tab is selected or the Reset Filter button (on the Knowledge tab) is clicked.

Follow these steps:

1. From the Administration tab, select Knowledge, CA SDM Integration, Request/Incident /Problem Search Configuration.
   The CA SDM Integration page displays.

2. Select the fields that you want to be available for Knowledge Base searches.

   - Summary
   - Description
   - Configuration Item
   - Severity
   - Impact
   - Urgency
   - Priority
   - Request Area
   - Root Cause

   Note: You cannot select both the Summary and Description fields.

3. Select the "Automatically run search when the Knowledge tab of a request is selected" option if you want to search the knowledge base automatically when the Knowledge tab on the detail page is selected.

4. Click Save.
   The fields in a request, incident, or problem to use for Knowledge Base searches search is configured.

Knowledge Suggestions

Employees and customers can, where permitted, view a list of knowledge suggestions when they create a ticket in the self-service interface.

If a solution is found, and the ticket is not saved, the documents that were suggested can be credited through a self-service rating system in the document form. This rating system differs depending on the self-service policy settings that are defined on the Search Settings page.

The data that is retrieved can be used for reports, dashboards and also while searching the knowledge base, where users can filter the documents that have successfully resolved their tickets.

The benefits of self-service are in the form of fewer support calls and redundant tickets that are created, which translates into reduced operational costs.

The administrator must enable this feature before use and must configure the appropriate issue categories and request areas for which knowledge is suggested in the self-service interface.

Define Issue Categories

You can define issue categories for which knowledge is suggested to customers and employees during ticket creation.

You can also mark the Suggest Knowledge feature as active or inactive. When you mark this feature as inactive, it is no longer available to customers and employees, but it remains available in the database for future use. If you decide to use this feature in the future, you can go back and can mark it as active.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Service Desk Integration, Suggest Knowledge, Issue Categories.
   The Suggest Knowledge for Issue Categories page appears.

2. Select the **Do not suggest knowledge** option to mark the Suggest Knowledge feature as active.
   Default: Inactive
   If you mark this feature active, the following options appear:

   - **By default knowledge will be:**

   - **Suggested**
     Indicates that you *do* want knowledge to be suggested for all issue categories except the definitions in the issue categories list.

   - **Not Suggested**
     Indicates that you *do not* want knowledge to be suggested for all issue categories except the definitions in the issue categories list.

   - **For all Issue Categories except the following:**
     Displays the list of request areas where knowledge is either suggested or not suggested to employees and customers in the self-service interface. The self-service user is not allowed to edit the request areas, they are read-only.

3. Click *one* of the following buttons:

   - **Add**
     Adds the selected request area to the list.

- **Remove**
  Removes the selected request area from the list.

- **Remove All**
  Removes all request areas from the list.

- **Save**
  Saves the request area information to the knowledge base.

The Issue categories are defined.

Define Request/Incident/Problem Areas

You can define request, problem, and incident areas for which knowledge is suggested to customers and employees during ticket creation.

You can also mark the Suggest Knowledge feature as active or inactive. When you mark this feature as inactive, it is no longer available to customers and employees, but it remains available in the database for future use. If you decide to use this feature in the future, you can go back and can mark it as active.

Follow these steps:

1. On the Administration tab, browse to Knowledge, CA SDM Integration, Suggest Knowledge, Request/Incident/Problem Areas.
   The Suggest Knowledge for Request/Incident/Problem Areas page appears.

2. Select the **Do not suggest knowledge** option to mark the Suggest Knowledge feature as active.
   Default: Inactive
   If you mark this feature as active, some additional options appear:

   - **By default knowledge will be:**

   - **Suggested**
     Specifies this option if you want knowledge be suggested for all request/incident/problem areas except those that are defined in the Request Area list.

   - **Not Suggested**
     Specifies this option if you *do not* want knowledge be suggested for all request/incident /problem areas except those that are defined in the request area list.

   - **For all Request/Incident/Problem Areas except the following:**
     Displays the list of request areas where knowledge is either suggested or not suggested to employees and customers in the self-service interface. The self-service user is not allowed to edit the request areas, they are read-only.

3. Click Save.
   The suggest knowledge request/incident/problem areas are defined.

Configure Self-Service Policies

You can configure self-service policies that credit documents based on a set of user scenarios.

Follow these steps:

1. On the Administration tab, browse to Knowledge, CA SDM Integration, Suggest Knowledge, Self-Service Configuration.
   The Search Settings page appears.

2. Specify the appropriate policy settings that credits documents and save avoided tickets that are based on the following user scenarios:

   - User did not open any suggested document.
   - User opened a suggested document.
   - User accepted a suggested document as a solution to their problem.
   - User searched for knowledge, opened the document, and exited.

   Click Save.
   Self-service policy settings are saved.

Create Knowledge Documents

This article contains the following topics:

Create the Knowledge Document

You can create knowledge documents to capture and organize information and expand your knowledge base. Knowledge documents provide users in your environment with solutions to complex issues.

Follow these steps:

1. Click the Administration tab and navigate to Knowledge, Knowledge Categories.

2. Select the desired knowledge category.

3. Click File, New Knowledge Document.
   The Create New Document page appears.

4. (Optional) Use the Find Similar tab to search for related documents.

5. (Required) Choose a document template from the drop-down list. The template specifies the content and format of documents that are displayed in the defined user view.
   You can also use templates to populate default values.

6. Depending on the template definition, complete the following fields display:

   Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

   - **Doc ID**
     A numeric unique ID is assigned to a knowledge document. The Doc ID is used by analysts and customers to refer to a particular knowledge document.

   - **Title**
     Defines a short, descriptive name for the document. For knowledge tree documents, Title defines the name of the primary node in the knowledge tree.

   - **Summary**
     Defines a summary that briefly describes the problem that is associated with the document.

   - **Problem**
     Defines the full description of the problem that is associated with the document.
     NLS search type is based on this field.

   - **Parent Document**
     Specifies the parent document of the knowledge document you are viewing. The tenant of the parent document also appears, depending on your permissions.
     Note: Modifying a parent document alerts you that the change can affect child documents.

   - **Related Documents**
     Specifies the related documents of the knowledge document you are viewing. The tenant of the related documents also appears, depending on your permissions.

   - **Resolution**
     Defines the description of how to resolve the problem.

   - **Quick View**
     Specifies to display content in the associated field as it appears at runtime. This field only displays when you are creating or updating a knowledge document.

   - **HTML Source**
     Specifies to display content in the associated field as HTML source code you can edit. Select this option to make simple changes directly to the HTML code. This field only displays when you are creating or updating a knowledge document.

- **Notes**
  Defines additional information about the document. The contents of this field are available only to analysts.

> **Note:** Modifying a parent document alerts you that the change can affect child documents.

7. Click Save and Close.
   The document appears on the Document List page and in the appropriate inboxes (see page 2741).

8. Edit the knowledge document (see page) and add permissions to the users to whom you have assigned the document.

Edit the Knowledge Document

You can edit a knowledge document that has not yet been published. All users with full write permissions can edit documents by default, but the administrator specifies your knowledge document permissions. For example, your administrator configures Knowledge Management so that only an assignee, the document owner, or a knowledge manager can edit documents.

Follow these steps:

1. On the Knowledge tab, select the appropriate category.
   The Knowledge Document List page displays documents in the selected category.

2. Right-click the title of the document, and select Edit from the shortcut menu. If the document has been published, create a rework version to modify the content.
   The Update Knowledge Document page appears.

3. (Optional) The properties (see page 2735) of a knowledge document can be changed on the Attributes tab, but you must have write access to the document to modify the properties.

4. (Optional) Complete or change the fields on the various tabs as appropriate.

   - Click the Attributes tab (see page 2735) to define the document attributes such as the Assignee, Approval Process Template.

     > **Note:** You must have write access to the document to modify the properties.

   - Click the Permissions tab (see page 2739) to define the permissions for the contacts who will be working on the document.

   - Click the Related Knowledge tab to add the related knowledge documents.

   - Click the Attachments tab to add a file or URL to the knowledge document.

- Click the Comments tab to add a comment for follow-up and assign the comment to a contact.
- Click the History tab to view the events that occurred on the knowledge document.
- Click the Versions tab to view the document versions and revisions.
- Click the Find Similar tab search for similar documents that may contain knowledge solutions. Locating similar documents can help you avoid creating duplicate information. You can also create knowledge relationships from the context menu.

5. (Optional) Do *one* of the following, as appropriate:
   - **Knowledge Document**
   - Click Edit Resolution on the Content tab to open the HTML Editor (see page 2740).
   - Modify the body (resolution) of the document.
   - Click OK to save your changes and close the HTML Editor.
   - **Knowledge Tree Document**
   - Click Design Tree on the Content tab to open the Knowledge Tree Designer (see page).
   - Edit the knowledge tree.
   - Click Save and Close.
6. (Optional) Click Spell Check to review the spelling in the content you entered.
7. (Optional) Click User View to open the Preview window, which presents the document as it appears when a user displays it.
   You can close the Preview window when you finish reviewing the document.
8. Click Save when you finish editing the document.
   The product saves your changes.
9. Do *one* of the following actions:
   - Click Save Version to save a new version of the document.
   - Click Publish to put the document in the knowledge base and make it available to users with the appropriate permissions.
   - Click Cancel to close the Update Knowledge Document window and open the Knowledge Document Detail window.

Update Document Attributes

You can use the Attributes tab to set properties of a knowledge document that define ownership, scheduling, approval process, layout, associations, and so on.

Note: You must have write access to a document to set its attributes.

Note: If the Priority Calculation is set up and a user opens a ticket on the Knowledge Document, the Priority, Urgency, and Impact fields on the Attributes tab automatically appear on the ticket.

The tab contains the following fields:

- **Initiator**
  (Read-only) Displays the name of the contact who created the document. You can click the name to open the Detail window for the contact.

- **Assignee**
  Defines the name (in "last name, first name" format) of the contact to whom the document is assigned during the current approval process task. You can enter or search the name of the contact in "last name, first name" format.

- **Author**
  Defines the name (in "last name, first name" format) of the contact with responsibility for the document content.

- **Owner**

  Defines the name (in "last name, first name" format) of the contact assigned to maintain the document. A document can have the same or a different owner in each stage of the approval process. All analysts with write access to a document can modify it, even if they do not own it.

  Note: If a guest user or customer submits a document using the Submit Knowledge feature, the document has no owner.

- **Subject Expert**
  Defines the name (in "last name, first name" format) of a contact with expertise in the subject matter of the document. Enter or search the name of the contact in "last name, first name" format.

- **Creation Date**
  (Read-only) Displays the date and time at which the document was created.

- **Modify Date**
  (Read-only) Displays the date and time at which changes to the document were last saved.

- **Published Date**
  (Read-only) Displays the date and time at which the document was published. If the document has not been published, the field is blank.

- **Last Accepted Date**
  (Read-only) Displays the date and time at which the document was last accepted as the solution to a ticket. If the document has not been accepted, the field is blank.

- **Start Date**

  Defines the date (in mm/dd/yyyy format) on which to make the document available in Search Tools. You can click the calendar icon to open the Date Helper window so you can select a date.

  > **Note:** A document can only become available on the Search Tools window when it is published and reaches its start date. For example, if you publish a document on March 1 with a start date of March 8, the document does not become available on the Search Tools window until March 8. If you publish a document with no start date specified, it immediately becomes available on the Search Tools window. The date format in Knowledge Management must match the date format that you have set up on your Windows operating system.

- **Expiration Date**

  Defines the date (in mm/dd/yyyy format) on which the product removes the document from the knowledge base and the Search Tools window. After the specified date, the document is available from the Administration tab to users with the appropriate permissions. You can click the calendar icon to open the Date Helper window so you can select a date.

  > **Note:** The date format in Knowledge Management must match the date format that you have set up on your Windows operating system.

- **Review Date**

  Defines the date on which the document must be next reviewed. Click the calendar icon to open the Date Helper window so you can select a date.

  > **Note:** The date format in Knowledge Management should match the date format that you have set up on your Windows operating system.

- **Disregard Life-Cycle Policies**
  Ignores the lifecycle policies in your organization.

- **Approval Process Template**
  (Required) Specifies an approval process template to associate with the document. The approval process template specifies the tasks in the document lifecycle. You can choose the default template provided with the product or a user-defined template. If left empty, it is set to the default template used in your knowledge environment.
  Note: For knowledge managers, knowledge engineers, and system administrators: The access

types that can select an approval process template during the first task (typically Create Knowledge Document) are selected on the Knowledge tab Access Type window. In subsequent stages of the approval process, the Approval Process Template box is read-only and displays the name of the template selected for the document.

- **Approval Process Priority**
  Specifies the approval process priority to associate with the document. Valid values include <empty>, Low, Normal, High, and Emergency.
  Default: Normal.

- **User Defined ID**
  Defines an ID for the document to use as an alternative to the product-defined ID.

- **FAQ Rating**
  (Read-only) Displays the current document FAQ rating, which the product calculates from the frequency at which a document is accessed, how helpful it has been to users, and its age.

- **Hits**
  (Read-only) Displays the number of times the document has been accessed.

- **Self-Service Count**
  (Read-only) Specifies the number of times that the knowledge document was used to solve a problem. It is a count of the number of times the customer responded with Yes to the question “Did this document solve your problem? “ in the document Solution Survey.

- **Average Rating**
  (Read-only) Specifies an average rating value. Each rating response (very helpful, somewhat helpful, and not helpful at all) has an assigned numeric value. The average rating is the total of the document response ratings divided by the total number of votes.

- **User Votes**
  (Read-only) Specifies the total number of votes for the document. Submitting a Solution Survey is considered a vote.

- **Priority**
  Specifies the priority to associate with the document, indicating the urgency of problems the document is meant to resolve.

- **Severity**
  Specifies the level of effect that the problem the document is meant to resolve may have on users.

- **Impact**
  Specifies the level of impact that you expect the document to have on work being performed.

- **Urgency**
  Specifies the importance level of the user tasks that are associated with the document.

- **Product**
  Defines a product to associate with the document. Enter the name of the product or click the magnifier to open the Product Search dialog so you can locate and select a product.

- **Configuration Item**
  Defines the name of a configuration item (hardware, software, or service) to associate with the document. Enter the name of the configuration item or click the magnifier to open the Configuration Item Search dialog so you can locate and select an asset.

- **Root Cause**
  Defines a root cause or core reason to associate with the document. Enter a root cause or click to open the Root Cause Selection window so you can locate and select a root cause.

- **Solution Count**
  (Read-only) Displays the number of tickets that are resolved by the document.

- **Parent Request**
  Defines an associated parent request record.

- **Parent Issue**
  Defines an associated parent issue record.

- **Problem**
  Defines a problem that is linked to this document.

Grant Permissions to Document Assignees

You can determine which groups or roles can access a knowledge document and which groups or roles can modify the knowledge document by modifying permissions for Knowledge Documents and Knowledge Categories.

Important! When creating a knowledge document, make sure that document permissions include users that can be assigned later on the document through the approval process. When a group is assigned to a document, users from that group cannot have the permission to view the document. If the document is assigned to a specific user, default data partition constraints allow the user to view the document. If you do not specify group permissions, the document is only viewable by privileged users.

You can view and grant permissions as follows:

- **From the Knowledge Category page**

  1. Right-click a category and select Edit Category from the shortcut menu.
  2. Click the Permissions tab.

- **From a Knowledge Document**
  If it is a published Knowledge Document:

  1. Click Rework.
  2. Create a Rework version, click Save.

3. Select the Permissions tab and make the appropriate changes.

Note: By default, a Knowledge Document inherits its permissions from Category Permissions. You can use empty write permissions for documents and categories. Empty write permissions are set when you do not select write permissions. Only privileged users can modify categories and documents with empty write permissions.

Use the HTML Editor

Use the HTML Editor for the following tasks:

- To define the layout and static content of a knowledge document template.
- To define the layout and content of the Resolution section of a knowledge document.
- To define the layout and content of a node in a knowledge tree document.

The HTML Editor opens when you do any of the following actions:

- Click Edit Detail on either of the following windows:
  - Create New Document Template
  - Update Document Template
- Click Edit Resolution on either of the following pages:
  - Create New Document
  - Update Knowledge Document
- Click Edit (HTML) in any of the following DT Builder panes:
  - Conclusion Text (HTML)
  - Query Text (HTML)
  - Tree Description (HTML)

Click the Insert menu to perform the following tasks:

- Insert a Horizontal Rule
- Insert a Link to a Document
- Insert a New Line
- Insert an Image
- Insert a Link to a New Ticket

- Insert a Link to Create a Change Order
- Insert Action Content

Working with Knowledge Documents

This article contains the following topics:

View Unassigned Documents

Documents that are not yet assigned to users are stored in the Unassigned queue on the scoreboard.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Follow these steps:

1. On the Service Desk tab, browse to Knowledge Documents, Unassigned.
   The Document List page displayed the documents that are unassigned.

2. (Optional) Right-click the title to edit the document.

View Inbox or Group Inbox

When a document is created or updated, it is placed in the Inbox of the owner. Items that appear in an Inbox require the attention of the user as part of the publishing process. Until they are published, items in the Inbox will not appear as resolutions and are not added to the knowledge base. You must regularly monitor your Inbox to check for new documents.

You can view summary information for the documents that are contained in your Inbox or Group Inbox on the Document List page.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Follow these steps:

1. On the Service Desk tab, browse to Knowledge Documents, Inbox, or Group Inbox.
   The Document List page displays the documents in the inbox.

2. (Optional) Right-click the title to edit a document.

3. All users with full permission to the document can edit the document. The current owner has full permissions to the document but may not have explicit write permissions. Only the owner can change the owner of the document (on the Attributes tab).

View Follow-Up Comments

You can view summary information for your follow-up comments on the Comment List page.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Follow these steps:

1. On the Service Desk tab, browse to Knowledge Documents, Follow-Up Comments.

2. Do *one* of the following actions:

   - Expand the My Follow-Up Comments folder to reveal nested folders for your assigned Open and Closed items.

   - Expand the All Follow-Up Comments folder to reveal the nested folders.

3. Select the folder for the comments you want to see.
   The Comment List page appears. This page contains the following columns:

   - **Comment Type**
     Identifies the type of comment that is used to flag a document for correction, promotion, or retirement.

   - **Date Logged**
     Identifies the date on which the comment was logged in the system.

   - **Status**
     Indicates whether the comment is active or inactive.

- **Target Date**
  Identifies the date by which the comment must be followed-up on.

- **Contacts**
  The contact who received the follow-up comment.

4. (Optional) Click Show Filter and complete one or more of the fields to specify search criteria that restrict the list to the comments of interest.

5. Click Search.

The Comment List page displays summaries of the comments that match your search criteria.

1. (Optional) Click the Edit in List button to display some additional fields that can be associated with a comment.

   - **Assignee**
     The name of the person that is assigned to handle the comment. Enter the name of the person directly, or click the search icon to search for the name.

   - **Target Date**
     Identifies the date by which the comment must be followed-up on. Enter the target date directly, or click the calendar icon to specify a target date.

   - **Status**
     Indicates whether the comment is active or inactive.

   - **Reply**
     Allows you to enter more information.

2. (Optional) Click the More link to display the Additional Search Arguments field.

Publish Knowledge Documents

When you are ready to add a document to the knowledge base, you can publish it from the Update Knowledge Document page. Analysts can publish documents when they are at the last stage of the approval process. Administrators can publish documents at any stage of the approval process.

Follow these steps:

1. Open the document for editing.
   The Update Document page appears.

2. Click Publish.
   The Publish Document page appears.

3. Complete the following fields as appropriate:

   - **Owner**

(Required) Defines the name of the contact that is assigned to maintain the document. Enter the name of the contact in "last name, first name" format or click the magnifier to open the Contact Search dialog so you can search for a contact.

- **Comment**

(Optional) Enter a brief comment about the document.

4. Click OK.
   The published document is added to the knowledge base.

Create Rework Versions

If you have full (read/write) permissions to edit documents, you can create a *Rework-Draft* version of a published knowledge document while the document is online and available to users.

A rework version starts as a copy of the document that is replaced in the knowledge base after it is verified and republished.

Follow these steps:

1. From the Document List page, right-click the title of the document to edit, then select Edit from the shortcut menu.
   The Update Knowledge Document page appears.

2. (Optional) Complete the various tabs as appropriate.

3. Click Rework.
   A page opens displaying the list of approved document tasks from which you can select tasks to start with (if you are permitted to do so). By default, a built-in approval process template allows you to create a document.

4. Select the appropriate task from the list.
   The Create Rework Version page appears.

5. Complete the appropriate fields:

   - **Document Title**
     Displays the published document name.

   - **Document Status**
     Displays the status of the record (published).

   - **Keep Published Version Available**
     Specify whether or not to keep the original published version available to all users.
     Default: Available

   - **KD Approval Task**
     Displays the workflow tasks that you are able to perform if you have permission to do so.

   Note: You can cancel the rework version and can add comments about why you want to cancel the rework version.

6. (Optional) Select the Assignee link to assign this rework version to another person or group for review or follow-up. Once saved, the rework version appears in their Inbox.

> **Note:** If *Keep Published Version Available* is checked in the *Create Rework Version* form, it does not copy the assignee value to the rework document. If *Keep Published Version Available* is unchecked, it copies the assignee value to the rework document.

7. (Optional) Enter information about this document in the Comment field.

8. Click Save.
   The Update Document page appears.

9. Click Save.
   The *rework-draft* version appears in your Knowledge Documents Inbox on scoreboard. To display this page, select the Service Desk tab, then Knowledge Documents, Inbox.

Save Versions

You can create a draft version of a document for backup. The Save Version option is available for draft documents and rework versions that have not yet been published.

Follow these steps:

1. On the Document List page, open a draft document to edit, and select Edit from the shortcut menu.
   The Update Document page appears.

2. Complete or change the fields on the various tabs as appropriate.

3. Click Save Version.
   The Create New Version page appears.

4. (Required) Add a comment in the Comment field.

5. Click Save.
   The draft version displays on the Versions tab.

Rollback to a Previous Version

If there is a problem with the current version, you can roll back to a previous version of a published document.

Before you begin, consider the following factors:

- When performing a rollback of a published document, the earlier version appears in the document list as a new *rework-draft* document, which must be re-published in order to replace the currently published document.

- When performing a rollback of a draft document, the content of the current document is replaced with the content of the earlier version. The document remains in draft status until it is published.

Follow these steps:

1. From the Documents List page, right-click the published document to edit, then select Edit from the short-cut menu.
   The Update Knowledge Document page appears.

2. Click the Versions tab.
   The Versions List appears.

3. In the Version Number column, click the version number link.
   The Save Version page appears.

4. Click Rollback.
   The document rolls back to the previous version. If the document is published, a rework version of the document is started.

Retire a Knowledge Document

A knowledge document can be retired after it reaches an expiration date, or if the product removes it from the knowledge base. A privileged user can retire or rework a knowledge document manually.

Follow these steps:

1. Open the document for editing.

2. Click Retire.
   The Retire Knowledge Document page appears.

3. Enter a comment about why you want to retire the document.
   For example, the knowledge document described a workaround task that no longer applies to your organization.

4. Click Save.
   The document is retired.

Unretire Knowledge Documents

When a published document reaches its expiration date, the product typically retires it. A retired document is removed from the knowledge base and the approval process). A system administrator or a user with full permissions can unretire or republish the document to return it to the approval process and the knowledge base.

Follow these steps:

1. Open the document for editing.

2. Click Unretire.
   The Unretire Document page appears.

3. Do *one* of the following, as appropriate:

- If you are a system administrator, you can republish the document. To do so, click Publish this Document. A confirmation message appears.
- If you are a system administrator and there are multiple approval process tasks to which the document might revert, you can choose the task to which to assign the document, choose an assignee, and (optionally) enter a comment:
  - Click the name of a previous task to which to assign the unretired document. The Unretire Document page refreshes.
  - Select the name of a contact to assign as the owner for the document from the Assignee list.
  - (Optional) Enter a brief comment in the Comment box.
  - Click OK. A confirmation message displays.
- If you are a knowledge administrator or analyst, you can choose an assignee for the task and (optionally) enter a comment:
  - Select the name of a contact to assign as the owner for the document from the Assignee list.
  - (Optional) Enter a brief comment in the Comment box.
  - Click OK. A confirmation message displays.

4. Click OK.
   The product assigns the document to the specified task and owner and returns the document to the knowledge base and the workflow.

Document Search Fields

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

- **Keywords for Advanced Search**
  Specifies the keywords (separated with comma or space) to use for the search in the Search field. The search result displays the keyword with the document frequency. This means the search result displays all the occurrences of the document names with that keyword. For example, in the following screenshot, we searched for a knowledge document associated with a CI and used the keyword as "updated". The search result shows updated(29), but does not display any document associated with this CI. This search result is correct. It means that 29 documents in the knowledge base contains the word "updated", but none are associated with the CI.

- **Search In**
  Specifies in which fields to search for specified keywords. When you click Search, the product returns only items that contain the specified keywords in the fields that are specified by the selected *Search In* check boxes.
  The check boxes only display when Keyword Search is the selected search type. If you select Natural Language Search from the Search Type list, the Search In check boxes do not display and the product only searches the Problem fields of documents.

- **Reset to my defaults**
  Resets all filters to their default values. This option is only available for knowledge documents.

- **Set as my defaults**
  Saves all filters and applies them as the default values. This option is only available for knowledge documents.

- **Search Type**
  Specifies the type of search to perform. Select one of the following options:

  - **Keyword Search** -- Searches for the specified keywords in the Title, Summary, Problem, and Resolution fields of documents. Use the Search In check boxes to exclude one or more of these fields.

  - **Natural Language Search** -- Searches for the specified text only in the Problem fields. Natural Language Search (NLS) lets you perform a search using natural language, which compares the pattern of words that are contained in the query with the patterns of words that are contained in the Problem field of knowledge base documents.
    Default: Keyword Search

  Note: Depending on how your administrator configured search capabilities, you may not have access to Keyword Search and Natural Language Search.

- **Match Type**
  Specifies the method for text matching during the search. Select one of the following options:

  - **Any of the Words (OR)** -- Retrieves the matches for *any* of the specified words in a document.

  - **All of the Words (AND)** -- Retrieves the matches only when the product finds *all* the specified words in a document.

  - **Exact Match** -- Retrieves the matches for *exactly* the specified words in a document.
    Default: Any of the Words (OR)

Important! Match Type and Match preferences only set the default search criteria when you search in Knowledge Management. For example, you log in as an analyst and click the Knowledge tab of any ticket. Knowledge searches from within a ticket always default to Match Type=Any of the words (OR) and Match=Whole Words, regardless of your preference settings.

- **Match**
  Specifies the method by which the product searches documents. Select one of the following options:
  - **Whole words** -- Retrieves only documents that contain the entire words entered.
  - **Words beginning with...** -- Retrieves the documents that contain the entire words entered or words that begin with the words entered. For example, a search for the word "print" also returns documents containing the words "printer" or "printing."
    The Match list setting overrides the default set on the Preferences window and is only available when you specify keywords or phrases for which to search.
    Default: Whole words
- **Order by**
  Specifies a criterion by which to sort search results. Select one of the following options:
  - **Relevance** -- Sorts documents by their relevance to the specified search criteria (expressed as EXCELLENT, GOOD, and so on). Documents with the highest relevance (EXCELLENT) are listed first.
  - **FAQ Rating** -- Sorts documents that are based on their FAQ rating, which considers how often the document is accessed, how helpful it has been to users, and its age. Documents with the highest FAQ ratings are listed first.
  - **Hits** -- Sorts documents by the number of times users have accessed them, with the most frequently accessed documents listed first. Hits may not be available for all record types. This field only displays for advanced searches on the Knowledge tab.
  - **Solution Count** -- Sorts documents by the number of issues or requests they have resolved, as reported by users. Documents with the highest solution counts are listed first. This field only displays for advanced searches on the Knowledge tab.
  - **Modify Date** -- Sorts the documents by the date on which they were last modified, with the most recently modified documents listed first.
- **Return only documents that solved tickets**
  Returns the documents that have successfully resolved tickets.
- **User Defined ID/Created By/Submitter**
  Define a user-defined ID or enter a name by which to filter documents retrieved. This field only displays for advanced searches of knowledge documents and free text content.
- **Product**
  Defines a product by which to filter documents retrieved. Enter the name of the product in the box, or click  to open the Product Search window so you can search for and can select one. When you click Search, the product returns only documents that are associated with the specified product.

- **Configuration Item**
  Defines the name of an asset (hardware, software, or service) by which to filter documents retrieved. Enter the name of the asset in the box, or click to open the Configuration Item Search window so you can search for and can select one. When you click Search, the product returns only documents that are associated with the specified asset.

- **Category**
  Define a category by which to filter documents retrieved. Enter the name of the category in the box or click to open the Category Search window. When you click Search, the product returns only documents that are associated with the specified category. Use the Remove and Clear Categories options as needed.

(Optional) Click the More link to display the following additional fields:

- **Owner**
  Defines the name (in "last name, first name" format) of the contact that is assigned to maintain the document. Enter the name of the contact in "last name, first name" format or click to open the Contact Search dialog so you can locate and select a contact.

- **Author**
  Defines the name (in "last name, first name" format) of the contact with responsibility for the document content. Enter the name of the contact in "last name, first name" format or click to open the Contact Search dialog so you can locate and select a contact.

- **Subject Matter Expert**
  Defines the name (in "last name, first name" format) of a contact with subject-matter expertise for the document. Enter the name of the contact in "last name, first name" format or click to open the Contact Search dialog so you can locate and select a contact.

- **Document Type**
  Specifies the type of document (knowledge document or knowledge tree document) to retrieve.

- **Approval Process Priority**
  Specifies the level (emergency, high, low, normal) by which to filter approvals retrieved.

- **Root Cause**
  Defines a root cause (that is, the core reason for opening the ticket) by which to filter documents retrieved. Possible root causes include Hardware Failure, Software Failure, and Network Cable. Enter the root cause in the box, or click the icon to open the Root Cause Selection window so you can search for and can select one. When you click Search, the product returns only documents that are associated with the specified root cause.

- **Priority/Severity/Impact/Urgency**
  Specifies the level (1, 2, 3, 4, 5, or None) by which to filter documents retrieved. When you leave <empty> as the field value, the product does not consider a level when filtering documents. When you click Search, the product returns only documents with the specified level.

> You can click the More icon to display the Additional Search Arguments field. This field is intended only for expert users who understand SQL and Majic. You can enter a SQL WHERE clause in this field to specify an additional search argument.

Manage Document Versions

Using the document versioning capabilities of Knowledge Management, an analyst with editing privileges can create a *Rework-Draft* version of a document. A rework version starts as a copy of the document that is replaced in the knowledge base after it is verified and republished. The need to unpublish the document first is avoided.

Users with editing privileges can also perform the following versioning tasks:

- Save a draft version of a document.
- Roll back to a previous version if a problem with the current version occurs (Draft or Published). The Versions tab on the Update Document page is where users can select different versions for rollback to replace the current version.
- Track the number of document versions that are saved, deleted, and archived in the knowledge base.

The Knowledge Documents Inbox on the CA SDM Scoreboard is the repository for documents in all statuses including saved and assigned draft and rework-draft documents.

Administrators can set up and can manage document versions by performing the following steps:

1. Identify who can edit published documents and can create the Rework-Draft versions. The role being used for a particular contact record controls editing privileges.
2. Define an approval process template that groups tasks or steps to complete during the document lifecycle. By default, a built-in approval process template allows users to create documents.
3. Determine whether to use the document approval process. Analysts who are permitted to bypass the approval process can identify which tasks they want to start with when they create a Rework-Draft version.
4. Create archive and purge rules for document version maintenance.

Create Knowledge Document Links

You can maintain your Knowledge Management environment by creating document links. Knowledge relationships let you create document hierarchies and manage changes to your knowledge documents.

Follow these steps:

1. Define knowledge document templates to display or hide the parent-child relationships in view mode.

2. Create or modify a knowledge document. You can only add links to an unpublished knowledge document by default. If the document is already published, open the document in edit or rework mode to create document links. You can modify the permissions for documents before the approval process and after publishing.

3. Create *any* of the following document links from the Related Knowledge tab, as appropriate to your Knowledge Management environment:

   - Link the document as a non-hierarchal See Also to link knowledge documents to other existing documents. Right-click the document in the Documents pane and select the option *Link this Document as See Also*.

   - Link the document as a parent or child. Right-click the document in the Documents pane and select the *Link this as Parent* or *Link this as Child* option to create the link between the documents. If you modify a parent document, an alert appears saying that child documents can be affected.

   - Link the global document to a tenanted document.
     You can link knowledge documents to a single tenant, or to multiple tenants. For example, a child document can have a different tenant than the parent document.

   The History tab updates when you create document links to help track changes.

4. Save the document and verify that the links appear when opening the document in User View. You can verify that the document links appear according to the permissions you established.

Create Action Content

Content

You can create "action content" (a live URL), which can be inserted into the Resolution field of a knowledge document. When the end user click the action content, it creates an incident, or performs some other action. Using action content, a substantial degree of definition and classification can be achieved without the user even realizing it.

The steps to insert a live "action content" link into a document are simple and no coding is required. The Knowledge Management HTML editor handles the generation of the HTML code.

Action content is primarily used for interaction with external applications.

Create Action Content (Action URL)

You can create Action Content for a knowledge documents. These action URLs can launch a live website that is accessible to all users of your system. You can also link action URLs to automated tasks on your server (any server where the KT daemon is running), and you can embed these scripts into knowledge documents, tree documents, document templates, and knowledge forums.

Follow these steps:

1. On the **Administration** tab, browse to **Knowledge**, **Action Content**.
   The Action Content list page appears.

2. Click **Create New**.
   The Create New Action Content page displays.

3. Complete the fields. The following fields require explanation:

   - **Code**
     Specifies a unique identifier for this action content item.

   - **Use Internal HTMPL**
     Creates an internal link (see page 2753)in the application that dynamically passes information, such as the user name and session ID, from knowledge documents into third-party applications. Do not select this option.

   - **Action URL**
     Specifies a URL that links to a web page, template, or automated script, for example: http://www.ca.com.

4. Click **Save**.
   The action content is created.

Create Action Content (Internal HTMPL)

These action URLs can launch self-service scripts and also third-party applications. This link is generated dynamically and automatically transfers attributes about the user, such as the user name, to the target application (http://www.ca.com?USERNAME=BBB, for example). User attributes are specified in an HTMPL file.

Follow these steps:

1. Create an internal HTMPL file that passes data to the target application.

   Note: The act_content_sample.htmpl file is available in the following location: NX_ROOT\bopcfg\www\htmpl\default.

2. Save the HTMPL file in the following location: NX_ROOT\site\mods\www\htmpl\default directory.

3. From the **Administration** tab, navigate to **Knowledge**, **Action Content**.
   The Action Content list page appears.

4. Click **Create New**.
   The Create New Action Content page appears.

5. Specify a unique identifier for this action content item in the **Code** field.

6. Select the **Use Internal HTMPL** check box.

7. Specify the appropriate HTMPL file in the Action URL field, for example: act_content_sample.htmpl

   Note: You can use Support Automation scripts by using the format *SA_SCRIPT=[Self-Service Script ID]* in the URL.

8. Click **Save**.
   The action content is created. When the user clicks this Action Content link within a knowledge document, attributes about the user, such as the user name, are dynamically passed on to the target application.

Create Knowledge Tree Documents

The Knowledge Tree Designer is a visual tool that is used to create knowledge trees quickly and easily. A knowledge tree is a representation of expert knowledge in a particular area. The Knowledge Tree Designer lets analysts and knowledge engineers build detailed trees that guide the user through a series of questions and potential answers until they reach a resolution. This tool eliminates the need for specialized scripting or programming skills and only involves an analyst working with a subject expert to create a tree design.

Knowledge trees can be complex in design. Therefore, it is recommended that you construct a diagram to map the design before creating a knowledge tree. The diagram must contain a series of question, possible responses, and associated resolutions. The hierarchy of questions and responses in the diagram you construct is the foundation on which the knowledge tree is built.

After you have mapped out a diagram of your knowledge tree, you build the tree using the Knowledge Tree Designer.

You can create a Knowledge Tree Document from the Knowledge tab.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select the desired knowledge category.

2. Click File, New Knowledge Tree Document.

Note: You cannot create a document directly under the TOP category. If necessary, add a new category in which to create the document.

3. Complete the required fields.
4. Choose a Document Template from the drop-down.
5. Click Save.
6. Click Design Tree on the Content tab to edit the knowledge tree in the Tree Designer (see page 2754).

Use the Tree Designer

The Knowledge Tree Designer tool employs rule-based modeling functionality that helps you develop and deploy business policies and intelligence by mapping any reasoning process into a knowledge tree structure. The knowledge tree is perfectly suited to guiding users through a logical process such as changing a toner cartridge in a printer or changing a hard drive in a server.

You can view the Tree Designer when you open a Knowledge Tree Document for editing.

Follow these steps:

1. Create or Edit a Knowledge Tree Document.
   The document opens.

   Note: If the document has been published, you may need to unpublish it before you can view it.

2. Click Design Tree on the Content tab.
   The Tree Designer opens.

   Note: You cannot perform any add or edit actions on the primary node. For example, you cannot add a query or conclusion to a primary node.

3. Click Node Actions, and select one of the following nodes:

   - Add Query (see page 2762)
     Allows you to write a question.
   - Add Conclusion (see page 2760)
     Allows you to write an answer.

- Link Jump Node (see page 2761)
  Links the currently selected jump node to the next node you select. You cannot link a jump node to the primary node or to another jump node.

- **Add Jump**
  Allows you to link to another document.

- **Delete**
  Deletes the currently selected node and its subnodes from the knowledge tree without putting them on the clipboard.

  Note: When you delete a query node, the query and its responses are removed from the knowledge tree. You cannot delete the primary node.

You can use the Quick View or HTML Source to modify the appearance of the nodes.

4. Click the Edit menu to perform copy and paste operations.

   Note: Use the Copy option to copy of the currently selected node (and its subnodes). Use the Copy Single Node option to copy the currently selected node (but not its subnodes or responses).

5. Click the Options menu to personalize your interaction with the Tree Designer. This menu contains the following commands:

   - **Copy Response**
     Specifies whether to use response text as the name of an associated node when you create it.

     - Select this command to automatically use the text of a node as its name when you create it. When the command is active, a check mark displays to the left of the command name on the menu.

     - Clear this command to use the default name (Default Node Name) when you create a node. You can use the Rename command on the Node Actions menu to change the name of the node.

     This command is also available on the shortcut menu that opens when you right-click a node in the Tree pane.

   - **Prompt on Node Delete**
     Specifies whether the Tree Designer prompts you before deleting nodes.

     - Select this command to display a confirmation prompt before deleting nodes. When the command is active, a check mark displays to the left of the command name on the menu.

- Clear this command if you do not want the Tree Designer to prompt you to confirm node deletion.

This command is also available on the shortcut menu that opens when you right-click a node in the Tree pane.

6. Click the Quick View option to view a preview of the node design.

7. Click Save.
   The Knowledge Tree Document is saved as a draft.

Access Knowledge Documents from the Self-Service Interface

This article contains the following topics:

Knowledge Submission from Self-Service

By default, any user that is logged in to Knowledge Management can submit knowledge for consideration . This page lets a customer submit knowledge without contacting their local service desk representative. After you submit knowledge, it passes through a publishing process. During this process, the knowledge is reviewed and edited before it is added to the knowledge base.

Specify information into every field that appears in the Submit Knowledge page. Pay special attention when completing the Summary field. Typically, this field contains a succinct overview of the document that you are submitting.

Knowledge Search

Knowledge Management provides users with the following options for retrieving knowledge:

- **Category browsing**
  Finds the solutions that are based on categories. In each category, additional subcategories can narrow the search results to a set of solutions that are likely to be most relevant to an issue.

Note: When you search for knowledge documents using the category, the search result displays the keyword count and the list of documents. The count within the parentheses is the total number of documents in the knowledge base that contains at least one occurrence of the keyword. For example, when searching for the string, "live assistance", if 3 documents each contain that keyword at least once, then "live assistance(3)" is displayed.

The count is not filtered according to the specified search criteria. So, it may not match the number of documents that are listed. Additionally, the count only includes documents that have been processed by pdm_k_reindex. So, documents which contain the specified string but which have been published after the most recent pmd_k_reindex are not included in the count.

To turn off the parenthesized count, add the following code to the $NX_ROOT/NX.env file:

```
@EBR_SHOW_WORDS_DF=No
```

- **Knowledge tree**
  Asks a series of questions to guide the user to possible solutions. The responses lead the individual to a solution that appears to be most relevant.

- **Bookmark**
  Provides access to frequently viewed documents that are included in a bookmark list.

Advanced Search

In Advanced Search Settings, customers and employees can use the following options to refine a search for the solution to a problem:

- **Knowledge Management Search**
  Searches for certain keywords, which serve as preliminary matches.

- **Natural Language Search**
  Searches for words and accounts for word proximity, word order, and relevance.

The search results are listed by relevance. The relevance is determined by the specified search criteria (expressed as EXCELLENT, GOOD, and so on). Documents with the highest relevance (EXCELLENT) are listed first.

Each result can include a title that appears as a link, a summary of the document, and additional statistics relevant to the document, such as Relevance Rating, Document ID, Modify Date, FAQ Rating, and Hits Received.

Depending on how the system administrator configures Knowledge Management, users can open an incident, rate a document, and can provide comments when a knowledge document is open.

Document Browsing and Bookmarking

You can categorize knowledge documents to let customers browse for information that is based on frequently asked questions (FAQs). By selecting a knowledge category, the related subcategories and knowledge documents appear. You can select the document that you would like to view or select a subcategory to narrow your search further.

To enhance self-service capabilities, a dynamic list of the most frequently used documents appear.

Note: Users can specify criteria about an item of interest and the search engine finds the matching knowledge documents and displays them on the search results page as a set of "recommended document" links. The search query can be expressed as a keyword or set of words (phrase) that identify the desired concept that one or more documents possibly contain. For more information, see Create New Recommended Documents (see page).

You can bookmark the document for easy access. The My Bookmarks folder stores links to the most frequently referenced documents. When you click My Bookmarks in the Category pane on the Knowledge tab, the list of bookmarked documents displays in the Knowledge Document List pane.

Incidents and Problems

Customers sometimes encounter problems that cannot be solved simply by searching for knowledge. Not all problems have a direct solution in the knowledge base. When a customer has a problem that cannot be solved, they can create an incident that is sent to an analyst for further processing. The incident describes the problem, and it can also be based on an existing knowledge document. The more information that is added to an incident, the easier it is for the analyst to solve.

Many ITIL-defined activities are supported in Knowledge Management, including the following activities:

- Incident Management
  - Knowledge searches can help find known errors during further incident investigation and diagnosis
  - Incident categorization
- Problem Management
  - Accessing information about known errors, and helping with problem matching to obtain the resolution when the problem has occurred before
  - Maintaining and providing access to information about workarounds
  - Recording information about procedures, work instructions, diagnostic scripts, and known errors (while supporting rich content, editing tools, measurement, and a definable approval process for the development of resolutions)
  - Problem analysis (through the linkage and analysis of incidents)

How to Use the Tree Designer

Contents

- Add the Tree Description (see page 2763)
- Add the Displayed Text for a Node (see page 2763)
- Add the Response Text for a Node (see page 2764)
- Check a Knowledge Tree for Errors (see page 2764)
- Set Tree Designer Options (see page 2764)

The following topics provide procedures for using the Tree Designer to create and edit knowledge trees.

Tree Pane

The Tree pane displays the nodes that comprise the knowledge tree. Each node represents a step in the process that is presented by the knowledge tree. A well-constructed knowledge tree guides the user along a systematic path to answering a question, resolving a problem, or completing a process. Click ⊞ or ⊟ as appropriate to open or close nodes in the Tree pane. When you click a node in the Tree pane, the associated information displays in the right pane.

The following information displays in the right pane of the Tree Designer window when you select a node in the Tree pane:

Icon	Node Type	Right Pane Display
 BSVC_r12.1--Tree pane (3)	Primary	Tree Description (HTML) pane
 BSVC_r12.1--Tree pane (4)	Query	Query Text (HTML) pane
 BSVC_r12.1--Tree pane (5)	Conclusion	Conclusion Text (HTML) pane
 BSVC_r12.1--Tree pane (6)	Jump	N/A

You can right-click a node in the Tree pane to open a shortcut menu that contains a subset of the menu commands.

Note: The right pane is empty when you select a Jump node.

Add a Conclusion Node

Use a conclusion node to describe the resolution for a particular problem, the final step in a procedure, or a possible termination point in a query. The Conclusion nodes do not have subnodes. You would not typically nest a conclusion node immediately beneath the root node of a knowledge tree. You can add up to seven subnodes to a query node.

Follow these steps:

1. Select the query node under which to add the conclusion node in the Tree pane.
   The Query Text (HTML) pane opens.

2. Click Add Conclusion.
   The Tree Designer adds a conclusion node below the selected node in the Tree pane and adds a response field in the Query Text (HTML) pane.

3. Enter a response to the question or statement that is posed in the parent node in the new field in the Query Text (HTML) pane.

4. (Optional) To rename the new node, right-click it in the Tree pane, then select Rename from the shortcut menu. The Prompt window opens. Enter a new name for the node and click OK to close the Prompt window. The Tree pane refreshes to show the new node name.

5. Select the new conclusion node in the Tree pane.
   The Conclusion Text (HTML) pane opens.

6. Do one of the following actions in the Conclusion Text (HTML) pane:

   - Enter the displayed text (that is, the information that is associated with the node) in the Conclusion Text (HTML) box. You can use plain text or can enter HTML codes as appropriate. To preview the text as it appears at run time, select the Quick View option.

   - Click Edit Conclusion Text (HTML) to open the HTML Editor so you can design the information that is associated with the node in WYSIWYG (what you see is what you get) format. When you finish editing the information, click OK to save your work and close the HTML Editor.

7. Click Save.
   The Tree Designer saves your changes.

Add a Jump Node

Use a jump node to link to previously defined nodes in the knowledge tree. For example, if the answer to the query posed in a parent node requires repetition of previous steps in a procedure. Jump nodes do not have subnodes. You would not typically nest a jump node immediately beneath the root node of a knowledge tree.

Follow these steps:

1. Select the query node under which to add the jump node in the Tree pane.
   The Query Text (HTML) pane opens.

2. Click Add Jump.
   The Tree Designer adds a jump node below the selected node in the Tree pane and adds a response field in the Query Text (HTML) pane.

3. Enter a response to the question or statement that is posed in the parent node in the new field in the Query Text (HTML) pane.

4. Right-click the new jump node in the Tree pane, then select Link Jump Node from the shortcut menu.

5. Select the query or conclusion node to which to link the jump node in the Tree pane.
   The jump node's name in the Tree pane changes to include the name of the linked query or conclusion node. For example, if you linked a node that is called "Wednesday", the jump node name changes to "NODE: Wednesday." When a user selects the jump node in the knowledge tree at runtime, the linked query or conclusion node displays.

6. Click Save.
   The Tree Designer saves your changes.

Add a Query Node

Use a query node to supply a possible answer to the question posed in its parent node and to serve as a parent node for further subnodes in the tree. The query text typically contains a question (the answer to which determines the next node in the tree) or a step in a procedure. The query nodes can have conclusion nodes, jump nodes, and other query nodes as subnodes.

Note: You can add up to seven subnodes to a query node.

Follow these steps:

1. Select the query node under which to add the new query node in the Tree pane.
   The Query Text (HTML) pane opens.

2. Click Add Query.
   The Tree Designer adds a query node below the selected node in the Tree pane and adds a response field in the Query Text (HTML) pane.

3. Enter a response to the question or statement that is posed in the parent node in the new field in the Query Text (HTML) pane.

4. (Optional) To rename the new node, right-click it in the Tree pane, then select Rename from the shortcut menu. The Prompt window opens. Enter a new name for the node and click OK to close the Prompt window. The Tree pane refreshes to show the new node name.

5. Select the new query node in the Tree pane.
   The Query Text (HTML) pane opens.

6. Do one of the following actions in the Query Text (HTML) pane:

   - Enter the displayed text (that is, the information that is associated with the node) in the Query Text (HTML) box. You can use plain text or can enter HTML codes as appropriate. To preview the text as it appears at run time, select the Quick View option.

   - Click Edit Query Text (HTML) to open the HTML Editor so you can design the information that is associated with the node in WYSIWYG (what you see is what you get) format. When you finish editing the information, click OK to save your work and close the HTML Editor.

7. Click Save.
   The Tree Designer saves your changes.

Add the Tree Description

The tree description displays at runtime when a user clicks the Tree Description link while viewing a knowledge tree document in tree view. For example, if you design a knowledge tree to help a customer choose a credit card, you can define a tree description such as "Use this document to find the best credit card for you."

Follow these steps:

1. Select the knowledge tree's primary node in the Tree pane.
   The Tree Description (HTML) pane opens.

2. Do one of the following action in the Tree Description (HTML) pane:

   - Enter the displayed text (that is, the information for the tree description) in the Tree Description (HTML) box. You can use plain text or can enter HTML codes as appropriate. To preview the text as it appears at run time, select the Quick View option.

   - Click Edit Tree Description (HTML) to open the HTML Editor so you can design the tree description in WYSIWYG (what you see is what you get) format. When you finish editing the information, click OK to save your work and close the HTML Editor.

3. Click Save.
   The Tree Designer saves your changes.

Add the Displayed Text for a Node

Use the Tree Description (HTML), Query Text (HTML), and Conclusion Text (HTML) panes to design the information that is displayed for a particular node. The displayed text presents the description of the knowledge tree, poses a question, or presents information to help the user navigate the knowledge tree.

Follow these steps:

1. Select the primary node, query node, or conclusion node for which to add displayed text in the Tree pane.
   Depending upon the node you selected, one of the following panes opens:
   If you selected the primary node, the Tree Description (HTML) pane opens.

   - If you selected a query node, the Query Text (HTML) pane opens.

   - If you selected a conclusion node, the Conclusion Text (HTML) pane opens.

2. Do one of the following actions in the Tree Description (HTML), Query Text (HTML), or Conclusion Text (HTML) pane:

   - Enter the displayed text (that is, the information that is associated with the node) in the field provided. You can use plain text or can enter HTML codes as appropriate. To preview the text as it appears at runtime, select the Quick View option.

- Click the Edit *xxx* (HTML) button to open the HTML Editor so you can design the information that is associated with the node in WYSIWYG (what you see is what you get) format. When you finish editing the information, click OK to save your work and close the HTML Editor.

3. Click Save.
   The Tree Designer saves your changes.

Add the Response Text for a Node

When you add a node to an existing query node in the Tree pane, the Tree Designer adds a response box for the added node in the right pane. Use the box to specify a response to the question or statement posed in the Query Text (HTML) pane.

Follow these steps:

1. Select the query node that contains the node for which to add response text in the Tree pane.
   The Query Text (HTML) pane opens.

2. Locate the response box for which to specify text in the Query Text (HTML) pane, then enter a response to the question or statement that is posed by the parent node.

   Note: By default, the response text you enter replaces the node name in the Tree pane (that is, the Tree Designer synchronizes the response text and the node name). To disable synchronization, select the Copy Response command from the Options menu to clear the check mark from it.

3. Click Save.
   The Tree Designer saves your changes.

Check a Knowledge Tree for Errors

Follow these steps:

1. Select Check Errors from the Tree menu.
   The Tree Designer scans the knowledge tree for missing displayed text, responses, and links, then displays the results in the Errors pane at the bottom of the window.

2. Select an error in the Errors pane to display its associated node.
   The Tree Designer selects the node in the Tree pane and displays its definition in the right pane.

3. Correct the indicated error.

4. Click Save.
   The Tree Designer saves your changes.

Set Tree Designer Options

Use the commands on the Options menu to control certain Tree Designer behaviors, as follows:

- To set whether the Tree Designer uses response text as the name of an associated node, select Copy Response from the Options menu.
  - If a check mark displays next to the command on the menu, the option is active and the response text you specify for a node replaces its name in the Tree pane. This is the default setting.
  - If no check mark displays, the option is inactive and you manually rename the node.
- To set whether the Tree Designer prompts you before deleting a node, Select Prompt on Node Delete from the Options menu.
  - If a check mark displays next to the command on the menu, the option is active and the Tree Designer displays a confirmation prompt when you attempt to delete a node. Click OK to close the prompt and delete the node and its subnodes. This is the default setting.
  - If no check mark displays, the option is inactive and the Tree Designer deletes the selected node and its subnodes without displaying a confirmation prompt.

Administering Knowledge Management

This article contains the following topics:

Document Permissions

You can set, view, and edit permissions for a document. These permissions can be assigned to different groups of individuals. When setting permissions, you can decide to inherit permissions from the primary category of a document or can specify new permissions. By default, documents inherit their permissions from their primary category. This default handles access permissions at the category level rather than the document level.

Important! When creating a knowledge document, verify that document permissions include users that can be later assigned on the document through the approval process. When a group is assigned to a document, users from that group may not have the permission to view the document. If the document is assigned to a specific user, default data partition constraints allow the user to view the document.

Version Documents

Using the document versioning capabilities of Knowledge Management, an analyst with editing privileges can create a *Rework-Draft* version of a document. A rework version starts as a copy of the document that is replaced in the knowledge base after it is verified and republished. The need to unpublish the document first is avoided.

Users with editing privileges can also perform the following versioning tasks:

- Save a draft version of a document.
- Roll back to a previous version if a problem with the current version occurs (Draft or Published). The Versions tab on the Update Document page is where users can select different versions for rollback to replace the current version.
- Track the number of document versions that are saved, deleted, and archived in the knowledge base.

The Knowledge Documents Inbox on the CA SDM Scoreboard is the repository for documents in all statuses including saved and assigned draft and rework-draft documents.

How to Manage Document Versions

Administrators can set up and can manage document versions by performing the following steps:

1. Identify who can edit published documents and can create the Rework-Draft versions. The role being used for a particular contact record controls editing privileges.
2. Define an approval process template that groups tasks or steps to complete during the document lifecycle. By default, a built-in approval process template allows users to create documents.
3. Determine whether to use the document approval process. Analysts who are permitted to bypass the approval process can identify which tasks they want to start with when they create a Rework-Draft version.
4. Create archive and purge rules for document version maintenance.

Document Expiration

When a published document reaches its expiration date, the product typically retires it (removes the document from the knowledge base and the approval process).

Document Archive and Purge

You can manage the size of your knowledge pool by using Archive and Purge, which removes old and unused documents automatically. Archive and Purge improve the efficiency of knowledge searches by returning only current documents.

Archive and Purge run as a background process and automatically removes inactive records in the CA SDM database according to rules that you configure. These rules act on CA SDM objects at specific time intervals.

Manage Export/ Import of Knowledge Documents

Contents

Knowledge Base Re-Index

The following changes to search settings require that you re-index the knowledge base using the Knowledge Re-index utility:

- After importing knowledge
- After changing parse settings
- After mass deletions
- When search failures occur

Re-indexing is necessary because existing documents do not reflect any changes that are made to the synonyms, noise words, special terms, and other research parameters until they have been re-indexed. All new synonyms, noise words, and special terms must be re-indexed to help ensure that keyword searches of the knowledge base are current and accurate.

You run Knowledge Re-index from the command line. The pdm_k_reindex.exe command is the executable file for Knowledge re-index.

Note: Re-indexing the documents in the knowledge base can be a time-consuming operation, depending on the size of your database. We recommend that you run the Knowledge Re-index utility after all changes have been added.

Export or Import Log Files

You can sort transactions by package, template, and status. All KEIT transactions are recorded in the following log files:

- **stdlog**
  Logs CA SDM information.
- **keitstat.log**
  Provides statistical information on the KEIT operation.
- **keitinfo.log**
  Provides detailed information on the KEIT operation.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

How to Export/Import Knowledge Documents

The Knowledge Management Export/Import tool (KEIT) migrates and synchronizes data between different Knowledge Management systems and enables export/import of Knowledge Documents. Use this tool to define export/import transactions.

Note: If multi-tenancy is installed, all tenanted and public categories that were imported from a previous system display as public in the new multi-tenancy system, but imported documents can be tenant-specific.

Follow these steps:

1. Allow Users to Export or Import Transactions (see page 2768).
2. Define the Export Import Directories (see page 2769)
3. Create an Export/Import Template (see page 2770)
4. Export and Import Transactions (see page 2773)

Allow Users to Export or Import Transactions

You can allow analysts to grant export and import permissions by managing your role list on the Administration tab.

Follow these steps:

1. Navigate to Security and Role Management, Role Management, Role List.
   The Role List appears.
2. Select a role with the Analyst Interface Type.
   The Role Detail page appears.
3. Click Edit.
   The Update Role page appears.
4. Click the Knowledge tab and select the options depending on the permissions that you want to grant.

5. Click Save.
   The Role Detail page reappears.
   Review your changes in the Knowledge tab and close the Role Detail page. You can also restrict users from exporting/importing by clearing the check boxes on the Knowledge tab of the Role Detail page.

Define the Export Import Directories

Follow these steps:

1. Select the **General Setting** page under **Administrator** tab, update the **Path For Knowledge Import/Export Files** option to define package directories.
   - (Conventional configuration) By default it uses "$NX_ROOT/site/keit". Restart the CA SDM servers after changing this path. Packages are stored in the following default directories:
     - Export Packages: $NX_ROOT/site/keit/export
     - Import Packages: $NX_ROOT/site/keit/import
   - (Advance Availability Configuration) This path must be UNC shared drive. Restart the CA SDM servers after changing this path. Packages are stored in the following directories:
     - Export Packages: *UNC Shared Location/*export
     - Import Packages: *UNC Shared Location/*import
2. To add attributes for the export/import availability, add the following attribute names to the NX.env file:
   - **@NX_KEIT_AVAILABLE_FIELDS**
     Adds the attribute name.
   - **@NX_KET_ADDL_FIELDS**
     Adds the attribute name, and if the new attribute is a SREL to another object, adds the attribute name that is used to synchronize the source and target systems.
     Example: Add Attributes
     @NX_KEIT_ADDL_FIELDS = STATUS_ID.STATUS,DOC_TEMPLATE_ID.TEMPLATE_NAME

   The export and import directories contain the following files:

   - **keit_config.xml**
     Contains the configuration file for an export or import package.
   - **data.xml**
     Contains the data file containing values of knowledge documents.
   - **rep.xml**
     Contains the repositories that are referenced in the data.xml file.
   - **images**
     Specifies the image files that are embedded in knowledge documents.

Create an Export/Import Template

You can create and modify a template using the Knowledge Export/Import Template Settings page in the Administration tab.

Follow these steps:

1. On the Administration tab, browse to Knowledge, Documents, Export/Import, Export/Import Templates.
   The Knowledge Export/Import Templates List appears.

2. Click Create New.
   The Create New Export/Import Template page appears.

3. Complete the following fields:

   - **Template Name**
     Identifies the name of the template.

   - **Description**
     Provides a brief description of the template.

4. Complete the appropriate fields on the following tabs:

   - Export Fields (see page)

   - Export Filter (see page)

   - Import Settings (see page)

5. Click Save.
   The template is created.

Export Fields

The Export Fields tab appears and contains the following fields:

- **Available**
  Displays the Knowledge Document fields that are available for export.

  Note: If you want to preserve status of the documents, such as Draft, for the export and import process, add STATUS_ID to the Exported column.

- **Exported**
  Specifies document fields to export.

- **Export Attachments**
  Exports the Knowledge Document file attachments.

You can use the arrows in the Select Document Attributes section to add document attributes export.

Note: If you edit the export/import template using Firefox, the list size does not change after you use the arrows in the first edit. Close and reopen the template in edit mode, and using the arrows again causes changes to the list size. This behavior does not occur when you use Internet Explorer.

Important! The exported fields in the KEIT have a higher priority than when the fields are selected as defaults in the Import Settings tab. If you select a default export field in the Import Settings tab, it is not processed as the default field.

Export Filter

The Export Filter tab appears and contains the following fields:

- **Category**
  Opens the Knowledge Category page. Use this option to add categories to the list on the Export Filter tab.
- **Remove Category**
  Removes categories from the list on the Export Filter tab.
- **Clear Category**
  Clears the category list on the Export Filter tab.
- **Include child categories**
  Exports the documents from child categories of exported categories.
- **Include secondary categories**
  Exports secondary categories of exported documents.
- **Include all documents linked to selected categories**
  Exports all documents that are linked to selected categories.

  Note: Enabled only if you select Include secondary categories.
- **Additional Filter**
  Provides an additional WHERE clause.

Import Settings

The Import Settings tab appears and contains the following fields:

- **Error Threshold (%)**
  Stops the import process (sets the status to Failed) if the percent of errors exceeds the specified number.

- **Override published documents**
  Allows imported documents to override published documents of the CA SDM server.

- **Override documents in all non-published statuses**
  Allows imported documents to override non-published documents of the CA SDM server.

- **Use default values when overriding documents**
  Uses default values on overridden documents for defined fields.

- **Index documents immediately**
  Indexes the document after the import process.

- **Status**
  Select Draft, Published or Retired.

- **Priority**
  Sets the priority level of the import settings.

- **Template**
  Selects one of the following default templates:

  - Built in - Knowledge Document
  - Built in - Knowledge Tree
  - Built in - Quick Editing

- **Owner**
  Allows you to set the owner by opening the Contact Search page.

- **Author**
  Allows you to set the author by opening the Contact Search page.

- **Subject Expert**
  Allows you to set the subject expert by opening the Contact Search page.

- **Assignee**
  Allows you to set the assignee by opening the Contact Search page.

- **Expiration date**
  Opens the date helper.

- **Review Date**
  Opens the date helper.

- **Product ID**
  Allows you to set the product ID by opening the Product Search page.

- **Asset**
  Opens the Configuration Item Search page.

- **Root Cause**
  Opens the Root Cause Search page.

- **Service Desk Priority**
  Sets the Service Desk priority of the import settings.

- **Severity**
  Sets the severity level of the import settings.

- **Impact**
  Sets the impact level of the import settings.

- **Urgency**
  Sets the urgency level of the import settings.

Export and Import Transactions

Follow these steps:

1. Export the data to another system by clicking **Export** on the **Export/Import Template Detail** page or by running the pdm_ket utility (see page).

   Note: In the advanced availability configuration, you cannot export packages from the application server using web interface. Use the pdm_ket utility to export packages from any server.

2. Import knowledge data from the package by performing any of the following actions, depending on your CA SDM configuration:

   - In the conventional configuration, copy the desired knowledge package from the default $NX_ROOT/site/keit/export directory and place it in the $NX_ROOT/site/keit/import directory. On the **Knowledge Import Packages List** page, right-click a knowledge package, and click **Import** on the shortcut menu.

   - In the advanced availability configuration, copy the desired knowledge package from the *UNC Shared Location*/export directory and place it in the *UNC Shared Location*/import directory. You cannot import packages from the application server using web interface. Use the pdm_kit_txt utility (see page 2775) to import packages from any server.

     Note: The knowledge package name must start with "package_" prefix for it to be listed in the Knowledge Import page.

     Important! The r11.0 import utility has been renamed pdm_kit_txt.exe to allow importing r11.0 text files. This utility does not support any of the r12.0 import enhancements.

3. Documents that are not indexed after import are stored in the Unindexed queue on the scoreboard. Users cannot search for unindexed documents, therefore, they do not appear on the Document list. To display this queue, select the **Service Desk** tab, **Knowledge Documents**, **Unindexed**. You can import knowledge data when the Index Document option is enabled. If Knowledge Documents are imported with the option disabled, you cannot search the documents after importing. Run pdm_k_reindex to make the documents searchable.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Knowledge Export/Import CLI

Contents

pdm_ket Utility -- Knowledge Management Export Tool

The pdm_ket utility exports knowledge from a source computer to a knowledge package, using a template that is created from the web interface.

Attachments and their links are exported to data.xml during the export. Before you import the attachments, manually move them to following directory on the background server:

$NX_ROOT/site/attachments/default

Note: For advanced availability configuration, you can execute the pdm_ket utility using attachments UNC path.

Use this utility to do the following tasks:

- Create configuration file based on the related knowledge export template.
- Export data with UUID of document, and content such as title, summary, problem, resolution and other document attributes like owner, status, and so on.
- Export all unique images that are used by the exported documents (always exported).
- Export all unique attachments that are used by the exported documents (EXP_ATTMNT field). The files are copied from the remote repository to the local package folder.

The utility is invoked as follows:

```
pdm_ket -n <template name> [-h] ]-v]
```

- **-n <template name>**
  Defines the name of the template that is used for export (case sensitive).

- **-h**
  (Optional) Displays help on the utility.

- **-v**
  (Optional) Enables extensive logging (bop_logging) of program events. This option is commonly used for internal problem solving.

Example: Using pdm_ket to Export Knowledge Using the my_template Template.

```
pdm_ket -n my_template
```

The pdm_ket utility can be scheduled using a third-party scheduler for exporting Knowledge Documents.

pdm_kit Utility -- Knowledge Import Tool

The pdm_kit utility imports data to the destination server according to the settings in the configuration file of a package.

Important! Before you execute the pdm_kit utility from the application server, ensure that the path (local or UNC) of the package is accessible by the background server. If the background server is not able to access this path, the package is not imported from the application server.**Important!** The r11.0 import utility has been renamed to pdm_kit_txt. exe to allow importing r11.0 text files. This utility does not support any of the Release 12.9 import enhancements.

The referenced data that is previously referenced by the pdm_ket utility gets the real UUID or ID value of the destination server. When running pdm_kit utility a new userid parameter is applied. The pdm_kit utility works as follows:

1. Imports the documents by replacing the userid value (for contacts) or referenced name (for fields like asset) with appropriate UUID of the destination server.
2. Imports the images.
3. Imports the attachments.
4. Uploads the files from the local package folder to the remote repositories.

Note: If editing published documents is disabled, then the imported document is created as a rework version.

The utility is invoked as follows:

```
pdm_kit [-h] -f -u [-v]
```

- **-h**
  (Optional) Displays help for the utility on the interface.
- **-f**
  Specifies the path to the package.
- **-u**
  Specifies the default user.
- **-v**
  (Optional) Enables extensive logging (bop_logging) of program events. This option is commonly used for internal problem solving.

Note: For advanced availability configuration, you can execute the pdm_kit utility on background server. For Windows, you can also execute the pdm_kit utility on application server if the package resides in a UNC shared drive. For non-windows platform, you cannot execute pdm_kit utility on application server.

Example: Using pdm_kit to Import a Package

```
pdm_kit -f c:\package_path -u ServiceDesk
```

Managing Automated Policies

Contents

An automated policy describes the condition by which documents are flagged for correction and are promoted to publication or retirement throughout the various stages of the document lifecycle process. For example, you can specify the "fix broken links" default policy that matches documents that are found in the knowledge base with broken links. The task of fixing the problem can be assigned to an analyst.

Administrators can automate certain tasks in the knowledge document approval process that is based on document lifecycle policies and actions they define. By automating tasks, end users who are searching for solutions can solve problems faster, and they can do so without contacting other individuals, which provides a benefit to the organization.

Automated policies work with events and macros. Each policy is associated with the following components:

- **Stored Query:** Contains a set of action macros that execute when the policies identify and match a document during processing. After processing, the stored query condition event displays a role-based Knowledge Management lifecycle policy report on the CA SDM Scoreboard. The administrator is responsible for monitoring the reports and for providing feedback and recommendations to the appropriate document editors.
- **Action Macro:** Contains code that lets users set a flag, increase the priority, or perform some other action. You can modify the macros that appear on the Macro list, or can define your own.

How to Set Up Automated Policies

Administrators can set up the Automated Policies feature by performing the following steps:

1. A batch process must be defined in the Automated Policies Scheduler that executes on the background server to present the data that is required to view the Knowledge Management Lifecycle Policy reports. This action step also applies to the Knowledge Report Card.
2. For security and role management, define the stage by which users can view and search on documents during their lifecycle on the Knowledge Document Visibility tab in Role Management.
3. On the Automated Policy List page, you can edit the default policies, or can define your own.

Create an Automated Policy

You can create an automated policy that activates when an action occurs, such as when a document is published or retired from the knowledge base.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Important! For new policies, the administrator must include the "Disregard Life Cycle Policies" field in the stored query; otherwise, it does not appear on the Attributes tab.

Follow these steps:

1. Select **Administration** tab, **Knowledge**, **Automated Policies**, **Policies**.
   The Create New Automated Policy page appears.

2. Enter a name and description for the policy in the appropriate fields.

3. Enter a stored query name or select one using the search icon.

4. Click **Add Action**.
   The Macro List page appears.

5. On the Macro List page, select one of the predefined action macros, or define your own (click **Create New**).
   The action macro appears in the Action Information list on the Create New Automated Policy page.

   Note: You can delete an action macro: right-click the name and select Delete from the shortcut menu.

6. Click **Save**.
   The new policy appears in the Automated Policy list.

Run the Automated Policies

The Automated Policies List page contains the details of the policies you can manage. To display this page, select the Administration tab, Knowledge, Automated Policies.

Each policy contains a stored query that executes when documents are matched during processing. After processing completes, a Lifecycle Policy report appears on the CA SDM Scoreboard. To view a report, select Knowledge Documents, Automated Policies. From the scoreboard, the analyst can manage their own documents, and by default, the administrator can manage all documents for each role.

To implement the reports, run a batch process with the Automated Policies Scheduler. The scheduler runs on the following CA SDM server, depending upon the configuration and displays the data that is required to view the reports.

- Conventional:Primary or secondary
- Advanced availability: Background

When you are finished, run the Knowledge Report Card (see page 2818).

Follow these steps:

1. Select the **Administration** tab, **Knowledge**, **Automated Policies**, **Scheduling**.
   The Automated Policies Scheduler appears.

2. Complete the following fields:

   - **Last Updated** -- Select the Run Calculation check box.

- **Schedule** -- Specify a date and time from which CA SDM performs the calculation and runs the policies.

3. Click Save.

View Document LifeCycle Policy Reports

Administrators can view the Document Lifecycle Policy Reports that are generated by the automated policies on the Document List page. Each report is role-specific and provides administrative information about the documents that are flagged for correction and promoted to publication or retirement throughout the various stages of the document lifecycle process.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Follow these steps:

1. On the **Service Desk** tab, **Knowledge Documents**, **Automated Policies**.
2. Do *one* of the following:
   - **Expand the My Documents** folder to reveal nested folders for your assigned items.
   - **Expand the All Documents** folder to reveal nested folders for all items.
3. Select the folder that you want to view.
   The Document List page displays the following columns:
   - **Title**
     Displays the title of the document that is either flagged for correction or promoted for publication or retirement.
   - **Policy/Actions**
     Displays the policy name and action content defined for the policy.
   - **Attributes**
     Displays the properties of the document that are affected by the policy it is assigned to.

Knowledge Documents Schedule

This article contains the following topics:

- schedConfig Macro -- Configure Schedule (see page 2783)
- schedAttr Macro -- Specify a Stored Attribute (see page 2785)
- schedGroup Macro -- Specify an Event Group (see page 2786)
- The setSchedEvents() JavaScript Function (see page 2787)

The Knowledge Documents Schedule provides Change Managers, Knowledge Managers, and Level 2 Analysts a high-level view of key events in the knowledge management lifecycle. The following events can be scheduled for a Knowledge Document:

- Submission
- Publication
- Review
- Expiration

The Knowledge Management Schedule tab displays a calendar format similar to the Change Calendar, but instead of showing start times and end times, it only shows specific dates.

Configuring scheduling views (see page 2783) involves setting macros statements.

The Knowledge Document Schedule can also be exported to iCalendar format.

Note: When exporting schedules on some calendar programs, selecting the Open option instead of Save causes the file to import incorrectly. To avoid this issue on Knowledge Management and Change Order schedules, select the Save option instead of Open. After you save the exported file, import it through the calendar program interface.

Knowledge Schedule Filter

The Knowledge Schedule Filter displays the following fields:

- **Tenant**
  Filters the search by tenant. This field displays for the privileged user in a multi-tenancy installation.
- **Event Type**
  Filters the search by the following event types:
  - Submission
  - Review
  - Publication
  - Retirement

- **Schedule Start Date**
  Specifies the date for the beginning of a range for filtering the history to show only entries for a specified time frame.

- **Schedule End Date**
  Specifies the date to specify the end of a range for filtering the history to show only entries for a specified time frame.

- **Schedule Timezone**
  Specifies a timezone to view your search results.
  Note: If no timezone is selected, the events are displayed in your current timezone.

- **Owner**
  Defines the name of the contact that is assigned to maintain the document. Enter or search the name of the contact in "last name, first name" format.

- **Assignee**
  Defines the name of the contact that is assigned to handle the record. Enter or search the name of the contact in "last name, first name" format.

- **Subject Expert**
  Defines the name of a contact with expertise in the subject matter of the document . Enter or search the name of the contact in "last name, first name" format.

- **Status**
  Select one of the following document statuses to perform your search:

  - Draft
  - Published
  - Retired

- **Category**
  Defines a category by which to filter documents retrieved. Enter the name of the category in the box or open the Category Search window. When you click Search, the product returns only documents that are associated with the specified category.

- **Initial View**
  Select the view of the Knowledge Management Calendar you want to see:

  - **Month**
    Displays a calendar for the full month that includes the earliest implementation start date that is specified in the Start Date field. The calendar shows abbreviated information about each change within the range (change number, start and end time, and first affected CI).

  - **Week**
    Displays seven consecutive days in a single column, beginning with the earliest implementation start date specified in the Start Date field. The calendar includes summary information about each change within the specified range (change number, start and end time, summary description, assignee, group, and the first ten affected CIs).

- **Day**
  Displays a view similar to the week view, except that it shows only the day that is specified in the Start Date field.

- ***n* Days**
  Displays a view similar to the week view, except that it continues for the specified number of days.

- **List**
  Displays a standard CA SDM list page.

  You can click the More icon to display the Additional Search Arguments field. This field is intended only for expert users who understand SQL and Majic. You can enter a SQL WHERE clause in this field to specify an additional search argument.

Knowledge Schedule Views

The Knowledge Documents Schedule has the following views:

- **Month**
  Displays a calendar for the full month that includes the earliest implementation start date that is specified in the Schedule Start Date field. The calendar shows abbreviated information about each change within the range (change number, start and end time, and first affected CI).
  The Knowledge Documents Schedule has similar functionality to the Change Orders Month view with the following exceptions:

  - Knowledge events only have a date (no time) and event type groups them, similar to change orders that are grouped for each time period and change type.

  - Events types have the following default predefined colors, using the schedGroup macros:

    - Submission -- Black

    - Review -- Green

    - Publication -- Blue

    - Retirement -- Red

  Note: If you see a review date referring to the past, it indicates that the review was probably not done.

- **Week**
  Displays seven consecutive days in a single column, beginning with the earliest implementation start date specified in the Schedule Start Date field. The calendar includes summary information about each change within the specified range (change number, start and end time, summary description, assignee, group, and the first ten affected CIs).

- **Day**
  Displays a view similar to the week view, except that it shows only the day that is specified in the Schedule Start Date field.

- ***n* Days**
  Displays a view similar to the week view, except that it continues for the specified number of days.

- **List**
  Displays a standard CA SDM list page.

Scheduling View Configuration

You configure the monthly and weekly scheduling views by specifying pdm_macro statements in the <head> section of the HTMPL forms defining the schedule. We recommend using the Source View of Web Screen Painter to edit these forms.

Any form that displays a schedule must contain the following:

- A schedConfig macro
- At least one schedAttr macro
- At least one schedGroup macro

The configuration macros are in a separate source file that is referenced by a pdm_include statement in the main source file. This file lets you configure your schedule without modifying the main source file.

For example, the configuration macros for the Change Calendar form list_chgsched.htmpl are in a file named list_chgsched_config.htmpl. For the Knowledge Lifecycle Schedule, you can modify the list_kdsched_config.htmpl using the same macros.

You can find list_chgsched_config.htmpl and list_kdsched_config.htmpl in the following directory:

$NX_ROOT\bopcfg\www\htmpl\web\analyst\

schedConfig Macro -- Configure Schedule

The schedConfig macro specifies that a form contains a schedule and provides basic configuration information. The following values are valid macro arguments:

- **autosearch=1|0**
  Specifies whether the schedule form reloads data from the server when the user selects a view outside the currently selected date range. Setting the value to 1 (default) causes the form to search automatically when the user selects a view with one or more days outside the date selection range of the search filter. Setting the value to 0 requires the user to press the Search button to initiate a search.

- **defaultView=0|1|7|30|99**
  Specifies the default view for the search filter as 0 (list), 1 (day), 7 (week), 30 (month), or 99 (n-day).
  The specification for defaultView affects only the initial display of the search filter. After the

schedule displays, CA SDM automatically keeps the filter view selection aligned with the current view.
Default: 30

- **firstday=0|1|2|3|4|5|6|7**
  Specifies the first weekday on the monthly view as a number between 0 (Sunday) and six (Saturday).
  Default: 0

export=xxx|0

Specifies

the code name of the template that is used for exporting in iCalendar format. Setting the value to 0 indicates the export and disables the buttons.

Default:

ChangeSchedule

- **legend=1|2|0**
  Specifies the location of the schedule legend showing the name and formatting of the groups on the schedule. You can set the value to 1 to position the legend above the schedule, or 2 to position the legend below the schedule. Set the value to 0 to disable the legend.
  Default: 2

- **maxGroups=0/*n***
  Specifies the maximum number of groups to be displayed in a single cell of the calendar month view.
  If there are more than maxGroups scheduled for a single day, CA SDM displays only the first maxGroups-1, and replaces the last with a "..nn more changes" hyperlink that the user can mouseover or click to see the full list. Set the value to 0 to disable this feature and allow an unlimited number of events in a calendar cell.
  Default: 4

- **nday=(n,n,...)**
  Specifies selections for the drop-down list for the n-day view.
  The specification is a list of day counts that are to be included in the drop-down list, or 0 to indicate that the n-day drop-down list is omitted from the schedule. The first value specified is the default for the drop-down list.
  Default: (3,7,14,28)

- **round=(*hr,min*)|0**
  Specifies whether schedule start and end dates are rounded when collecting change orders or knowledge documents into groups. Specify round=0 to disable rounding.
  By default, schedule start and end date groups objects. All CA SDM dates include a time, and without rounding, objects scheduled as little as a minute apart would be in separate groups. Rounding determines the group after adjusting the start date to an earlier hour or minute and the end date to a later hour or minute.
  The value of round specifies either an hour or a minute (but not both). Times are rounded to the nearest multiple of the value specified, for example:
  round=(0,15) rounds to the nearest quarter hour
  round=(0,30) rounds to the nearest half hour

round=1 rounds to the nearest hour
round=12 rounds to the nearest half day (12:00 AM or PM)
round=24 rounds to the nearest day
Default: (0,15)

- **timefmt=24hr|([am],[pm])**
  Specifies the format of times on the calendar views of the schedule.
  The default value of 24hr specifies that times are displays in 24 hour format (0:01 - 23:59). The alternative value of (am,pm) specifies a suffix for either morning or afternoon times, or both.

Note: All schedConfig arguments are optional.

schedAttr Macro -- Specify a Stored Attribute

The schedAttr macro specifies an attribute stored for each item selected for the list. Stored attributes are available for hover information on the monthly view, for the detailed or summary information in views other than the monthly view, and in the setSchedEvents() JavaScript function. The following values are valid macro arguments:

- **attr=xxxx**
  (Required) Specifies an attribute from the object on the schedule, such as a change order or Knowledge Document. Dotted attributes are permitted. The keyword attribute name CI*nn* can be used on the Change Calendar to specify that first *nn* CIs associated with the change order are included with the information stored.

Note: This argument is the only required argument for the schedAttr macro.

attrRef=.COMMON_NAME|xxxx

Stores the attribute of the referenced

table stored

for an SREL attribute (ignored for non-SREL attributes). The attribute name must be prefixed with a dot.

Default:

.COMMON_NAME

- **label=**
  Displays a label for the attribute on the n-day view.
  Default: the Majic DISPLAY_NAME of the attribute

- **ident=1|0**
  Specifies whether the attribute is an identifier for the object (such as a reference number of a change order). The identifier attributes are displayed without a label in front of the group name in hover information and the n-day view.
  Default: 0

- **detail=1|0**
  Specifies whether the attribute is included in the detail information that is shown on views other than the monthly view. Detail information is the information shown when the Summary Only check box on the view is not selected.
  Default: 1

- **hoverInfo=1|0**
  Specifies whether the attribute is included in the hover information pop-up that is displayed on the monthly view. The hover information appears when the mouse pointer hovers over a group, or the user presses Alt+Right Arrow when focus is on the group.
  Default: 0

- **summary=1|0**
  Specifies whether the attribute is included in the detail information that is shown on views other than the monthly view. Detail information is the information shown when the Summary Only check box on the view is not selected.
  Default: 0

Note: CA SDM displays attributes in summary, detail, or hover information in the same order as their schedAttr macros.

schedGroup Macro -- Specify an Event Group

The schedGroup macro specifies the name and color coding of a group of items. The monthly view aggregates all items in a group into a single event. Views other than the monthly show individual items in the format for the group to which they belong. The following optional values are valid macro arguments:

- **grpname=xxx**
  (Required) Specifes the name of the group. The macro automatically assigns a number to the group and assigns the number to a JavaScript variable with a name of the form schedGroup_xxx, where xxx is the name of the group. This variable can be used in the setSchedEvents() JavaScript function to create an event belonging to the group.

  Note: This argument is the only required argument for the schedGroup macro.

- **label=xxx**
  Specifies a label for the group. If specified, the label is displayed in all views.

- **legend=xxx|0**
  Displays a description of the group for the legend that appears at the bottom of the schedule. Groups appear in the legend if at least one example of the group exists in the current view. Specifying 0 causes the group always to be excluded from the legend.
  Default: 0

- **color=black|*color***
  Specifies the color of text in items of this group. You can specify color in CSS format, either a valid web color or a hexadecimal value that is preceded by a pound sign.
  Example: Enter either "#FF0000" or "red" for red.
  Default: black

- **bgcolor=white|*color***
  Specifies the background color of items of this group. You can specify bgcolor in CSS format, either a valid web color or a hexadecimal value that is preceded by a pound sign.
  Example: Enter either "#FF000" or "red" for red.
  Default: white.

- **style=normal|bold|italic**
  Specifies the style of text of this group in the normal, bold, or italic style.
  Default: normal

The setSchedEvents() JavaScript Function

The setSchedEvents() JavaScript function creates events in the schedule. Modify this function when you want to view any new group objects. The predefined group objects appear by default.

CA SDM calls setSchedEvents() once for each object (change order or knowledge document) selected by the schedule search filter. The function creates events for the object by calling a second function, schedEvent(), and passing the group ID, start date, and end date of the event.

The function can create any number of events (including zero) for an object. The default setSchedEvents() function for the Change Calendar (list_chgsched.htmpl) creates one event for each change order and groups change orders by change type. This function is coded as follows:

```
1.    function setSchedEvents( chg )
2.    {
3.    var grpnum;
4.    switch( chg["chgtype"] - 0 ) {
5.        case 100: grpnum = schedGroup_std;  break;
6.        case 300: grpnum = schedGroup_emer; break;
7.        default:  grpnum = schedGroup_norm; break;
8.    }
9.    chg.schedEvent( grpnum, chg["sched_start_date"], chg["sched_end_date"] );
10.    }
```

The case parameter specifies the change type ID. To list the case IDs, see Create a Change Type.

The function has a single argument of a JavaScript object containing the attributes that are specified by schedAttr macros. The switch statement in lines 4-8 examines the chgtype attribute of the change order, and assigns the appropriate group number from one of the schedGroup_xxxx variables that are defined by previous schedGroup macros. On line 9, it calls the schedEvent() function to create an

event in the schedule, passing the group number that is previously assigned and the schedule start and end dates. The dates are available in the argument object because they were specified in earlier schedAttr macros.

Integrating Multiple Search Engines Using Federated Search

The Federated Search feature extends the capabilities of the CA SDM built-in knowledge base.

- When a user performs a knowledge search, the results from the internal knowledge database are augmented with results from the external search engines. We provide out-of-the box search adapter configuration for CA Open Space, Microsoft SharePoint, and Google.

The Federated Search architecture is flexible. Support for other search engines can be added by developing a custom search adapter using the CA Federated Search SDK. The SDK interface provides information and source code samples for extending the Federated Search functionality.

- Information that is contained in CA SDM tickets and knowledge articles can also be searched with an external search engine. The new Crawler Surface component allows an external search engine crawler to discover the CA SDM information easily. The crawler stores this information in its repository. This indexed information can be searched using Federated Search. Attachments for tickets and knowledge articles is also supported.

The main components of Federated Search are as follows:

- Configure Federated Search
- Configure Crawlers
- SDK Custom Search Adapter

How to Configure Federated Search

The Federated Search feature consists of the following components:

- **UI components**
  Enables the CA SDM Analyst users to enter search arguments and pass the search request to the Federated Search server.
- **CAFedSearch servlet**
  Main component of the federated Search feature and uses a REST interface. The Federated Search servlet runs on a dedicated Tomcat instance within the CA SDM application.
- **Plug-in search adapter**
  The plug-in search adapter interfaces the CA SDM application to an external search engine. The adapter translates the generic search requests to a search engine proprietary format and calls the search engine. The Federated Search servlet returns the configured search engine results to the CA SDM UI component.

Follow these steps:

- Complete the Prerequisites (see page 2789)
- Enable Federated Search (see page 2789)

Complete the Prerequisites

Complete the following prerequisites:

- Ensure to select the Federated Search option on the Configure Federated Search wizard while installing the CA SDM application.
- Know and decide the search engines that you want to use for Federated Search.
- Ensure to have an active Google Account for configuring the Google Plug-in Search Adapter. A Google API key and Google Custom Search Engine ID is also required. For more information, see Google Custom Search Engine https://www.google.com/cse/all
- Verify that IIS on the SharePoint server is configured with basic authentication. The Microsoft SharePoint adapter requires the basic authentication. By default, Basic Authentication is turned off in SharePoint. For more information about how to enable basic authentication in SharePoint, see the Microsoft SharePoint Documentation.

  Note: Enable Basic Authentication for _vti_bin in IIS.

- To integrate with CA Open Space, version 2.0 SP1 on-premise solution is required. For more information, see the CA Open Space documentation. The CA Open Space SaaS offering is not currently supported.

Enable Federated Search

A dedicated Tomcat instance is installed to host the CAFedSearch and FSCrawl servlets. The Federated Search Tomcat is under the control of the Daemon Manager. Tomcat Starts and stops automatically when CA SDM runs or shuts down respectively.

Configure the Federated Search (FS) Tomcat with the following installation options:

- **Configure Federated Search**
  Ensure to select this option when installing the CA SDM application. The Tomcat options are available only after selecting this option.
- **Tomcat Port**
  Specifies the Federated Search Tomcat Port.
  Default: 8040

- **Tomcat Shutdown Port**
  Specifies the Federated Search Tomcat Shutdown Port.
  Default: 8045

Generate Configuration XML Files for Federated Search

To configure Federated Search and to decrease editing errors, a utility file fs_adapters_cli is provided. A batch file for Windows and a Shell script for Linux and Unix is provided. The utility file is a Java application that is contained in two Jar files.

Three template files are supplied for CA Open Space, Google, and SharePoint adapters. The adapters-config.xml file is used for both input as well as output to the utility. The adapters.properties file is used as input to the utility. This file holds all the necessary configuration parameters for the adapters. The jfedsearch.log file contains the log file information.

The fs_adapters_cli utility is used to configure the adapters-config.xml file. The utility file installs and uninstalls the adapters by adding or removing entries from the adapters-config.xml. Individual adapter XML configuration files are generated. These files are then included in the adapters-config. xml with the <import> bean directive. Ensure to maintain a clean copy of the adapters-config.xml.

- To install an adapter, two entries are added for registering and importing the adapter in the adapters-config.xml file.
- To uninstall an adapter, two entries are removed for registering and importing the adapter from the adapters-config.xml file.

Federated Search Utility Files

The fs_adapters_ cli utility file is located in the CA SDM $NX_ROOT\samples\cafedsearch directory. The following utility file components are available in this location:

- The following Script files are located in the NX_ROOT\bin folder:
  - fs_adapters_cli .bat (for Windows)
  - fs_adapters_cli.sh (for Non-Windows)
- The following JAR files are available in the NX_ROOT\java\lib folder:
  - fs_adapters_config_cli.jar
  - fs_adapters_config_schema.jar
- The following templates and properties files are located in the $NX_ROOT\samples\cafedsearch directory:
  - openspace-tmpl.xml
  - google-tmpl.xml
  - sharepoint-tmpl.xml

- adapters.properties

To install the federated search utility file, run the following command:

```
fs_adapters_cli -i -k <key> -b <bean> -t <filename> -p <filename>  -o <filename> [-c <filename>]
```

Use the fs_adapters_cli - h option to get Help on the Utility file. The following attribute options are available:

- **-b (Optional)**
  Attribute value to map adapters. Refers to an actual ID of an adapter bean. If not specified, then the value from - k is taken as the value for - b.
- **-c (Optional)**
  The main XML file that contains all the configured adapters.
- **-h (Optional)**
  Provides Help for the Federated Search Utility.
- **-i**
  Specifies the option that is used for installing the adapter.
- **-k**
  Specifies the adapter key attribute.
- **-o**
  Specifies the Output XML filename to be generated. Name of the XML file to create and update the merged content of the XML template and SharePoint properties file.
- **-p (Optional)**
  Indicates the properties file name to merge with the Adapter Definition XML template.
- **-t**
  Specifies the name of the XML template file for defining an adapter.
- **-u**
  Specifies the name of the adapter XML file to uninstall the adapter.

Invoke the Utility File to Configure the Search Adapters

A Search engine requires specially coded plug-in adapters. A plug-in search adapter translates generic search requests to a search engine proprietary format, calls the search engine, and returns the search requests.

Note: If CA SDM is configured for multi-tenancy, your Tenant is passed along to the search engine. Federated Search has built-in support for multi-tenancy. You can use federated search to isolate data by a tenant in a single SharePoint implementation.

Important! Do not use ampersands or spaces in the adapters.properties file values.

Follow these steps:

1. Encrypt the passwords for search adapters using the encrypt password utility. To encrypt passwords, navigate to the following CA SDM directory:

   ```
   $NXROOT\bin
   ```

2. Run the following command for generating encrypted passwords:

   ```
   encrypt_pwd [-e] <search engine password>
   ```

   The default option is -e.

3. Open the adapters.properties file from the following CA SDM directory:

   ```
   $NX_ROOT\samples\cafedsearch
   ```

4. Edit the adapters.properties file. Specify the appropriate parameters for the adapters you want to configure.

5. For SharePoint, update the following values in the adapters.properties file:

   - **sharepoint_username=**
     Enter the user name for SharePoint access.
   - **sharepoint_password=**
     Enter the encrypted password for SharePoint access as shown in Step1.
   - **sharepoint_hostname=**
     Enter the hostname.
   - **sharepoint_domainName=**
     Enter the domain name.
   - **sharepoint_protocol=**
     Enter the communication protocol (http or https).
   - **sharepoint_portNumber=**
     Enter the port number. Default is 80.

6. For Google, update the following values in the adapters.properties file:

   - **google_googleCx=**

     Enter the unique key value that Google uses to decide which Google Custom Search Account to use.

- **google_googleApiKey=**
  Enter the unique key value that helps Google determine the identity of an application. To retrieve the key in the APIs Console, activate JSON/Atom Custom search API. This API provides a new API key for Simple API Access.

7. For CA Open Space, update the following values in the adapters.properties file:

   - **openspace_protocol=**
     Enter the communication protocol (http or https).

   - **openspace_portNumber=**
     Enter the port number for CA Open Space. Default is 8686.

   - **openspace_default_tenant_userName=**
     If CA SDM is not configured with multi-tenancy, enter a username to perform search in CA Open Space.

   - **openspace_default_tenant_password=**
     Enter the CA Open Space encrypted password. For more information, see Step1.

   - **openspace_default_tenant_companyHost=**
     Enter the tenant company host details.

     a. If CA SDM uses multi-tenancy, add an entry for each tenant in the openspace-tmpl.xml: For example, if CA SDM has a tenant that is named Tenant 1, provide the following values in the openspace-tmpl.xml file:

     ```
     <entry key="Tenant1">
      <bean class="com.ca.ServicePlus.cafedsearch.adapters.openspace.
     OpenSpaceCompanyDetail">
       <property name="userName" value="$(openspace_tenant1_userName)"/>
        <property name="password" value="$(openspace_tenant1_password)"/>
       <property name="companyHost" value="$(openspace_tenant1_companyHost)"/>
       </bean>
     </entry>
     ```

     b. Add the following entries for Tenant 1 in the adapters.properties file:

     ```
     openspace_tenant1_userName=
     openspace_tenant1_password=
     openspace_tenant1_companyHost=
     ```

     Repeat steps a and b for all required tenants in the openspace-tmpl.xml file.

8. Invoke the fs_adapters_cli once for each adapter you want to configure.

   - If you want to configure a CA Open Space adapter, use the bean value as OpenSpaceSearchAdapter and the template as openspace-tmpl.xml as shown in the following example:

   ```
   fs_adapters_cli -i -k OpenSpace -b OpenSpaceSearchAdapter -t "openspace-tmpl.xml" -o "openspace.xml"
   ```

- To configure a Google adapter, provide the the bean value as GoogleSearchAdapter and the template as google-tmpl.xml as shown in the following example:

  ```
  fs_adapters_cli -i -k Google -b GoogleSearchAdapter -t "google-tmpl.xml" -o "google.xml"
  ```

- If you want to configure a SharePoint adapter, use the bean value as SharePointSearchAdapter and the template as sharepoint-tmpl.xml as shown in the following example:

  ```
  fs_adapters_cli -i -k SharePoint -b SharePointSearchAdapter -t "sharepoint-tmpl.xml" -o "sharepoint.xml"
  ```

  Modify the -k and -o attribute values with a name of your choice. For more information about the federated search utility file and attributes,.see Federated Search Utility Files (see page 2790).

9. After the installation, if there are any errors, check the log file that is located in the CA SDM directory:

   ```
   $NXROOT\log\jfedsearch.log
   ```

10. Optionally, you can also create your own XML file for registration. All adapter entries are registered in the adapters-config.xml located in the following directory:

    ```
    $NX_ROOT\samples\cafedsearch
    ```

11. To create your own XML file for registration, you can also make a copy of the existing adapters-config.xml file name. Optionally, change the name of the modified adapters-config. xml file.
    Use the -c option with the modified XML file (xyz.xml) to register adapters.

12. Change the resource value in bean.xml <import resource="adapters-config.xml"/>.

13. Copy the adapters-config.xml or the modified xyz.xml (step 11) and any associate adapter-specific XML files for Google (google.xml), CA Open Space (openspace.xml), SharePoint (sharepoint.xml) in the following CA SDM directory:

    ```
    $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF
    ```

14. Restart the Federated Search Tomcat instance:

    ```
    pdm_tomcat_nxd  - c STOP  - t FS
    pdm_tomcat_nxd  - c START  - t FS
    ```

    The federated search adapters are configured.

15. Verify and check the error log files in the CA SDM directory:

    ```
    $NX_ROOT\log\jfedsearch.log
    ```

Create the Federated Search Sources in CA SDM

The CA SDM web UI is loosely coupled with the CAFedSearch Servlet. Configure Search Sources in CA SDM to create a new record.

Follow these steps:

1. Log in to the CA SDM application as Service Desk Administrator.

2. Select **Administration**, **Knowledge**, **Federated Search**, **Search Source** to create a new record that represents a federated search engine.
   The Search Source contains the Name of the Federated Search Source that is displayed to users.

   Note: Code value must match the key value attribute of an entry in the adapters-config.xml.

3. Click Create New to add a Federated Search Source.

4. Enter the following field values:
   Search Source Name
   Specifies a unique name for the search source.
   Code
   Specifies a unique identifier for the search source.
   Record Status
   Specifies the status of the search source. If the search source is inactive, you cannot find information from this source and this source option is not displayed in the Knowledge Search Source page.

5. (If multi-tenancy is enabled) Click Update Tenants and add the tenants.

6. Click Save.
   You added the search source.

Search the Knowledge Solution using the New Custom Search Adapter

Search for knowledge documents and articles in the CA SDM application using the new custom search adapter.

Follow these steps:

1. Log in as a CA SDM Service Desk Administrator.

2. Navigate to **Administration**, **Knowledge**, **Federated Search**, **Search Sources**.

3. Add search source **Code** Key value.

4. Click **Save**.

5. Navigate to **Knowledge Management** using a new or existing ticket.

6. Search for the knowledge source that you have created. Click **Show Filter** to enter the search criteria and click **Search**.
   The search information is displayed.

Modifying the Cross-Origin Resource Sharing (CORS) Filter

The default CORS filter setting allows any server to send requests to Federated Search. We recommend that you restrict this setting to allow incoming requests only from the web interface servers.

Follow these steps:

1. Navigate to the following CA SDM directory on the server where you have installed federated search:

   ```
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF\web.xml
   ```

2. Open the web.xml file and check for:

   ```
   <web-app><filter><init-param><param-name>cors.allowOrigin</param-name>
   ```

3. Update the <param-value> tag with a space-separated list of domains. For example, the base URL address of the servers from which you want to allow incoming requests:

   ```
   <param-value>http://web01:8080 http://web02:8080 http://web03:8080</param-value>
   ```

4. Save the web.xml file. Tomcat is restarted automatically.

5. Test and verify the Federated Search configuration on the web client interface. Ensure that it is functional.

6. For the web interface updates to persist after running the CA SDM Configuration, repeat the same updates to the web.xml.tpl file.

Uninstall the Search Adapter

To uninstall the search adapters, use the fs_search_cli utility command with the - u option. Use the following utility file command:

```
fs_adapters_cli -u -k <key> -b <bean> [-c <filename>]-f <filename>]
```

- **-u**
  Specify the -u option to uninstall the search adapters.
- **-k**
  Specify the key name value that is provided at the time of installation.
- **-b**
  Specify the bean value that is provided at the time of installation.
- **-c**
  Specify the name of the new search adapter configuration xml, if you created any while configuring the search adapters with Utility.
- **-f**
  Gives the Generated output file name at the installation time.

For example, if you want to uninstall the Google search adapter, perform the following steps:

Follow these steps:

1. Run the utility file command with the -u option for uninstalling the Google search adapter:

   ```
   fs_adapters_cli -u -k Google-b GoogleAdapter-f Google.xml
   ```

2. Check and verify that the adapters-config.xml removes registration for Google.

3. Google.xml file is deleted from the following CA SDM directory:

   ```
   $NX_ROOT\samples\cafedsearch
   ```

4. Copy the adapters-config.xml to the following directory:

   ```
   $NX_ROOT\samples\cafedsearch\WEB-INF
   ```

   Delete the google.xml file from this location.

5. Restart the FS Tomcat:

   ```
   pdm_tomcat_nxd  - c STOP  - t FS
   pdm_tomcat_nxd  - c START  - t FS
   ```

6. In the CA SDM UI, verify the Activate Search source entry for this Adapter (Google, in this case).

7. To uninstall other external search adapters, repeat steps 1 through 6.

How to Configure SDK Custom Search Adapters

This article contains the following topics:

Important! CA Federated SDK sample source code is provided to users for creating and deploying alternate custom adapters. However, CA Support does not provide support to write the actual custom code. We do not actively support the creation and deployment of additional adapters beyond the SDK source code samples shipped with CA SDM.

The CA Federated Search SDK architecture is designed for extensibility. The SDK contains all the necessary JAR files to develop a custom adapter. Sample Eclipse projects can be imported, and Ant build targets are also provided to build custom search adapters. The SDK is located in the CA SDM directory:

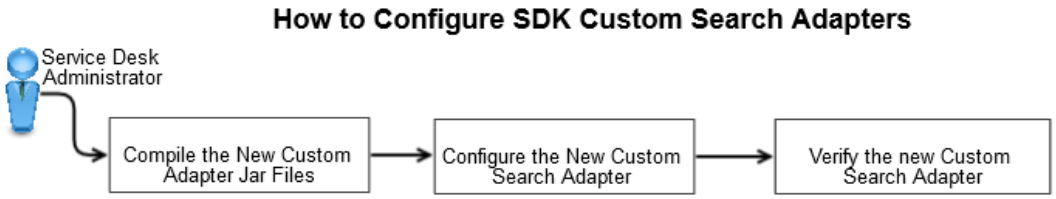
```
$NX_ROOT\samples\sdk\fedsearch\adapters-source.tar.gz
```

The source code of the following adapters can be used to write more custom adapters:

- Google
- CA Open Space
- Microsoft Share Point

> **Note:** Source code for the CAFedSearch servlet, its underlying framework, and the security filter are not provided. No source code is provided for any of the Crawler Surface components.

The SDK component is written in java and is shared as a jar file (cafedsearch-adapter-sdk-1.0.0.jar). The SDK provides a simple interface to enable customers to develop and deploy their own search adapters.



Compile the New Custom Adapter Jar Files

Compile the custom adapter jar files successfully.

Follow these steps:

1. Compile the new custom search adapters. Ensure that you have the following jar files in your Java Classpath:
   - **jsr311-api-1.0.jar**
     This jar file is available in the CA SDM directory:

     ```
     %NX_ROOT%\java\lib\CXF\
     ```

   - **cafedsearch-core.jar**
     This file is available in the directory:

     ```
     %NX_ROOT%\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF\lib
     ```

   - **cafedsearch-adapter-sdk-1.0.0.jar**
     This file is available in the directory:

     ```
     %NX_ROOT%\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF\lib
     ```

- **log4j-1.2.15.jar (optional)**
  This file is available in the directory:

  ```
  %NX_ROOT%\java\lib
  ```

2. Write a new Java Class which extends the SearchAdapter Class and provides an implementation for the abstract method.

   `search`

   The CAFedSearch component invokes and passes search method parameters. These parameters are embedded inside the SearchOptions parameter for each search request from the client.

   Note: Ensure that your implementation is thread safe as the CAFedSearch component maintains only one instance of the Java Class. For each search operation, search method is invoked on the same instance.

3. The SearchOptions parameter for the search method has the following methods:

   - **getSearchTerms()**
     Specifies the method for retrieving the search string.
   - **getStartIndex()**
     Specifies the start index method, the number from which the client wants to search items. Index starts from 1.
   - **getItemsPerPage()**
     Specifies the maximum number of search results that the client expects.

   Note: You can also use other Java Class methods. For example: getUserId()

4. Send the collected information to the external search engine API for retrieving the search results.

   Note: For information about Java Class Methods, see Java Documentation.

5. The search method returns an instance of ResultCollection class. Create an instance of ResultCollection and populate values using the following methods:

- **setSources(String name)**
  Specifies the name of the search adapter. Names are case-sensitive and must match exactly with the name that is provided in the utility configuration file. For convenience, SearchAdapter provides a method getName() which should be used.
  For example:

```
results.setSources(getName());
```

- **setTotalResults (int total)**
  Specifies the total search result count.

- **setStartIndex(int startIndex)**
  Specifies a start index of results. This value is as per results from your search engine.

```
results.setStartIndex(startIndex);
```

6. A collection of ResultItems must be passed to the ResultCollection object by calling the setSearchResultItems method. To add an instance of ResultItem at a time, use the addSearchResultItem() method.

   Note: For more information about ResultCollection Java class, see the Java documentation.

7. The ResultItem class has the following important methods, which must be filled for each search result item (row).

   - **setContentText(String txt)**
     Specifies a method for setting the search result actual content.

   - **setContentHTML(String txt)**
     Specifies a method for setting the HTML (can contain the HTML tags) content. If the search engine gives HTML highlighted, then set the highlighted text using this method.

   Note: If your search engine does not have this feature, you can write a simple Java class method to highlight the text. The CA Open Space adapter has a simple method to bold terms in the search results.
   Note: If the search adapter requires more jar files, modify the build.xml to compile and prepare an adapter jar file. Ant binaries are required to use the build.xml. Use Ant to run the targets in build.xml to compile and make the JAR files Keep the build. xml along with your source (src) folder. The build.properties file is optional. For more information about Ant binaries, see Ant Help.

   The jar file is successfully compiled.

Configure the New Custom Search Adapter with the CAFedSearch Component

Configure the new search custom adapter jar file with the CAFedSearch Component for creating the CA SDM search sources.

Follow these steps:

1. Copy the jar file from the location dist\lib (created in Compile the New Custom Adapter Jar Files (https://wiki.ca.com/display/CASM1401/How+to+Configure+SDK+Custom+Search+Adapters#HowtoConfigureSDKCustomSearchAdapters-CompiletheNewCustomAdapterJarFiles)) to the following CA SDM directory:

   ```
   %NX_ROOT%\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF\lib
   ```

2. Navigate to the following CA SDM directory:

   ```
   $NX_ROOT\sample\cafedsearch\
   ```

Create template xml file for the custom search adapter. For example, the XYZ-tmpl.xml file.

- The template file contains the following contents:

```
<?xml version="1.0" encoding="UTF-8"?>

<beans default-autowire="byName" xsi:schemaLocation="http://www.springframework.org/schema/beans

http://www.springframework.org/schema/beans/spring-beans-2.5.xsd

http://cxf.apache.org/core

http://cxf.apache.org/schemas/core.xsd

http://cxf.apache.org/jaxrs

http://cxf.apache.org/schemas/jaxrs.xsd" xmlns:cxf="http://cxf.apache.org/core"

xmlns:jaxrs="http://cxf.apache.org/jaxrs"

xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

xmlns="http://www.springframework.org/schema/beans">

    <bean autowire="autodetect"

        class=" com.abc.xyz.XYZAdapter "

            id="XYZAdapterConfiguration" scope="singleton">

<property name="username" value="$(xyz_username)"/>

    <property name="password" value="$(xyz_password)"/>

</bean>

<bean autowire="autodetect" class="com.abc.xyz.XYZAdapter" id="XYZSearchAdapter" init-method="init" destroy-method="

destroy" depends-on="XYZAdapterConfiguration">

            <property name="config" ref="OpenSpaceAdapterConfiguration" />

    </bean>

</beans>
```

- You can create property values that are based on the input values provided for the search adapters in step 4.
  Add xyz_username and xyz_password in the adapters.properties file and provide values to the property.

- Run the utility file to generate configuration XML for custom search adapters:

```
fs_adapters_cli -i -k XYZ - b XYZSearchAdapter -t "XYZ-tmpl.xml " -o "xyz.xml
```

- The xyz.xml file is created and registered in the adapters-config.xml file.

- Copy the xyz.xml file and adapters-config.xml to the following CA SDM directory:

```
$NX_ROOT\samples\cafedsearch\WEB-INF
```

- Run the following command to restart Federated Tomcat Services:

```
pdm_tomcat_nxd  - c STOP  - t FS

pdm_tomcat_nxd  - c START  - t FS
```

- Create the federated search sources for the XYZ adapter in the CA SDM UI.
  For more information about federated search sources, see Create the Federated Search Sources in CA SDM (see page 2794).

- In CA SDM, navigate to the **Knowledge Management** Tab. Select the XYZ check box and perform search operations.
  The new custom search adapter is successfully configured with the CAFedSearch component.

Verify the new Custom Search Adapter

Verify the functionality of your new custom search adapter by using the REST client.

Follow these steps:

1. Download the REST client from the Internet:
   https://code.google.com/p/rest-client/ (http://www.code.google.com/p/rest-client/)

2. Launch it using Java (JRE is required).

3. Enter the following URL in the REST client UI:

   ```
   http://sdmhostname:<FS_Tomcat_Port>/cafedsearch/sdm/search?
   q=search&userid=<sdmuserid>&source=<Adapter Name>
   ```

4. Turn off the CA SDM security interceptor. Open the following file for editing and comment out the “<jaxrs:inInterceptors> “ section:

   ```
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF\beans.xml
   ```

> **Note:** Turning off the security filter is not recommended in a production environment. Turn off the Security filter in a test environment for verifying the new custom search adapter functionality.

5. Verify that the new custom search adapter is functioning properly. If search results are not displayed, try reviewing the logs, or increase the log level to Debug.

Call the CAFedSearch Servlet Using REST

The CAFedSearch servlet exposes a RESTful interface where custom search clients, programs, and User Interfaces (UI) can send search requests.

This RESTful interface only accepts the HTTP Collection GET requests following the OpenSearch specification. It provides support for JSON and XML responses. Each request must contain a Service Desk BOPSID token which can be obtained from CA SDM RESTful or SOAP Web Services.

Follow these steps:

1. Obtain a BOPSID token using a CA SDM RESTful Web Service.

2. Get a REST Access Key by sending an HTTP POST request on the rest_access resource along with login credentials.
   You can also obtain a BOPSID token using the REST Access Key by sending an HTTP POST request on the bopsid resource.

3. For the details on sending requests to CA SDM RESTful Web Services, see the sample files in the following CA SDM directory:

   ```
   NX_ROOT\samples\sdk\rest\java
   ```

4. To use the Federated Search API for searching, send an HTTP GET request on the search resource and pass search criteria and BOPSID token through the CA SDMURL.

   ```
   GET
   http://<sdmhostname>:<FS_TOMCAT_PORT>/cafedsearch/sdm/search?
   q=<searchTerms>&source=<adapterName>&BOPSID=<bopsidToken>&userid=<userId>
   ```

   - **searchTerms**
     Specifies a space delimited list of keywords. Must be URL encoded.

   - **adapterName**
     Specifies search engine name as specified in the Search Source record Code field using the adapters configuration utility.

   Other supported arguments are as follows:

   - **index**
     Specifies the first index that is desired in the search results, must be integer > = 1.

   - **page**
     Specifies Indicates the first page that is desired in the search results, must be integer >= 1.

- **size**
  Specifies the number of results per page that is desired by the search client.

- **type**
  Valid values include JSON or XML.

How to Configure the Crawler Surface for SharePoint

This article contains the following topics:

The administrators can configure CA SDM to allow Microsoft SharePoint 2010 and SharePoint 2013 Servers to crawl the Crawler Surface. The Crawler Surface contains a FSCrawl Servlet component that lets you search the CA SDM knowledge solutions and articles.

A crawler is a search engine component that browses the Internet and indexes search terms. The Crawler Surface is a read-only web-based interface to the CA Service Desk Manager application. With this interface, external search engine crawlers can discover information using the Java Server Page (JSP) technology. The Crawler Surface uses the JSP to provide the information in plain text and individual hyperlinks to tickets and knowledge documents.

Note: The CA Service Desk Manager content that is exposed to a crawler can be modified using an XML configuration file. For more information, see Crawler Surface XML Configuration File. (see page 2807)

Complete the Prerequisites

Complete the following prerequisites before you start configuring the Crawler Surface for a Microsoft SharePoint Server:

- To enable Federated Search, select the Configure Federated Search option while installing CA Service Desk Manager.

- Identify a dedicated User ID for accessing the search result information. The User ID controls the information that is present in the Crawler Surface. For multi-tenancy configuration, you can create several user IDs to allow the segregation of tenant information.

Create the CA Service Desk Manager User Crawler Surface

In your CA Service Desk Manager configuration, create user identities to segregate information by tenant.

The process of creating a user ID for the Crawler Surface is the same as creating the CA Service Desk Manager user identities for regular users. Create a contact with Access Type and Role as "Crawler" in the CA Service Desk Manager Application. The Crawler Access Type and Role provide the user with read-only access to the CA Service Desk Manager data. A contact is a person who uses the system regularly, such as an analyst or customer. After you have created the business structure and groups, you can create contacts and can map them to their respective location and organization. You can create contacts using the following ways:

- Create Contacts Manually
- Create Contacts Using the LDAP Database

Configure the Tomcat Remote IP Address Filter

Change the Tomcat Remote IP Address Filter setting to point to the remote system that hosts the SharePoint Server. The IPV4 and IPV6 addresses are supported.

The crawler surface uses the Tomcat Remote IP Address Filter mechanism to access the CA Service Desk Manager information. The Tomcat filter mechanism uses an IP Address pattern (maintained by the CA Service Desk Manager administrator) to match authorized IP addresses. By default, the Remote IP Address filter is configured with the loopback adapter IP address 127.0.0.1. For a secure communication in a production environment, consider using Secure Sockets Layer (SSL) encryption between the crawler and the crawler surface.

Follow these steps:

1. Log in to the following server, depending on your CA Service Desk Manager configuration:
   - Conventional: Primary or Secondary Server
   - Advanced Availability: Application Server
2. Open the web.xml file in the following CA Service Desk Manager directory:

   ```
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\fscrawl\WEB-INF
   ```

3. Save a backup of the web.xml file.
4. Find the <filter-name>Remote Address Filter</filter-name> section. Change the pattern in <param-value> in the <filter>.
   This parameter allows you to specify a range of IP Address patterns and provides access from the remote system hosting the SharePoint server. For more information about the Tomcat Remote IP Address Filter, see the Apache Tomcat documentation.

5. Save the XML file.

6. Restart the Federated Search Tomcat server.
   The Tomcat Remote IP Address Filter value is changed and the Crawler Surface can now be accessed from the remote system.

   Note: Do not access the crawler surface from an unconfigured IP address. You are redirected to the CA Service Desk Manager UI.

7. The Crawler Surface is accessed through a URL like other web application. To validate SharePoint logging, enter the following URL in a browser:

   ```
   http://<sdmhostname>:<FS_TOMCAT_PORT>/fscrawl/index.jsp?farm=<FarmName>
   ```

   Note: All elements of the URL are case-sensitive.

Configure the Crawler Surface User ID

The CA Service Desk Manager information content that is exposed to a crawler surface can be modified using a configuration xml file. External search engine discovers information using the Java Server Page (JSP) technology. The crawler surface user ID controls the information that is present in the Crawler Surface.

To modify the crawler surface, you can configure the crawler surface user ID in the crawler_surface_config.xml file.

Important! Verify the language settings of your browser as Microsoft SharePoint is sensitive to the language used in the search request.

Follow these steps:

1. Log in to the following CA Service Desk Manager server that hosts the Crawler Surface depending on your install configuration:

   - Conventional: Primary or secondary Server
   - Advanced Availability: Application Server

2. Open the crawler_surface_config.xml from the following CA Service Desk Manager directory:

   ```
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\fscrawl\WEB-INF
   ```

3. Save a backup of the crawler_surface_config.xml file.

Important! Make all XML file modifications in a test environment before porting the final changes to a production server.

4. In the original file, locate *<sdm_user>CHANGE_THIS</sdm_user>* under each *<farm>* section and replace *CHANGE_THIS* with the crawler user ID that you created earlier.

5. You can further modify and restrict the XML object attributes depending on your requirements.

Note: For more information, see the Crawler Surface XML Configuration File.

6. Save the XML file.

7. Restart the Federated Search Tomcat server to reload the file.
The Crawler Surface XML file is modified.

Crawler Surface XML Configuration File

The crawler_surface_config.xml file contains the following XML sections.

- **<objects>**
Specifies the information about the objects and attributes that the Crawler Surface exposes for an object. The objects section describes the layout of a detail page for each object type that is exposed to a crawler. This section does not control the selection of individual records. The <objects> section is a collection of <object> sections.
Each object is defined in an <object> section. The default specifications for these objects are provided as:

  - **KD**
  Specifies Knowledge Documents.

  - **chg**
  Specifies Change Orders.

  - **iss**
  Specifies Issues.

  - **in**
  Specifies Incidents.

  - **pr**
  Specifies Problems.

  - **cr**
  Specifies Requests.

The XML file contains the following sections that create the <head> section of a detail page in CA Service Desk Manager:

- **<name>**
  Specify the Majic object name of the exposed object.

- **<note>**
  Specify a location for a short description of the object. This element is only for documentation purposes, and the Crawler Surface ignores this element.

- **<last_mod_dt>**
  Specify the attribute name that stores the last modified date and time. The time and date is exposed to the search engine crawler to allow the search engine to determine whether the record was updated. The search engine crawler skips the crawl when the record is not updated.

- **<title>**
  Specify the attribute that is used for the title of the detail page. The search engines use this element as the title of the document that is returned in search results. This element entry generates an HTML <title> tag in the <head> of the detail page. For a knowledge document, the title defaults to the title of the knowledge document. The summary is used for the title for incidents, problems, requests, change orders, and issues.

- **<meta_data>**
  Specify one or more properties that is exposed as a metadata. A Metadata allows a search engine to store extra characteristics of the document in its index. Metadata is not searched directly but instead is used to filter search results. This section generates HTML <meta> tags in the <head> of the detail page.
  Each entry in the <meta_data> section contains one or more <property> entries. Each <property> element consists of a <name> element and a <content> element.

  - **<name>**
    Specify the name of the metadata property.

  - **<content>**
    Specify the attribute of the object that is used as the value for the metadata.
    Together, each <name> and <content> element pair of a <property> generate an HTML <meta> tag. The search engine crawlers use the following two metadata properties by default:

    - **Description**
      Specify the metadata property of a search engine that stores a short summary of the document.

    - **Author**
      Specify the author of the document.

The CASDMTENANT metadata property is also configured by default for each object. This property is a CA Service Desk Manager specific-metadata property. The Crawler Surface uses this property to expose the Tenant name of the object to the crawler of the search engine. During a Federated Search, the results that are obtained from the search engine are filtered based on this metadata property.

The Crawler Surface XML Configuration file contains the following attributes that are used to create the <body> section of a detail page in CA Service Desk Manager:

- **<additional_attributes_to_index>**
  Indicates a list of attributes from the object that the Crawler Surface exposes. Separate multiple entries with a comma and a space. For example, PROBLEM, RESOLUTION, SD_ASSET_ID.name (http://SD_ASSET_ID.name).

- **<activity_logs>**
  The Crawler Surface displays information from Activity Logs for objects that have activity logs. The <activity_logs> section contains the <object>, <select_criteria>, <rel_attr>, and <attributes> elements.

  - **<object>**
    Specifies the object name that contains the activity log entries for the object. For example:

    - *alg* is the activity log object entry for Incidents, problems, and requests.
    - *chgalg* is the activity log object entry for change orders.
    - *issalg* is the activity log object entry for issues.
    - O_COMMENTS is the activity log object entry for knowledge documents.

- **<select_criteria>**
  Allows you to filter the activity log objects that are exposed. This element is important to increase the relevancy of your search results by decreasing frequently occurring words. For example, the <select_criteria> for chgalg contains the following Magic Where clause:

  ```
  "type IN ('ST', 'UPD_RISK', 'CB', 'RS', 'LOG', 'TR', 'ESC' ,'NF', 'UPD_SCHED')"
  ```

  Includes only activity log entries that allow a user to enter comments and eliminates activity log entries with fixed text like Initial or Attached document.

- **<rel_attr>**
  Specifies how an activity log entry relates to its parent object. The <rel_attr> subsection contains <parent_obj_attr> and <join_attr> elements.

  - **<parent_obj_attr>**
    Indicates an attribute of an activity log that contains an SREL (or foreign key pointer) to the parent object. For example, the change_id is the attribute of activity log object *chgalg*.

  - **<join_attr>**
    Indicates the relational attribute (Rel Attr) of the parent object that is stored in <parent_obj_attr>. You can verify these values by using the following command:

    ```
    bop_sinfo -df chgalg
    ```

  You can verify both of these values by using the bop_sinfo -df chgalg command. The output must show that the value for change_id is *SREL -> chg.id (http://chg.id)* and ISS is *SREL -> iss. persistent_id.*

- **<attachments>**
  The attachments subsection allows you to expose attachments to the crawler so that content can be indexed. The <attachments> section is only allowed for objects that have attachments.

The attachments are handled in a special manner by the Crawler Surface. The Crawler Surface exposes a hyperlink that the crawler follows to download the attachment from CA Service Desk Manager. If an attachment is included in the search results, you can click on the hyperlink to navigate to the parent object.

The <attachments> section contains <object>, <rel_attr>, <attmnt_id>, and <is_parent_updated> elements.

- **<object>**
  This element specifies the Majic object that links the Attachment to its parent object.

- **<rel_attr>**
  This subsection works the same as it does in activity logs. Specifies how the parent object relates to this object which links the parent object to the attachment.

- **<attmnt_id>**
  This element specifies the attribute of this linking object that points to the attachment.

- **<is_parent_updated>**
  Specifies the Crawler Surface on how to expose the last-modified date for the object. For some objects like Knowledge Documents (KDs) when an attachment is added, the last modified date of the Knowledge document is not updated. The last-modified date is important when the search engine is doing an incremental crawl.

- **<configuration_items>**
  Used for objects that contain a list of configuration Items. This section contains the <object>, <rel_attr>, and <attributes> elements.

  - **<object>**
    Works the same as in activity logs and attachments.

  - **<rel_attr>**
    Work the same as they do in activity logs and attachments.

  - **<attributes>**
    This element works the same as in attachments.

- **<multi-farm_datasets>**
  The <multi-farm_datasets> specifies how records are selected. The <multi-farm_datasets> section is a collection of <farm> sections.

- **<farm>**
  Each <farm> section controls the CA Service Desk Manager information that is exposed to a crawler. When a crawler is configured, the <farm> section is specified in the URL. Only the information that is specified in the <farm> section is exposed to the crawler. Each <farm> section contains <name>, <data_sets>, and <sdm_user> elements.<name>.

  Note: This value is case-sensitive.

Configure the SharePoint Crawler

Configure Crawlers to crawl and search for content in SharePoint. The Crawler is a multithreaded application capable of high throughput and can sometimes have a negative impact on the CA Service Desk Manager performance. To improve performance, ensure that you have considered the following factors:

- Limit the number concurrent SharePoint crawle rs accessing the Crawler Surface at any one time.
- Use SharePoint Crawler Impact Rules to throttle the crawlers
- Schedule crawls at off-peak times of the day
- Dedicate an Object Manager <sdm_domsrvr_name> to the Crawler Surface in crawler_surface_config.xml. For more information, see Crawler Surface XML Configuration File (see page 2807).
- For CA Service Desk Manager Advanced Availability, dedicate an entire Application Server to the Crawler Surface.

Follow these steps:

1. Create the Content Source in SharePoint (see page 2811)
2. Create Crawler Rules (see page 2812)
3. Run the Crawler in SharePoint (see page 2813)
4. Configure the Metadata in SharePoint (see page 2814)
5. Verify the Crawler Data in SharePoint (see page 2814)

Create the Content Source in SharePoint

Create Content Sources for identifying the type of content that the SharePoint crawler processes.

Note: The names of SharePoint specific settings can vary depending on the SharePoint version you are using. For more information about creating content sources in SharePoint, see the Microsoft SharePoint Documentation.

Follow these steps:

1. Log in to the MS SharePoint Central Administration console.
2. Click **Manage Services Application**, **Search Service Application**.
3. Click **Content Source** for creating new content Sources:
4. Enter data name for the Content Source in **Name** as CA Service Desk Manager.

5. Set the Content Source Type to Web Sites.

6. Enter the following URL in **Start Address**:

   ```
   http://<sdmhostname>:<FS_TOMCAT_PORT>/fscrawl/listObject.jsp?farm=<Farm Name>
   ```

7. To prevent the crawler from straying away from the Crawler Surface, consider limiting the Page Depth to 2 and the Server Hops to 1. Minimum recommended values to allow crawling of Attachments.

8. Click **Save**.

Create Crawl Rules

The Crawl rules define how the SharePoint Web Crawler Surface URL is crawled. Define the following Crawl Rules:

- A crawl rule that lets SharePoint crawl the Crawler Surface.
- A crawl rule that allows SharePoint to access attachments.

Follow these steps:

1. Log in to the MS SharePoint Central Administration console.

2. Click **Manage Services Application**, **Search Service Application**.

3. Click **Crawler Rule**. Create new Crawler Rule.

4. Enter the following URL in the browser:

   ```
   http:// <sdmhostname>:<FS_Tomcat_Port>/fscrawl/*farm=<farm-name>*
   ```

   Important! The Crawler Surface URL is case-sensitive. SharePoint changes uppercase hostnames to lowercase. For SharePoint 2010, ensure to select the **Match Case** check box.

5. Select '**Include all items in this path**' to configure the crawler.

6. Select '**Crawl complex URLs (URLs that contain a question mark - ?)**'.

7. Select '**Specify a different content access account**'.

8. If you have Disabled the Basic Authentication (see page 2815) in CA Service Desk Manager Crawler Surface;

   a. Select one of the following options:

- (SharePoint 2013), Select the '**Specify a different content access account**' and ' **Anonymous access**' options.
- (SharePoint 2010), Select the default content access account (NT AUTHORITY\NETWORK SERVICE).

b. Save this Crawl rule and skip to step 10 for defining second crawl rule.

9. Enter the CA Service Desk Manager user account name and password for the Crawler Surface.
10. Create a second crawler rule for the CA Service Desk Manager attachments:

    `http://<sdmhostname>:<WEB_TOMCAT_PORT>/CAisd/*`

    Note: <sdmhostname> is the configured host name that is used for downloading the CA Service Desk Manager attachments.

11. Specify the default authentication:

    Note: The Crawler Surface uses Basic Authentication. The CA Service Desk Manager Repository Daemon uses proprietary BOPSID security which is not directly supported by Microsoft SharePoint. Specify any user ID and password or choose Anonymous Access if that option is available in your version of SharePoint.

12. For (SharePoint 2013), select the '**Specify a different content access account**' and ' **Anonymous access**' options or for (SharePoint 2010) select the default content access account (NT AUTHORITY\NETWORK SERVICE).

    The Microsoft SharePoint Crawl rule is created.

Start a Crawl in SharePoint

Start a full or incremental crawl of the content sources in SharePoint to index the search content.

Follow these steps:

1. Navigate to the Microsoft SharePoint Central Administrator page.
2. Click **Manage Services Application**, **Search Service Application**.
3. Click **Content Sources**. Select the that you configured for the SharePoint Crawler Surface.
4. Select **Start Full Crawl** or **Start Incremental Crawl**.
   A full crawl crawls the entire content under a content source. Full crawls take more time and resource to complete than Incremental crawls.

In an incremental crawl, the index remains intact, and the crawler crawls only the content that is added or modified since the last successful crawl. For more information, see the Microsoft SharePoint Documentation.

Configure the Metadata in SharePoint

Note: This topic is applicable to CA Service Desk Manager multi-tenancy environments.

When the crawler encounters a CA Service Desk Manager metadata, it stores the metadata in SharePoint as Crawled properties. These properties are discovered during the initial full crawl of the CA Service Desk Manager Crawler Surface. The SharePoint crawler discovers the metadata and creates the Crawled properties.

The metadata is used to pass extra information to a crawler in the detail pages using the <meta> tag in the <head> section. This information is available for searching and filtering. When CA Service Desk Manager is configured for multi-tenancy, the Crawler Surface exposes only the tenant metadata information.

When you perform a Federated Search, the tenant name is passed to the search engine to filter the results appropriately.

Follow these steps:

1. Log in to the MS SharePoint Central Administration console.
2. Click **Manage Services Application**, **Search Service Application**, **Metadata** (SharePoint 2010), or **Search Schema** (SharePoint 2013).
3. Ensure that the SharePoint crawling is successful on the CA Service Desk Manager data.
4. Click **Managed Properties**.
5. Click **New Managed Property**.
6. Enter **CASDMTENANT**as Property Name.
   CASDMTENANT Indicates the tenant name for the CA Service Desk Manager object. The sub tenant information is not displayed.
7. Select **Text** as **Property Type**.
8. Scroll down. Click **Add a Mapping**.
9. Search for the CASDMTENANT Crawl Property and select it.
10. Click **OK** to save the new Managed Property.
    The metadata in SharePoint is configured.

Verify the Crawler Data in SharePoint

Verify the Crawler data in SharePoint in order to display search results.

Follow these steps:

1. Log in as CA Service Desk Manager Service Desk Administrator.
2. Click the **Knowledge Management** tab for a new or existing ticket.
3. Select **SharePoint Search Source**.
4. Enter the search key. Click **Search**.
   The Crawler displays the search results.

(Optional) Disable Basic Authentication

The Basic authentication authenticates and authorizes the users accessing CA Service Desk Manager content from an HTTP client and provides additional security to the Crawler Surface. However, basic authentication is an overhead for every HTTP request to the Crawler surface and eventually impacts product performance. If you have configured the remote IP address filter on Tomcat to limit the computers that can access CA Service Desk Manager content, you can disable basic authentication.

Follow these steps:

1. Take a backup of web.xml at
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\fscrawl\WEB-INF.
2. Open the file using a text editor.
3. Comment or remove the tags <security-constraint>, <login-config>, <security-role>.
4. Save the file.
5. Restart FS Tomcat.

The basic authentication for Crawler Surface is disabled.

Troubleshooting

The Crawler Surface has the usual array of log files:

1. If you want to enable the debug mode for Federated Search, navigate to the following CA Service Desk Manager directory:

   ```
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\cafedsearch\WEB-INF
   ```

2. Open the log4j.properties file and modify info to debug mode.
3. To enable debug mode for fscrawl, navigate to the following CA Service Desk Manager directory:

   ```
   $NX_ROOT\bopcfg\www\CATALINA_BASE_FS\webapps\fscrawl\WEB-INF
   ```

4. Open the log4j.properties file and modify info to debug mode.
5. To correct the syntax errors that are encountered while configuring the SharePoint crawler surface, open the jfscrawl log file from the CA Service Desk Manager directory:

```
$NX_ROOT\logs directory
```

6. If you locate any syntax errors, correct the XML file and restart the Federated Search Tomcat. The log is located in the CA Service Desk Manager directory:

   ```
   $NX_ROOT\logs\jfscrawl.log
   ```

   For example, if a <meta_data> tag is accidentally corrupted, then the log indicates the following error:

   ```
   08/06 15:43:52.624 [pool-2-thread-1] ERROR FSCrawlApplicationListener 302
   XmlException::Problem loading config_file::C:
   \PROGRA~2\CA\SERVIC~1\bopcfg\www\CATALINA_BASE_FS\webapps\fscrawl\WEB-
   INF\crawler_surface_config.xml:274:8: error: </meta_dataxxxxx> does not close
   tag <meta_data>
   08/06 15:43:52.625 [pool-2-thread-1] ERROR FSCrawlApplicationListener 144
   crawler_surface_config.xml could not be loaded, cannot read.
   ```

7. If there are no syntax errors, the following message is displayed:

   ```
   08/06 15:46:27.924 [pool-2-thread-1] INFO FSCrawlApplicationListener 58 fscrawl
   context had been loaded successfully.
   ```

8. Correct any other errors that do not show up until you try to access CA Service Desk Manager. For example, an unknown attribute xxxxx is requested to be exposed for Incidents in the <additional_attributes_to_index> element of crawler_surface_config.xml. The Crawler Surface application does not detect the error. But, when the Crawler Surface sends the request to the Object Manager, the error is detected and reported in the stdlog.x file as follows:

   ```
   08/06 15:51:23.92 SDMSERVER domsrvr 10860 ERROR domset.c 8049 Unknown attribute
   "xxxxx" requested from domset MLIST_STATIC of factory
   ```

9. Use the bop_sinfo -d command to resolve the error.

10. Modify the crawler_surface_config.xml file.

11. Restart the Federated Search Tomcat.
    The Crawler Surface objects are configured without any errors.

Knowledge Management Reports and Metrics

This article contains the following topics:

You can monitor the efficiency of the knowledge base using the reporting tools that are described in this article. These tools let you view statistics on the usefulness of your documents and their effectiveness in solving problems.

Knowledge Report Card

The Knowledge Report Card displays information about the knowledge contribution from each end user and provides feedback about which knowledge documents are most effective. You can use the information to improve the processes of creating knowledge documents and providing the best support to end users in your environment.

Define Knowledge Report Card Statistics

As an Administrator, you define the schedule at which the product calculates and sends notifications about the Knowledge Report Card. You also define content of Knowledge Report Card notification emails.

Note: Rework versions and retired documents are not presented when the Knowledge Report Card calculation is run.

Follow these steps:

1. Select the **Administration** tab, **Knowledge**, **Knowledge Report Card**.
   The Report Card page opens.

2. Complete the following fields as appropriate.

   - **Last Updated**
     Runs the Report Card calculation.
     Default: Deactivated
     Note: When the calculation is not run, and the statistics to present the data are not collected. The following message appears when the Knowledge Report Card command is specified from the View menu on the Knowledge tab: "Please Run Report Card Calculation."

   - **Schedule**
     Schedules the Report Card.

     - **Report Card Calculation will next run on xxx and will run every xxx**
       Specifies the frequency at which to recalculate the Report Card statistics.

     - **Report Card Email Notifications will be sent on xxx and will be sent every xxx**
       Specifies the frequency at which to send the Report Card notifications.
       Default: Never

     - **Report Card Email Should Display Statistics for the Past xxx**
       Specifies the amount of time for which the Report Card notification contains information. This field is only available when you select a value other than Never from the Report Card Email Notifications will be Sent Every xxx list.
       Default: 365 days

3. Click **Save**.
   The Knowledge Report Card statistics are defined.

Run the Knowledge Report Card

The Knowledge Report Card displays information about the knowledge contribution from each end user and provides feedback about which knowledge documents are most effective. You can use the information to improve the processes of creating knowledge documents and providing the best support to end users in your environment.

Note: After you run the knowledge report card, the analyst will be able to view their knowledge report card statistics.

Follow these steps:

1. Select the **Administration** tab, **Knowledge**, **Knowledge Report Card**.
   The Knowledge Report Card appears.

2. Complete the following fields and click Save.

   - **Last Updated** -- Select the Run Calculation check box.

   - **Schedule** -- Specify a date and time from when CA SDM performs the calculation and runs the Report Card.

Note: For information about using Automated Policies and the Knowledge Report Card, see View Document LifeCycle Policy Reports (see page 2779)

Web-Based Reports for Knowledge Management

CA Business Intelligence installs a set of predefined Knowledge Management reports. These reports are automatically deployed to the CA Business Intelligence after the CA SDM installation.The reports are developed with either BusinessObjects Web Intelligence or Crystal Reports. The authorized users can display reports on the CA SDM Reports Tab.

Role-Based Report Web Forms

If you are an authorized manager or analyst, perform the following:

Follow these steps:

1. Click the Report List icon on the Reports tab to define the report web forms.

2. Additionally, you can click the **Administration**, **Security and Role Management**, **Role Management** to see how Report web forms are managed through the Role List.
   For more information, see Define Role-Based Reports for the Role (see page 3184).

Define Knowledge Report Card Statistics

The Knowledge Report Card provides feedback to analysts and administrators about which knowledge documents are most effective. You can use the provided information to improve the processes of creating knowledge documents and providing the best support to customers.

Note: These statistics are collected only when the Knowledge Report Card calculation service is run, as specified by your Knowledge Management administrator.

As an Analyst, you use the Knowledge Report Card to view statistics about knowledge you submitted and reviewed. These statistics are collected only when the calculation runs, as specified by your Knowledge Management administrator.

Note: The rework versions are not presented when you run the Knowledge Report Card calculation.

Follow these steps:

1. On the Knowledge tab, select View, Knowledge Report Card.

   Note: Access to the Knowledge Report Card tab depends on your role.

   The Knowledge Report Card appears.

2. Complete the following fields as appropriate.

   - **My Documents:** Specifies the number of days on which to recalculate the Report Card statistics.
   - Specifies the section on which to recalculate the Report Card statistics.
   - **My Statistics:** Displays the totals of any documents the analyst has authored as follows:
     - **Submitted** -- Specifies the document totals, regardless of status (Published, Draft, Rework-Draft, Retired).
     - **Published --** Specifies the number of published documents.
     - **Hit --** Specifies the total number of page visits to the knowledge documents.

- **Voted --** Displays the number of votes an individual document has received from its Solution Survey form. You can click the Vote column header to display all documents in descending order, by document votes.

Create a Forum

Forums let you communicate about existing issues. Using the forums, you can share documents globally or among predefined groups that work together in knowledge-sharing and brainstorming over existing challenges. Forums broaden the scope of knowledge contributions by allowing communication on general questions, usability tips, and so on. You can create a forum from the Knowledge tab and from a service desk ticket.

You can create a new forum from the Knowledge tab.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

A forum can be created using the following ways:

- From the Knowledge tab
- From a Knowledge category
- From a Knowledge document
- From a ticket

Follow these steps:

1. Depending on your requirement, perform one of the following actions:
   - From the Knowledge tab, click File, New Forum.
   - From the Knowledge tab, right-click a category, click New Forum.
   - Open a Knowledge Document and click New Forum from the Page Options menu.
   - Click a support ticket (for example, click an incident from My Incidents on the Service Desk tab), Knowledge tab and click New Forum.
2. Specify the title for your post and the question.
3. Click Save.
   The forum is created.
4. (Optional) Click the Attributes tab and select Assignee to assign a contact to the forum during the content approval process task.

Support Automation

This article includes the following topics:

You can implement a support strategy using a combination of processes and tools. CA SDM provides the tools to administer live assistance and develop automated tasks. The application also lets you deliver the tools through various channels.

Use the associated processes to create and maintain an environment that provides the following benefits:

- Reduced average support call duration
- Reduced overall support costs
- Increased resolution rates
- Improved end-user satisfaction

Support Automation Users

System administrators and tenant administrators configure CA SDM contacts, role permissions, access levels, and privacy levels to define user permissions. The users that use Support Automation are as follows:

- **System Administrator**
  Defines system-wide access to add, edit, and modify all Support Automation defaults and functions in the Administration tab. The system administrator sets up tenants and analysts, modifies Support Automation system properties, and performs system password resets.
- **Tenant Administrator**
  Defines administrative rights at the tenant level. The rights do not include granting access to creating or editing other tenants or resetting user passwords. The Service Provider tenant determines permissions.
- **Analyst**
  Defines the rights for users that provide live assistance to end users in your support environment.
- **End User**
  Defines the rights for users that request live assistance from analysts in your support environment, such as employees and customers.

Support Automation Anonymous and Registered Users

The Support Automation server accepts registered or anonymous users, depending on CA SDM permissions. If permitted, the guest user lets anonymous users log in to CA SDM. You can authenticate with the server to gain access to the following tools and services:

- Live Assistance
- Self-Service
- Automated Tasks Editor
- End-User Client

Live Assistance

Live Assistance provides end-user support through tools that enhance remote interaction between analysts and end users. You can use automated, predefined responses to communicate with the end user. You gather detailed information about an end-user computer and act to provide support.

You provide live assistance using the Support Automation Analyst Interface and End-User Client.

Support Automation Analyst Interface

Important! The Support Automation Analyst Interface only runs on Windows. For more information about supported operating systems, see the Supportability Matrix (see page 119).

You can provide Live Assistance to end users by using the Support Automation Analyst Interface. You monitor queues, manage multiple end-user assistance sessions, and interact with end users to resolve their computer problems.

You access Live Assistance from a ticket page, such as an incident, issue or request, or the Support Automation tab. You can also open a CA SDM ticket from Live Assistance.

Important! Analysts without read access to their tenant cannot launch the Support Automation analyst client. A warning message appears in CA SDM, such as from the main Support Automation tab or a ticket.

Use the following tools to provide live assistance to end users in your support environment:

- **Chat**
  Launches instant message to the end user or to use preset text and URLs. If the end user uses the web client, only chat is enabled in a browser. You can request to use the full Support Automation tools by selecting Sessions, Launch Full Tools.

- **Automated Tasks**
  Runs predefined diagnostic or repair scripts on the end-user computer.
  Note: Scripts are created and uploaded from the Automated Task Editor IDE and your administrator configures permissions.

- **File Explorer**
  Browses the files on the end-user computer and lets end users create, modify, rename, or delete files and directories.

- **File Transfer**
  Copies and transfers files and folders to the end-user computer. You can also copy and transfer files from the end-user computer.

- **Remote Registry**
  Performs the following registry management operations:

  - Create, edit, or delete registry records.

  - Export or import registry values from the end-user registry.

- **Screenshot**
  Captures the screenshots of the end-user computer when connection quality is not sufficient for remote control assistance.

- **Remote Control**
  Controls the end-user computer remotely.

- **Remote System Tools**
  Restarts or shuts down the end-user computer.

- **Run Program**
  Launches a program on the end-user computer without using the Remote Control tool.

- **Impersonate**
  Impersonates authentication credentials on the end-user computer, such as a privileged user. Impersonation credentials are configured in System Wide Credentials, Default Credentials.

Note: Your system administrator or tenant administrator can configure access levels, role permissions, and can disable any Live Assistance tools.

End-User Client

The end-user client connects end users to analysts in live assistance sessions. End users chat with analysts in WebChat. When you use the tools in the Support Automation Analyst Interface, the client is launched on the end-user computer. When the client launches, instructions appear for the end user specific to their web browser.

How to Set Up Live Assistance for Analysts

As an administrator, set up the live assistance and manage access levels for tools that the analysts use. You can enable and disable Support Automation tools for specific tenants. If a tool is disabled for a tenant, analysts cannot use that tool in assistance sessions.

Follow these steps:

Set Up Access Level Permission

You can configure the CA SDM roles to have Support Automation permissions. In some cases, there can be a few analysts that are categorized within a single access level. For example, Analyst. In some cases, the tenant administrator sets up many analyst access levels, each with different privileges.

Important! If you are in a multi-tenancy environment, analysts that do not belong to the service provider only have write access to their own tenant and subtenants. You can give the write access to the analyst to other tenants and subtenants. To give the access, update the function access of the accessed tenant and include non-service provider tenants.

The following access levels are available:

- **Analyst**
  Specifies the contact type that provides live assistance to end users in your support environment. Access levels define which queues, automated tasks, and tools are available for the analyst to use.

- **End User**
  Specifies the contact type that receives live assistance from analysts, such as employee and customer.

Create an Analyst Access Level

You can create access levels for Support Automation analysts. Access levels define which queues, automated tasks, and tools analysts use in the Support Automation Analyst Interface.

Follow these steps:

1. Select Security and Role Management, Support Automation Access Control from the Administration tab.
   The Support Automation Access List page appears.

2. Click Create New.
   The Create New Support Automation Access Level page appears.

3. Enter the analyst name, select Analyst from the drop-down list, and click Save.
   The Support Automation Access Level page appears.

4. Click Edit.
   The Update Support Automation Access Level page appears.

5. Assign the appropriate permission, queues, and tools for the access level.

   - Allow to Join Existing Session.

   - Allow to use Automated Tasks IDE.

     Note: In a multi-tenancy environment, enable the Update Public option for analysts that belong to the Service Provider tenant. This setting lets analysts upload task and library content.

6. Click Update Queues on the Queues tab.
   The Queues Assigned Update page appears. You can add the queues this access level can select.

   Note: You can select a queue and click Set Default Queue to set the desired queue as default. The default queue displays at the top of queue list in Support Automation Analyst client. If you do not set a default queue, the queue list displays in alphabetically order.

7. Click Update Tools on the Tools tab to modify the tools this access level can use.
   The Tools Assigned Update page appears.

8. Click Update Target Queues on the Transfer Target Queues tab to modify the queues this access level can select.
   The Target Queues Assigned Update page appears.

9. Click Update Tasks on the Automated Tasks tab to modify the automated tasks this access level can select.
   The Automated Tasks Assigned Update page appears.

10. Click Save.
    The analyst access level is created.

Create an End User Access Level

You can create access levels for end users to determine what actions the analyst can perform on the end-user computer.

Follow these steps:

1. Select Security and Role Management, Support Automation Access Control from the Administration tab.
   The Support Automation Access List page appears.

2. Click Create New.
   The Create New Support Automation Access Level page appears.

3. Enter the end-user name, select End User from the drop-down list, and click Save.
   The Support Automation Access Level Detail page appears.

4. Click Edit to assign the appropriate permissions and security levels.

   - Allow Editing Privacy Level
   - Default Privacy Level
   - End-User Client Launch Mode

   The Update Support Automation Access Level page appears.

5. Click Update Privacy Levels.
   The Privacy Levels Assigned Update page appears.

6. Modify the privacy levels for the end-user access level and click OK.
   The Update Support Automation Access Level page appears.

7. Click Save.
   The end-user access level is created.

Assign an Access Level to a Role

You can assign Support Automation access levels to existing CA SDM roles in your environment.

Follow these steps:

1. Select Security and Role Management, Role Management, Role List from the Administration tab.
   The Role List page appears.

2. Click the role that you want to assign the access level, such as Administrator.
   The Role Detail page appears.

3. Click Edit.
   The Update Role page appears.

4. On the Authorization tab, select the access level that you created from the SA Access drop-down list. Click Save.
   The Role Detail page appears. Verify that the Support Automation access is assigned to the role.

Manage Queues for the Live Assistance Environment

You use queues to route the assistance session requests to the most appropriate analyst. The end user can select a category, or can enter a description of their computer problem. When the ticket (such as an incident) is saved, it routes to the appropriate queue. Consider the following capabilities:

- Set up several queues to sort and track different support requests, according to your business needs. To achieve this capability, you need to assign a queue to an issue and/or incident/ request area.
  For example, you map an issue category to a queue. Once mapped, and the customer selects the same category for a assistance request, he or she is routed to the appropriate queue.
  Similarly, you can map an incident/ request area to a queue. If the end-user has selected the same area, the related assistance session request is routed to this queue.

  Note: If no category is defined to a queue, the assistance session request is routed to the default tenant queue. If the default tenant queue is missing, the default public queue is used.

- You can activate or deactivate queues, specify tenant and analyst permissions.

- Assign a default queue. After the initial product installation, the default queue is named as Support. You can assign only one default queue per tenant.

  Note: If the default tenant queue is missing or unavailable, the default public queue is used.

- Assign the hours of operation for your queues.
  You can manage queues that are based on the availability of users in your support environment. For example, you can enable Support Automation services during business hours.

Important! You can assign workshifts to both your Support Automation hours and individual live assistance queues. Different workshifts assigned to Support Automation hours and individual queues can cause conflicts for analysts and end users in your support environment.

- Establish a session escalation process.

Follow these steps:

1. Select Queues, Queue List from the Support Automation menu.
   The Queue List page appears.

2. Click Create New.

3. On the Create New Queue page, complete the fields. The following fields require explanation:

   - **Default**
     Specifies if this is the default queue. You can route end users to the default queue when their queries do not match the queues in your environment. You must have a default queue.

     Note: You can configure only one default queue per tenant.

   - **Status**
     Specifies the status of the queue.

   - **Default Chat Preset**
     Specifies the default chat preset for the queue.

   - **Queue Hours**

     You can enable Support Automation for each queue for specific hours of the day, to accommodate the working hours of analysts.Use the following procedure:

     - Create a separate schedule for each queue and for all automated support services.

       Note: These settings do not limit self-service functions.

     - Define support hours for the Support Automation server by a global open or close status. An entry for each hour of the week indicates a difference from the global status of the server.

     - The server uses the first entry for each hour that is based on the rules you establish. This action effectively merges the support hour definitions from the parent tenant (or public) settings. This action can have counter-intuitive results if a mix of ‘default-closed’ and ‘default-open’ is used in the hierarchy.

You can set the hours of operation for each queue. The queues determine multi-tenancy, which is optional on the tenant. The queues are automatically filtered from the list page to the tenancy of the currently logged in user.

- **Issue Category**
  Associate an issue category to this queue. When a customer selects the same category for an assistance request, he or she is routed to the appropriate queue.

- **Incident/Request Area**
  Associate an incident/request area to this queue. When a customer selects the same area for an assistance request, he or she is routed to the appropriate queue.

- **Auto Transfer Users**
  Select the check box to automatically transfers the users to another queue if this queue is not addressed within a specified time. You can specify the timeout (in seconds) and the target queue where the users will be transferred.

4. Click Save.

The queue is ready for use.

Note: You can deactivate a queue if it is no longer needed. Edit a queue and select Inactive from the Status drop-down list. You must have at least one queue active. If it is the only queue, you cannot make it inactive.

Manage Activity Notifications for the Live Assistance Environment

As a system administrator, you can modify how end users and analysts track and can receive notifications for activities. For example, a notification can be sent when an analyst ends an assistance session. You create email notifications to alert analysts when they get an assistance session request in their queue. Go to Administration, Notification, Activity Notifications and select a notification.

Select any of the following default notifications (as they are inactive), as appropriate to your environment:

- **Queue Entry Notification**
  Notifies the analyst when an end user joins an assistance session queue and when the session is transferred to another queue.

- **Analyst Notification**
  Notifies the analyst when end-user queue wait time expires. The event of expiration is recognized with a CA SDM Event conditional macro.

- **Invite End User to Assistance Session - Incident**
  Notifies the end user when the analyst invites them to an incident or request assistance session.

- **Invite End User to Assistance Session - Issue**
  Notifies the end user when the analyst invites them to an issue assistance session.

- **Session Ended Notification**
  Notifies the system when the assistance session ends.

> **Note**: When Support Automation is used with an external system such as Star, System_SA_User is set to *Session Ended Notification* by default.

Create Chat Presets for the Live Assistance Environment

You can create common responses to frequently asked questions. Instead of repeatedly typing the same response, you can save a response and can reuse it in other chat sessions. These saved responses are named chat presets. You can send the presets to the end users at the beginning of each session automatically, such as a greeting. You can also automatically populate the presets with information specific to the current session, such as the analyst name.

You can use the following presets types in a live assistance session:

- **Chat Preset**
  Identifies a commonly used text response to an end-user question.

- **URL Preset**
  Identifies a commonly used URL that the end user can access.

You can localize each chat preset. The chat preset is synchronized with the end-user localization so that the end user receives correct localized presets. You can use predefined responses to commonly asked questions and situations.

Create a Chat Preset Group

You can manage chat presets responses into categories (groups).

Follow these steps:

1. Select Tools, Chat Presets, Chat Preset Group List from the Support Automation menu.
   The Chat Preset Group List page appears.

2. Click Create New.
   The Create New Chat Preset Group page appears.

3. Complete the fields and click Save.
   The chat preset group is created.

4. (Optional) Click Edit in List to modify the Chat Preset Group Localizations.
   The Localized Chat Preset Group List page appears.

Create a Text Preset

You can create a chat preset for commonly used text responses to end-user questions. When you save a response, you can use it in other chat sessions.

Follow these steps:

1. Select Tools, Chat Presets, Text Preset List from the Support Automation menu.
   The Chat Text Presets List page appears.

2. Click Create New.
   The Create New Chat Text Preset page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Default Chat Preset for Session Join**
     Select to define as the default Chat Preset for Session Join.

   - **Text Preset Group**
     Specifies the text preset group.

   - **Text Preset Name**
     Specifies the text preset name.

   - **Preset Text**
     Specifies the text of the preset.

   Click Save.
   The text chat preset is created.

4. (Optional) Click Edit to modify the Localized Chat Text Preset List.
   The Update Chat Text Preset page appears.

5. Click a localization link.
   The Chat Text Preset Localization Detail page appears.

6. Click Edit.
   The Update Chat Text Preset Localization page appears.

7. Enter the localized name and text and click Save.
   The localized text for the text chat preset is added.

Create a URL Preset

You can create a URL preset for a commonly used URL that the end user can access. When you save a URL, you can use it in other chat sessions.

Follow these steps:

1. Select Tools, Chat Presets, URL Preset List from the Support Automation menu.
   The Chat URL Preset List page appears.

2. Click Create New.
   The Create New Chat URL Preset page appears.

3. Complete the following fields:

- **Tenant**
  Specifies the tenant.
- **URL Preset Group**
  Specifies the URL preset group.
- **URL Preset Name**
  Specifies the URL preset name.
- **Preset URL**
  Specifies the URL of the preset.
- **URL Title**
  Title for the URL Preset.

Click Save.
The URL chat preset is created.

4. (Optional) Click Edit to modify the Localized URL Chat Preset List.
   The Update Chat URL Preset appears.
5. Click a localization link.
   The Chat URL Preset Localization Detail page appears.
6. Click Edit.
   The Update Chat URL Preset Localization page appears.
7. Enter the localized URL information and click Save.
   The localized URL preset is added.

Manage Automated Tasks for the Live Assistance Environment

Install and configure the Automated Tasks Editor to manage the automated tasks that the Support Automation analysts use. The end user can launch an automated task from a knowledge document and the self-service interface. Whereas an analyst executes an automated task during an assistance session. The automated tasks provide analysts the detailed information about an end-user computer. You create self-service automated tasks that interact with the end user and process their input. These tasks can change the file system, registry, download install software, and so on.

Follow these steps:

1. Install the Automated Tasks Editor.
   Use the following location and launch the installer on the installation media from the DVD:

   ```
   casd.nt\SAScriptWriter
   ```

   Note: In your support environment, you can also copy and deploy the installer to the appropriate users. The Automated Task Editor is installed and creates a shortcut on your desktop.

2. Double-click to open the Automated Tasks Editor.

3. Click Tools, Server.
   The Server Configuration dialog appears.

4. Enter your hostname and port.

5. Enter the user name and password of a user with read or write access to the Automated Task Editor. For example, Support Automation Analyst.

6. Click Test.
   The tool tries to access the Service Desk application using the webservices call. It also verifies whether the application exists and is able to access it using the credentials.

7. Click OK.
   The automated tasks are created and uploaded to your server.
   You can upload public tasks or can assign them to specific tenants and subtenants.

   Important! Only the roles from the Service Provider tenant can upload tasks and libraries to the server. The roles must have the Update Public flag enabled. All task library content and static content are stored as public data.

The setup is completed and analysts can use this setup to help the users. Support Automation analysts monitor and manage multiple end-user requests in the live assistance sessions. Analysts use Support Automation tools to interact with end users and provide the live assistance. Analysts access the interface from a CA SDM ticket or the Support Automation tab and initiate a session.

How to Set Up Support Automation for a Guest User

As a system administrator, you configure your live assistance environment to allow guest users to interact with the analysts. You can configure a guest user for a specific tenant or can make the user available to the entire system. Tenant is a user who uses a single instance of a software application that serves multiple customers in a multi-tenancy environment.

Follow these steps:

- Create an Access Type for a Guest User (see page 2833)
- Assign the Guest Access Type to a Contact (see page 2834)
- Verify the Guest User (see page 2834)

Create an Access Type for a Guest User

To let the guest users log in to CA SDM without an authentication, create a specific access type in CA SDM. If you are the service provider, you can create a guest access type for each tenant in your environment.

Follow these steps:

1. Log in to CA SDM.

2. On the **Administration** tab, click **Security and Role Management**, **Access Types**.
   The **Access Type List** page opens.

3. Click **Create New**.
   The **Create New Access Type** page opens.

4. Complete the fields as appropriate.

5. Click the **Web Authentication** tab. In the **Validation Type** drop-down list, select **Open-always allow access**.

6. Click **Save**.
   The access type for guest users is created.

7. (Optional) Right-click the **Access Type List** page and select **Refresh**.
   The guest access type appears in the list.

Assign the Guest Access Type to a Contact

Assign the guest access type to a contact after you create an access type. This helps the guest user use Support Automation live assistance functionality. The guest user uses a web authentication to log in to CA SDM. A contact is a person who uses the system regularly.

Follow these steps:

1. On the **Administration** tab, click **Security and Role Management**, **Contacts**.
   The **Contact Search** page opens.

2. Click **Create New**.
   The **Create New Contact** page opens.

3. Select a guest from the **Contact Type** drop-down list.

4. (Optional) **Associate the contact with a tenant and make the contact public**. This association helps the contacts to accept an automatic assignment of a request.

5. Click **Save**.
   The guest access type is assigned to the contact.

Verify the Guest User

After you assign the access type, you can verify the existence of the appropriate users in your environment.

Follow these steps:

1. On the **Administration** tab, click **Security and Role Management**, **Contacts**.
   The **Contact Search** page opens.

2. Select the **Contact Type** as **Guest** and **Access Type** that you have assigned.

3. Click **Search**.
   The **Contact List** page opens.

The contact type and the access type are available on the **Contact List** page.

This step completes the Support Automation setup for a guest user.

How to Resolve Tickets Using Live Assistance

An *assistance session* lets a Service Desk Analyst provide Live Assistance to End Users in CA SDM to resolve tickets. You view details in a CA SDM ticket about an End User that has a computer problem. You chat with the user and can invite the user to an assistance session. Use the Support Automation functionality in CA SDM to resolve tickets using Live Assistance. For example, the End User creates a ticket about a network connection problem with a software application.

Follow these steps:

- Initiate the Live Assistance (see page 2835)
- Provide Live Assistance (see page 2837)
- (Optional) View the Session Log (see page 2839)
- (Optional) View or Modify your Support Automation Security Settings (see page 2840)
- End the Assistance Session and Close the Ticket (see page 2840)

Initiate the Live Assistance

A end user can request live assistance (see page 2841) or submit a ticket that describes an issue.

If a ticket is submitted, the analyst can view the ticket details from an email alert or the CA SDM Scoreboard and launch the support automation interface.

Important! By default, Java uses browser network settings. If you are unable to launch the Support Automation Analyst Interface, change your Java Web Start network settings to "Direct connection" by entering java -viewer in the command line.

Note: Ensure that 32-bit Java Runtime Environment (JRE) version 1.6 or later is installed in your environment. The Support Automation Analyst Interface does not support the 64-bit JRE. Safari browser requires the 32-bit JRE 1.6.0_30 or later. The sa_login_session table creates a record every time an analyst launches the Support Automation Analyst Interface and when an end user launches the Web Client.

Follow these steps:

1. As an analyst, log in to CA SDM and select Scoreboard, My Queue.

2. Open a ticket and review the ticket description.

3. (Optional) Add a comment to the ticket asking the user to provide more information about the application they configured incorrectly.

4. On the Support Automation tab of the ticket Detail page, click Invite End User.

   Note: If you are unable to connect to Support Automation, Edit Browser or Java Connection Setting Options (https://wiki.ca.com/display/CASM/.Edit+Browser+or+Java+Connection+Setting+Options+v14.1).

5. Enter a greeting for the End User.

   - Enter text in the chat window.
   - Whisper a message to the end user.
     Whisper messages do not appear in the Session Log. You can only use whisper messages when more than one analyst handles the session.
   - Push a specific URL to the end user.
     The end user can open the link, or you can open their browser, depending on the administrative settings.
   - Send a preset response to commonly asked questions and common situations.
     Presets can consist of text messages or commonly pushed URLs.

   The message appears in the chat window.

6. Click Launch.
   The Support Automation Analyst Interface appears and you wait for the user to join the assistance session.
   As the end user, you will receive an email notification with the URL to join the session. You can click on the URL from the email notification or click the Join Analyst Now link from the Home page to open the session. The Join Session Code is available in the email (URL).
   Important! You cannot run the Support Automation Analyst Interface on multiple computers using the same login credentials. If you try to launch the interface on one computer, the already running instance appears. If you try to launch the interface on a different computer, a warning message appears telling you that someone is already logged in with the same account.

7. Click Application, Configuration to u se the Communication Configuration dialog to configure your local connection settings. The end-user computer inherits these communication settings in their home directory in a configuration file. Configuring communication settings lets you do the following:

   - Restore a connection when the server fails.
   - Specify a unique proxy with an optional password.
   - View and edit your Support Automation communication settings.

Provide Live Assistance

As an analyst, use the Support Automation Analyst Interface to provide Live Assistance by performing different actions on the end-user computer. Perform the actions such as running diagnostic scripts, browsing the file system, and controlling the end-user computer remotely. For example, a chat session determines that you can resolve the application synchronization issue by using Live Assistance. On the Support Automation Analyst Interface, click the appropriate tool tab to resolve the ticket. For example, execute a program on the end-user computer or force the computer to reboot.

The following table lists the assistance that an analyst can provide:

Assistance	How?
Execute an Automated Task You can execute predefined automated tasks that run on end-user computer. The automated tasks let you gather telemetry information, diagnose common problems, and implement resolutions. The administrator sets your automated task permissions. **Note:** You can enable autorun and execute an automated task when the tool launches.	1. Select an automated Task, click Execute. 2. Right-click the task in the Executed Tasks pane and click View Result.
Browse the End-User File System Browse the file system of the user. For example, browse the hard drive to locate a specific file in the installation directory of the software application. The File Transfer tool can transfer files in both directions (see page).	1. Select File Explorer. 2. Browse the file system of the end user in the assistance session. 3. Use the context menu and select Download to transfer files.
Transfer Files with the End User Transfer a file between computers. For example, transfer a file from your computer to replace a corrupt file in the installation directory.	1. Select File Transfer. 2. Select the appropriate transfer

Assistance	How?
	option, such as Local to Remote. 3. Select the appropriate destination folder, such as Desktop. 4. Click Add to Transfer Queue.
Modify the End-User Registry Browse the end-user registry and modify a registry entry. For example, modify registry values for the software application.	1. Select Remote Registry, navigate through the end-user registry. 2. Modify the appropriate registry entries.
Capture a Screenshot Capture a screenshot of the end-user computer. For example, connection issues prevent remote control from operating successfully, so you guide the user after viewing screenshots.	Click Get Screenshot on the Screenshot tab, click the picture.
Impersonate the End User You can impersonate CA SDM login credentials during an assistance session. By default, you perform actions on the end-user computer with the end-user rights. You can also impersonate user rights with more privileges, such as an administrator. Use impersonation when attempting to use tools that require higher privileges. For example, when modifying the end-user registry, or executing an automated task.	1. Click Session, Impersonate. 2. Select an available impersonation login or use other credentials. 3. Click Impersonate.

Assistance	How?
Control the End-User Computer Remotely You can take full control of the end-user computer, to perform diagnostic and repair functions remotely. You can see and manipulate everything on the end-user computer, as if you were physically sitting at the end-user desk. **Note:** Your administrator establishes security levels for end users. **Note:** Remote Control uses Message Routing Servers to locate the best connection. If the connection quality is poor, you can use screenshots and can chat to diagnose the end-user computer. Connection quality symbols appear on the interface. For example, an excellent connection appears as green, yellow as fair, and red as poor.	1. Select Remote Control. 2. Wait for the end user to click Accept. 3. After the user accepts, control the computer and provide live assistance.
Run a Program on the End-User Computer Execute a program on the end-user computer or force the computer to reboot. For example, execute the configuration interface of the software application.	1. Select Remote System Tools. 2. Enter a command to run on the end-user computer. 3. Click Run Program.

(Optional) View the Session Log

As an analyst, all actions that you perform during the assistance session are updated in the Session Log. The actions include chat dialog (excluding Whisper conversations), automated task results, and using a specific Support Automation Analyst Interface tool.

Follow these steps:

1. Open the active session view.
   The Active Session page appears.

2. Select the Session Log from the toolbar or Sessions menu.
   The Session Log page appears.

3. Click Refresh Now.
   The page refreshes.

4. (Optional) Select the Auto-Refreshing check box.

5. (Optional) Click Save Log to Disk.
   The save dialog appears. You can save the session log locally as an HTML file.

(Optional) View or Modify your Support Automation Security Settings

As an end-user, you can view your Support Automation security settings during an assistance session. The administrator sets your privacy levels for when connecting with analysts. Depending on your settings, analyst actions can prompt you for confirmation, such as remote control. Click Security and select the appropriate security level.

Note: Your administrator sets privacy levels, so some options cannot be modified.

End the Assistance Session and Close the Ticket

As an analyst, after you verify that the ticket has been resolved, update the ticket and close the assistance session.

Follow these steps:

1. Click End in the Support Automation Analyst Interface to close the session.
   The user receives an email notification with the session log.

2. (Optional) Click Session Log to view chat logs and Support Automation tool results.

3. Click the ticket number on the Support Automation Analyst Interface. For example, click Incident 40.
   The Incident 40 Detail page opens in CA SDM.

4. Click Edit.

5. Change the ticket status to SA-Resolved.

6. Click Save and Close.
   The Activity Log for the ticket is saved and the Live Assistance process is complete.

Edit Browser or Java Connection Setting Options

Edit the browser or Java connection setting options if the Support Automation Analyst Interface is unable to connect to the server. The issue occurs when the browser of the analyst is not configured for your environment and the browser fails to launch Live Assistance. You can edit the analyst connection settings from a browser or the Java Control Panel.

Follow these steps:

1. Open any web browser. Click **Tools**, **Internet Options**.

2. Configure the appropriate connection settings, such as a direct connection or proxy server.

3. To configure connection options in the Java Control Panel, enter the following command to open the Java Control Panel:

   ```
   javaws –viewer
   ```

4. On the General tab, click **Network Settings**.
   Configure the appropriate settings, such as a direct connection or proxy server.

Request Live Assistance

You can chat with an analyst to discuss your CA SDM ticket or whenever you need live assistance. The analyst works to diagnose and fix your computer problem.

Follow these steps:

1. Click Live Chat in the Customer Service/Request Support section of your home page.
   The Support Automation Live Chat Launch page appears.

2. Complete the appropriate fields, such as Incident area (employees), Issue category (customers), and description.

3. Click Continue.
   The console displays your position in the help queue.
   The end-user client appears, and you can chat with the analyst.

4. If you are in a non-Windows environment, WebChat appears.
   Your administrator can also enable or disable the end-user client in Windows. If your ticket is not resolved by using WebChat, CA SDM launches the end-user client on your computer. The end-user client lets the analyst perform privileged actions on your computer. Your administrator can enable or disable this option

Important! If you lose connection to an active assistance session, you can rejoin the session in the end user client by double-clicking the temporary shortcut that appears on your desktop. You do not have to log in to CA SDM again.

Note: When the Support Automation end-user client is launched, an executable is downloaded to launch the program. The end user starts it manually, however for security reasons there is a limited time to launch the executable. After the time expires, an error message appears on the end-user computer when they try to start the launcher executable.

Manage Existing Live Assistance Session

Contents

Join Existing Assistance Session

You can join an existing assistance session as a consultant when another analyst invites you to the session.

Follow these steps:

1. Perform *any* of the following tasks:

   - Accept the invitation from another analyst.
     The assistance session appears.

   - Click **Queues** in the Support Automation Analyst Interface.
     Select a handled session.
     Click **Join Queued** User Sessions.

2. Proceed to provide live assistance to the end user.
   You help the other analyst complete the assistance session or they transfer it for you to control.

Invite Another Analyst to the Assistance Session

You can invite another analyst to help you in your assistance session. The invited analyst can perform the same support functions as you, and can take control over the session, if necessary.

Follow these steps:

1. Click I**nvite Analyst** from the active sessions page.
   The list of available analysts appears.

2. Select an analyst from the list, click **Add Analyst**.
   Messages appear indicating the submitted and accepted invite.
   The other analyst joins the assistance session.

Transfer the Assistance Session to Another Analyst

You can transfer an assistance session to another analyst.

Follow these steps:

1. Click Sessions, Transfer Session from the toolbar or the Transfer to Queue button in an active assistance session.
   The list of queues that are available for session transfer appear.

2. Select the appropriate queue and click OK.
   The assistance session transfers to another queue, where another analyst handles it.

Create a Ticket from the Support Automation Analyst Interface

You can create a CA SDM ticket from the Support Automation Analyst Interface, such as an incident.

Follow these steps:

1. Open an active assistance session.
   The active session appears.

2. Provide live assistance to the end user.

3. Select a template, such as *SA-Open* or *SA-Resolved,* from the Status drop-down list.
   CA SDM creates the ticket when you close the assistance session by selecting a status.

> **Note:** Your administrator configures the ticket status types available in Live Assistance.

Associate an Assistance Session with an Existing Ticket

You can associate an assistance session with an existing CA SDM ticket. You can also link multiple assistance sessions to a single ticket.

Follow these steps:

1. Open an assistance session from the queue.
   The assistance session begins.

2. Click Incident, Associate with Existing from the Sessions menu.

> **Note:** The administrator configures the ticket type that you see in the file menu.

3. Enter the ticket number, click OK.
   The CA SDM ticket page appears.

Administering Support Automation

Contents

Update a Support Automation Property

You can modify many of the ways in which Support Automation handles activities to differ from the default installation. You can use the property list settings to modify Support Automation behavior. For example, you can enable or disable some of the following Support Automation properties:

- Display the live chat link to employees and customers on the home page.
- Display the link that lets employees and customers join assistance sessions from the home page.
- Create a CA SDM incident when the end user disconnects while waiting to be served on a Support Automation queue.

You do not have to restart CA SDM after changing the Support Automation properties. However, some properties do require launching the Support Automation client or logging in to CA SDM. The Global properties cannot be tenanted and require restarting CA SDM.

Note: System properties are tenant optional. If a tenant has not defined its properties, Support Automation uses the public (shared) settings. The product installation creates the default public properties.

You can configure the Support Automation properties in the Property List node under Support Automation in the Administrator tab. Select and edti the property. The following properties are available:

Support Automation Properties	Description
system.art.fe.shownetworkdrives	Defines if network drives are displayed in File Explorer. This option is set to True by default, which allows the analyst to see the end-users network drives.
system.chat.agent.msg.color	Specifies the color of the analyst message in the Chat window.
system.chat.agent.showWhisperDialog	Displays the Whisper tab to analysts. When set to False, the whisper tab is removed.
system.chat.agent.url.color	Specifies the color of an analysts URL push in the Chat window, and by default is set to dark blue.

Support Automation Properties	Description
system.chat.agent.whisper.color	Specifies the color of the analyst whisper message in the Chat window and by default is set to blue.
system.chat.autoopen.pushed.urls	Automatically opens the end-users Internet Explorer with the pushed URL sent by the analyst. When you set this feature to False, it does not open the end-users Internet Explorer with the pushed URL. However, the pushed URL is shown in the Chat window and the end user can click it.
system.chat.cust.msg.color	Specifies the color of the end-users chat messages in the Chat window and is set to black by default.
system.chat.logging.removeCreditCards	Specifies that any credit card numbers in chat logs are cleared when they are written to the session log.
system.chat.notifyClientWhenConsultantJoins	Specifies the end user is notified when consulting analysts join or leave an Assistance Session.
system.chat.presets.hideUnusedLocalizations	Displays only the localized presets per the language of the end-user session.
system.chat.showChatPresets	Specifies the chat presets that can be selected in Chat.
system.chat.showTimestamps	Specifies a timestamp with each chat message received.
system.consult.restrictToSameRole	Displays the analysts having at least one Access Control in common with the consulting analyst when in consult.
system.customer.createRejoinLink	Set to False by default. When set to True, it creates a rejoin link on the end-users desktop in case of disconnection from the analyst.

Support Automation Properties	Description
system.customer.view.live.log	Allows the end user to view the Live Log for activities that are performed during their session. If the key is set to False, it removes the Live Log button from the end-users Assistance Session window.
system.log.consulting.inhibitCustomerNotification	Logs in the end-user Live Log when a consulting analyst joins or leaves an Assistance Session. When set to True, the end-user Live Log does not show that a consulting analyst has joined the Assistance Session.
system.security.forceFIPSCompliance	Forces the encryption to use FIPS Compliant libraries. This option requires a client-side download of 3.2 MB in addition to normal downloads.
system.security.prompt.autoallow	Indicates whether the end-user executable automatically allows the requested action to occur after the prompt timeout expires.
system.security.prompt.timeout	Specifies the duration of the countdown on the end-user security prompt.
system.selfServe.maxScriptsAllowed	Specifies the maximum number of scripts an end user can execute before they are offered Live Automation.
system.selfServe.maxSessionTimeAllowed	Specifies the maximum time (in minutes) a Self-Service Automation session can run.
system.sharing.countdown	Specifies the countdown that end users see before giving permission to the analyst to share a desktop.
system.sharing.countdown.defaultAction	Declines desktop sharing when the countdown has reached zero. If this key is set to True, desktop sharing initiates after the countdown has reached zero.
system.sharing.default.color	Sets the default color quality when the Remote Control starts.
system.sharing.drs.mainserver.	Specifies the main server is a Message Routing Server. Setting this value to false off-loads MRS traffic (remote control, and so on) from the main server. It also improves performance for some larger deployments, depending on system configuration and

Support Automation Properties	Description
enabled (Global Property)	usage patterns. Ensure that an MRS equivalent to the main server has been configured before you enable this setting. If it is not configure, you may experience a drop in remote control performance. **Note:** The Global properties cannot be tenanted and cannot require a CA SDM restart.
system. sharing. takecontrol. default	Gives the control of the mouse and keyboard to the analyst when sharing the desktop. The end user can enable or disable this check box whenever desktop sharing is requested.
system. sharing. takecontrol. prompt	Prompts the end user when the analyst tries to take control of the mouse and keyboard. If this key is set to False, the message is disabled and the end user is not prompted.
system. SDM. HomePage. LiveChat. Link	Enables or disables the link for live chat from the CA SDM Employee and Customer home page.
system. SDM. HomePage. JoinSession. Link	Enables or disables the link for joining a session from the CA SDM Employee and Customer home page.
system.use. WebChat	Specifies to use the Web Client instead of the End-User Client.
system. SDM. create. abandon. Incident	Enables or disables the option of creating a CA SDM Incident when the end user disconnects while waiting to be served on a Support Automation queue.
system. SDM. analyst.JRE. Location	Specifies the URL of the JRE installation page.
system. dataRoutin gServers	Enables or disables the Message Routing Server option.

Create a Privacy Level

Privacy levels determine the actions that are allowed to be performed on different end users to protect user privacy. Privacy levels are associated with Support Automation Access Control. Three default permissions exist: High, Medium, and Low, but more can be defined if necessary. You can add, update, and delete the privacy levels that are available to the end user.

You can set the privacy level name and its description. You can define permissions for specified tools (File explorer, Remote registry, Run program) that are enabled for this privacy level.

Follow these steps:

1. Select Settings, Privacy Levels from the Support Automation menu.
   The Privacy Levels List page appears.

2. Click Create new.
   The Create New Privacy Level page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Privacy Level Name**
     Specifies the privacy level name.

   - **Privacy Level**
     Specifies the privacy level.

   - **Privacy Level Description**
     Describes the privacy level.

4. (Optional) You can define permissions for specified tools (File explorer, Remote registry, Run program) that are enabled for this privacy level. When an analyst is assigned this privacy level, these tools are available for use. On the Permissions tab, select the Function name and click Yes or No from the drop-down list.

5. (Optional) You can modify the privacy level name and its description. You can also define which functions are enabled for this privacy level. On the Localization tab, select the Localization name to modify the name and description.

6. Click Save.
   The privacy level is created.

Create a Request/Incident Template Association

You can specify which Request/Incident ticket templates are available for the Analyst interface. You can also set the template as default or inactive.

Follow these steps:

1. Select Service Desk Integration, Request/Incident Templates Association from the Support Automation menu.
   The Request/Incident Templates Association List page appears.

2. Click Create New.
   The Create New Request Template Association page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Name**
     Specifies the template name.

   - **Set Ticket Status to**
     Specifies the ticket status that is set for the association.

   - **Default**
     Specifies if the template is the default template.

   - **Active**
     Specifies if the template is active.

   Click Save.
   The request template is created.

Create an Issue Template Association

You can specify which Issue ticket templates are available for the Analyst UI. You can also set the template as default or inactive.

Follow these steps:

1. Select Service Desk Integration, Issue Templates Association from the Support Automation menu.
   The Issue Templates Association List page appears.

2. Click Create New.
   The Create New Issue Template Association page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Name**
     Specifies the template name.

   - **Set Ticket Status to**
     Specifies the ticket status to set for the association.

- **Default**
  Specifies if the template is the default template.

- **Active**
  Specifies if the template is active.

Click Save.
The issue template is created.

Create a Support Automation Hour Configuration

You can set Support Automation to operate at specific hours or to operate always. You manage these hours of operation that is based on the needs of end users in your support environment. The end users cannot access Support Automation functionality when operation hours are over. You can make quick changes to several workshifts in a single step.

Important! You can assign workshifts to both your Support Automation hours and individual live assistance queues. Different workshifts that are assigned to Support Automation hours and individual queues can cause conflicts for analysts and end users in your support environment.

Each tenant can have one active configuration. A newly created configuration is active until another active configuration is defined.

Follow these steps:

1. Select Settings, Support Automation Hours from the Support Automation menu.
   The Support Automation Hours page appears.

2. Click Create New.
   The Create New Support Automation Hours page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Label**
     Specifies the name that displays.

   - **Workshift**
     Specifies the hours.

4. Click Save.

The hours of operation are saved.

Create a Queue Summary

Queue summaries enable the support automation analyst to view the end-user information (for example, language) before starting a live chat. An administrator can configure the type of information that can be displayed from CA SDM. The Queue Summaries are public. You can add a queue summary for a specific tenant. If you want to select more than one queue summary, define the order in which they are supposed to appear.

Follow these steps:

1. Select Queues, Queue Summary from the Support Automation menu.
   The Queue Summary Fields List page appears.

2. Click Create New.
   The Add New Queue Summary Field page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant for the queue.

   - **Field**
     Specifies the field name.

   - **Order**
     Specifies the order that you want the field to display.

4. Click Save.
   The queue summary is created. For example, if the administrator has selected IP Address, Language, Questions, and Status, then the analyst will see the information (under End Users in Queue) on the analyst console.

Support Automation Connectivity

The analyst and end user never communicate directly with each other. You do not require a direct peer-to-peer connectivity between the two users. Data transfer is routed through the server, verifying that you can communicate even when the end-user computers are behind firewalls.

You can connect to end-user computers using the following connections:

- **Socket**
  Using a socket connection is the best way for you to connect. The socket connections are the fastest and the most efficient, with the least overhead, and minimal latency.

- **HTTP (or HTTPS)**
  Using an HTTP connection is better than a direct socket connection, because corporate firewalls can block direct socket connections. The HTTP connections generate a significant amount of network traffic overhead, when compared to direct socket connections. The number of simultaneous sessions is lower when the connections to the server are over HTTP. This happens due to the overhead and processing on the server,

- **Proxy**
  Socket Proxy is a mode of operation for the Support Automation server to off-load some of the CPU-intensive operations. For example, encryption or decryption from the main server, and a server component that can go into the DMZ within the logical network topology.

Typically, you attempt to connect through the direct socket connection first. If the direct socket connection fails, then connect through HTTP. However, you can specify custom connection settings on the client computer to alter this sequence.

How to Overcome Server Load

In large deployments, high server load can degrade the application performance. For this reason, you can off-load some of the processing to one or more Socket Proxy servers as follows:

- Offload encryption and decryption of the incoming and outgoing data for all analysts or clients. The clients must connect either through Direct Socket or through HTTP.
- Offload the processing of HTTP traffic from and to those clients connecting through HTTP to the Socket Proxy.

Use Socket Proxy Within DMZ

In some network environments, allowing direct socket access to the application servers that run Support Automation can be considered a security risk. In such environments, you can use Socket Proxy within the DMZ. Using Socket Proxy in this scenario offloads some of the processing from the main server. The Socket Proxy works as follows:

1. On the configured external port, the Socket Proxy listens for incoming connections from analysts or end users.
2. The Socket Proxy establishes a peer connection to the main server on the configured internal port for every connection. These two connections are named the end-user connection and the server connection, respectively.
3. The end-user connections are encrypted and the Socket Proxy encrypts or decrypts data coming in or going out. The server connection is not encrypted.
4. For each incoming data-packet, the protocol structure is verified and a checksum value is validated. This happens before the data is passed on to the main server through the server connection.
5. The main server off-loads the encryption and decryption processing.
6. The Socket Proxy closes the matching peer connection once the end user or server connection closes.

Create a Message Routing Server

Use Message Routing Servers (MRS) to manage multiple Remote Control servers, based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions. When you enable MRS, the analyst interface and end-user client connect to the analysts preferred (local) server for sharing. If the connection is unsuccessful, the sharing session falls back to the main default server. The Live Log records which MRS you use during the assistance session.

You can create, search for, update, remove, enable, or disable a message routing server object.

Note: To use this option, the *system.dataRoutingServers* system property must be enabled in the Property List.

Follow these steps:

1. Select Settings, Message Routing Servers from the Support Automation menu.
   The Message Routing Servers List page appears.

2. Click Create New.
   The Create New Message Routing Server page appears.

3. Complete the following fields:

   - **Active**
     Specifies that the message routing server is active. When you enable the MRS, the analyst interface and end-user agent connect to the analysts preferred (local) server for sharing.

   - **Label**
     Specifies the name of the message routing server.

   - **Socket Server Host**
     Specifies the host for the socket server.

   - **Socket Server Port**
     Specifies the port for the socket server.

   - **HTTP Connection URL**
     Specifies the URL for the HTTP connection.

4. Click Save.
   The new Message Routing Server is saved.

Update a Support Automation Property

You can modify many of the ways in which Support Automation handles activities to differ from the default installation. You can use the property list settings to modify Support Automation behavior. For example, you can enable or disable some of the following Support Automation properties:

- Display the live chat link to employees and customers on the home page.

- Display the link that lets employees and customers join assistance sessions from the home page.
- Create a CA SDM incident when the end user disconnects while waiting to be served on a Support Automation queue.

You do not have to restart CA SDM after changing the Support Automation properties. However, some properties do require launching the Support Automation client or logging in to CA SDM. The Global properties cannot be tenanted and require restarting CA SDM.

Note: System properties are tenant optional. If a tenant has not defined its properties, Support Automation uses the public (shared) settings. The product installation creates the default public properties.

You can configure the Support Automation properties in the Property List node under Support Automation in the Administrator tab. Select and edti the property. The following properties are available:

Support Automation Properties	Description
system.art.fe.shownetworkdrives	Defines if network drives are displayed in File Explorer. This option is set to True by default, which allows the analyst to see the end-users network drives.
system.chat.agent.msg.color	Specifies the color of the analyst message in the Chat window.
system.chat.agent.showWhisperDialog	Displays the Whisper tab to analysts. When set to False, the whisper tab is removed.
system.chat.agent.url.color	Specifies the color of an analysts URL push in the Chat window, and by default is set to dark blue.
system.chat.agent.whisper.color	Specifies the color of the analyst whisper message in the Chat window and by default is set to blue.
system.chat.autoopen.pushed.urls	Automatically opens the end-users Internet Explorer with the pushed URL sent by the analyst. When you set this feature to False, it does not open the end-users Internet Explorer with the pushed URL. However, the pushed URL is shown in the Chat window and the end user can click it.
system.chat.cust.msg.color	Specifies the color of the end-users chat messages in the Chat window and is set to black by default.

Support Automation Properties	Description
system.chat.logging.removeCreditCards	Specifies that any credit card numbers in chat logs are cleared when they are written to the session log.
system.chat.notifyClientWhenConsultantJoins	Specifies the end user is notified when consulting analysts join or leave an Assistance Session.
system.chat.presets.hideUnusedLocalizations	Displays only the localized presets per the language of the end-user session.
system.chat.showChatPresets	Specifies the chat presets that can be selected in Chat.
system.chat.showTimestamps	Specifies a timestamp with each chat message received.
system.consult.restrictToSameRole	Displays the analysts having at least one Access Control in common with the consulting analyst when in consult.
system.customer.createRejoinLink	Set to False by default. When set to True, it creates a rejoin link on the end-users desktop in case of disconnection from the analyst.
system.customer.view.live.log	Allows the end user to view the Live Log for activities that are performed during their session. If the key is set to False, it removes the Live Log button from the end-users Assistance Session window.
system.log.consulting.inhibitCustomerNotification	Logs in the end-user Live Log when a consulting analyst joins or leaves an Assistance Session. When set to True, the end-user Live Log does not show that a consulting analyst has joined the Assistance Session.
system.security.forceFIPSCompliance	Forces the encryption to use FIPS Compliant libraries. This option requires a client-side download of 3.2 MB in addition to normal downloads.

Support Automation Properties	Description
system.security.prompt.autoallow	Indicates whether the end-user executable automatically allows the requested action to occur after the prompt timeout expires.
system.security.prompt.timeout	Specifies the duration of the countdown on the end-user security prompt.
system.selfServe.maxScriptsAllowed	Specifies the maximum number of scripts an end user can execute before they are offered Live Automation.
system.selfServe.maxSessionTimeAllowed	Specifies the maximum time (in minutes) a Self-Service Automation session can run.
system.sharing.countdown	Specifies the countdown that end users see before giving permission to the analyst to share a desktop.
system.sharing.countdown.defaultAction	Declines desktop sharing when the countdown has reached zero. If this key is set to True, desktop sharing initiates after the countdown has reached zero.
system.sharing.default.color	Sets the default color quality when the Remote Control starts.
system.sharing.drs.mainserver.enabled (Global Property)	Specifies the main server is a Message Routing Server. Setting this value to false off-loads MRS traffic (remote control, and so on) from the main server. It also improves performance for some larger deployments, depending on system configuration and usage patterns. Ensure that an MRS equivalent to the main server has been configured before you enable this setting. If it is not configure, you may experience a drop in remote control performance. **Note:** The Global properties cannot be tenanted and cannot require a CA SDM restart.
system.sharing.takecontrol.default	Gives the control of the mouse and keyboard to the analyst when sharing the desktop. The end user can enable or disable this check box whenever desktop sharing is requested.

Support Automation Properties	Description
system.sharing.takecontrol.prompt	Prompts the end user when the analyst tries to take control of the mouse and keyboard. If this key is set to False, the message is disabled and the end user is not prompted.
system.SDM.HomePage.LiveChat.Link	Enables or disables the link for live chat from the CA SDM Employee and Customer home page.
system.SDM.HomePage.JoinSession.Link	Enables or disables the link for joining a session from the CA SDM Employee and Customer home page.
system.use.WebChat	Specifies to use the Web Client instead of the End-User Client.
system.SDM.create.abandon.Incident	Enables or disables the option of creating a CA SDM Incident when the end user disconnects while waiting to be served on a Support Automation queue.
system.SDM.analyst.JRE.Location	Specifies the URL of the JRE installation page.
system.dataRoutingServers	Enables or disables the Message Routing Server option.

Create a Privacy Level

Privacy levels determine the actions that are allowed to be performed on different end users to protect user privacy. Privacy levels are associated with Support Automation Access Control. Three default permissions exist: High, Medium, and Low, but more can be defined if necessary. You can add, update, and delete the privacy levels that are available to the end user.

You can set the privacy level name and its description. You can define permissions for specified tools (File explorer, Remote registry, Run program) that are enabled for this privacy level.

Follow these steps:

1. Select Settings, Privacy Levels from the Support Automation menu.
   The Privacy Levels List page appears.

2. Click Create new.
   The Create New Privacy Level page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Privacy Level Name**
     Specifies the privacy level name.

   - **Privacy Level**
     Specifies the privacy level.

   - **Privacy Level Description**
     Describes the privacy level.

4. (Optional) You can define permissions for specified tools (File explorer, Remote registry, Run program) that are enabled for this privacy level. When an analyst is assigned this privacy level, these tools are available for use. On the Permissions tab, select the Function name and click Yes or No from the drop-down list.

5. (Optional) You can modify the privacy level name and its description. You can also define which functions are enabled for this privacy level. On the Localization tab, select the Localization name to modify the name and description.

6. Click Save.
   The privacy level is created.

Integrate with Support Automation Tickets

Contents

You can integrate Support Automation tickets with CA SDM by specifying which ticket templates are available for the Analyst Interface. You can select the ticket templates for Incident/Requests and Issue ticket types.

You can define if the template is default or active. When you create a ticket template, you can select from existing CA SDM templates. The default template must be active.

You can have only one ticket template as a default per tenant.

Create a Request/Incident Template Association

You can specify which Request/Incident ticket templates are available for the Analyst UI. You can also set the template as default or inactive.

Follow these steps:

1. Select Service Desk Integration, Request/Incident Templates Association from the Support Automation menu.
   The Request/Incident Templates Association List page appears.

2. Click Create New.
   The Create New Request Template Association page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Name**
     Specifies the template name.

   - **Set Ticket Status to**
     Specifies the ticket status that is set for the association.

   - **Default**
     Specifies if the template is the default template.

   - **Active**
     Specifies if the template is active.

   Click Save.
   The request template is created.

Create an Issue Template Association

You can specify which Issue ticket templates are available for the Analyst UI. You can also set the template as default or inactive.

Follow these steps:

1. Select Service Desk Integration, Issue Templates Association from the Support Automation menu.
   The Issue Templates Association List page appears.

2. Click Create New.
   The Create New Issue Template Association page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Name**
     Specifies the template name.

   - **Set Ticket Status to**
     Specifies the ticket status to set for the association.

   - **Default**
     Specifies if the template is the default template.

- **Active**
  Specifies if the template is active.

Click Save.
The issue template is created.

Create a Support Automation Hour Configuration

You can set Support Automation to operate at specific hours or to operate always. You manage these hours of operation that is based on the needs of end users in your support environment. The end users cannot access Support Automation functionality when operation hours are over. You can make quick changes to several workshifts in a single step.

Important! You can assign workshifts to both your Support Automation hours and individual live assistance queues. Different workshifts that are assigned to Support Automation hours and individual queues can cause conflicts for analysts and end users in your support environment.

Each tenant can have one active configuration. A newly created configuration is active until another active configuration is defined.

Follow these steps:

1. Select Settings, Support Automation Hours from the Support Automation menu.
   The Support Automation Hours page appears.

2. Click Create New.
   The Create New Support Automation Hours page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Label**
     Specifies the name that displays.

   - **Workshift**
     Specifies the hours.

   Click Save.
   The hours of operation are saved.

Create Queue Summary

Queue summaries enable the support automation analyst to view the end-user information (for example, language) before starting a live chat. An administrator can configure the type of information that can be displayed from CA SDM. The Queue Summaries are public. You can add a queue summary for a specific tenant. If you want to select more than one queue summary, define the order in which they are supposed to appear.

Follow these steps:

1. Select Queues, Queue Summary from the Support Automation menu.
   The Queue Summary Fields List page appears.

2. Click Create New.
   The Add New Queue Summary Field page appears.

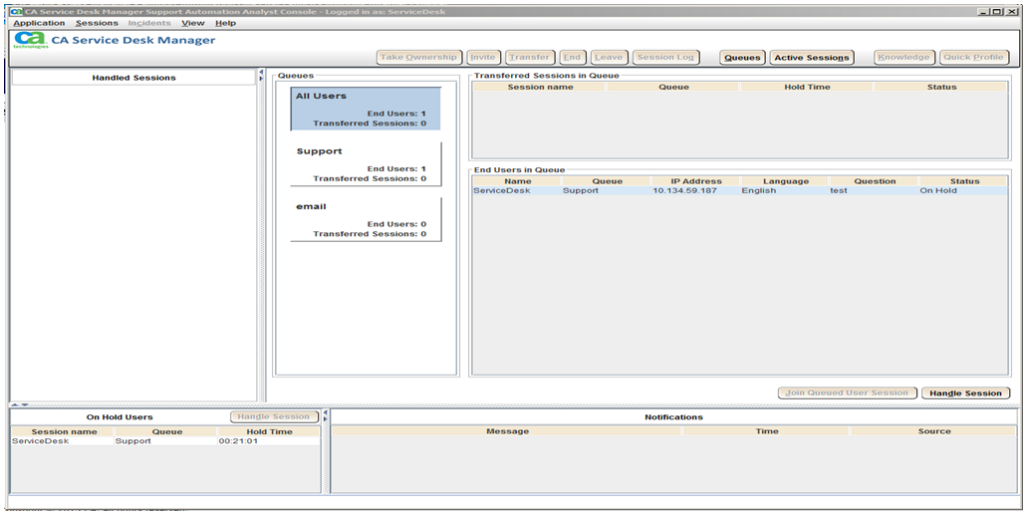
3. Complete the following fields:

   - **Tenant**
     Specifies the tenant for the queue.

   - **Field**
     Specifies the field name.

   - **Order**
     Specifies the order that you want the field to display.

   Click Save.
   The queue summary is created. For example, if the administrator has selected IP Address, Language, Questions, and Status, then the analyst will see the information (under End Users in Queue) on the analyst console, as displayed in the following diagram:



Queue Summaries

Manage Connnectivity

Support Automation Connectivity

The analyst and end user never communicate directly with each other. You do not require a direct peer-to-peer connectivity between the two users. Data transfer is routed through the server, verifying that you can communicate even when the end-user computers are behind firewalls.

You can connect to end-user computers using the following connections:

- **Socket**
  Using a socket connection is the best way for you to connect. The socket connections are the fastest and the most efficient, with the least overhead, and minimal latency.

- **HTTP (or HTTPS)**
  Using an HTTP connection is better than a direct socket connection, because corporate firewalls can block direct socket connections. The HTTP connections generate a significant amount of network traffic overhead, when compared to direct socket connections. The number of simultaneous sessions is lower when the connections to the server are over HTTP. This happens due to the overhead and processing on the server,

- **Proxy**
  Socket Proxy is a mode of operation for the Support Automation server to off-load some of the CPU-intensive operations. For example, encryption or decryption from the main server, and a server component that can go into the DMZ within the logical network topology.

Typically, you attempt to connect through the direct socket connection first. If the direct socket connection fails, then connect through HTTP. However, you can specify custom connection settings on the client computer to alter this sequence.

How to Overcome Server Load

In large deployments, high server load can degrade the application performance. For this reason, you can off-load some of the processing to one or more Socket Proxy servers as follows:

- Offload encryption and decryption of the incoming and outgoing data for all analysts or clients. The clients must connect either through Direct Socket or through HTTP.

- Offload the processing of HTTP traffic from and to those clients connecting through HTTP to the Socket Proxy.

Use Socket Proxy Within DMZ

In some network environments, allowing direct socket access to the application servers that run Support Automation can be considered a security risk. In such environments, you can use Socket Proxy within the DMZ. Using Socket Proxy in this scenario offloads some of the processing from the main server. The Socket Proxy works as follows:

1. On the configured external port, the Socket Proxy listens for incoming connections from analysts or end users.

2. The Socket Proxy establishes a peer connection to the main server on the configured internal port for every connection. These two connections are named the end-user connection and the server connection, respectively.

3. The end-user connections are encrypted and the Socket Proxy encrypts or decrypts data coming in or going out. The server connection is not encrypted.

4. For each incoming data-packet, the protocol structure is verified and a checksum value is validated. This happens before the data is passed on to the main server through the server connection.

5. The main server off-loads the encryption and decryption processing.

6. The Socket Proxy closes the matching peer connection once the end user or server connection closes.

Create a Message Routing Server

Use Message Routing Servers (MRS) to manage multiple Remote Control servers, based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions. When you enable MRS, the analyst interface and end-user client connect to the analysts preferred (local) server for sharing. If the connection is unsuccessful, the sharing session falls back to the main default server. The Live Log records which MRS you use during the assistance session.

You can create, search for, update, remove, enable, or disable a message routing server object.

Note: To use this option, the *system.dataRoutingServers* system property must be enabled in the Property List.

Follow these steps:

1. Select Settings, Message Routing Servers from the Support Automation menu.
   The Message Routing Servers List page appears.

2. Click Create New.
   The Create New Message Routing Server page appears.

3. Complete the following fields:

   - **Active**
     Specifies that the message routing server is active. When you enable the MRS, the analyst interface and end-user agent connect to the analysts preferred (local) server for sharing.

   - **Label**
     Specifies the name of the message routing server.

   - **Socket Server Host**
     Specifies the host for the socket server.

- **Socket Server Port**
  Specifies the port for the socket server.

- **HTTP Connection URL**
  Specifies the URL for the HTTP connection.

Click Save.
The new Message Routing Server is saved.

Support Automation User Administration

This article contains the following topics:

System administrators and tenant administrators configure CA SDM contacts, role permissions, access levels, and privacy levels to define user permissions. The users that use Support Automation are as follows:

- **System Administrator**
  Defines system-wide access to add, edit, and modify all Support Automation defaults and functions in the Administration tab. The system administrator sets up tenants and analysts, modifies Support Automation system properties, and performs system password resets.

- **Tenant Administrator**
  Defines administrative rights at the tenant level. The rights do not include granting access to creating or editing other tenants or resetting user passwords. The Service Provider tenant determines permissions.

- **Analyst**
  Defines the rights for users that provide live assistance to end users in your support environment.

- **End User**
  Defines the rights for users that request live assistance from analysts in your support environment, such as employees and customers.

Support Automation Anonymous and Registered Users

The Support Automation server accepts registered or anonymous users, depending on CA SDM permissions. If permitted, the guest user lets anonymous users log in to CA SDM. You can authenticate with the server to gain access to the following tools and services:

- Live Assistance
- Self-Service
- Automated Tasks Editor
- End-User Client

Support Automation Access Level Administration

You manage Support Automation access levels and assign them to CA SDM roles in your support environment. Support environments vary in size and structure, so your implementation of access levels can vary.

In some cases, there can be a few analysts that are categorized within a single access level. For example, Analyst. In some cases, the tenant administrator sets up many analyst access levels, each with different privileges.

Important! If you are in a multi-tenancy environment, analysts that do not belong to the service provider only have write access to their own tenant and subtenants. You can give the write access to the analyst to other tenants and subtenants. To give the access, update the function access of the accessed tenant and include non-service provider tenants.

The following access levels are available:

- **Analyst**
  Specifies the contact type that provides live assistance to end users in your support environment. Access levels define which queues, automated tasks, and tools are available for the analyst to use.

- **End User**
  Specifies the contact type that receives live assistance from analysts, such as employee and customer.

You manage Support Automation access levels from the Administration tab. For more information about Support Automation access levels, see the Support Automation Access Control (see page 2864) article.

Support Automation Queue Administration

This article contains the following topics:

You use queues to route assistance session requests to the most appropriate analyst. The end user can select a category, or can enter a description of their computer problem. The ticket (such an as incident) is then routed to the appropriate queue.

After the initial product installation, the default queue is named Support. You can set up several queues to sort and track different support requests, according to your business needs. You can assign only one default queue per tenant. If a default is not set or it is unavailable, the public default queue is used. You set the working hours per queue.

The system automatically determines where to place the end user by mapping queues to incident areas. If mapped, and the end user selects a category, the end user is routed to the appropriate queue. The search capabilities are applied to the description of an incident or issue category to identify relevant queues. The end user is routed to the best matched queue.

You can perform the following queue management activities:

- Add (define) uniquely named queues to sort and differentiate between support requests.
- Specify the hours of operation for each queue.
- Deactivate a queue that is no longer needed.
- Assign a default queue for support requests to enter when no Issue category or Incident/Request Area is selected.
- Establish a session escalation process.

The Queue list page displays a list of queues containing information about each queue. You can manipulate the queue details.

Queue Management

You configure queues to help end users receive the appropriate live assistance from analysts. You manage queues to improve how end users are routed to assistance sessions as follows:

- Customize the queues for analysts and tenants in your live assistance environment.
  You can activate or deactivate queues and specify tenant and analyst permissions.
- Assign a default queue.
  You can route end users to the default queue when their queries do not match the queues in your environment. You can also customize queues for tenants in your environment.

  Note: If the default tenant queue is missing or unavailable, the public queue is used.

- Assign the hours of operation for your queues.
  You can manage queues that are based on the availability of users in your support environment. For example, you can enable Support Automation services during business hours.

  - **Important!** You can assign workshifts to both your Support Automation hours and individual live assistance queues. Different workshifts assigned to Support Automation hours and individual queues can cause conflicts for analysts and end users in your support environment.

Create a Queue

You can add or define a uniquely named queue to sort and differentiate between support requests.

Follow these steps:

1. Select Queues, Queue List from the Support Automation menu.
   The Queue List page appears.

2. Click Create New.
   The Create New Queue page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant for the queue.

   - **Queue Name**
     Specifies the queue name.

   - **End User Display Name**
     Specifies the name that displays for the end user.

   - **Default**
     Specifies if the queue is the default queue.

   - **Status**
     Specifies the status of the queue.

   - **Default Chat Preset**
     Specifies the default chat preset for the queue.

   - **Queue Hours**
     Specifies the queue hours.

   - **Issue Category**
     Specifies the Issue Category that is associated with this queue.

   - **Incident/Request Area**
     Specifies the Inciedent/request Area that is associated with this queue.

   - **Auto Transfer Users**
     Transfers the users to this queue automatically.

   Click Save.
   The queue is created.

Search for a Queue

You can search for queues by Name, Customer display name, and Status fields. You can view and edit queue details using the links on queue names.

Follow these steps:

1. Select Queues, Queue List from the Support Automation menu.
   The Queue List page appears.

2. Click Show Filter.

3. Complete the fields and click Search.
   The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Set Queue Hours of Operation

You can enable Support Automation for each queue for specific hours of the day, to accommodate the working hours of analysts.

Use the following procedure:

- Create a separate schedule for each queue and for all automated support services.

  Note: These settings do not limit self-service functions.

- Define support hours for the Support Automation server by a global open or close status. An entry for each hour of the week indicates a difference from the global status of the server.

- The server uses the first entry for each hour that is based on the rules you establish.
  This action effectively merges the support hour definitions from the parent tenant (or public) settings. This action can have counter-intuitive results if a mix of 'default-closed' and 'default-open' is used in the hierarchy.

You can set the hours of operation for each queue. The queues determine multi-tenancy, which is optional on the tenant. The queues are automatically filtered from the list page to the tenancy of the currently logged in user.

Follow these steps:

1. Select Queues, Queue List from the Support Automation menu.
   The Queue List page appears.

2. Click a queue.
   The Queue Detail page appears.

3. Click Edit to modify to the settings.
   The Update Queue page appears.

4. Click Queue Hours.
   The Workshift Search page appears.

5. Complete the information and click Save.
   The hours of operation are saved.

Deactivate a Queue

You can deactivate a queue that is no longer needed. You must have at least one queue active. If it is the only queue, you cannot make it inactive.

Follow these steps:

1. Select Queues, Queue List from the Support Automation menu.
   The Queue List page appears.

2. Click a queue.
   The Queue Detail page appears.

3. Click Edit to modify to the settings.
   The Update Queue page appears.

4. Select Inactive from the Status drop-down list and click Save.
   The queue is deactivated.

Assign a Default Queue

You can route end users to the default queue when their queries do not match the queues in your environment. You must have a default queue.

Note: You can configure only one default queue per tenant.

Follow these steps: Select Queues, Queue List from the Support Automation menu.

1. The Queue List page appears.

2. Click a queue.
   The Queue Detail page appears.

3. Click Edit to modify to the settings.
   The Update Queue page appears.

4. Select the Default check box and click Save.
   The queue is set as default.

Establish an Auto Transfer Process

You can establish an auto transfer process for each queue.

Follow these steps:

1. Select Queues, Queue List from the Support Automation menu.
   The Queue List page appears.

2. Click a queue.
   The Queue Detail page appears.

3. Click Edit to modify to the settings.
   The Update Queue page appears.

4. Complete the following fields:

   - **Issue Category**
     Specifies the Issue Category that is associated with this queue.

   - **Auto Transfer Users**
     Transfers the users to this queue automatically.

   Click Save.
   The auto transfer process is saved for the queue.

How to Configure Support Automation Role Permissions

This article contains the following topics:

You can configure the CA SDM roles to have Support Automation permissions. You can set role permissions by configuring Support Automation access levels for analysts and privacy levels for end users. You set role permissions in your live assistance environment as follows:

1. Configure the appropriate access levels for analysts (see page 2870) in your live assistance environment.
   You create access levels to manage permissions for analysts. The permissions could be enabling or disabling specific Support Automation Analyst Interface tools.

2. Configure the appropriate privacy levels for end users (see page 2872) in your live assistance environment.
   You create privacy levels to manage end-user access levels in your system.

3. Assign (see page 2872) access levels to roles.
   You assign end-user privacy levels and analyst access levels to roles in your environment.

For more information about Support Automation access levels for analysts and security levels for end users, see the Support Automation Access Control topic.

Create an Analyst Access Level

You can create access levels for Support Automation analysts. Access levels define which queues, automated tasks, and tools analysts use in the Support Automation Analyst Interface.

To create an analyst access level:

1. Select Security and Role Management, Support Automation Access Control from the Administration tab.
   The Support Automation Access List page appears.

2. Click Create New.
   The Create New Support Automation Access Level page appears.

3. Enter the analyst name, select Analyst from the drop-down list, and click Save.
   The Support Automation Access Level page appears.

4. Click Edit.
   The Update Support Automation Access Level page appears.

5. Assign the appropriate permission, queues, and tools for the access level.

   - Allow to Join Existing Session.

   - Allow to use Automated Tasks IDE.

   Note: In a multi-tenancy environment, enable the Update Public option for analysts that belong to the Service Provider tenant. This setting lets analysts upload task and library content.

6. Click Update Queues on the Queues tab.
   The Queues Assigned Update page appears. You can add the queues this access level can select.

   Note: You can select a queue and click Set Default Queue to set the desired queue as default. The default queue displays at the top of queue list in Support Automation Analyst client. If you do not set a default queue, the queue list displays in alphabetically order.

7. Click Update Tools on the Tools tab to modify the tools this access level can use.
   The Tools Assigned Update page appears.

8. Click Update Target Queues on the Transfer Target Queues tab to modify the queues this access level can select.
   The Target Queues Assigned Update page appears.

9. Click Update Tasks on the Automated Tasks tab to modify the automated tasks this access level can select.
   The Automated Tasks Assigned Update page appears.

10. Click Save.
    The analyst access level is created.

Create an End User Access Level

You can create access levels for end users to determine what actions the analyst can perform on the end-user computer.

To create an end-user access level:

1. Select Security and Role Management, Support Automation Access Control from the Administration tab.
   The Support Automation Access List page appears.

2. Click Create New.
   The Create New Support Automation Access Level page appears.

3. Enter the end-user name, select End User from the drop-down list, and click Save.
   The Support Automation Access Level Detail page appears.

4. Click Edit to assign the appropriate permissions and security levels.

   - Allow Editing Privacy Level
   - Default Privacy Level
   - End-User Client Launch Mode

   The Update Support Automation Access Level page appears.

5. Click Update Privacy Levels.
   The Privacy Levels Assigned Update page appears.

6. Modify the privacy levels for the end-user access level and click OK.
   The Update Support Automation Access Level page appears.

7. Click Save.
   The end-user access level is created.

Assign an Access Level to a Role

You can assign Support Automation access levels to existing CA SDM roles in your environment.

Follow these steps:

1. Select Security and Role Management, Role Management, Role List from the Administration tab.
   The Role List page appears.

2. Click the role that you want to assign the access level, such as Administrator.
   The Role Detail page appears.

3. Click Edit.
   The Update Role page appears.

4. On the Authorization tab, select the access level that you created from the SA Access drop-down list. Click Save.
   The Role Detail page appears. Verify that the Support Automation access is assigned to the role.

Session Log Administration

This article contains the following topics:

The session log lets you view all actions that the analyst performed during an assistance session. The actions include the tools that are used and chat details, but exclude whispers. You can print or Email the session log to the end user. The end users can also view and save the log, but they cannot modify the log.

View the Session Log

All actions that you perform during the assistance session are updated in the Session Log. The actions include chat dialog, automated task results, and using a specific Support Automation Analyst Interface tool. The Whisper conversations are not included in the log.

Follow these steps:

1. Open the active session view.
   The Active Session page appears.

2. Select the Session Log from the toolbar or Sessions menu.
   The Session Log page appears.

3. Click Refresh Now.
   The page refreshes.

4. (Optional) Select the Auto-Refreshing check box.

5. (Optional) Click Save Log to Disk.
   The save dialog appears. You can save the session log locally as an HTML file.

Support Automation Activity Notification Administration

You can use activity notifications to manage Support Automation activities. You can modify how end users, analysts, and administrators can track and receive notifications when an activity occurs. For example, you can modify the notification for the end of an assistance session.

Configure any of the following default notifications, as appropriate to your environment:

- **Queue Entry Notification**
  Notifies the analyst when an end user joins an assistance session queue.
  Notifies the analyst when the assistance session is transferred to another queue.

- **Analyst Notification**
  Notifies the analyst when end-user queue wait time expires. The event of expiration is recognized with a CA SDM Event conditional macro.

- **Invite End User to Assistance Session - Incident**
  Notifies the end user when the analyst invites them to an assistance session from an incident or request.

- **Invite End User to Assistance Session - Issue**
  Notifies the end user when the analyst invites them to an assistance session from an issue.

- **Session Ended Notification**
  Notifies the system when the assistance session ends.

Note: When using Support Automation functionality with an external system such as Star, System_SA_User is set to *Session Ended Notification*.

Message Routing Servers

This article contains the following topics:

Use Message Routing Servers (MRS) to manage multiple Remote Control severs, based on the geographical location of the local server. Using MRS helps improve performance during assistance sessions. When you enable MRS, the analyst interface and end-user client connect to the analysts preferred (local) server for sharing. If the connection is unsuccessful, the sharing session falls back to the main default server. The Live Log records which MRS you use during the assistance session.

You can create, search for, update, remove, enable, or disable a message routing server object.

Note: To use this option, the *system.dataRoutingServers* system property must be enabled in the Property List.

Create a Message Routing Server

You can create a message routing server to improve the performance of remote control during assistance sessions.

Follow these steps:

1. Select Settings, Message Routing Servers from the Support Automation menu.
   The Message Routing Servers List page appears.

2. Click Create New.
   The Create New Message Routing Server page appears.

3. Complete the following fields:

   - **Active**
     Specifies that the message routing server is active.

   - **Label**
     Specifies the name of the message routing server.

   - **Socket Server Host**
     Specifies the host for the socket server.

   - **Socket Server Port**
     Specifies the port for the socket server.

   - **HTTP Connection URL**
     Specifies the URL for the HTTP connection.

   Click Save.
   The new Message Routing Server is saved.

Search for a Message Routing Server

You can search for a message routing server to improve the performance of remote control during assistance sessions.

Follow these steps:

1. Select Settings, Message Routing Servers from the Support Automation menu.
   The Message Routing Servers List page appears.

2. Click Show Filter.

3. Complete the fields and click Search.
   The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Enable a Message Routing Server

After you create a Message Routing Server (MRS), you can enable it. When you enable the MRS, the analyst interface and end-user agent connect to the analysts preferred (local) server for sharing.

Follow these steps:

1. Select Settings, Message Routing Servers from the Support Automation menu.
   The Message Routing Servers List page appears.

2. Click a Message Routing Server.
   The Message Routing Server Detail page appears.

3. Click Edit.
   The Update Message Routing Server page appears.

4. Select the Active check box and click Save.
   The Message Routing Server is enabled.

Customizing Live Assitance Pages

This section contains the following articles:

Create a Branding

You can modify the header and footer of end-user facing pages, such as self-serve. You can change HTML code of the header and footer and can modify the location of the CSS file.

You can view a list of branding records, one for each tenant at maximum. Tenants can create their own branding. If branding is not defined for a tenant, they use the default system settings. You can also enable localization of branding and view a list of all localized branding for enabled localizations.

Important! Branding modifications from CA Support Automation r6.0 SR1 eFix5 do not migrate to CA SDM automatically. We recommend that you review the modified branding to verify that it corresponds to the CA SDM branding. If necessary, copy and paste the Header, Footer, and CSS URL data of each division to the corresponding tenant (or public) in CA SDM. This helps in migrating the branding data.

Follow these steps:

1. Select Adaptations, Branding from the Support Automation menu.
   The Branding List page appears.

2. Click Create New.
   The Create New Branding page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant that the branding displays for.

   - **Localization**
     Specifies the localization language.

- **CSS Location**
  Specifies the location of the CSS file.

- **Header Text**
  Specifies the text that displays for the header.

- **Footer Text**
  Specifies the text that displays for the footer.

Click Save.
The new branding is created.

Localization Administration

This article includes the following topics:

Localization lets you support multiple languages simultaneously on the same install. Multiple languages are supported by translating elements of the application to a particular language. These elements can include system messages, icons, and content. Information is presented in the best form for the end user, no matter their native language.

The localized versions of Support Automation meet the needs of your global environment. Each tenant can handle multiple languages, and the localizations are supported across multiple tenants. Each tenant shares the default system settings with its localization. You can configure what language the end user and analyst use, before launching Live Assistance. The analyst can use a different language than the end user within an assistance session.

You can edit localized text for disclaimers. You cannot create or remove localizations, but you can enable or disable localizations.

Note: The administrator interface is available in the default server localization only.

Localization IDs

Localization IDs are assigned to each localization installed with the software. You are assigned the appropriate localization ID when you log in to CA SDM. All file versions are retrieved using the localization ID. This localization ID determines the following properties:

- The versions of the automated tasks to download. The version is required to get the correct view of the automated task results in the Session Log.

- The version of the chat presets used.
  You can create a translated version of the text for every chat preset, for each of the localizations. The preset tree structure is duplicated for each language that is specified on the system. A default language preset must be created before you can add a localized version. If localized text is not created, the preset tree presents the default server language text.

- The version of the log display templates to use when displaying the Session Log.

- The end-user login pages and static content that are viewed.
  The Web Client is fully localized. The administrator interface is based in the default server language. It supports management of the localization properties that are presented to the end user. The Support Automation Analyst Interface is also in English, but supports chat communications with the end user in any language. You can override all or some of the localization properties available.

Enable or Disable Localizations

You cannot create or remove localizations, you can only enable or disable localizations. The server localization is the default and cannot be disabled. When a tenant is created, the tenant shares localization settings.

Follow these steps:

1. Select Adaptations, Localization Admin from the Support Automation menu.
   The Localization Admin List page appears.

2. Click Edit in List to select a localization name from the list.
   The name is displayed with a drop-down list.

3. Select Yes or No, and click Save.
   The localization is enabled or disabled.

Configure the Page Layout

Contents

When end users log in to Live Assistance from CA SDM, they view a default launch page. Likewise, when they are initially placed on-hold in a queue, they again view a default page.

If no special settings are specified for tenants, they default public settings. You can configure the following public settings for queues that do not have their own specialized settings:

- Wait Page

- End-user Post-Launch Page

- In Session
- Post-Logout Page
- Exit Survey Page

Each page has its own detail page. The detail page comprises a text field for entering the URL and a check box for marking this page as external.

Create a Default Layout Page

The default layout pages are public and not associated with a queue. You can create modified pages to override the default for a queue or a tenant to suit your business requirements.

Follow these steps:

1. Select Adaptations, Page Layout from the Support Automation menu.
   The Page Layout List page appears.

2. Click Create New.
   The Create New Page Layout Configuration page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant that the page displays for.

   - **Page Type**
     Specifies the page type.

   - **Page URL**
     Specifies the location of the page URL.

   - **Queue**
     Specifies the queue that displays the page.

   - **External URL**
     Select to define the URL as external.

   Click Save.
   The default page is created.

Define the Default Wait Page

Initially, the Wait Page advises end users that they are on-hold for the next available analyst. You can modify the Wait Page for a queue or a tenant.

Follow these steps:

1. Select Adaptations, Page Layout from the Support Automation menu.
   The Page Layout List page appears.

2. Click the Wait link.
   The Page Layout Configuration page appears.

3. Click Edit to modify the settings.
   The Update Page Layout Configuration page appears.

4. Modify any of the following fields:

   - **Page URL**
     Specifies the location of the page URL.

   - **External URL**
     Select to define the URL as external.

   Click Save.
   The configuration is saved.

Define the End User Post-Launch Page

The End User Post-Launch Page is displayed to the end users when they log in to Live Assistance and are placed on hold in a queue. This page can be closed after the end user has logged in and the software has been successfully launched. You can modify the End User Post-Launch Page for a queue or a tenant.

Follow these steps:

1. Select Adaptations, Page Layout from the Support Automation menu.
   The Page Layout List page appears.

2. Click the End User Post-Launch link.
   The Page Layout Configuration page appears.

3. Click Edit to modify the settings.
   The Update Page Layout Configuration page appears.

4. Modify any of the following fields:

   - **Page URL**
     Specifies the location of the page URL.

   - **External URL**
     Select to define the URL as external.

   Click Save.
   The configuration is saved.

Define the In Session Page

The In Session Page is the web page that the end user sees when the support session starts. You can modify the Post-Logout Page for a queue or a tenant.

Follow these steps:

1. Select Adaptations, Page Layout from the Support Automation menu.
   The Page Layout List page appears.

2. Click In Session link.
   The Page Layout Configuration page appears.

3. Click Edit to modify the settings.
   The Update Page Layout Configuration page appears.

4. Modify any of the following fields:

   - **Page URL**
     Specifies the location of the page URL.

   - **External URL**
     Select to define the URL as external.

   Click Save.
   The configuration is saved.

Define the Post-Logout Page

The Post-Logout Page is the web page that the end user sees when the support session has concluded. You can modify the Post-Logout Page for a queue or a tenant.

Follow these steps:

1. Select Adaptations, Page Layout from the Support Automation menu.
   The Page Layout List page appears.

2. Click the Post-Logout link.
   The Page Layout Configuration page appears.

3. Click Edit to modify the settings.
   The Update Page Layout Configuration page appears.

4. Modify any of the following fields:

   - **Page URL**
     Specifies the location of the page URL.

   - **External URL**
     Select to define the URL as external.

   Click Save.
   The configuration is saved.

Define the Exit Survey Page

The Exit Survey Page presents a feedback survey to the end user at the conclusion of the session. The survey helps you measure your effectiveness and customer satisfaction. You can modify the Exit Survey Page for a queue or a tenant.

Follow these steps:

1. Select Adaptations, Page Layout from the Support Automation menu.
   The Page Layout List page appears.

2. Click Exit Survey Location.
   The Page Layout Configuration page appears.

3. Click Edit to modify the settings.
   The Update Page Layout Configuration page appears.

4. Modify the configuration and click Save.
   The configuration is saved.

Note: By default, the Exit Survey Page is not displayed at the end of a Live Assistance session. The administrator must define the Exit Survey Page for it to display.

Create a Disclaimer

When end users launch self-service tasks, they are presented disclaimer text that they must agree to before they can continue. You can create, update, and delete the disclaimer business objects.

Follow these steps:

1. Select Tools, Disclaimers from the Support Automation menu.
   The Disclaimer List page appears.

2. Click Create New.
   The Create New Disclaimer page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Disclaimer Name**
     Specifies the name of automated tasks classification.

   - **Disclaimer Text**
     Specifies the text that displays for the disclaimer.

   Click Save.
   The disclaimer is created.

4. (Optional) Click a localization link.
   The Localized Disclaimer Detail page appears.

5. Click Edit.
   The Update Disclaimer page appears.

6. Enter the localized text for the disclaimer and click Save.
   The localized text for the disclaimer is added.

Automated Tasks

Contents

An *automated task* is a collection of steps that define an automated process that the analyst or end user follows. The automated task steps are routines that are written in VBScript or JavaScript. The routines execute specific actions on the analyst or the end-user computer. You can create automated tasks and task steps using the Automated Task Editor. Some of the common routines include gathering telemetry information, diagnosing problems, and implementing resolutions.

When you execute an automated task, the log updates. This log is both linked and accessed from the assistance session log. Entries in the automated task log consist of a number of timestamped text entries. The entries are created by calling Functions.LogMessage() or WScript.Echo().

How to Configure Automated Tasks

You install and configure the Automated Tasks Editor to manage automated tasks that analysts use to provide support for end users. The end user can launch an automated task from a knowledge document and the self-service interface. An analyst can execute an automated task during an assistance session. The automated tasks provide analysts with detailed information about an end-user computer. You create self-service automated tasks that interact with the end user and process their input. These tasks can change the file system, registry, download install software, and so on. You configure automated tasks as follows:

1. Install the Automated Tasks Editor.
   You launch the installer from the following location on the installation media:

   ```
   casd.nt\SAScriptWriter
   ```

   Note: You can also copy the installer and deploy it to the appropriate users in your support environment.

   The Automated Task Editor is installed.

2. Open the Automated Tasks Editor.
   The Automated Tasks Editor installation creates a shortcut on your desktop.

3. Set the following connection parameters:

    a. Click **Tools, Server**.
    The **Server Configuration** dialog appears.

    b. Enter your hostname and port.
    Default Port: 8070

    c. Enter the user name and password of a user with read/write access to the Automated Task Editor. For example, enter the details of a Support Automation Analyst.

    d. Click **Test**.

    e. Click **OK**.

4. Create automated tasks and upload them to your server.
    You can upload public tasks or can assign them to specific tenants and subtenants.

    Important! Only the roles from the Service Provider tenant with the Update Public flag enabled can upload tasks and libraries to the server. All task library content and static content are stored as public data.

How to Implement Automated Tasks

You can use automated tasks to assist end users in your support environment. The automated tasks complete specific actions on the end-user computer, without the analyst or end user having to complete the process. These scripts can help you gather telemetry information, diagnose computer problems, and implement resolutions.

To implement automated tasks, do the following tasks:

1. Identify the opportunities for support automation.
    Identify common problems that end users encounter, and decide that you can automate some solutions to reduce your support costs.

2. Research automation of the potential solutions.
    Research resolutions to common problems and gather data about diagnostic processes you plan to use.

3. Design tasks to automate end-user support.
    Design the end-user experience that you want for each task with the Automated Task Editor.

4. Implement and test the automated tasks.
    Test the automated tasks to verify that they resolve common problems that are encountered in your support environment.

5. Deploy and monitor the automated tasks.
    Deploy the automated tasks to end users in your environment by allowing analysts to use them in assistance sessions. You can attach scripts to knowledge documents that end users can download and use.

Note: In a multi-tenancy environment, enable the Update Public option for analysts that belong to the Service Provider tenant. This setting lets analysts upload task and library content.

Note: CA Technologies can provide training in creating automated tasks and components. The training can include creating automated task step templates and libraries, which you can use in your environment. For more information about developing automated tasks, contact *CA Technologies Services*.

Automated Tasks Administration

You can create automated tasks and can associate them with the server. You need read/write access to all the automated task-related tables to use the Automated Tasks Editor. You can perform user management functions with the application, such as assigning automated tasks to roles and tenants.

Note: Service Provider analysts who have access to multiple tenants can select the tenant context of any task update operation against the server. Service Provider analysts can also assign an automated task as public.

Create an Automated Tasks Classification

You can classify the automated tasks that are displayed to differentiate between the types of automated tasks.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks Classification from the Support Automation menu.
   The Automated Tasks Classification List page appears.

2. Click Create New.
   The Create New Automated Tasks Classification page appears.

3. Complete the fields and click Save.
   The automated tasks classification is added to the list.

Update the Automated Tasks List

You can view the automated tasks that are available for use. You can configure the script to run for Live Assistance or Self-Service. You can also configure the script for the end-users even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.
   The Automated Tasks List page appears.

2. Click an automated task.
   The Automated Task Detail page appears.

3. Complete the following fields:

   - **Classification**
     Specifies the classification or group the automated task belongs to.

   - **Description**
     Displays a description of the automated task.

   - **Disclaimer**
     Specifies the disclaimer that must be agreed to before the script can run.

4. (Optional) Click the Update Permissions button on the Configure script for the Live Assistance tab and select the permissions. Use the arrow buttons to move them from column to column and click OK.

5. (Optional) Select the Impersonate field and complete the Login name, Password, and Domain information about the Impersonation tab.

6. (Optional) On the Support Automation Access Level tab, click Update Tasks to add an access level. Click Edit in List to select the automated script for Auto Run and save.
   The automated task is added to the list.

Specify Default Credentials

Run automated tasks on the end-user computer even if the end user does not have access rights to perform such activities. If the end user does not have administrative rights to view system information, run a restricted automated task. Use the default credentials to gain access.

Follow these steps:

1. Select Tools, Default Credentials from the Support Automation menu.
   The Default Credentials List page appears.

2. Click Create New.
   The Create New Default Credentials page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Label**
     Specifies the name that displays.

- **Domain**
  Specifies the domain.

- **Login**
  Specifies the login name.

- **Password**
  Specifies the password.

- **Confirm Password**
  Specifies the password was typed correctly.

- **Active**
  Specifies the default credentials is active.

Click Save.
Default credentials are saved.

Configure an Automated Task Script

You can view the automated tasks that are available for use. You can configure the script to run for Live Assistance, Self-Service, or on the end-users computer even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.

   The Automated Tasks List page appears.

2. Click an automated task.

   The Automated Task Detail page appears.

3. Click the Update Permissions button on the Configure script for Live Assistance tab.

   The Permissions Assigned Update page appears.

4. Depending on the requirement, perform any of the following actions:

   - Select the permissions and use the arrow buttons to move them from column to column. Click OK.

   - Select the Impersonate field and complete the Login name, Password, and Domain information on the Impersonation tab.

   - Click Support Automation Access Level tab. Click Update Tasks to add an access level. Click Edit in List to select the automated script for Auto Run.

5. Click Save.

   The automated task is configured for Live Assistance.

Automated Task Deployment

This article contains the following topics:

After you author and test an automated task in the Automated Task Editor, you can deploy it to a classification on the CA SDM server. The task can then be used in assistance sessions or self-service. Some settings that are not part of the automated task definition are set when you deploy the task.

You can upload or download automated tasks directly to the server from the Automated Task Editor. You select the appropriate tenant when creating automated task classifications. If you upload scripts, select the classification or tenant for which you have access. Or, you can even set the script as public. You can also import automated tasks from XSDF files and export them to XSDF files.

Note: In a multi-tenancy environment, enable the Update Public option for analysts that belong to the Service Provider tenant. This setting lets analysts upload task and library content.

Upload an Automated Task

You can upload automated tasks that you created in the application. When you select a task, all dependent content automatically uploads, such as libraries and static content.

Follow these steps:

1. Open the Automated Task Editor.
   The Support Automation Task Editor appears.

2. Select the automated task that you want to upload.

3. Select the classification where you want to upload the task.

   Note: A user with right privileges in a multi-tenancy environment can select the appropriate tenant when the automated task is uploaded. Or, can make the task public.

4. On the toolbar, select the Upload Automated Task icon.

The Support Automation Task Editor uploads the task to the server.

Edit an Automated Task

You can download automated tasks from the server and can edit them in the Automated Task Editor. Any content that is newer in the version than the existing content on the server is imported into the database. The content is then made available to administrators of that tenant.

To edit an automated task:

1. Open the Automated Task Editor.
   The Support Automation Task Editor appears.

2. On the toolbar, select the Upload Automated Task icon.
   The Open Automated Task from Server pane appears.

3. Select the automated task that you want to download.

   Note: If you are a privileged user in a multi-tenancy environment, you can edit public or tenant-specific automated tasks.

4. Click Open Task.

The Support Automation Task Editor downloads the task to the client and opens it in the application. The download creates a text file on the computer of the task author that contains the dependent content.

Automated Task Credentials

You can execute an automated task that you need administrative privileges to run, such as performing a software installation. Use the following process to execute such a task:

- Define Default Credentials for the tenant and configure the automated task to use the default credentials in automated task administration.
- Define Default Credentials for the tenant and select that you use the Execute As dialog in the Assistance Session window.
- Define automated task credentials for the task and specify to use the Execute as dialog in the Assistance Session window.
- Specify the credentials in the Execute As dialog in the Assistance Session window.

Role Assignment

You assign the appropriate roles (for example, Analyst, Administrator) to use the automated task. You assign individual automated tasks to selected roles to limit the automated tasks to only those analysts in the assigned role. You can manage the different skill sets or levels of experience within the support organization.

You can manage the roles at a task level, selecting certain commonly executed tasks. The tasks include diagnostics that run automatically when the end user enters a session.

Assign an Access Level to a Role

You can assign Support Automation access levels to existing CA SDM roles in your environment.

Follow these steps:

1. Select Security and Role Management, Role Management, Role List from the Administration tab.
   The Role List page appears.

2. Click the role that you want to assign the access level, such as Administrator.
   The Role Detail page appears.

3. Click Edit.
   The Update Role page appears.

4. On the Authorization tab, select the access level that you created from the SA Access drop-down list. Click Save.
   The Role Detail page appears. Verify that the Support Automation access is assigned to the role.

Support Automation Reports

CA Business Intelligence installs a set of predefined Support Automation reports. CA SDM automatically deploys these reports to the BusinessObjects server during the installation.

The Support Automation Administrator and Support Automation Analyst roles can use Business Intelligence Launch Pad to view detailed and summary information about the following metrics:

- Analyst login metrics
- Assistance Sessions metrics
- Queue entries metrics
- Automated task execution metrics
- Tool usage per ticket category
- Real-time data about end users that are placed in support queues, active assistance sessions, and active (logged-in) analysts.

Employee or Customer Interface

This section contains the following articles:

Search for Existing Solutions

The Home page allows you to search for solutions using keywords. This section allows you to search for a solution using keywords and submit new solutions to the database.

Follow these steps:

1. Type your keyword(s) in the Search for a Solution section and click Go.

2. Click the document that addresses your issue.

3. Choose from the following options:
   Add/Remove Bookmark
   Stores a link to the document in My Bookmarks.
   Subscribe
   Allows you to receive updates if the document is modified.
   Rate & Comment
   Allows you to rate the usefulness of the document, based on the following questions:

   - Did this forum solve your problem?

   - How helpful was this forum?

   Email

   Allows you to email the document.

   New Incident

   Creates a new incident.

   New Incident based on this Document

   Creates a new incident based on the current document.

View Contact Information and Hours of Operation

You can view information about site hours of operation and how to contact your sites. Your administrator provides the content of this page so that you can see the hours of operation of each service desk site in your organization and details about how to contact the appropriate personnel at each site.

Follow these steps:

1. Browse to the Customer Service/Request Support section of your home page.

2. Click Service Desk contact information and hours of operation.

The Contact Information and Hours of Operation page appears.

Automating Support in Your Environment

This article includes the following topics:

You can implement a support strategy using a combination of processes and tools. CA SDM provides the tools to administer live assistance and develop automated tasks. The application also lets you deliver the tools through various channels.

Use the associated processes to create and maintain an environment that provides the following benefits:

- Reduced average support call duration
- Reduced overall support costs
- Increased resolution rates
- Improved end-user satisfaction

Live Assistance

Live Assistance provides end-user support through tools that enhance remote interaction between analysts and end users. You can use automated, predefined responses to communicate with the end user. You gather detailed information about an end-user computer and act to provide support.

You provide live assistance using the following interfaces:

- **Support Automation Analyst Interface**
  Lets the analysts interact with end users and provide support during assistance sessions.
- **End-User Client**
  Lets the end-user chat with the analyst, while the analyst provides support to their computer.

Support Automation Analyst Interface

You can provide Live Assistance to end users by using the Support Automation Analyst Interface. You monitor queues, manage multiple end-user assistance sessions, and interact with end users to resolve their computer problems.

You access Live Assistance from a ticket page, such as an incident, issue or request, or the Support Automation tab. You can also open a CA SDM ticket from Live Assistance.

Important! Analysts without read access to their tenant cannot launch the Support Automation analyst client. A warning message appears in CA SDM, such as from the main Support Automation tab or a ticket.

Use the following tools to provide live assistance to end users in your support environment:

- **Chat**
  Launches instant message to the end user or to use preset text and URLs. If the end user uses the web client, only chat is enabled in a browser. You can request to use the full Support Automation tools by selecting Sessions, Launch Full Tools.

- **Automated Tasks**
  Runs predefined diagnostic or repair scripts on the end-user computer.
  Note: Scripts are created and uploaded from the Automated Task Editor IDE and your administrator configures permissions.

- **File Explorer**
  Browses the files on the end-user computer and lets end users create, modify, rename, or delete files and directories.

- **File Transfer**
  Copies and transfers files and folders to the end-user computer. You can also copy and transfer files from the end-user computer.

- **Remote Registry**
  Performs the following registry management operations:

  - Create, edit, or delete registry records.

  - Export or import registry values from the end-user registry.

- **Screenshot**
  Captures the screenshots of the end-user computer when connection quality is not sufficient for remote control assistance.

- **Remote Control**
  Controls the end-user computer remotely.

- **Remote System Tools**
  Restarts or shuts down the end-user computer.

- **Run Program**
  Launches a program on the end-user computer without using the Remote Control tool.

- **Impersonate**
  Impersonates authentication credentials on the end-user computer, such as a privileged user. Impersonation credentials are configured in System Wide Credentials, Default Credentials.

Note: Your system administrator or tenant administrator can configure access levels, role permissions, and can disable any Live Assistance tools.

Support Automation Analyst Administration

Support Automation analysts monitor and manage multiple end-user requests in live assistance sessions in your environment. Analysts use Support Automation tools to interact with end users and provide live assistance.

Analysts access the interface from a CA SDM ticket, such as an incident, or the Support Automation tab. You can manage access levels to set permissions for tools that the analysts can use. You can enable and disable Support Automation tools for specific tenants. If a tool is disabled for a tenant, analysts cannot use that tool in assistance sessions.

Important! The Support Automation Analyst Interface only runs on Windows. For more information about supported operating systems, see the *Release Notes*.

Support Automation Connectivity

The analyst and end user never communicate directly with each other. You do not require a direct peer-to-peer connectivity between the two users. Data transfer is routed through the server, verifying that you can communicate even when the end-user computers are behind firewalls.

You can connect to end-user computers using the following connections:

- **Socket**
  Using a socket connection is the best way for you to connect. The socket connections are the fastest and the most efficient, with the least overhead, and minimal latency.

- **HTTP (or HTTPS)**
  Using an HTTP connection is better than a direct socket connection, because corporate firewalls can block direct socket connections. The HTTP connections generate a significant amount of network traffic overhead, when compared to direct socket connections. The number of simultaneous sessions is lower when the connections to the server are over HTTP. This happens due to the overhead and processing on the server,

- **Proxy**
  Socket Proxy is a mode of operation for the Support Automation server to off-load some of the CPU-intensive operations. For example, encryption or decryption from the main server, and a server component that can go into the DMZ within the logical network topology.

Typically, you attempt to connect through the direct socket connection first. If the direct socket connection fails, then connect through HTTP. However, you can specify custom connection settings on the client computer to alter this sequence. For more information about configuring communication settings, see the Online Help.

End-User Client

The end-user client connects end users to analysts in live assistance sessions. End users chat with analysts in WebChat. When you use the tools in the Support Automation Analyst Interface, the client is launched on the end-user computer. When the client launches, instructions appear for the end user specific to their web browser.

Server Load

In large deployments, high server load can degrade the application performance. For this reason, you can off-load some of the processing to one or more Socket Proxy servers as follows:

- Offload encryption and decryption of the incoming and outgoing data for all analysts or clients. The clients must connect either through Direct Socket or through HTTP.
- Offload the processing of HTTP traffic from and to those clients connecting through HTTP to the Socket Proxy.

DMZ Server Component

In some network environments, allowing direct socket access to the application servers that run Support Automation can be considered a security risk. In such environments, you can use Socket Proxy within the DMZ. Using Socket Proxy in this scenario offloads some of the processing from the main server.

How Socket Proxy Works

The Socket Proxy works as follows:

1. On the configured external port, the Socket Proxy listens for incoming connections from analysts or end users.
2. The Socket Proxy establishes a peer connection to the main server on the configured internal port, for every connection. These two connections are named the end-user connection and the server connection, respectively.
3. The end-user connections are encrypted and the Socket Proxy encrypts or decrypts data coming in or going out. The server connection is not encrypted.
4. For each incoming data-packet, the protocol structure is verified and a checksum value is validated. This happens before the data is passed on to the main server through the server connection.
5. The main server off-loads the encryption and decryption processing.
6. The Socket Proxy closes the matching peer connection once the end user or server connection closes.

How Live Assistance Works

This article includes the following topics:

How Analysts Launch Live Assistance

As an Analyst, you can launch Live Assistance as follows:

1. Perform *one* of the following tasks:
   - Log in to CA SDM and selects the Support Automation tab.
   - Open a CA SDM ticket and selects the Support Automation tab.
2. if it is not already installed, install the 32-bit Java Runtime Environment (JRE) version 1.6 or later. The Support Automation Analyst Interface does not support the 64-bit JRE.

Note: The Safari browser requires the 32-bit JRE 1.6.0_30 or later. The sa_login_session table creates a record every time an analyst launches the Support Automation Analyst Interface and when an end user launches the Web Client. For more information about the sa_login_session table, see the *sa_login_session Table* topic.

Configure Java Connection Options

Configure Java connection options to resolve an issue where Support Automation Analyst Interface cannot connect to the Support Automation server. The issue occurs when the browser of the analyst is not configured for your environment and the browser fails to launch Live Assistance. You can edit the analyst connection settings from a browser or the Java Control Panel.

Follow these steps:

1. Open your web browser, such as Internet Explorer.
   The browser appears.
2. Click Tools, Internet Options.
   The Internet Options dialog appears.
3. Configure the appropriate connection settings, such as a direct connection or proxy server.

4. Click OK.
   The connection opens are configured.

To configure connection options in the Java Control Panel

1. Open the Java Control Panel with the following command:

   ```
   javaws -viewer
   ```

   The Java Control Panel appears.

2. On the General tab, click Network Settings.
   The Network Settings dialog appears.

3. Configure the appropriate settings, such as a direct connection or proxy server.
   Click OK.
   The connection opens are configured.

How End Users Join Assistance Sessions

An end user requests assistance sessions from the CA SDM home page or by contacting the help desk. The Support Automation analyst invites the end user to a session from the CA SDM ticket.

1. As an end user, do one of the following tasks:

   - Request Live Chat from the CA SDM Home Page.
     The Live Chat Launch page appears asking you for the incident area and description. Click Continue, the session opens, and you are placed in the appropriate queue.

   - Click a link from an email notification and log in to the assistance session. Use the credentials and a session join code that the analyst has provided.
     If you join from the email notification, you bypass the queue.

   - Click Join Analyst Now and provide the session join code to bypass the queue.

     Note: When the Support Automation end-user client is launched, an executable is downloaded to launch the program. The end user starts it manually, however for security reasons there is a limited time to launch the executable. After the time expires, an error message appears on the end-user computer when they try to start the launcher executable.

2. The analyst provides live assistance through chat. You use the web browser to chat with the analyst, or launch the agent executable.

Note: If the analyst cannot resolve the session using WebChat, they can invite the end user from the Analyst Session window. The analyst can use the full tools available in the Support Automation Analyst Interface.

How Analysts Automate Support for End Users

As an Analyst, you use Live Assistance tools to perform the following tasks on end-user computers:

- Host live chat sessions.
- View file systems.
  - Create, modify, rename, or delete files and directories.
  - Copy and transfer files and folders to the end-user computer.
- View system registries
  - Create, edit, or delete registry records.
  - Export or import registry values from the end-user registry.
- Capture end-user screenshots when connection quality is not sufficient for Remote Control assistance.
- View the end-user computer desktop.
- Remotely control the end-user computer.
- Launch a program on the end-user computer.
- Restart or shut down the end-user computer.
- Run automated tasks.

How Analysts Provide Live Assistance

Analysts provide Live Assistance to end users by using the Support Automation Analyst Interface. Analysts handle end users that are routed to their queues, manage assistance sessions, and join sessions for which they have permission.

1. The end-user requests assistance from the CA SDM home page, or a ticket, such as an incident, a request, or an issue.
2. The end user joins a queue. If the end user joins the session using the link from the analyst email invitation, they bypass the queue.
   You configure CA SDM request areas and issue categories for queue routing.
3. The analyst selects the end user from the queue.
4. The assistance session begins and the analyst provides live assistance.

> **Note:** If the analyst launches the Support Automation Analyst Interface from the Support Automation tab, no CA SDM ticket is associated with the assistance session.

5. The analyst creates the ticket when closing the assistance session. The analyst defines the status or transfers the assistance session to another queue. The status can be as *SA-Open* or *SA-Resolved.*

6. The analyst closes the session and the end user receives an email notification with the Session Log.

How to Provide Live Assistance to End Users

This article contains the following topics:

The Support Automation Analyst Interface lets you provide live support to end users in your environment. Click the tab that corresponds to the tool you want to use.

Initiate a Chat with the End User

You can chat with the end user during a live assistance session. The chat displays inside the Support Automation Analyst Interface. The end users can see the chat in WebChat or in the end-user client executable.

To chat with the end user

1. Open an assistance session.
   The assistance session appears.

2. Do any of the following tasks:

   - Enter text in the chat window.

- Whisper a message to the end user.
  This message is private and not seen by the other analyst that is logged in to the assistance session.

- Push a specific URL to the end user.
  The end user can open the link, or you can open their browser, depending on the administrative settings.

- Send a preset response to commonly asked questions and common situations.
  Presets can consist of text messages or commonly pushed URLs.

The message appears in the chat window.

Support Automation Chat

The analyst, administrator, or tenant administrator creates chat presets that you can use in assistance sessions, such as greetings. You can chat with the end user during a live assistance session. While you use live assistance concurrently with telephone conversations, the chat tool lets you communicate using text messages.

The chat displays directly inside both the end user and Support Automation Analyst Interface windows. The chat notifies you when any of the following events occur:

- When someone joins your session
- When someone initiates a new chat
- When someone leaves a session that is still in progress with other participants
- When someone ends a session

You can also use the following chat functionality:

- **Whisper Messages**
  Sends private messages to selected members. Analysts that you invited to your assistance session cannot see these messages.
  Note: Whisper messages do not appear in the Session Log. You can only use whisper messages when more than one analyst handles the session.

- **Push URL**
  Directs the end user to a specific URL. The administrator sets whether the URL opens automatically or if the end user must open the URL manually.

- **Chat Presets**
  Sends preconfigured text messages to commonly asked questions and common situations. Presets can consist of text messages or commonly pushed URLs. Chat presets display in the Preset Tree area of the Chat Tool view.
  Chat presets include greetings and typical answers that can be populated automatically with information specific to the current assistance session. An example of a preset is the name of the participant.

Execute an Automated Task

You can execute predefined automated tasks that run on end-user computer. The automated tasks let you gather telemetry information, diagnose common problems, and implement resolutions. The administrator sets your automated task permissions.

To execute an automated task

1. Select Automated Tasks.
   The Automated Tasks page appears.

2. Select an automated task from the left pane.
   The script details appear, such as the name and description.

3. Click Execute.
   The automated task runs on the end-user computer.
   The Executed Tasks pane updates.

4. (Optional) Right-click the task in the Executed Tasks pane and click View Result.
   The results of the automated task execution appear.

Note: You can enable autorun and execute an automated task when the tool launches.

Browse the End-User File System

You can browse the end-user file system in a live assistance session. Use the File Browser to transfer from the end-user computer to your computer. The File Transfer tool can transfer files in both directions (see page 2901).

To browse a file system

1. Select File Explorer.
   The File Explorer page appears.

2. Browse the file system of the end user in the assistance session.

3. Use the context menu and select Download to transfer files.
   The File Transfer page appears.

Transfer Files with the End User

You can transfer files with the end-user computer. You can locate the appropriate file using the file explorer.

To transfer files

1. Select File Transfer.
   The File Transfer page appears.

2. Select the appropriate transfer option, such as Local to Remote.
   Locate the Source File.
   The Source File field populates.

3. Select the appropriate destination folder, such as Desktop.

4. Click Add to Transfer Queue.
   The Transfer Queue updates with the file transfer status.

Modify the End-User Registry

You can modify the registry of the end-user computer.

To modify the registry

1. Select Remote Registry.
   The Remote Registry Tool appears.

2. Navigate through the end-user registry and modify the appropriate registry entries.
   The registry is modified.

Capture a Screenshot

You can capture a screenshot of the end-user desktop when the connection quality is poor for remote control.

To capture a screenshot

1. Click the Screenshot tab.
   The Screenshot page appears.

2. Click Get Screenshot.
   The screenshot file transfers to your computer and displays in the right pane.
   The screenshot pane stores your capture history.

3. Click the picture to view it in original size.

4. (Optional) Save the picture as an external file.

5. Complete the assistance session.
   You can handle another end user from the queue.

Impersonate the End User

You can impersonate CA SDM login credentials during an assistance session. By default, you perform actions on the end-user computer with the end-user rights. You can also impersonate user rights with more privileges, such as an administrator.

Use impersonation when attempting to use tools that require higher privileges. For example, when modifying the end-user registry, or executing an automated task.

To impersonate the end user

1. Click Session, Impersonate.
   The Impersonation dialog appears.

2. Select an available impersonation login or use other credentials.

3. Click Impersonate.
   You impersonate the end-user rights.

Control the End-User Computer Remotely

You can take full control of the end-user computer, to perform diagnostic and repair functions remotely. You can see and manipulate everything on the end-user computer, as if you were physically sitting at the end-user desk.

Note: Your administrator establishes security levels for end users.

To control the end-user computer

1. Select Remote Control.
   The Remote Control page appears.

2. Wait for the end user to click Accept.
   The end user accepts your request for control.

Note: Remote Control uses Message Routing Servers to locate the best connection. If the connection quality is poor, you can use screenshots and can chat to diagnose the end-user computer. Connection quality symbols appear on the interface. For example, an excellent connection appears as green, yellow as fair, and red as poor.

3. (Optional) You can modify the behavior of remote control. Open the session as full screen, set the scrolling option and switch between the viewing and full control mode.

4. Control the computer and provide live assistance.
   The assistance session completes.

5. Disconnect from the computer.
   The Session Log updates to contain a record of which Remote Control server was used during the session.

Run a Program on the End-User Computer

You can run a program on the end-user computer without using Remote Control.

To run a program

1. Select Remote System Tools.
   The Remote System Tools page appears.

2. Enter a command to run on the end-user computer.
   The command executes and the program runs.

3. Click Run Program.
   The Run Program dialog appears.

Restart or Shutdown the End-User Computer

You can restart, restart and reconnect, or shut down the end-user computer.

To restart or shut down a computer

1. Select Remote System Tools.
   The Remote System Tools appear.

2. Select the appropriate action from the drop-down list, such as Restart and Reconnect.

3. Click Proceed.

4. The end user is prompted with your selection and confirms your selected action.
   The action performs and the end-user computer restarts or shuts down.

View the Session Log

All actions that you perform during the assistance session update the Session Log. The actions include chat dialog (excluding Whisper conversations), automated task results, and using a specific Support Automation Analyst Interface tool.

Follow these steps:

1. Open the active session view.
   The Active Session page appears.

2. Select the Session Log from the toolbar or Sessions menu.
   The Session Log page appears.

3. Click Refresh Now.
   The page refreshes.

4. (Optional) Select the Auto-Refreshing check box.

5. (Optional) Click Save Log to Disk.
   The save dialog appears. You can save the session log locally as an HTML file.

Configuring Support Automation Tools

This section contains the following articles:

Automated Tasks Administration

This article contains the following topics:

You can manage automated tasks as follows:

- View the automated tasks that are available for use.
- Update the automated task list to select from.
- Add, modify, or delete automated tasks classifications.

Create an Automated Tasks Classification

You can classify the automated tasks that are displayed to differentiate between the types of automated tasks.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks Classification from the Support Automation menu.
   The Automated Tasks Classification List page appears.
2. Click Create New.
   The Create New Automated Tasks Classification page appears.
3. Complete the following fields:
   - **Tenant**
     Specifies the tenant.
   - **Automated Task Classification Name**
     Specifies the name of automated tasks classification.

   Click Save.
   The automated tasks classification is added to the list.

Search for an Automated Tasks Classification

You can search for the automated tasks classifications that are displayed to differentiate between the types of automated tasks.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks Classification from the Support Automation menu.
   The Automated Tasks Classification List page appears.

2. Click Show Filter.
   Complete the fields and click Search.

3. The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Search for an Automated Task

You can search for the automated tasks that are available for use. You can configure the script to run for Live Assistance or Self-Service. You can also configure the script for the end-users even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.
   The Automated Tasks List page appears.

2. Click Show Filter.
   Complete the fields and click Search.

3. The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Update the Automated Tasks List

You can view the automated tasks that are available for use. You can configure the script to run for Live Assistance or Self-Service. You can also configure the script for the end-users even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.
   The Automated Tasks List page appears.

2. Click an automated task.
   The Automated Task Detail page appears.

3. Complete the following fields:

   - **Classification**
     Specifies the classification or group the automated task belongs to.

   - **Description**
     Displays a description of the automated task.

   - **Disclaimer**
     Specifies the disclaimer that must be agreed to before the script can run.

   (Optional) Click the Configure script for Live Assistance tab (see page 2907).
   (Optional) Click the Impersonation tab (see page 2907).
   (Optional) Click the Support Automation Access Level tab. (see page 2908)
   Click Save.
   The automated task is added to the list.

Configure an Automated Task Script for Live Assistance

You can view the automated tasks that are available for use. You can configure the script to run for Live Assistance or Self-Service. You can also configure the script for the end-users even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.
   The Automated Tasks List page appears.

2. Click an automated task.
   The Automated Task Detail page appears.

3. Click the Update Permissions button on the Configure script for the Live Assistance tab.
   The Permissions Assigned Update page appears.

4. Select the permissions and use the arrow buttons to move them from column to column. Click OK.
   The Permission Assigned Update page closes.

5. Click Save.
   The automated task is configured for Live Assistance.

Configure an Automated Task Script for Impersonation

You can view the automated tasks that are available for use. You can configure the script to run for Live Assistance or Self-Service. You can also configure the script for the end-users even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.
   The Automated Tasks List page appears.

2. Click an automated task.
   The Automated Task Detail page appears.

3. Select the Impersonate field and complete the Login name, Password, and Domain information about the Impersonation tab.
   Click Save.
   The automated task is configured for impersonation.

Configure an Automated Task Script for Access

You can view the automated tasks that are available for use. You can configure the script to run for Live Assistance or Self-Service. You can also configure the script for the end-users even if they do not have system access rights.

Follow these steps:

1. Select Tools, Automated Tasks, Automated Tasks List from the Support Automation menu.
   The Automated Tasks List page appears.

2. Click an automated task.
   The Automated Task Detail page appears.

3. Click Support Automation Access Level tab.
   Click Update Tasks to add an access level.
   Click Edit in List to select the automated script for Auto Run.
   Click Save(Y).

4. Click Save.
   The automated task is configured for access.

Chat Preset Administration

This article contains the following topics:

You can create common responses to commonly asked questions and situations. Instead of repeatedly typing the same information, you can save a response and can use it in other chat sessions.

You can send the presets to end users at the beginning of each session automatically, such as a greeting. You can also automatically populate the presets with information specific to the current session, such as the analyst name.

You can use the following types of presets in an assistance session:

- **Chat Preset**
  Identifies a commonly used text response to an end-user question.

- **URL Preset**
  Identifies a commonly used URL that the end user can access.

You can localize each chat preset. The chat preset is synchronized with the end-user localization so that the end user receives correct localized presets.

Create a Chat Preset Group

You can manage chat presets responses into categories (groups).

Follow these steps:

1. Select Tools, Chat Presets, Chat Preset Group List from the Support Automation menu.
   The Chat Preset Group List page appears.

2. Click Create New.
   The Create New Chat Preset Group page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Group Name**
     Specifies the Chat Preset Group name.

   Click Save.
   The chat preset group is created.

4. (Optional) Click Edit in List to modify the Chat Preset Group Localizations.
   The Localized Chat Preset Group List page appears.

Search for a Chat Preset Group

You can search for a chat preset group.

Follow these steps:

1. Select Tools, Chat Presets, Chat Preset Group List from the Support Automation menu.
   The Chat Preset Group List page appears.

2. Click Show Filter.

3. Complete the fields and click Search.
   The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Create a Text Preset

You can create a chat preset for commonly used text responses to end-user questions. When you save a response, you can use it in other chat sessions.

Follow these steps:

1. Select Tools, Chat Presets, Text Preset List from the Support Automation menu.
   The Chat Text Presets List page appears.

2. Click Create New.
   The Create New Chat Text Preset page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **Default Chat Preset for Session Join**
     Select to define as the default Chat Preset for Session Join.

   - **Text Preset Group**
     Specifies the text preset group.

   - **Text Preset Name**
     Specifies the text preset name.

   - **Preset Text**
     Specifies the text of the preset.

   Click Save.
   The text chat preset is created.

4. (Optional) Click Edit to modify the Localized Chat Text Preset List.
   The Update Chat Text Preset page appears.

5. Click a localization link.
   The Chat Text Preset Localization Detail page appears.

6. Click Edit.
   The Update Chat Text Preset Localization page appears.

7. Enter the localized name and text and click Save.
   The localized text for the text chat preset is added.

Search for a Text Preset

You can search for a chat preset for a commonly used text response to an end-user question. When you save a response, you can use it in other chat sessions.

Follow these steps:

1. Select Tools, Chat Presets, Text Preset List from the Support Automation menu.
   The Chat Text Presets List page appears.

2. Click Show Filter.

3. Complete the fields and click Search.
   The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Create a URL Preset

You can create a URL preset for a commonly used URL that the end user can access. When you save a URL, you can use it in other chat sessions.

Follow these steps:

1. Select Tools, Chat Presets, URL Preset List from the Support Automation menu.
   The Chat URL Preset List page appears.

2. Click Create New.
   The Create New Chat URL Preset page appears.

3. Complete the following fields:

   - **Tenant**
     Specifies the tenant.

   - **URL Preset Group**
     Specifies the URL preset group.

   - **URL Preset Name**
     Specifies the URL preset name.

   - **Preset URL**
     Specifies the URL of the preset.

   - **URL Title**
     Title for the URL Preset.

   Click Save.
   The URL chat preset is created.

4. (Optional) Click Edit to modify the Localized URL Chat Preset List.
   The Update Chat URL Preset appears.

5. Click a localization link.
   The Chat URL Preset Localization Detail page appears.

6. Click Edit.
   The Update Chat URL Preset Localization page appears.

7. Enter the localized URL information and click Save.
   The localized URL preset is added.

Search for a URL Preset

You can search for a URL preset for a commonly used URL that the end user can access. When you save a URL, you can use it in other chat sessions.

Follow these steps:

1. Select Tools, Chat Presets, URL Preset List from the Support Automation menu.
   The Chat URL Preset List page appears.

2. Click Show Filter.

3. Complete the fields and click Search.
   The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Default Credential Administration

This article includes the following topics:

Run automated tasks on the end-user computer even if the end user does not have access rights to perform such activities. If the end user does not have administrative rights to view system information, run a restricted automated task. Use the default credentials to gain access.

Specify Default Credentials

Run automated tasks on the end-user computer even if the end user does not have access rights to perform such activities. If the end user does not have administrative rights to view system information, run a restricted automated task. Use the default credentials to gain access.

Follow these steps:

1. Select Tools, Default Credentials from the Support Automation menu.
   The Default Credentials List page appears.

2. Click Create New.
   The Create New Default Credentials page appears.

3. Complete the following fields:

- **Tenant**
  Specifies the tenant.
- **Label**
  Specifies the name that displays.
- **Domain**
  Specifies the domain.
- **Login**
  Specifies the login name.
- **Password**
  Specifies the password.
- **Confirm Password**
  Specifies the password was typed correctly.
- **Active**
  Specifies the default credentials is active.

Click Save.
Default credentials are saved.

Search for a Default Credential

You can search for default credentials. Use the default credentials to run an automated task on the end-user computer to view system information. You can also use the credentials to gain access to the end-user computer.

Follow these steps:

1. Select Tools, Default Credentials from the Support Automation menu.
   The Default Credentials List page appears.
2. Click Show Filter.
3. Complete the fields and click Search.
   The search limits the list to the information of interest.

Note: Click Export to export the list results to a Microsoft Excel (.xls) file.

Service Catalog Management

CA Service Catalog provides system forms for users to complete as part of their requests. A service consists of hardware, software, or other resources that users request from the catalog. Administrators can manage services to meet the needs of their users and organization. You can use events, rules, and actions to automate the processing of requests, users, and accounts in the CA

Service Catalog system. All rules are initially disabled. A rule must be enabled to be used. You can add a dashboard, configure content elements, manage outages, create business hours, news, content packs as shown in the following:

Manage Forms

CA Service Catalog provides the following system forms for users to complete as part of their requests:

- General Information Form
- Request Information Form

These forms request user-related information that is typically required to complete a request. For example, basic personal data and shipping address.

General Information Form

The General Information form asks the user to provide the required details for completing any checkout process. This form is not modifiable and therefore does not appear in the Form Designer. This form appears on the checkout page and other pages of the request.

Request Information Form

By default, the Request Information form asks the user to provide any custom descriptive information about the request. This form appears in any checkout process for services. The default version of the form appears in the Forms, System folder in the Form Designer.

You can optionally customize the Request Information form. Click the Customize button in the Component Tree when the form is selected. After confirming that you want to customize the form, you can edit it.

Use caution when modifying this form: Changes apply to all checkout-process for services in your business unit and all sub-business units. Even past (fulfilled requests, no archiving), present, and future are affected.

A tenant can have *one* active custom copy of this form.

Search the Forms

You can search for a specific form using either the Form Display name or Folder name option. You can use the Search Form UI option to modify or view an existing form. The search mechanism provides auto suggestion as the user types search terms in the form search text box. Search terms are case insensitive. The search results are displayed in a hierarchical manner.

Note: This capability is available only if you have installed the CA Service Catalog 14.1.01 patch updates available on CA Support.

Delete the Forms

After you customize this form, you can optionally delete the customized version to revert to the parent form.

The Delete function is disabled for the Service Provider (SP) business unit, because deleting the parent form is prohibited.

Hide the Forms

You can hide the Request Information form. Doing so ensure that the form does not appear to users or administrators during the request life cycle. By default, the request information form appears.

To hide it, open Catalog, Configuration, Request Management Configuration, and change the setting *Access Control: Show Request Information* to include no roles. Hence, no users or administrators can view or edit the Request Information form during request processing.

Restrictions

Keep in mind the following restrictions:

- Copying and pasting the Request Information form creates a copy that does *not* become the system form.
- You cannot move the Request Information form out of the Forms, System folder.
- You cannot alter the Forms, System folder, other than customizing the forms that can be edited.

Pre-Defined JavaScript Functions for System Forms

Customize the pre-defined JavaScript functions to update fields in the request information form when the general information form is changed. This optional customization helps integrate the request information form with the checkout and request edit pages. The pre-defined JavaScript functions are as follows:

- **custom_onPriorityChange(newPriority)**
  This function is invoked when the priority of the request is changed in the general information form. You can add code to update the customized request information form to reflect the priority change. By default, this function does nothing.
  newPriority is a string that corresponds to the new priority.

- **custom_onDateRequiredChange(newDateRequired)**
  This function is invoked when the date required is changed in the general information form. You can add code to this function to update the request information form. By default, this function does nothing.
  newDateRequired is a JavaScript date object set to the new required date.

- **custom_onRequestedForChange(type, id, name, shippingAddress)**
  This function is invoked when the requested for user or account for a request is changed. You can add code here to update values in your request information form. Example: Changing the shipping address fields in the request information form to have the address of the requested for user or account.
  By default, this function updates the shipping address of the request information form with the shipping address of the new user or account.

  Important! If you change the shipping address section of the request information form, update this code to reflect those changes.

type is the user when a user is selected and account when an account is selected.

id is the CA Service Catalog ID of the selected user or account.

name is the display name of the selection.

shippingAddress is a JavaScript map with the following keys: address_1, address_2, city, state, zip code, and country. If the user or account has no address, shippingAddress can be null or empty.

Elements of a Form

You can drag and drop the form element to Form Preview section. For each form element, the _id value is auto generated. This value is a combination of text and numbers and depends upon the element you are creating. The first element of the form always begins with 1. For example, in a form the _id for the first text field element is txtf_1 and the _id for the first text area element is txta_1. In the same form, the _id for the second text field element is txtf_2 and the _id for the second text area element is txta_2.

You can modify this auto generated _id value of the form elements, if required.

Important! We recommend that you do not specify the same _id value for the different form elements in the same form. Having multiple form elements with the same _id value can cause validation errors.

To reuse the elements that you have customized, copy and paste the elements from one form to another.

The Form Designer provides the following elements for you to create and modify forms:

Check Box

Enables the user to select or decline a single option.
You can optionally use multiple check boxes to group related choices, of which users can select two or more. For example, you can add one check box each for the peripheral devices that are associated with a laptop computer. These devices include a mouse, docking station, carrying case, and external backup drive.

Column Layout

Enables the user to organize the components on the form for maximum efficiency. The column layout includes two vertical columns, Column 1 and Column 2, aligned next to each other. You can place form components in one or both of these columns. You cannot insert one column inside another, and you are not allowed to add more than two columns per Column Layout place holder. However, you can place multiple column layouts in a form.

Date

Sets the format of the date and time. The date and time that appear on the Form Designer match the date and time of the browser that you are using to access CA Service Catalog. The date and time that appear to other users accessing the form match the date and time of their browsers. The date and time of form settings -- even on the same forms -- can differ between users in different time zones. This principle applies whether users access the form through the Form Designer or while requesting a service.

- **Date**
  Use the date portion of this field whenever date information is required. **Example:** Start Date, Date Required, Estimated Date of Arrival. Users can select a date from the calendar.
  By default, the date format for the Date Time field matches the date format of the current business unit.

  Note: As an administrator, you can optionally change the default format for the business unit to a different format: Edit the profile of the business unit on the Administration, Business Units page and select a new date format. Examples include M/d/yyyy, d-M-yyyy, or yyyy/M/d.

  Specify date formats in Date Time fields on your forms according to the following rules:

Letter	Meaning	Format	Example
y	year	Number	2009
M	month in a year	Text or Number	July or 07
d	day in a month	Number	10

  CA Service Catalog supports the date format attributes supplied with the Google Web Toolkit (GWT) 1.6. For more information about these attributes, see the Google website, www.google.com (http://www.google.com).

- **Time**
  Use the time portion of the Date Time field whenever time information is required. **Example:** Start Time, End Time, and Estimated Time of Arrival. When you use the time portion of this field, a drop-down list of time values appears next to the calendar. Users can select a time from this list. **Default:** The time format for the Date Time field matches the time format of the business unit of the user.

  Note: As an administrator, you can optionally change the default format for the business unit to a different format: Edit the profile of the business unit on the Administration, Business Units page and select a new time format.

  Specify time formats in Date Time fields on your forms according to the following rules:

Format	Separator
HH:mm	colon
HH.mm	period

  If the Hide Time attribute is set to *true*, then the time portion of the field is hidden. This time format is ignored. The drop-down list for selecting the time does not appear on the form. Otherwise, the field accepts valid values that are separated by a space. CA Service Catalog

supports the time format attributes supplied with the Google Web Toolkit (GWT) 1.6. For more information about these attributes, see the Google web site, www.google.com. (http://www.google.com.) You can add literal values that are enclosed in quotation marks (such as "hours" or "minutes") before or after the hour and minute values.

The HTML attributes (see page 2928) named *hidetime* and *increment* control whether and how incremented time values appear in each Date Time field.

Dual List

Displays two columns in a box: The left column lists available options, and the right column lists the selected options.
A toolbar of arrows appears between the columns. For example, to select an option, highlight it in the left column. Then, you click the arrow to move the option to the right column.
Users can highlight multiple options in one column and click the arrow to move them as a group to the other column. Users can click the double arrows to move all options from one column to another. This action selects or deselects *all* options.
While you are designing the form, you can perform the same actions as the user to select and clear options.
By default, the dual list field contains *no* available options. To populate the dual list with available options, use *one* of the following methods:

- Specify a report data object (see page 3232) for the dual list: Enter the HTML attributes (see page 2928) named Report/Plug-in Id and Report/Plug-in Variables.
- Create a static list of individual options for the dual list: Add options to the dual list. You can add, move, and delete options to the dual list. The default dual list element in the Component Tree includes one option. You can copy and modify this option to create more options.

To enable users to specify the order of the selected options, specify *true* for the HTML attribute named ordered. When you do so, the toolbar is updated to include up and down arrows. Users can highlight selected options and click these arrows to move the options up or down in the list. When you are designing the form, you can order the selected options in the right column. The available options in the left column always appear in the order that you arrange them on the Component Tree.

Field set

Enables the user to group multiple elements as a set. Examples include the following groups:

- Accessories for a laptop such as battery charger, carrying case, and docking station.
- Telephone numbers for a user such as home, work, cell, and fax.

Elements in a field set have a box around them to show that they are related. For maximum accessibility, do *not* place one of the following elements immediately after a field set: check box, Date Time field, radio group, and radio buttons.

Image

Enables the user to provide a picture representing an item that can be included in an associated service or service option. The image that you specify must reside in the filestore, the central location for CA Service Catalog files. Use the following format:

FileStore/*path*/*filename.ext*

Important! The folder name *FileStore* is case-sensitive. Use the correct case in path names and all other references.

Label

Identifies a form or an area of the form. **Example:** A title in a form, such as Medical History Form. Within the form, you can have other labels, such as Family History, Eating Habits, and Illnesses. If you use a multiple-column format in your form, it can be helpful to use a label as a heading for each column.

Use the HTML attribute (see page 2928) that is named Label Text to configure the label that users see on the form. You can optionally perform the following tasks for labels:

- Use the HTML attribute (see page 2928) that is named Hidden to hide the label when the conditions you specify are met.
- Use the JavaScript attribute (see page 2940) named onClick to run a JavaScript function (see page 2967) when the user clicks the label.

Lookup Field

Works with the JavaScript function ca_fdDoFieldLookup(fieldId, reportId) to populate fields based on user input to a report data object (see page 2970).
You configure the lookup field to prompt the user to enter the data for the query of the data object. **Example:** user ID, asset ID, or city. The data object queries the data source, which is based on the user input. The results are used to populate the fields you specify.
The user clicks the search icon for the lookup field and enters the requested data. The query runs and returns the search results in rows. Each matching value appears in a row. Users review the rows and select one. When the user selects a row, the results from that row populate the matching fields on the form.
For example, the lookup field can prompt the user to enter a user ID. The query then searches the database for the first name and last name of the user ID. The user can select one row to populate the corresponding First Name and Last Name fields on the form.

Radio Group

Presents a list of options to the user. A radio group contains radio buttons *only*. A radio group cannot contain any other element. The user must select only one. **Example:** A radio group that is named Size with three buttons: one each for Small, Medium, and Large. In contrast to options in select boxes (see page), radio group buttons *always* appear on the form. To save space, you can use a radio group only for fields having four or fewer options.

Select

Presents a list of options, of which the user select either one (the default) or multiple options.
A select box contains select options *only*. A select box cannot contain any other element. **Example:** You can create a select box that is named Width with two options: Narrow and Standard.
The options for select boxes appear on the form only when the user clicks the drop-down list box.

Therefore, you can use a select box rather than an option group to save space on a form. Doing so is especially relevant when the number of options is four or more.
Optionally change the default setting of a select box to enable users to select more than one option. To do so, change the Multi-Select attribute of the select box from False (the default) to True. If you change this setting to True, the select box changes from a drop-down list to a sequential list or list box. Hence, all the options are always displayed and more screen space is required. The user sees multiple lines in the select box and can select multiple options.
When this attribute is set to false, the select box appears as a combo box on the form: The user sees a list box and can select only one item from the list. The Catalog users cannot enter a *custom* value in a select box. However, users can type inside a select box. As they type, the drop-down list is populated with the options that begin with the typed text. Users can then select an option from this "auto-complete" list.
To set specifications for the auto-complete list, use the Minimum Search Characters attribute. For more information, see HTML attributes for select boxes only (see page 2934).

Slider

Enables the user *slide* a control forwards or backwards to increase or decrease the selected value. Each slide updates the selected value according to the increment that you set. Specify the unit of measure for the slider in a message that appears each time that the user increases or decreases the selected value. Sample messages include *0 CPUs, 1 CPU, 2 CPUs, and 3 CPUs*.

To configure the contents and behavior of the slider, use the following attributes:

- Attributes for most or all elements (see page 2929)
- Attributes for sliders only (see page 2935)

Spinner Field

Enables a user to select a numerical value from a range of incremented values. **Example:** 100, 200, 300, and 400. The user clicks the up or down arrows to increase or decrement the selected value. Use the HTML attributes for spinner fields only (see page 2928) to configure the contents and behavior of the spinner field.

Table

Enables the user to create tables. You can create either a Static Table or a Dynamic Table.

Static Table

A static table is a type of container, like a field set, that can contain certain elements of a form. You can use the columns in the table to organize the data from each type of element. In contrast to a dynamic table, a static table consists of fixed data that you specify manually.

You can create a static table to enter structured data into a form.

Follow these steps:

1. Edit or create the form in which you want to add the table. Expand the form.
2. Add the table element to the form:

a. (Optional) Create a field set to contain the table.

b. Expand the System folder, drag the Table element, and drop it on the form. If applicable, drop the table onto the field set that you created in the previous step.

c. Specify an _id value for the table and save the form.

3. Add an element to the table:

a. Expand the table and display the Row field.

b. Drag one of the following elements (see page 2916) from the System folder and drop it on the Row field:

- Date Time field
- Label
- Select field whose Multi-Select attribute is set to false. This setting allows only a *single* selection.
- Spinner
- Text

The name of the element that you drag-and-drop becomes the name of the first column. For example, if you drag-and-drop a Date element, the name of the first column becomes Date.
Similarly, the data that you enter in the column must match its element. For example, in a Date column, you can enter only dates.

c. Specify an _id value for the column and save the form.
After you save the form, you can optionally rename the element that you dragged and dropped. If you rename the element, the name of the column changes accordingly. For example, if you rename the element to Start Date, the name of the column also changes to Start Date.

d. Configure each element that you add to a table. The steps are the same as adding the element to the form without a table.
For date fields, the value returned must be a long or appropriately formatted string. For label columns, the value is converted to a string. For spinner columns, the value must be an integer or double. For text columns, the value is converted to a string.

4. To add rows to the table, perform the following steps:

a. Select the Row field on the Table element on the System folder.

b. Drag-and-drop it on the Table element on the form.

c. Repeat these steps until you have added all the rows that you want. You cannot move, copy, cut, or paste rows.

5. Define the values for each row in the table, as follows:

a. In the first row, specify the static values of each cell, using their value attribute.

b. In the remaining rows, specify values using the column attribute.
The Form Designer does *not* validate any data or the data format that you enter in the table rows. When users display the form in a request, the Catalog system validates the data and displays it *only* if you use the correct format. Thus, any invalid values that you specify do *not* appear when users view the form in a request. **Example:** If you specify a string value for a date column, the corresponding table cell appears empty to the user.

c. Perform this step if applicable; otherwise, skip it.
If you are using a Select field (see page) whose Multi-Select attribute is set to false, then the Select field does *not* contain the value attribute. In that case, perform the following actions:

- For the first row: Enter the value of the Selected Index attribute of the Select field. For example, to specify the first option, enter 0. To specify the second option, specify 1, and so on.
- For the remaining rows: Copy the value of the *value* attribute from the select option of the Select field. Paste this value into the column attribute of the row.

6. Specify any of the following attributes:
   - HTML attributes (see page 2928)
   - Attributes for tables only (see page 2937)
   - JavaScript functions for tables only

Dynamic Table

A dynamic table is also a type of container that can contain certain elements of a form. You can use the columns in the table to organize the data from each type of element.

You can create a dynamic table to enter structured data from a report data object into a form.

Follow these steps:

1. Create or edit the report data object or API plug-in that you plan to use to populate the dynamic table.
   The variables in the report data object or API plug-in must return data in the format that the table columns require. Otherwise, users do not see this data when they open the form in a request.
2. Edit or create the form in which you want to add the table. Expand the form.
3. Add the Table element to the form, as follows:
   a. (Optional) Create a field set to contain the table.
   b. Expand the System folder, drag the Table element, and drop it on the form. If applicable, drop the table onto the field set.

c. Specify an _id value for the table and save the form.

4. Add the report data object or API plug-in to the table, as follows:

   a. Select the Table element.

   b. If you are using an API plug-in, specify the values of the following attributes:

      Report/Plug-in Id: Enter the ID of the API plug-in that you want to use. You can find values for these attributes on the Administration, Tools, Plug-ins page. Report/Plug-in Variables: Open the API plug-in that you selected to display its details, including variables. On the details page, the Inputs section lists the ID values and descriptions of the input variables for the plug-in.

   c. If you are using a report data object, specify the values of the following attributes:

      - Report/Plug-in Id: Enter the ID of the report data object that you want to use. You can find values for these attributes on the Administration, Report Builder, Data Objects page.

      - Report/Plug-in Variables: Click the Edit icon for the report data object that you selected to display its properties, including variables. On the properties page, the input variables for the report data object appear as follows:
        For a Query: The input variables appear as *%expression%* statements.
        For Plug-in: The input variables appear in the Arguments field.
        For CSV: The input variables do not apply.

      For both attributes, enter variables as a JSON expression, for example:

```
$({'<variable name>' : '<variable value>', ...})
$({'userid':_.user.id,'rm_orgunit':ca_fdGetSelectedOptionValues(ca_fd.f
```

> **Important!** Specify the variables carefully. If you specify *no* variables, unpredictable results can occur.

5. Save the form.
   When users complete this form, the report data object or API plug-in runs and returns the data that you specified.

Next, you configure the dynamic table (see page 2924).

Configure the Dynamic Table

After you create a dynamic table, you configure it to contain the data and use the format that you require.

Follow these steps:

1. Review the following requirements for adding elements to the table. Each element that you add becomes a column in the table.

- Add one element for each variable that you specified in the Report/Plug-in Variables attribute of the table element.
- (API plug-ins) The value of the _id attribute of each element (column) in the table must match a value of an Output Id of the plug-in.
- (Report data objects) The value of the _id attribute of each element (column) in the table must match a value of a Field of the data object.

2. Add an element to the table, according to the requirements in the previous step, as follows:

   a. Expand the table to display the Row field.

   b. Drag the element from the System folder and drop it on the Row field. You can drag-and-drop the following elements:

      - Date Time field
      - Label
      - Spinner
      - Text
      - Select the field whose Multi-Select attribute is set to False. This setting allows only a *single* selection.

   c. Perform this step if applicable; otherwise, skip it.
   If you are using a Select field (see page) whose Multi-Select attribute is set to false, then the Select field does *not* contain the value attribute. In that case, you can populate the Select field using *either* a static list *or* a report data object.
   To populate the Select field *using a static list,* perform the following actions:

      - For the first row: Enter the value of the Selected Index attribute of the Select field. For example, to specify the first option, enter 0. To specify the second option, specify 1, and so on.
      - For the remaining rows: Copy the value of the *value* attribute from the select option of the Select field. Paste this value into the column attribute of the row.

   The name of the element that you drag-and-drop becomes the name of the first column. For example, if you drag-and-drop a Date element, the name of the first column becomes Date.
   You cannot move, copy, cut, or paste rows.

   d. Specify an _id value for the column and save the form.

   Important! The _id value for the column must meet the requirements noted in the previous step. Also, the data type and data format must also be the same. Otherwise, the column is not populated with data.

Example: You are using an API plug-in, and you want a table column to specify the start date of an event. You drag-and-drop a Date Time element onto the table and specify an _id value of start_date. This element becomes a column in the table. Therefore, the Output Id of a variable of the API plug-in must also be start_date. The sequence does not matter. This variable must also return the required date and time data in the format that matches the Date Time element.

3. Configure each element that you add to a table. The procedure is the same as if you were adding the element to the form without a table.
   Each one is a basic element (see page), except the Date Time field (see page) and the Select field (see page). The data that you enter in the column must match its element. For example, in a Date column, you can enter only dates.

4. (Optional) Specify a custom value for pagination for the table, as follows:

   a. Specify the value of the Page Size attribute of the Table element.

   b. For API plug-ins, configure sorting and pagination parameters. For report data objects, further action is necessary.

5. (API plug-ins only) Enable users to sort the results in the table, as follows:

   a. Specify a value of True for the Sortable attribute of the Table element.

   b. Configure sorting and pagination parameters. Sorting does not apply to report data objects.

6. Specify any of the following attributes:

   - HTML attributes (see page 2928)
   - Attributes for tables only (see page 2937)
   - JavaScript functions for tables only

Text Area

Enables the user to enter more than one line of input. **Example:** A free-form description of the offering.

Text Field

Enables the user to enter free-form text. **Example:** Fields for the user to enter a name, address, telephone number, or multiple-digit numeric entries. Use text fields when only one line of input is required.

Page Layout

Enables the user to place the form components within a page layout for maximum efficiency. You cannot place one page layout inside another and you can have only one page layout in a form.

You can have any number of pages within a page layout.

Page layout element can be one of the following:

- Card layout - Displays the element as pages with next and back button if there are multiple pages. This is the default page layout.
- Tab layout - Displays the element as tabs on top of the page layout.

Default page height: 400 pixels

Form Attributes

Form attributes apply to the *entire* form rather than to one field only.

- **name**
  Specifies the name of the form.
  Specify this attribute for each form, and verify that this attribute is unique for each form.
- **_id**
  Specifies the identifier of the form.
- **class**
  Specifies the CSS class name to use for the form.
  Define the new CSS class in the formdesigner.css file in the folder named USM_HOME\view\webapps\usm\gwt\fdBase\css.
  For example, to apply a class that changes the form to a 12-point, blue, boldface font, Follow these steps:

  1. Back up the formdesigner.css file before you edit it.
  2. Append the following class statement to formdesigner.css, as follows:

```
/* custom class by author-name, date for purpose */
.blue12-class {
color: blue;
font-size:12px;  /* Make sure to mention font size in pixels(px) */
font-weight:bold;
}
```

  > **Note:** Text fields have a preset height limit and therefore ignore the font-size attribute.

  3. Enter blue12-class as the value for CSS class attribute.
  4. Verify your updates by using the form in a request.

- **Form Type**
  Specifies whether the form is a configuration form type, as follows:
  - Request - for a request of a service from the catalog

- Configuration - for a content configuration form (see page 3070)

Default: Request
This attribute *cannot* be written using JavaScript expression.

- **Label Align**
  Applies to labels *only*. This attribute specifies the alignment of the label in relation to the fields on the form. Select top, right, or left (default).

- **Label Width**
  Specifies the width in pixels of the field labels in the form.
  You can also specify Label Width as an HTML attribute (see page 2928) for the column layouts and field sets on the form.

- **onLoad**
  Specifies the JavaScript function to run when the user opens the form in a request.
  Multiple forms having an onLoad attribute can appear on a single page. In that case, each JavaScript function (see page 2966) runs when the user opens the form that includes the function.
  An alert appears if an onLoad function fails to run correctly. For example, if the function cannot be found.

  If you receive an alert, verify that function is correctly defined and referenced to ensure that it runs without errors.

  Note: Use the Script dialog on each form to create and maintain the custom JavaScript functions for the form.

- **onSubmit**
  Specifies the JavaScript function to run when the user submits the request that contains the form. This function must return a Boolean value. If the function returns any value except *true*, the form is not submitted.
  Multiple forms having an onSubmit attribute can appear on a single page. In that case, each JavaScript function runs when the user submits the form that includes the function.
  The information about alerts for the onLoad function also applies to the onSubmit function.

HTML Attributes for Elements

You can use HTML attributes to configure the appearance and behavior of the elements of a form. For more information on how to use the JavaScript Functions, see JavaScript Function APIs (see page 2928).

Keep in mind the following principles:

- Not all HTML attributes apply to all elements (fields). Click an element to see which attributes apply to it.

- Required HTML attributes appear in **bold** in the Item Inspector. When you add an element to a form, complete the required attributes and save the form immediately after adding the element. Afterwards, you can add optional HTML attributes and JavaScript attributes.

- The HTML attributes are primarily internal, in that they regulate the appearance and behavior of the form. They *typically* do not supply literal text that appears to the administrator in the Design Area or to the user in a request.
- You view and modify the names and values of the HTML attributes in the Item Inspector as needed. However, you generally do not see the changes as literal text in the Design Area. The exceptions are:
  - The Checked attribute for radio buttons and check boxes
  - The Value attribute for labels, text fields, and text areas
- For an HTML attribute, you can optionally enter a JavaScript expression, but you cannot call a JavaScript function.
- For most elements, you specify the literal text that appears to end users by adding and configuring elements (see page 2951) on the form. Specifically, you rename the elements on the form in the Component Tree, and you verify their appearance in the Preview Area.

For more information about the different HTML Attributes, see the following sections.

- Attributes for Most or All Elements (see page 2929)
- Attributes for Date Time Field Only (see page 2932)
- Attributes for Dual List and Select Boxes Only (see page 2932)
- Attributes for Field Sets Only (see page 2932)
- Attributes for Labels Only (see page 2933)
- Attributes for Radio Groups Only (see page 2933)
- Attributes for Select Boxes and Tables Only (see page 2933)
- Attributes for Select Boxes Only (see page 2934)
- Attributes for Sliders Only (see page 2935)
- Attributes for Spinner Fields Only (see page 2936)
- Attributes for Tables Only (see page 2937)
- Attributes for Text Fields and Text Areas Only (see page 2940)

Attributes for Most or All Elements

Some HTML attributes apply to *all or most* elements (fields) of a form. The following attributes of that group may require explanation:

- **_id**
  Specifies an auto-generated unique identifier for the form field.
  If the _id is not unique, a warning message appears.

  Important! The Form Designer *warns* you if the _id attribute values are duplicated for multiple fields; however, it does *not* prevent you from saving them. Therefore, change any duplicate _id attributes a soon as you become aware of them. If the form contains duplicate _id attributes, JavaScript functions can run on the wrong form field and cause errors. If you change the value of the _id attribute, verify that you also change any references to it, especially in JavaScript functions.

- **CSS Class**
  Specifies a space-separated list of CSS classes. This class is associated with style information.

- **Empty Text**
  Provides extra description of a field to the user.
  The value that you specify for this attribute appears inside the field when the user opens the form. This text disappears when the user begins entering a value in the field. A sample value follows, for a password field: You can optionally use the Empty Text, Hint, and Tool Tip attributes together to assist the user.

- **Name**
  Specifies the name of the element.

- **Value**
  Specifies the value of the input component. This attribute is often useful for entering sample data or instructions. For example, for the value attribute of a text field named Address, you can specify something like "123 my street" or “Enter your address here.” In both examples, the value suggests that users replace the default text with their actual addresses.

- **Disabled**
  Specifies a value of true or false.

- **Hidden**
  Specifies whether to hide a field, including the label. Specify true or false. When the value is set to true, the field is *not* visible.
  You can use JavaScript expressions to specify this value as a condition, as follows: If the condition is met, hide the field. Otherwise, display the field.
  For example, you can hide a fulfillment-related field before the request reaches the Pending Fulfillment status. Similarly, you can hide a salary-related field from any user other than the manager of the user and the Human Resources user group.
  You can specify all the same conditions (see page) that apply for the Policies. Similarly, you can use the JavaScript expressions to specify the value as a condition for the **Include in Email Notification** attribute too.

- **Include In Email Notification**

  Specifies whether to display a field or component value, including the label. Specify the value as true or false. When the value is set to true, the field or component value is visible in the email. To set or edit this attribute, you must have admin rights. Navigate to **Catalog**, **Forms**, select the Form Component and click on the **Include in Email Notification** attribute.

  When you set the **Hidden** and **Include In Email Notification** element attributes to true/false in the CA Service Catalog UI, the following is reflected in UI and email notifications:

Hidden Attribute	Include In Email Notification Attribute	Result
true	true	Form component is not displayed anywhere.
true	false	Form component is not displayed anywhere.
false	true	Form component and value is displayed in the Form Designer, the Request Form while raising a request, and in the email notification.

Hidden Attribute	Include In Email Notification Attribute	Result
false	false	Form component appears in the Request Form UI, the Form Designer UI, but the component value is not displayed in Email Notifications.

- **Hide Label**
  Specifies whether to hide *only* the name of a field. The field remains visible regardless of whether you name the label. This attribute provides flexibility when space is a concern.
  Specify true or false. When the value is set to true, the name for this field is *not* visible.
  You can use JavaScript expressions to specify this value as a condition, as follows: If the condition is met, hide the name. Otherwise, display the name. You can specify all the conditions (see page) that apply for the Policies.
  For example, you can hide the names of obvious fields, such as Name, Address, and Telephone Number, after the user submits the request. Doing so can be helpful to save space on the form when the additional fields become visible for approval and fulfillment statuses only.

  Note: The Hide Label attribute does *not* apply to the Label element. Instead, the Hide Label attribute applies to the *name* of certain other fields that you enter in the Component Tree of the Form Designer. After you enter the name of a field in the Component Tree, the name appears in the Preview Pane.

- **Hint**
  Specifies help text for a field. This text *always* appears below the field, regardless of the position of the mouse.
  For example, for a password field, you can specify the following hint: "Passwords must be six to eight characters and must include both letters and numbers."
  You can optionally use the Empty Text, Hint, and Too tip attributes together to assist the user.

- **Required**
  Specifies whether this field is required. Enter a value of true or false.
  When a user submits the form, the system verifies that all the required fields are not empty. A required field is a field whose required attribute is set to true. If any required fields are empty, the system prompts the user to complete them.

- **Style**
  Specifies associated style information.

- **Tab Index**
  Specifies the position in the tabbing order. Enter numeric value only.

- **Tool Tip**
  Specifies helpful text appears *only* when the user hovers the mouse over the field.
  You can optionally use the Empty Text, Hint, and Tool Tip attributes together to assist the user.

- **Text Direction**
  Specifies the supported values for left-to-right and right-to-left for the direction of the text.

Attributes for Date Time Field Only

The following HTML attributes apply to the Date Time field (see page) *only*.

- **Hide Time**
  Applies *only* to the time portion of the Date Time field; this field is an optional element of a form (see page 2916).
  Specifies whether to display the drop-down list for users to select the time. Specify *true* to hide this list or *false* to display it.

- **Time Increment**
  Applies *only* to the time portion of the Date Time field; this field is an optional element of a form (see page 2916).
  Specifies the increment (in minutes) of the times that appear in the drop-down list for users to select the time. Specify any positive integer greater than zero.
  For example, if you specify 15, the following values appear in the list: 9:00, 9:15, 9:30, 9:45, 10:00, and so forth. Similarly, if you specify 30, the following values appear in this list: 9:00, 9:30, 10:00, 10:30, 11:00, and so forth.

Attributes for Dual List and Select Boxes Only

The following HTML attributes apply to dual lists (see page 2919) and select boxes (see page) only.

Additional attributes (see page 2934) apply to select boxes only.

- **Height**
  (Dual List) Controls the height of the dual list. Using this attribute displays the entire list of options *without* a scroll bar.
  (Select Box) Controls the maximum height of the drop-down list that appears when the user clicks the arrow to display the options.
  For select boxes that allow users to select multiple options, using this attribute displays the entire list of options *without* a scroll bar.

See also:

- attributes for select boxes only (see page 2934)

Attributes for Field Sets Only

The following HTML attributes apply to field sets *only*. Fields sets are basic elements of a form (see page).

- **Collapsed**
  Applies *only* to the field set element.
  Specifies whether the label of the field set is initially collapsed (true) or expanded (false).

- **Label Width**
  Specifies the width in pixels of the column layout and field set.
  You can also specify Label Width as a form attribute (see page 2927).

Attributes for Labels Only

The following HTML attributes apply to labels *only*. Labels are basic elements of a form (see page)
.

- **Label Text**
  Specifies the text for a label.
  A label identifies a form or an area of the form. For example, you can use a label at the top of the form to provide the title, such as Medical History Form. Within the form, you may have other labels, such as Family History, Eating Habits, and Illnesses. If you use a multiple-column format in your form, it may be helpful to use a label as a heading for each column.
  The Label Text attribute of a label contains the text that users see on the form, for example, as a title or heading. This Label Text attribute can contain HTML tags, which are especially helpful for highlighting purposes. For example, to specify the Family History label in bold, enter the following data in the Label Text field:

  ```
  <b>Family History Form</b>
  ```

Attributes for Radio Groups Only

The following HTML attributes apply to radio groups *only*. Radio groups are basic elements of a form (see page).

- **Orientation**
  Lets the user control the orientation of the options for the group.
  Specify horizontal or vertical (default).

Attributes for Select Boxes and Tables Only

The following HTML attributes apply only to select boxes (see page) and tables (as noted).

- **Report/Plug-in Id**
  Specifies the ID of the report data object (data object). This data object is used to pre-populate a combo box (see page 2972) or to pre-populate rows in a dynamic table (see page 2923).
  The data object returns two fields:

  - The first field returns the list of values in the combo box. Users can select one or more of these values, depending on the setting of the multiple attribute.
  - The second field returns the label for the combo box.

  The data object represents a stand-alone MDB query that does not require a JavaScript function to run.

- **Report/Plug-in Variables**
  Specifies the attribute to use user input to pre-populate a select box (see page 2973) or to pre-populate rows in a dynamic table (see page 2923).
  For example, you can specify this attribute to use the selection in one select box to determine the values in a second select box.

- **Page Size**
  Specifies the number of options that appear on one page in a drop-down list. The drop-down list appears when a catalog user performs one of the following actions:

  - Clicks the arrow of a drop-down list
  - Types text in a field and activates the auto-complete feature

  The Page size attribute applies *only* to the following elements:

  - Select boxes whose Multi-Select attribute is set to False.
  - Static table (see page 2921)
  - Dynamic table (see page 2923)

  The Page size attribute is optional and accepts *only* positive integers.
  This attribute is useful when report object returns too many options to list on a single page. In such cases, the drop-down list contains a scroll bar and page numbers. To view the values in the list, users can either scroll or click a page number.
  A blank (empty) value effectively disables pagination.
  The default is 50.

See also:

- attributes for select boxes only (see page 2934)
- attributes for tables only (see page 2937)

Attributes for Select Boxes Only

The following HTML attributes apply to select boxes only.

- **Eager**
  Applies *only* when both of the following settings are used:

  - The value of the Multi-Select attribute of the select box is False.
  - The Report/Plug-in Id attribute is set.

  Specifies a value of true or false.

  - **True**
    Loads the data from the Report/Plug-in Id attribute into the select box as soon as the user requesting the service displays the form.
  - **False**
    Loads the data from the Report/Plug-in Id attribute into the select box when the user requesting the service clicks the select box.

- **List Width**
  Specifies the minimum width of the drop-down list for a select field.
  The Form Designer uses the *larger* of the following values:
  - The width of the select field
  - The value of the List Width attribute
- **Multi-Select**
  Specifies a value of true or false.
  - **True**
    Specifies that the select box appears as a list box on the form. The user sees multiple options in the select box and can select multiple options.
  - **False**
    Specifies that the select box appears as a combo box on the form. The user can select one item from the list. The user cannot enter a custom value for this attribute.
- **Minimum Search Characters**
  Applies *only* when the value of the Multi-Select attribute of the select box is False. When this value is False, the select box appears as a combo box on the form: The user sees a list box and can select only one item from the list. Catalog users cannot enter a *custom* value in a select box. However, users can type inside a select box. As they type, the drop-down list is populated with the options that begin with the typed text. Users can select an option from this "auto-complete" list.
  The auto-complete list starts to populate after the user types the *n*th character, where *n* is the value you set for Minimum Search Characters attribute. For example, if you specify a value of 7, the auto complete options appear after the user types the seventh character.
- **Selected Index**
  Specifies the default selection.
  For example, the select box contains 10 values. If you specify 0 for the Selected Index attribute, the first value in the list becomes the default. Similarly, if you specify 5 for the Selected Index attribute, the fourth value in the list becomes the default.
  You can use a select box in a static table.

See also:

- attributes for select boxes and tables only (see page 2933)
- attributes for dual list and select boxes only (see page 2932)

Attributes for Sliders Only

The following HTML attributes apply to sliders only.

- **Increment**
  Specifies the increment by which the selected value increases or decreases with each forward or backward slide, for example, 1, 5, 10, 25, or 100.

- **Value**
  Specifies the initial value of the slider, for example, 10.

- **Maximum Value**
  Specifies the maximum value of the slider, for example, 100.

- **Minimum Value**
  Specifies the minimum value of the slider, for example, 1.

- **Message**
  Specifies the message that appears as the user slides the control. Use the following format:

  - **{0}** ***text***
    {0}displays the selected value. As the user slides the control, this value is automatically replaced with the selected value.
    text specifies the unit of measure, for example, CPU, RAM, or another meaningful unit.

For best results, specify values for these parameters and test the slider until you obtain the results that you want.

Note: You can optionally use JavaScript functions to set the values of these attributes. For details about predefined JavaScript functions, including slider-specific functions, select Administration, Tools, Links, Form Designer JavaScript API. The values are not saved if both of the following conditions exist: You use JavaScript functions to set the minimum and maximum values of these attributes, and the value is dynamic. Therefore, use the JavaScript functions to apply the values individually on each page.

Attributes for Spinner Fields Only

The following HTML attributes apply to spinner fields *only.* Spinner fields are basic elements of a form (see page).

This field enables users to select one of many values by clicking the up or down arrow. Each time the user clicks an arrow, the selected value increases or decreases by the amount that the Increment attribute specifies.

Typically, the values for a spinner field appear in meaningful, equal increments. An example is 50, 100, 150, and so forth.

- **Allow Decimals**
  Specifies whether to use decimal values, for example, in the rate or cost.

- **Allow Negative Numbers**
  Specifies whether to use negative values.

- **Increment**
  Specifies the amount by which the selected value increases or decreases each time that the user clicks the up or down arrow. For example, suppose you want to use the following values: 100, 200, 300, and 400. In this example, the increment is 100. If the selected value is 200 and the user clicks the up arrow, the selected value increases to 300.

- **Minimum Value *and* Maximum Value**
  Specify the minimum and maximum values, respectively.
  In the example for the previous attribute (Increment), the minimum value is 100 and the maximum value is 400.

- **Number Format**
  Specifies the format of the number that appears to the user, for example, 1, 2, 3, and so forth. The Form Designer uses the number format of the Google Web Toolkit. For details, see the Google Web Toolkit website. At publication time, the website is www.google-web-toolkit.googlecode.com.

Attributes for Tables Only

The HTML attributes in this topic apply to tables *only*.

Table elements have the following types of attributes:

- Table attributes apply to the entire table, that is, to *all rows* in the table.
- Row attributes apply only to the selected row.

Table Attributes

The following table attributes require explanation:

- **Report/Plug-in ID and Report/Plug-in Variables**
  Apply to dynamic tables (see page 2923).

- **Allow Edits**
  Specifies whether catalog users can manually update the data that is dynamically inserted into a row by a JavaScript function. The use of a JavaScript function for this purpose is described in the Note for the next attribute, Allow Inserts.
  If the value of Allow Edits is true, users *can* manually update this data in a form as they request a service.
  If this value is false, users *cannot* manually update this data in a form as they request a service.
  The Allow Edits attribute takes effect *only* if the Allow Inserts attribute is set to false.
  If the Allow Inserts attribute is set to true, users can *always* update data in a row, regardless of the following settings:
  - Whether you populate the row with default text, a JavaScript function, or not at all
  - Whether you set Allow Edits to true or false

- **Allow Inserts**
  Specifies whether catalog users can manually add rows to tables in a form when they are requesting a service.
  When this value is false, users *cannot* add rows.
  When this value is true, users *can* add rows by clicking an Add icon in the table. For example, you can design a service that contains a table with several predefined options. You can also enable

the user to add custom values to the table. The advantage of using such a table over a text box is that the table stores the data in *structured* format.
If Allow Inserts is true, the following conditions exist when users update the form as they request a service:

- Users can click the Add button in the table to add rows. The data that users enter must meet the validation criteria for each cell, such as minimum text length, and data format. For each cell, the type of element that you specify determines this validation criteria.
- Users *cannot* add, delete, move, or edit rows that you specify when you create the form. All rows that a user inserts are marked with red dots in their cells.
- When users add or update rows, JavaScript functions run *only* on the row being added or updated.
- User-created rows always appear at the *top* of the table, *before* all rows populated through a report data object, an API plug-in, or static data. Moreover, user-created rows always appear in the reverse order that they were added: The first rows in the table are the last rows added.
- Sorting does not apply to user-created rows. However, sorting does apply to the rows populated through an API plug-in or static data.

Note: As a form designer, you can use JavaScript functions to add rows to tables in a form while users are requesting a service. For example, use a JavaScript function to populate a row when a user clicks an option button in a radio group. This ability exists regardless of the setting of Allow Inserts. You can use either a custom JavaScript function or the predefined JavaScript function named ca_fdAddTableRow. For more information about predefined JavaScript functions, select Administration, Tools, Links, and view the *JavaScript API Reference*.

- **Auto Number**
  Specifies whether the first column of each row contains the row number.
  If the value is true, then the first column of each row displays the row number.
  The default is true.
- **Height**
  Specifies the height of the table, in pixels.
  The default is 125.
- **Maximum Selected Rows**
  Specifies the maximum of rows that users can select in the table while completing the form in a request.
  If the number of selections exceeds this value, an error occurs.
  If this value is not specified, then the number of rows that users can select is unlimited.
- **Minimum Selected Rows**
  Specifies the minimum of rows that users can select in the table while completing the form in a request.
  If this value is not specified, then the user is not required to select any rows.

- **Mode**
  Specifies whether the table functions in *selection mode* or *data mode* during the request life cycle, as follows:

  - In selection mode, the table automatically includes a check box in the first column, so that users can select one or more rows from the table. The user-selected rows appear in the request throughout the request lifecycle.

  - In data mode, the table does *not* include the check box. Therefore, users cannot select rows from the table.

  In *both* modes, if the value of the Allow Inserts attribute is True users *can* perform the following action: Configure the request by adding rows to the table and entering custom values. The catalog system automatically saves any rows that the user adds and displays them throughout the request life cycle. Users can remove each row that they added by clicking the row and selecting Remove.
  Selection mode is useful when you want users to select a set of related options for the request by selecting a row on the table. For example, you can specify the following table:

Check Box	Disk Space, GB	Memory, GB	Processor Speed, GHz	Operating System
_	700	4	2	Windows XP
_	900	6	2.4	Windows 7
_	1000	8	3	Windows 2008 Server
_	1400	8	4	Windows 7 Server

In this example, each row contains one set of configuration options for a computer reservation. Users cannot select each option individually, but they can select a set by selecting a row.

Row Attributes

The following table attributes apply to the selected row only, not the entire table:

- **Column Widths**
  Specifies a list of comma-separated values for the *widths* of each column in the table, from left to right.
  For example, if the table contains three columns, then the following points apply:

  - The first value applies to the first (left) column

  - The second value applies to the second (middle) column

  - The third value applies to the third (right) column

  Note: This attribute *applies* to the entire table, but *appears* only in the first row.

See also attributes for select boxes and tables only (see page 2933).

Attributes for Text Fields and Text Areas Only

The following HTML attributes apply to text fields and text areas *only*. Text fields and text areas are basic elements of a form (see page).

- **password**
  Specifies an attribute for text fields. Can have a value of true or false. When the value is set to true, this component becomes a password component.

- **Height**
  Specifies the number of rows in the text area. For example, if you specify 3, the text area contains three rows.

- **Maximum Length**
  Specifies the maximum number of characters that the user can enter in the field.

- **Pattern**
  In the value for this attribute, you specify regular expressions to validate numeric and address data (see page 2980). Such data includes credit card numbers, social security numbers, email addresses, IP addresses, and telephone numbers.

- **Pattern Message**
  Applies only when *pattern* (the previous attribute) is specified.
  You can specify an error message to appear when the user input violates the pattern attribute.
  You can optionally localize (see page 2987) this error message.

JavaScript Attributes for Elements

You can use JavaScript attributes to invoke JavaScript functions (see page 2966) while the user is completing the form in a request. JavaScript functions include predefined functions for validating user input into fields and any custom functions that you have written. All JavaScript attributes are named with the prefix *on*, such as onClick.

You can use the following JavaScript attributes in elements on forms. Not all attributes apply to all elements, however. Click an element to see which attributes apply to it.

Important! JavaScript attributes *must* have JavaScript functions but not JavaScript expressions as values. Conversely, HTML attributes can have JavaScript expressions but *not* JavaScript functions as values. Thus, JavaScript expressions apply to HTML attributes *only*, and JavaScript functions apply to JavaScript attributes only.

JavaScript functions in JavaScript attributes are validated when the user performs the action that the attribute specifies. Examples are clicking (for onClick) and mousing over (for onMouseOver). If the field does not validate, it is highlighted in red and an error message appears.

Note: Verify that the error messages (if any) returned by each JavaScript function are localized for the users of the form.

- **onFocus**
  Specifies the JavaScript function to run when the element comes into focus.

- **onBlur**
  Specifies the JavaScript function to run when the element loses the focus.

- **onChange**
  Specifies the JavaScript function to run when the element value is changed.

- **onClick**
  Specifies the JavaScript function to run when the component is clicked with the left mouse button.

- **onLoad**
  Applies to dual lists (see page 2919) and select boxes (see page) only.
  Specifies the JavaScript function to run when the data associated with the select is loaded. This attribute is ignored if the dual list or select box specifies static options.
  An alert appears if an onLoad function fails to run correctly, for example, if the function cannot be found. If you receive an alert, verify that function is correctly defined and referenced, and that the function runs without errors.
  Use the Script dialog (see page 2969) on each form to create and maintain the custom JavaScript functions for the form.

- **onMouseDown**
  Specifies the JavaScript function to run when a mouse button is pressed.

- **onMouseUp**
  Specifies the JavaScript function to run when a mouse button is released.

- **onMouseOver**
  Specifies the JavaScript function to run when the component is moused over.

- **onMouseMove**
  Specifies the JavaScript function to run when the mouse passes over the component.

- **onMouseOut**
  Specifies the JavaScript function to run when the mouse was moved away from the component.

- **onKeyPress**
  Specifies the JavaScript function to run when a key is pressed and released.

- **onKeyDown**
  Specifies the JavaScript function to run when a key is pressed.

- **onKeyUp**
  Specifies the JavaScript function to run when a key is released.

- **onValidate**
  Specifies the JavaScript function to run when the field is validated. The field is validated whenever the user navigates away from a field or when the user submits the form.
  If you specify a custom JavaScript function for the onValidate attribute, code that function as follows:

  - Specify an attribute that is named _val; this attribute is required to pass the current value of the field.
  - If no validation error occurs, return null.
  - If a validation error occurs, return a string with a helpful error message explaining the problem and solution. Localize error messages for each browser locale applicable to your users.

- **onLookup**
  Applies to lookup fields *only*. When the user clicks the magnifying glass for the lookup field, the JavaScript function for this attribute runs. You can use a lookup field to populate fields based on user input to a report data object (see page 2970).

Customize a Predefined Form

This scenario illustrates how Service Managers create a form by copying a predefined form and customizing the copy. You add fields and specify some fields to be auto-populated. You use spinner fields and radio buttons so that users can specify only valid options. You also show or hide fields according to the options selected by the user. Creating form in this manner helps reduce user errors and helps increase efficiency.

This scenario focuses on the onboarding of a new employee into the Lab Services group in your organization. You can use this scenario *as a model* to create a form using similar techniques.

For other use cases, search the **Catalog**, **Forms** folder for the form that most closely matches the form that you want to create. **Example:** To create a form for ordering hardware, review the Procure New Hardware form in the IT Support Services subfolder.

Note: Service Managers typically have one or more of the following roles in CA Service Catalog: Service Delivery Administrator, Services Manager, Super Business Unit Administrator, and Catalog Administrator.

Follow these steps:

- Step 1 - Review and Copy the Form (see page 2943)
- Step 2 - Add Fields for Contact Information (see page 2944)
- Step 3 - Configure Fields to be Populated Automatically (see page 2945)
- Step 4 - Copy and Modify Radio Buttons (see page 2945)
- Step 5 - Add Text Areas (see page 2946)
- Step 6 - Show and Hide Text Areas (see page 2947)
- Step 7 - Add Spinner Fields (see page 2949)

- Step 8 - Test the Form in a Service (see page 2949)

Important! We recommend that you do not create multiple forms with the same _id value for each form. If you already have multiple forms with the same _id value, do not associate such forms to a single Service Option. Having multiple forms with the same _id value in a single Service Option can cause validation errors.

Step 1 - Review and Copy the Form

All services include at least one predefined or custom form to record essential information from the user requesting the service. In this scenario, you review and copy the predefined form included with the standard New Hire Onboarding service. Afterwards, you modify the copied form for use by the New Hire Onboarding for Lab Services group.

Follow these steps:

1. Click **Catalog**, **Forms**.
2. Expand **Forms**, **CA Catalog Content** in the Component Tree.
3. Select **New Hire Onboarding**.
4. Click Copy.
5. Move the top level of the Forms folder and complete these actions:
   a. Click **Add** and create a subfolder and call it Custom.
   b. Select the Custom folder and click Paste.
   The form is copied, and its new name is "copy of *original name*." The copied elements under the copied form are *not* renamed.

      Note: If you copy the form from one business unit to another, the pasted form, including all elements under it, belong to the business unit of the destination folder.

   c. Select the form and click Rename.
   d. Enter the new name as New Hire Onboarding for Lab Services. Click OK.

Note: The name must be unique within its business unit.

6. Specify new_hire_onboard_labservices in the _id attribute for the form, press Enter, and click Save.

> **Note:** After you specify a new value for any attribute, press Enter to enable the Save button. This value of the _id attribute of the form is the form ID. Specify a unique ID for each form in a business unit.

Step 2 - Add Fields for Contact Information

Modify the form that you copied in the previous procedure by adding more contact information fields. These new fields increase the options for other employees to communicate with the Lab Services employees.

Follow these steps:

1. Expand the New Hire Onboarding for Field Lab Services form.
   The list of components in the form appear in the tree under the form name. This list matches the same named components in the middle pane.

2. Copy the Last Name field, to create another field, as follows:

   a. Select the Last Name field in the tree, and click the Copy icon.

   b. Select the name of the New Hire Onboarding for Lab Services form in the tree, and click Paste.

   c. In the _id attribute in the right pane, specify a unique ID. For example, employee_id. Press Enter and click Save.

3. Rename the new field, as follows:

   a. Select the field and click Rename.
      The Name dialog appears.

   b. Enter the new name as Employee ID. Click OK.

4. Move the Employee ID field, as follows:

   a. Select the name of the field in the tree.

   b. Drag it upwards until the horizontal line for the field appears above the Job Title field, and drop it.

   c. Verify that the First Name, Last Name, and Employee ID fields now appear sequentially in the tree.

5. Using steps 2-4 as a model, add the following new fields and move them under the Employee ID field:

- Email
- Phone number
- Address

You have added more fields for contact information.

Step 3 - Configure Fields to be Populated Automatically

Use JavaScript expressions to retrieve the data from the user database and populate the fields automatically to reduce errors and increase efficiency.

Follow these steps:

1. Expand the Forms tree to display the fields of the New Hire Onboarding for Lab Services Only form.
2. Specify the following JavaScript expressions in the Value attributes of the following fields. Press Enter and click Save after you specify each value.
   - First name: $(_.user.firstName)
   - Last name: $(_.user.lastName)
   - Employee ID: $(_.user.id)
   - Email: $(_.user.email)
   - Phone: $(_.user.phone)
   - Address: $(_.user.address)

When a catalog user opens this form while requesting a service, these fields are automatically populated based on the user ID specified at login.

Step 4 - Copy and Modify Radio Buttons

You can add radio buttons to the New Hire Onboarding for Lab Services Only form to allow users to select the type of server. Copying and modifying the radio buttons is more efficient than creating them. Therefore, you copy the radio buttons from the Procure Sun Server form and modify them for this form.

Follow these steps:

1. Expand **CA Catalog Content** in the Forms tree and perform these actions:
   a. Expand **Procure Server** and **Procure Sun Server**.
   b. Select the Choose Server Model field and click the Copy icon.
   c. Navigate the Forms tree to the New Hire Onboarding for Lab Services Only form. Select this form and click the Paste icon.

2. Move the Choose Server Model field, as follows:

    a. Select the name of the field in the tree.

    b. Drag it upwards until the horizontal line for the field appears above the Additional Info field, and drop it.

    c. Verify that the Hiring Manager, Choose Server Model, and Additional Info fields now appear sequentially in the tree, followed by the other fields.

    d. Verify that the Choose Server Model field includes these options Starter, Mid Size, and High End.

Note: The values for _id and other attributes for these fields are already set, because you copy them rather than create them. We use the same attribute values in this scenario because the values remain unique within the same form.

Step 5 - Add Text Areas

Add a text area to provide specifications for each type of server.

Follow these steps:

1. Verify that the New Hire Onboarding for Lab Services Only form is displayed in the Preview Pane.

2. Click **Components**, **System** in the Form tree.

3. Drag and drop the the Text Area element to your form directly above the Additional Info field.

4. Verify that the text area appears above the Additional Info field in the Preview Pane.

5. Select the Text Area in the tree and click the **Rename** button. Specify the new name as Starter.

6. Specify these values for the following attributes. After you specify each value, press Enter and click Save.

    - _id: starter_description
    - Value: 10K (ULTRA 10000, Starfire) UltraSPARC® processor
    - Disabled: true
      This setting means that this field is read-only, so that users *cannot* change the text that you specified.
    - Hidden: false

7. Repeat the previous steps for the next two text areas: Mid Size and High End. Use the following specifications for the attributes:
   Mid Size Text Area:

   - Name: Mid Size
   - _id: midsize_description
   - Value: 20K UltraSPARC IV & UltraSPARC III Processors
   - Disabled: true
   - Hidden: true

   High End Text Area:

   - Name: High End
   - _id: highend_description
   - Value: E25K UltraSPARC IV & UltraSPARC III Processors
   - Disabled: true
   - Hidden: true

8. Verify that the three Text Area fields appear on the form before the Additional Info field.

Step 6 - Show and Hide Text Areas

Add JavaScript functions to the form so that *only* the description of the selected server type (Starter, Mid Size, or High End) appears. If the user selects a new server type, the previous description is replaced with the description for the new selection. This enhancement helps save time for the user by eliminating the need to scroll through multiple static descriptions. This reduced scrolling is especially helpful for mobile users.

Follow these steps:

1. Select the New Hire Onboarding for Lab Services Only form in the Preview Pane.
2. Click the Script icon at the top of the form and proceed as follows:
   a. Delete the existing sample code.
   b. Copy and paste the JavaScript code from the section that is named JavaScript for New Hire Onboarding for Lab Services into the Script dialog.
   c. Save the script, and close the dialog.
3. Expand the form to show the fields for the Choose Server Model radio buttons.

4. Enter the following JavaScript function call in the onClick attribute of the Starter, Mid Size, and High End fields. After you update the attribute for each field, press Enter and click Save.

   ```
   ca_fd.js.onFormLoad();
   ```

   This call loads the JavaScript code that you copied earlier to the Script dialog for the form.

JavaScript for New Hire Onboarding for Lab Services

```
{
  onFormLoad : function() {
    ca_fd.js.clickStarter();
    ca_fd.js.clickMidSize();
    ca_fd.js.clickHighEnd();
  },

// ShowFields/HideFields either shows or hides the description field for Starter
servers when Starter radio is changed
// ResetFields will reset MidSize and HighEnd when selected and clicked away from
Starter
// This function is called in to Starter radio's onChange
  clickStarter : function() {
    if (ca_fdIsSelectRadio('new_hire_onboard_labservices','class','starter')) {
ca_fdShowField('new_hire_onboard_labservices','starter_description'); }

    else {
ca_fdHideField('new_hire_onboard_labservices','starter_description');

        ca_fdResetFields('new_hire_onboard_labservices',['starter_description']); }
  },

// ShowFields/HideFields will either show or hide the description field for Mid Size
servers when MidSize radio is changed
// ResetFields will reset the description field for Mid Size servers when selected
and clicked away from MidSize
// This function is called in to MidSize radio's onChange
  clickMidSize : function() {
    if (ca_fdIsSelectRadio('new_hire_onboard_labservices','class','midsize')) {
            ca_fdShowField('new_hire_onboard_labservices','midsize_description'); }

    else {
ca_fdHideField('new_hire_onboard_labservices','midsize_description');

        ca_fdResetFields('new_hire_onboard_labservices',['midsize_description']); }
  },

// ShowFields/HideFields will either show or hide the description field for High End
servers when HighEnd radio is changed
// ResetFields will reset hide the description field for High End servers when
selected and clicked away from HighEnd
// This function is called in to HighEnd radio's onChange
  clickHighEnd : function() {
```

```
    if (ca_fdIsSelectRadio('new_hire_onboard_labservices','class','highend')) {
        ca_fdShowField('new_hire_onboard_labservices','highend_description'); }

    else {
ca_fdHideField('new_hire_onboard_labservices','highend_description');

        ca_fdResetFields('new_hire_onboard_labservices',['highend_description']); }

  },
}
```

Step 7 - Add Spinner Fields

As a best practice, configure each form so that users can specify only a valid number of items. This practice helps reduce errors. To implement this practice, the form uses a spinner to field to let users request 0-10 servers of each type.

Follow these steps:

1. Verify that the New Hire Onboarding for Lab Services Only form is displayed in the Preview Pane.
2. Click **Components**, **System** in the Form tree.
3. Drag and drop the Spinner Field element to your form directly above the Additional Info field.
4. Verify that the Spinner Field appears above the Additional Info field in the Preview Pane.
5. Select the Spinner Field in the tree and click the **Rename** button. Specify the new name as Number of Starter Servers.
6. Specify these values for the following attributes. After you specify each value, press Enter and click Save.
   - Maximum Value: 10
   - Minimum Value: 0
   - Increment: 1
7. Repeat the previous steps for the next two fields: Mid Size and High End.
   Letting users specify 0-10 of each type of server provides flexibility for users. To prevent users from specifying 0 for all three types, specify a value of 1 or higher as the default value of one field.
8. Verify that the three spinner fields appear on the form before the Additional Info field.

Step 8 - Test the Form in a Service

Test the form before you make the form available in a service.

Follow these steps:

1. Select the service to which you want to add the form.
2. Add the form to a service option group in that service.
3. Verify that the service is available.
4. View the service in the catalog, complete the form, and submit the request.
5. Verify the specifications if you detect any errors.
   For example, if the text areas do not show or hide as planned, verify that the related JavaScript code and attributes (see page 2947) are correct.

Create and Customize a Form

This article contains the following topics:

Administrators add and configure elements on forms, including text fields, check boxes, radio buttons, and more. Each element of the form captures information for approving and completing a request for a service. All services include at least one

Important! We recommend that you do not create multiple forms with the same _id value for each form. If you already have multiple forms with the same _id value, do not associate such forms to a single Service Option. Having multiple forms with the same _id value in a single Service Option can cause validation errors.

Follow these steps:

1. Verify that the elements do *not* duplicate fields on other forms for the same service, including system forms (see page).
2. Decide which elements you want on the form and in which order. Verify that each part of the draft form has a matching element on the Form Designer.
3. Using the Form Designer, create a form (see page 2951).
   Alternatively, consider these options:
   - Use an existing Form Designer form.
   - Use an existing Form Designer form as a starting point, and modify it to include the changes you want.
     For both possibilities, see the forms in the predefined services and any custom services that you have. See also the forms in the content packs.

- Use the Customize a Predefined Form (see page 2942) scenario and create a form by copying and modifying the predefined form.

4. For each element, specify the HTML attributes and JavaScript attributes (see page 2954).
5. Attach the form to a service option group (see page 2954) and test it in a service.

Create a Form

You can create a form to include in a request. You can also capture user input that is required to complete the request. For example, a form typically lists options and records the ones that the user selects.

Note: The form level associations are showed only for the selected Business Unit level.

Follow these steps:

1. Click **Catalog**, **Forms**.
2. Click the **Forms** folder to select it.
3. Click the **Add** button above the **Components** folder and select **Form** from the drop-down list.
4. Enter the name of the new form and click OK.
   The new form appears in the Forms folder. The form attributes appear in the Item Inspector (the right pane).
5. Specify the required and optional form attributes (see page 2927). These attributes are for *the form itself*. These attributes are *not* the same as the HTML and JavaScript attributes of the *elements* on the form.

Add, Move, and Delete Elements

You can add and configure the elements (see page 2916), such as text fields, text areas with check boxes and radio buttons.

Follow these steps:

1. Click **Components** and expand **System**. Verify that the element you want to add appears in the tree view under the System folder.
   For example, to add a text field, verify that the System folder appears and is expanded to show the Text Field option. Similarly, to add a select box and its options, verify that the System, Radio Group folder appears and is expanded to show the Radio option.
2. Verify that the form to which you want to add the element already exists.
3. Expand the **Forms** folder. Scroll to the form to which you want to add the element.

4. Verify that both the element you want to add and the intended form are visible in the tree view simultaneously.

5. Click the element (for example, Text Field), drag and drop it on the intended form in the Component Tree.
   For example, you have a custom form named Model Options. Click Text Field under the System folder. Drag Text Field to Model Options, and drop it there. All these actions can be on the Component Tree or the Preview Pane.
   When you click and drag an element, both a checked circle and the message "1 object selected" appear next to the cursor.
   As you drag the element over a form or existing form element on which it can be dropped, the checked circle turns green. Also, the cursor changes to appear as a hand. Conversely, the checked circle turns red when the dragged element is not over a form or form element on which it can be dropped.

   Note: The element is not added if the attempted action violates a rule. Examples include attempting to drop a select option onto a radio group or to drop a select group onto another select group.

6. Specify the *required* HTML attributes (see page 2928) for the new element, and click Save.
   The required HTML attributes for each element appear in bold.

   Note: Attempts to perform a different action *before* completing this step fail. For example, attempts to drag-and-drop a new element *before* saving this element fail.

7. Check the form in the Preview Area (the middle pane) to verify that the element was added to the form as intended. If it was not, you can either rearrange the elements or delete the new element and try adding it again.

8. Specify the optional HTML (see page 2928) attributes (see page 2928) (if any) that you want for the new element, and click Save.

9. By default, components are organized in one column. You can optionally configure the form to use two columns, as follows:

   a. Drag Column Layout from the System folder and drop it onto a desired form.

   b. When you drop this layout, the tree updates with Column Layout and its two children, Column 1 and Column 2 automatically.

   c. Click the icon next to Column Layout to display the two columns, which are named Column1 and Column 2.

   d. Drag-and-drop other elements, such as text fields, radio groups, and select boxes, onto Column 1 and Column 2.

> **Note:** When you highlight the Column Layout or a Column, the corresponding sections in the Preview Area of form may be rendered gray and disabled, and the elements within the column may be highlighted with red border.

10. Specify the JavaScript attributes (see page 2940) (if applicable) for the new element, and click Save.

11. Specify a meaningful name for the new element, as follows:

    a. Select the new element in the Component Tree and click the **Rename** button at top of the Component Tree.

    > **Note:** Verify that you select the new element on *your* form in the Component Tree. Do *not* select the same-named element on the *System* folder in the Component Tree.

    b. Enter the new name and click OK.

    For example, perform these actions in a custom External Storage Drive Order Form:

    - Drag-and-drop a radio group and change its name from the default Radio Group to Capacity in GB.
    - Drag-and-drop three radio buttons onto that radio group. Change their names from the default radio button to Small (50), Medium (100), and Large (150), respectively.

    > **Note:** When you create a new element, a colon (:) is automatically included at the end of its name. The colon does not appear in the Name dialog when you rename the element. However, it does appear in the Preview Area after you click OK to close the dialog. Verify that you do not enter another colon in the Name dialog. Otherwise, the element has *two* colons after its name in the Preview Area.

12. Verify that the new element appears and functions as you intended. If necessary, refine any attributes to obtain the appearance and function you want.

13. (Optional) Move elements on the form by dragging and dropping them onto a different location in the form.

14. (Optional) Delete the elements that you no longer want on the form by selecting them and clicking **Remove**.

Specify Attributes for an Element

After administrators add an element to a form, they specify its required HTML attributes and any optional HTML attributes or JavaScript attributes. Specifying these attributes helps you modify the element to meet your requirements.

Follow these steps:

1. Click **Catalog**, **Forms**.
2. Open your form. For example, expand the Forms folder and select the form whose elements you want to configure.
3. Click the icon next to the form name to expand the folder for the form and display its elements.
4. Select the element whose attributes you want to set.
   The Item Inspector (the right pane) displays the names and values of all HTML attributes and JavaScript functions available for the selected element.
5. In the Item Inspector, search the Name column and locate the attribute, one of the following types:
   - HTML Attributes (see page 2928)
   - JavaScript Attributes (see page 2940)
6. Move your cursor to the adjacent field in the Value column and click.
7. Enter the value for this attribute and click Save.
   For example, you can set the value for Hidden attribute of a Label element.
8. Verify that all required attributes are set correctly.

Attach a Form to a Service Option Group

Administrators attach a form to one or more applicable service option groups. Users who select one of these service options in a request are prompted to complete the form. The form lets the user enter data to complete the request.

Follow these steps:

1. Click **Catalog**, **Service Offerings**,**Option Groups**.
2. Click the service option group name to which you want to add the form.
3. Click the **Edit** icon for the service option to which you want to add the form.
4. Click the **Add** button for the form.
5. Enter meaningful text that describes the purpose of this form, in the Display Text Field.

6. Click the magnifying glass icon in the Form Name field to select a form.
7. Navigate through the form tree and select the form that you want to attach.
8. Click the Select Form button.

   Note: You can add a form to a service option only once.

9. If you do *not* want to hide or disable the entire form at any point, leave the Hidden and Disabled fields blank. In that case, skip the remainder of this step.
   If you want to hide or disable the entire form according to a criteria, enter the corresponding JavaScript expression in the Hidden or Disabled field. Use the following format: $(_.*object*.*property*). The expression must return a value of true or false.
   Example:

   - To hide or disable the form when the request status is Pending Approval, enter: $(_.request.status == 400)
   - To hide or disable the form for end-user roles *only*, enter: $(_.user.role == 'enduser')

   You can also specify other JavaScript expressions in fields (see page 2957).

   Note: When a form is disabled, it is disabled but visible during all stages of the request life cycle *except* check-out. During check-out, a disabled form is both disabled and hidden.

10. Click the Options tab and complete the remaining fields on the Service Option Element Options Window--Options Tab (see page 3019).
11. Click Update and click Save.

Perform Automated Tasks in Form Fields

Administrators can use JavaScript expressions and JavaScript functions to perform automated tasks in form fields. At runtime, when the user fills out the form while completing a request, the JavaScript expression or function runs and performs the specified task.

Important! To use JavaScript expressions and functions, you must have a working knowledge of HTML, CA Service Catalog administration, and JavaScript.

Follow this process to specify automated tasks in fields, using one or more of the following options: JavaScript expressions, JavaScript functions, and report data objects.

1. Verify that you can represent the field or fields as one or more of the elements (see page 2916) available for creating forms. The elements can be text fields, check boxes, select boxes, or radio groups.

2. Determine whether to achieve the goal you intend for the field by one or both of the following methods:

   - Specifying a JavaScript *expression* for the value of an *HTML* attribute of the element
   - Specifying a custom or pre-defined JavaScript *function* for the value of a *JavaScript* attribute of the element

3. Consider specifying a JavaScript expression (see page 2957) for the value of an HTML attribute of the element. The JavaScript expression runs only once, as soon as the form appears. Examples:

   - Pre-populating user-related data in one or more fields on a form.
   - Disabling a field based on the request status, on the business unit or role of the user completing the form.
   - Hiding a field based on the request status, on the business unit or role of the user completing the form.

   JavaScript expressions retrieve the values of object properties from the CA Service Catalog database at runtime. These properties are grouped into the following categories: user, business unit, service, service option groups, and request.

   Note: To hide an *entire* form, you do not specify JavaScript expressions for any fields but for the entire form when you attach the form to a service option group.

4. Consider specifying a JavaScript function (see page 2966) for the value of a JavaScript attribute of the element. (For more information about *predefined* JavaScript functions, select Administration, Tools, Links, Form Designer JavaScript API.)
   This method is best suited for dynamic events that occur when the user performs an action while completing the form. The JavaScript function can run multiple times when a user checks a box, enters a value, or performs some other action. Thus, JavaScript functions are most useful when you want to create dynamic relationships between fields.

   - Enabling or displaying a list of options or fields under a check box when a user enables the check box.
   - Disabling or hiding a list of options or fields under a check box when a user clears the check box.

5. Test the JavaScript expressions and JavaScript functions to verify that they accomplish your goals for the fields on the form.

Use JavaScript Expressions in Fields

This article contains the following topics:

Administrators follow this process to use JavaScript expressions to perform automated tasks in fields:

1. Decide the fields on the form for which you want to specify a JavaScript expression. Also, decide the task that you want the JavaScript expression to perform. For example, you can pre-populate fields. You can hide or disable forms or fields under certain specific conditions. Another example is to pre-populate the value attribute of a field with the runtime value of one of many objects and properties from the CA Service Catalog database. To pre-populate a field for a user while the user is completing a form, specify a simple JavaScript expression for the value attribute of the field, using the following format: $(_.*object*.*property*), such as $(_.user.lastName)

2. Verify that you can represent the field as one of the elements (see page 2916) available for creating forms.

3. Verify that the purpose or goal you intend for the field is represented in one of the following HTML attributes (see page 2928). You can specify JavaScript expression for the values of the following HTML attributes *only*.

   - Value - Value is the only attribute for which you can use JavaScript expressions to pre-populate values in fields. The value attribute is most frequently used for this purpose, especially for pre-populating user-related data such as address, phone numbers, business unit, and other personnel-related data

   - Disabled - You can disable a field, according to the user's role or business unit, the request status, or other criteria that you specify.

   - Hidden - You can hide a field, according to the user's role or business unit, the request status, or other criteria that you specify.

   - Checked - Check boxes and radio buttons support the checked attribute.
     You can select a check box or a radio button, according to the user's role or business unit, the request status, or other criteria that you specify.

   - Required - You can set a field as required, according to the user's role or business unit, the request status, or other criteria that you specify.

4. Keep in mind these rules when coding JavaScript expressions for use in the HTML attributes:

- For the disabled, hidden, checked, and required attributes, the JavaScript expression must return a value of true or false.

- If the returned value is any value except true, CA Service Catalog automatically uses a value of false. The value attribute is the only attribute that is used for pre-populating fields.

5. Review the objects and properties that you can specify in JavaScript expressions (see page 2958) and determine which ones you need. These objects and properties are retrieved from the CA Service Catalog database at runtime, as noted earlier, and are grouped according the following categories: user, business unit, service, service option group, and request.

6. If the objects and properties that you need cannot be retrieved using a JavaScript expression, consider using the following pre-defined JavaScript function (see page 2967) to retrieve them: ca_reportQuery(reportId, variables, onSuccess, onFailure).

7. Review and follow the instructions for performing any of the following tasks or use them as a model for a similar task, if applicable:

   - Pre-populate fields (see page 2963)

   - Hide or disable a field (see page 2964) based on the request status, the business unit or role of the user completing the form, or on other criteria

   - Select options for fields by default (see page 2965) based on the request status, the business unit or role of the user completing the form, or on other criteria; you may select a check box or an option in a radio group by default, based on such criteria

   - Hide, enable, or disable an entire form under specified conditions (see page 2966).

8. Using all applicable information from the previous steps, construct and test the JavaScript expression to accomplish your goals for the fields on the form.

Objects and Properties that You Can Specify in JavaScript Expressions

You specify objects and properties in JavaScript expressions. You can use these expressions for the runtime values of the *value* attribute for the elements that you use as fields on forms. Typically, you specify these expressions in the following format: $(_.*object*.*property*).

For example, to capture the runtime value of the logged in user completing the form in a request, specify $(_.user.firstName). You can also concatenate strings, as explained later in this topic.

Forms

The form object contains the following property that you can use in JavaScript expressions or as a first parameter in JavaScript functions (see page 2967): ca_fd.formId.

formId refers to the *active* form. The form is in active when a field in the form triggers an event. The following are a few sample actions that activate forms:

- The user opens the form while working on a request, which activates the JavaScript attribute named onLoad.

- The user clicks a label or image, which activates the JavaScript attribute (see page 2940) named onClick.
- The user submits the form, which activates the JavaScript attribute named onSubmit.

User

The user object contains an array of user properties that you can access using _.user.

Each user object has the following properties, listed in related groups:

- id, uuid, status (0 = active, 1 = inactive)
- firstName, lastName, middleName, commonName, alias, title
- groups
  The _.user.groups property specifies the name of a user group in CA EEM. You can use this property to manipulate a field based on whether the user belongs to a specific CA EEM group. For more details, see the Example section.
  The _.user.groups property contains an array with all the CA EEM groups to which the user belongs.
- manager, delegate, description
- phone (an array: phone[0] = primary and phone[1] = secondary)
- mobile, fax, pager, email
- timezone, localeLanguage, localeCountry, defaultRole, defaultDomain, location.uuid, location.name, location.city, location.state, location.country, location.postalCode, location.phone, location.fax, location.description, location.address[0-5]
- roles.<domain>

Examples

You can use the _.user.groups property to hide a field from members of a CA EEM group, for example, the group named developers. To do so, set the value of the HTML attribute (see page 2928) named Hidden to the following:

```
_.user.groups.indexOf("developers") >= 0
```

In contrast, you can also make a field visible to users who are *not* members of a CA EEM group. To do so, set the value of the Hidden attribute to the following:

```
_.user.groups.indexOf("developers") < 0
```

Business Unit

The business unit object contains an array of business unit properties that you can access using _.bu.

Each business unit object has the following properties, listed in related groups:

- id, name
- type(business unit type where SP=service provider, ST=can have child business units, TE=cannot have child business units)
- singleAccountMode (true or false)
- status (0=inactive, 1=active)
- openedDate, description, timezone, federalTaxId, stateTaxId, taxRegion, currency, dateFormat, parent (parent bu id)
- email, website, primaryContact (contact userid), location.uuid, location.name, location.city, location.state, location.country, location.postalCode, location.phone, location.fax, location. description, location.address[0-5]
- data1, data2, data3, data4, and data5

Request

The request object contains an array of request properties that you can access using _.request.

Each request object has the following properties, listed in related groups:

- id, name, requestedFor, requstedForAccountId, requestedBy, requestedByAccountId
- description, priority, status
- dateCreated, completionDate, dateRequired, and lastModified
- newDateRequired, newName, and newPriority
  These properties reflect the new value of an object as soon as the user updates the object during the request lifecycle. (The user is typically a request manager or the requestor.)
  The user can update the object, for example, while approving, rejecting, or pushing through the pending action for the item associated with the property. The *new* value takes effect *immediately* when the user updates the property; saving is *not* required.
  When creating or editing forms, you can use these properties at your discretion. For example, you can use these properties in a custom JavaScript function for validation that you use in the JavaScript attribute (see page 2940) named OnSubmit. For example, if a user enters an invalid date such as a holiday, your custom JavaScript function can display text explaining the valid dates.

Service

The service object contains an array of services that you can access using _.service.

Each service object has the following properties, listed in related groups:

- id, bu, name, description
- status(0=deleted, 1=available, 2=unavailable, 3=created, 4=cancelled, 5=total)
- website, code, version, dateAvailable, dateUnavailable, dateCreated, dateCancelled

Service Option Groups

The service option groups object contains an array of service options that you can be access using _.sog.name.

Each service option group has the following properties, listed in related groups:

- id, bu, name, description
- status(0=deleted, 1=available, 2=unavailable, 3=created, 4=cancelled, 5=total)
- code
- dateAvailable, dateUnavailable, dateCreated, dateCancelled

Service Options

The service option object applies *only* to the predefined JavaScript function (see page 2967) named _.serviceoption.status( ).

The _.serviceoption.status( ) function contains a single property, which is named newStatus.

Note: This function does *not* take any parameters.

- **newStatus**
  Specifies the *new* value for the status when a user action updates the status of the service option. This property takes the new value for the status as soon as the user does one of the following:
  - Selects a new status value from the drop-down list in the Action column while managing requests pending action (see page 2205) . A request manager typically performs this action. The value of newStatus changes dynamically as soon as the user selects the new status of the service option.
  - Opens a page or dialog that changes the status to a fixed value when the user clicks OK. For example, when a user creates a request, the value of newStatus changes dynamically as soon as the user creates the request. In this example, the value of newStatus immediately becomes Submitted.

  In both cases, the value of _.serviceoption.newStatus() changes immediately. In contrast, the value of _.serviceoption.status( ) remains unchanged until the page is submitted and refreshed.

Examples

You can use the newStatus property to help your implementation process reservations efficiently. For example, suppose a user submits a main request for a computer and additional requests for related options. These options include extra memory, an upgraded keyboard, and so forth. You can create a custom JavaScript function so that if the main request is rejected, the onSubmit function runs for all optional requests. Examples of optional requests include accessories, extra memory, and so forth. For example, the following expression evaluates to True when the original status is 400 and the newStatus is changed to 800:

```
if (_.serviceoption.status() == 400 && _.serviceoption.newStatus == 800)...
```

Operators

The operators most commonly used for form design are described here. For complete details about standard operators, see the JavaScript standards reference that your organization uses, for example, www.developers.sun.com, or www.javascript.com.

You can specify all standard operators in your JavaScript expression *except* assignment operators.

The assignment operators are as follows: =, +=, -=, *=, /= .

For example, the folowing expression is invalid because it uses the = assignment operator:

```
$(var x = 1+2)
```

Required Return Values

Specify JavaScript expressions for the disabled, checked, and hidden attributes that return one of the following values:

- true or “true”
- false or “false”

If the expression returns any other value, CA Service Catalog replaces it with a value of false. Therefore, if you specify $(_.user.firstName) for the disabled attribute of a text field, the field is not disabled unless "true" is the first name of the user.

Concatenation Operators

You can optionally concatenate two strings together, using the + operator,

For example, $(‘Hello ‘ + _.user.firstName + ‘ ‘ + _.user.lastName) returns the following text: Hello *first-name last-name.* "Hello John Doe" and "Hello Jane Smith" are samples.

Comparison Operators

You can optionally use the following comparison operators:

- == is equal to
- === is exactly equal to (value and type)
- != is not equal
- > is greater than
- < is less than
- >= is greater than or equal to
- <= is less than or equal to

Logical Operators

You can optionally use the following logical operators:

- and (&&)
- or (||)
- not (!)

Pre-Populate Fields Based on JavaScript Expressions

When you use an element (see page 2916) that includes the *value* attribute as a field on a form, you can use a JavaScript expression to pre-populate the element's value attribute with the runtime value of one of many objects and properties from the CA Service Catalog database.

For example, in the text field for First Name on your form, you can specify the JavaScript expression $(_.user.firstName) to pre-populate the field with the first name of the logged in user ID who is creating the request and completing the form. Similarly, in the text field for Last Name, you can specify the JavaScript expression $(_.user.lastName) to pre-populate the field with the user's last name.

Follow these steps:

1. Design and create the form (see page 2951).
2. Review the guidelines for using JavaScript expressions in fields (see page 2957) and verify that you want to pre-populate the value attribute of an element in the field.
3. Verify that the data that you want to pre-populate is one of the objects and properties that you can specify in JavaScript expressions (see page 2958). These objects and properties are related to the logged in user's personnel data, to one or more business units, or to service, service options, status, or other data related to the request that contains the form.
4. Specify the JavaScript expression in the value attribute of the element for the field. When specifying the expression, follow all syntax rules in objects and properties that you can specify in JavaScript expressions (see page 2958), especially the rules related to using operators to link properties. The following examples are some valid expressions:
   - User's first name: $(_.user.firstName)
   - User's last name: $(_.user.lastName)
   - User's first name and last name, concatenated in a single field: $(_.user.firstName + ' ' + _.user.lastName)
   - User's physical address data, concatenated in a single field: $(_.user.location.address[0] + ' ' + _.user.location.address[1] + ' ' + _.user.location.city + ' ' + _.user.location.state)
     This example returns the street address, city, and state of the user, for an address in the United States.
   - User's role: $(_.user.roles[domainId])

- User's business unit, with parent: $(_.bu.id)
- User's business unit, without parent: $(_.bu.id.parent)

5. Test the JavaScript expression to verify that it accomplishes your goals for pre-populating the field on the form.

Hide or Disable a Field Based on Request Status, Business Unit, Role or Other Criteria

Decide to use JavaScript expressions to hide or disable a field based on the request status, on the business unit or role of the user completing the form, or on other criteria.

As an administrator, you typically disable fields that you want users to view but *not* update. Examples include options for a service that the user's manager selected or that the request manager selected based on available inventory.

In contrast, as an administrator, you can hide fields when you either do not want users to be aware of them at all, for some reason, or when the fields add distracting information that the user does not need. Examples include cost data, inventory options available to certain roles only or certain business units only, or data that does affect the end user, such as the estimated administrative cost of fulfilling the service.

To hide a field, specify the JavaScript expression that specifies your criteria in the hidden attribute of the field element. Similarly, to disable a field, specify the JavaScript expression that specifies your criteria in the disabled attribute of the field element.

Important! Hiding or disabling a *field* is not completely secure. While the field and its value are not displayed on the CA Service Catalog page, the data does still exist on the form's HTML page and can be accessed by viewing the source text of the browser. Therefore, to restrict sensitive data, create two versions of the form and hide the form that contains the sensitive data from users who you do not want to see it. For more information, see How to Hide, Enable, or Disable an Entire Form Under Specified Conditions (see page 2966).

Follow these steps:

1. Design and create the form (see page 2951).
2. View the field that you want to enable or disable and verify that it includes the HTML attribute (see page 2928) named disabled.
3. Determine the exact criteria that you want to use to disable or enable the field. Examples of the criteria are the request status, the business unit or role of the user completing the form. If the disabled attribute is set to true, users can view the field but cannot edit it. Conversely, if the disabled attribute is set to false, users can both view and edit the field.
4. Verify that the data that you want to use to determine whether to enable or disable the field is one of the objects and properties that you can specify in JavaScript expressions (see page 2958).
5. Review the guidelines for using JavaScript expressions in fields (see page 2957).

6. Specify the JavaScript expression in the value attribute of the element for the field. The following examples are some valid expressions:

- To hide or disable a field if the user has the end-user role, set the hidden or disabled attribute of that field to the following JavaScript expression: $(_.user.roles[_bu.id]==’enduser’).
  This expression returns a value of true and therefore hides or disables the field *only* if the user filling out the form has an enduser role in the current business unit.
  You can use this setting or a similar one to restrict users from either viewing or editing the text field that is named Memory in a form for a request for a new laptop computer. Conversely, this example displays or enables the field for all other roles in the business unit. Thus, when used with the disabled attribute, this example permits the request manager to edit the field, based on the available inventory.
  To display or enable a field for only request managers, hide or disable it for all other roles, by setting the hidden or disabled attribute of that field to $(_.user.roles[_.bu.id] != ‘requestmanager’).

- To hide or disable a field in a form that is shared by all business units *only* if the current business unit is PBJ222, set the hidden or disabled attribute of that field to $(_bu.id==’PBJ222’).

Select Options for Fields by Default Based on Request Status, Role, Business Unit, or Other Criteria

As an administrator, you can use JavaScript expressions to select a check box by default or select an option for a radio group by default,.Conversely, you can clear certain check boxes or radio group options by default according to such criteria. For example, select the check boxes related to publicly known managerial duties by default for managers only, while clearing them for other users.

Selecting or clearing the check box or radio group option by default does not prevent the user from changing the default that you specified before submitting the request that contains the form. Therefore, before using this feature, verify that permitting users to change the default is appropriate. Consider redesigning the form to either hide or disable the field (see page 2964) the options that you want to prohibit users from changing, according to the criteria specified in your JavaScript expression.

Follow these steps:

1. Design and create the form (see page 2951).

2. On the Form Designer, view the check box or radio group option that you want to select by default and verify that it includes the HTML attribute (see page 2928) named checked.

3. Determine the exact criteria that you want to use to select the check box or radio group option by default. The criteria can be based on the request status, on the business unit or role of the user completing the form, or some other criteria.

4. Verify that the data that you want to use to make the selection is one of the objects and properties that you can specify in JavaScript expressions (see page 2958). These objects and properties are related to the logged in user's personnel data, to one or more business units, or to service, service options, status, or other data related to the request that contains the form.

5. Review the guidelines for using JavaScript expressions in fields (see page 2957).

6. To select a check box or select an option for a radio group by default, specify the JavaScript expression that specifies your criteria in the checked attribute of the field element. When the user opens the form, the expression runs as follows:

   - If the criteria *are* satisfied, then value that is returned is true. Therefore the check box or radio group option is selected by default.
   - If the criteria are *not* satisfied, then value that is returned is false. Therefore the check box or radio group option is *not* selected by default.

   When specifying the expression, follow all syntax rules in objects and properties that you can specify in JavaScript expressions (see page 2958), especially those related to using operators to link properties. The following examples are some valid expressions: In these examples, the term *option* refers to both a check box and a radio group option.

   - To select an option by default if the user has the enduser role, set the checked attribute of that field to the following JavaScript expression: $(_.user.roles[_bu.id]==’enduser’). This expression returns a value of true and therefore selects the option by default *only* if the user filling out the form has an enduser role in the current business unit.
   - To select an option by default for request managers only, set the checked attribute of that option to $(_.user.roles[_.bu.id] != ‘requestmanager’).
   - To select an option by default in a form that is shared by all business units *only* if the current business unit is PBJ222, set the checked attribute of that option to $(_bu.id==’ PBJ222’).
   - To select an option by default in a form that is shared by all business units *only* if the parent of the current business unit is PBJ222, set the checked attribute of that option to $(_bu.id.parent==’PBJ222’).

Hide, Enable, or Disable an Entire Form Under Specified Conditions

To hide, enable, or disable an entire form under certain conditions, you attach the form to a service option group and enter the JavaScript expression you want in the Disabled and Hidden fields of the Service Option Group Definition dialog. You can hide, enable, or disable an entire form according to the request status, the role or business unit of the logged in user, or according to other criteria that you specify. For more information, see Attach a Form to a Service Option Group (see page 2954).

Use JavaScript Functions in Fields

This article contains the following topics:

Administrators follow this process to use JavaScript functions to perform automated tasks in fields:

1. Consider using the pre-defined JavaScript functions (see page 2967).
2. If none of the pre-defined functions meets your goals, then write your own custom function:
   - Follow the guidelines for custom JavaScript functions (see page 2968).
   - As a best practice, use the Script dialog (see page 2969) on each form to create and maintain the custom JavaScript functions for the form.

   Consider these examples:

   - Retrieving the values of one or more object properties from the CA Service Catalog database, the MDB, or other data source. This option especially useful when the value *cannot* be retrieved with a JavaScript expression. Consider all options to populate and pre-populate fields automatically (see page 2969).
   - Validating user input (see page 2980), specifically validating the format of numeric or address data entered by the users, including social security numbers, credit card numbers, telephone numbers, email addresses, and IP addresses.
3. As needed, specify JavaScript functions to link fields in two forms for simultaneous updates (see page 2983).
4. Using all applicable from the previous steps, construct and test the JavaScript function to accomplish your goals for the fields on the form.
5. As a best practice, ensure that you test the function in a form used with a service in a test environment before you use the form and the service in a production environment.

Pre-Defined JavaScript Functions

CA Service Catalog provides several options for performing automated tasks for fields (see page 2955) in forms, including report data objects, JavaScript expressions, and JavaScript functions.

Important! Information and documentation pertaining to Predefined JavaScript API functions, descriptions, and examples are available on the CA Service Catalog console. Select **Administration**, **Tools**, **Links**, **Form Designer JavaScript API, Components.** Click **Global, Checkbox, Date, Lookup, Radio, Select, Slider, Table,** and/or **Text options** to view the Javascript APIs, functions, and description**.**

Guidelines for Custom JavaScript Functions

Use the following guidelines for creating custom JavaScript functions in forms:

- Follow the instructions for using predefined JavaScript functions (see page 2967), as applicable.
- Follow the instructions for using JavaScript attributes (see page 2940).
- You can use either the Script dialog (see page 2969) or the custom_form_lib.js file to store your custom JavaScript functions, as follows:
  - As a best practice, use the Script dialog on each form to create and maintain the custom JavaScript functions for the form. If only one form uses the custom JavaScript function, the Script dialog is preferred over the custom_form_lib.js file for the following reasons:
    - The Catalog system loads the form most efficiently when the custom JavaScript function is in the Script dialog.
    - Using the Script dialog enables you to more efficiently move the form, custom functions, and related services or service option groups together. This consideration is important if you move these objects because of an upgrade, migration, or other event.

    Note: To move these objects, use the Import Export utility. For more information about the utility, see the Migrate Data between Catalog Systems (see page 1486) section.

  - Alternatively, store custom JavaScript functions in the custom_form_lib.js file in the filestore. This method is preferred *only* when two or more forms use the same custom JavaScript function.

    Important! If you use the custom_form_lib.js file, use a third-party JavaScript minification tool to *minify* this file on production sites. Minifying the file removes unnecessary characters from the file and reduce its size. As a result, the Catalog system loads the form more efficiently. Several third-party JavaScript minification tools are available on the Internet.

- Do not write excessively long custom JavaScript functions.
- Design your forms with usability as a high priority.
- Take into account the browser locale, to support other language users and to localize forms (see page 2987) as needed.

Use the Script Dialog to Maintain Custom JavaScript Functions

The Script dialog for each form lets you create and maintain JavaScript functions that apply to a form. The functions that you save in the dialog apply *only* to the form that you are editing. To use the Script dialog for a form, you require access rights to edit the form.

Follow these steps:

1. Click the name of the form in the Form Designer tree.
   The form attributes appear, and the Script button activates. The Script button appears on the toolbar with the Localize, Save, Restore, and other buttons.

2. Click the Script button.
   The Script dialog appears and displays the custom JavaScript functions already specified for the form, if any. You can enter new JavaScript functions before or after any existing ones.

   Note: To view a template for a function, click Show Help on the Script dialog. The template shows the product-specific implementation of a standard JavaScript function.

3. Write and save the custom function. Use the format shown in the sample functions that appear when you click Show Help on the Script dialog. This format is known as *JavaScript object literal notation*.

4. Save the form.

5. Specify the name of the function in the JavaScript attribute (see page 2940) from which you want to call it. Use the following format:

   ```
   ca_fd.js.function-name
   ```

   An example follows:

   ```
   ca_fd.js.calculateCostQty()
   ```

   Typically, you specify a custom JavaScript function in one of the following:

   - The onSubmit or on Load attribute of the form attributes (see page 2927)
   - The onChange or onValidate attributes of applicable fields

You have used the Script dialog to maintain JavaScript functions that apply to a form.

Options to Populate and Pre-populate Fields Automatically

Administrators have several options for using JavaScript functions to populate and pre-populate fields automatically. *Populating* fields means that the fields are filled with the results of a database query *based on* user input. The affected fields are empty when the user opens the form. When the user enters the requested input, the database query is run and the results are used to populate the fields.

Conversely, *pre-populating* fields means that the fields are filled with the results of a database query *without* any user input. As soon as the user opens the form, the data source query is run and the results are used to populate the fields. Thus, the affected fields are populated when the user opens the form.

Review the options and choose the one that best suits your needs. Use the pre-populating options when no user input is required for the requested information to be retrieved by the database query. Use the populating options when the user's input is critical for the requested information to be retrieved by the database query.

The options for using JavaScript functions to *populate* fields automatically follow:

- Use the pre-defined JavaScript function (see page 2967) named ca_fdDoFieldLookup with a lookup field to populate fields based on user input to a report data object (see page 2970).
- Use ca_fdDoFieldLookup with a lookup field, and use other pre-defined JavaScript functions like ca_fdSetTextFieldValue to set the values of elements in your form with a custom JavaScript function.

The options for using JavaScript functions to *pre-populate* fields automatically follow:

- Pre-populate a combo box based on a report data object (see page 2972).
- Use user input to pre-populate a select box (see page 2973).
- Use user input for personal data to pre-populate a select box (see page 2976).
- Pre-populate fields based on a report data object and JavaScript functions (see page 2978).

Populate Fields Based on User Input to a Report Data Object

This topic explains how to populate fields based on user input, by using a lookup field, a report data object (data object), and the pre-defined JavaScript function named ca_fdDoFieldLookup(fieldId, reportId). You use them together to run a data object and return the results in the matching field or fields on the form.

When the user clicks the magnifying glass icon for the lookup field on the form, CA Service Catalog prompts the user to enter the variable that you specified in your data object. An example is the user ID.

When the user answers the prompt or prompts in the lookup field, CA Service Catalog runs the data object and searches the data source for the data requested in fields of the data object; for example, the first name and last name of the user ID entered in the lookup field. In this example, you create matching First Name and Last Name fields on the form, and CA Service Catalog returns the results to the user. The user selects which result (if any) to use to populate the form fields.

To populate fields based on user input, by using a lookup field, a data object, and the pre-defined JavaScript function named ca_fdDoFieldLookup(fieldId, reportId), follow these steps:

1. In the Report Builder, create a data object (see page 3232) that queries the data source (such as the MDB) for the data you want (the data copied to the matching fields on the form). The query is based on the user input to the prompt or prompts that you specify, such as user ID. Record the name of the data object for later reference.
   The following sample query for the MDB matches the example started earlier in this topic:

   ```
   SELECT userid,first_name,last_name FROM ca_contact WHERE userid = '%use
   ```

   The ca_fdDoFieldLookup function processes this query as follows:

   - "WHERE userid = '%userid%" specifies that the user is prompted to enter this value, and this value is used in the SELECT clause.
   - "SELECT userid,first_name,last_name" specifies which values to return.
   - "FROM ca_contact" specifies that the data source is the ca_contact table in the MDB.

2. On the form, add the lookup field; it is one of the elements of a form (see page 2916).

   a. For the _id attribute, specify the first field returned by the query, and save the form. Thus, in the continuing example, you specify *userid* as the value of the _id attribute.

   b. For the value of the JavaScript attribute (see page 2940) named onLookup, specify the pre-defined JavaScript function (see page 2967) named ca_fdDoFieldLookup(fieldId, reportId) and save the form.
   This function runs the data object, associates it to the lookup field, and copies the data returned by the data object to the matching fields on the form.
   For fieldId, specify the value of the _id attribute of the lookup field.
   For reportId, specify the value of the _id attribute of the data object that you created earlier.

   c. For the tool tip attribute, optionally specify instructional text, such as "Click the magnifying glass and enter the requested data." Save the form.
   In the continuing example, for the tool tip attribute, you may optionally specify text such as "Click the magnifying glass and enter user ID."

   d. Optionally rename the default display text from the lookup field from "Lookup Field" to a more meaningful name, by selecting the element in the Component Tree and clicking the Rename icon at the top of the tree.
   In the continuing example, you may rename the display text to "User ID" or something similar.

   e. Leave value attribute empty. This value is populated with the first result returned by the query. The value appears on the form to the user as the value of the lookup field.

3. Also on the form, typically under the lookup field, add the fields that hold the results returned by the query. For each field, specify the value of the HTML Attribute (see page 2928) named _ic to match exactly the ID attribute of the corresponding object in the database.

> **Note:** To optionally disable a field so that users cannot change the result returned by the query, set the disabled attribute of the field to true. You can also set the disabled attribute to true only under certain conditions that you specify.

In the continuing example, create matching First Name and Last Name fields on the form, and specify first_name and last_name, respectively, in the _id attributes of these fields.
Thus, all matching values of userid are returned in the lookup field; each result appears as a row in the search results. Users can review the search results and select a row. When the user selects a row, the lookup field closes, and the form is populated with the results from that row. The user sees something like the following on the form:
User ID: johsmi515
First Name: John
Last Name: Smith

4. Test the form to verify that it works as you intended.

> **Important!** The lookup field displays *only* the first 25 matches in the search results. If your query returns more than 25 matches, refine your query to return fewer matches.

Pre-Populate a Combo Box Based on a Report Data Object

This topic explains how to pre-populate a combo box using a data object. On a form, a combo box appears as a single line item; the user clicks its arrow to open the entire list. You configure the combo box to specify whether the user can select only one option or multiple options.

On the Form Designer, you add and configure the select group element (see page 2916) to function as a combo box. To pre-populate the combo box with the results of the data object, you use the HTML Attribute (see page 2928) named reportobjid. When the user opens the form, the data object runs and return the results in the combo box. The user then selects one or more of the options in the combo box while completing the form.

This option is useful when you want to provide the user with multiple valid choices from your data source but do not want to enable the user to specify a custom selection. This option thus helps enforce the standardization and validity of users' selections while still typically providing users with multiple options from which to choose.

Follow these steps:

1. In the Report Builder, create a data object (see page 3232) that queries the data source (such as the MDB) for the data you want. The query must specify *two* fields from the data source, as follows:

   - The first field returns the list of all possible values and populates the combo box with this list.

   - The second field returns the label for the combo box.

When the form appears, the report data object runs and populates the combo box with the resulting data.
Record the name of the data object for later reference.
Consider the following sample query for a data object for the MDB. This example returns the list of available service option groups (rate plans).

```
SELECT rate_plan_id,rate_plan_name FROM usm_rate_plan
```

This query does the following:

- "SELECT rate_plan_id,rate_plan_name" specifies which values to return:
  - rate_plan_id returns the list of all service option groups. Each plan becomes an option in the combo box; for example, Budget, Standard, Deluxe, and so forth.
  - rate_plan_name returns the label for the combo box; for example, Service Option Groups.
- "FROM usm_rate_plan" specifies that the data source is the usm_rate_plan table in the MDB.

2. On the form, add a select box; it is one of the elements of a form (see page 2916).
   a. For the _id attribute, specify a meaningful name, and save the form.
   b. For the value of the HTML Attribute (see page 2928) named reportobjid, specify the id of the data object, and save the form.

Note: When you use a data object to populate a combo box, do not add any options to the select box, because they are ignored (not used) when the user opens the form. Any options for the select box are ignored, only the data object "matters."

Use User Input to Pre-Populate a Select Box

You can use input provided by the user in one or more fields in the form to determine the values in a select box. This technique is useful when you want to provide the user with two sets of multiple valid choices from your data source but do not want to enable the user to specify a custom selection. This option thus helps enforce the standardization and validity of users' selections while still typically providing users with multiple options from which to choose.

A common application of this technique occurs on a form with select boxes for both country and state. Using the reportobjid and reportobjvars attributes, you can configure the state select box to display only the states for the country selected by the user.

To use this technique of pre-populating a select box based on a user's selection in an earlier select box, follow this process. This process uses the country-state scenario as a running example.

1. In the Report Builder, create a data object (see page 3232) that queries the data source (such as the MDB) for the data you want in the first select box. The query must return the list of all possible values and populate the combo box with this list. This step is part of the process of

pre-populating a combo box based on a report data object (see page 2972).
In our running example, create a report data object to retrieve the list of countries from the database.
When the form appears, the report data object runs and populates the combo box with the resulting data.
Record the ID of the data object for later reference.
Consider the following sample query for a data object for the MDB. This example returns the list of available countries for the service or service option to which the form is attached

```
SELECT country_id,country_name from my_country_table
```

This query does the following:

- "SELECT " specifies which values to return. In this example, it returns the ID and the name of the country in the database.
- "FROM my_country_table" specifies the name of the database table.

2. On the form, add the first select box; it is one of the elements of a form (see page 2916).
    a. For the _id attribute, specify a meaningful value, and save the form. Record the value for later reference when you specify the reportobjvars attribute.
    b. For the value of the HTML Attribute (see page 2928) named reportobjid, specify the id of the data object, and save the form.

Note: When you use a data object to populate a combo box, do not add any options to the select box, because they are ignored (not used) when the user opens the form. Any options for the select box are ignored, only the data object "matters."

3. Create a second report data object to retrieve a list of values from the database, based on the user's selection in the first select box. In this report data object, specify some report variables in the query that are to be filled using the input provided by user in other fields in the form
In our running example, create a second report data object to retrieve the states from the database, based on the country that the user selected. Follow the guidelines in Step 1 to create the second report data object.

4. On the form, add the second select box. This box is to be pre-populated, based on the user's selection for the first select box. Follow the guidelines in Step 2 to create the second select box, but account for the following considerations:
    - The second query contains a report variable and is similar to the following:

      ```
      select state_id,state_name from my_state_table where country_id=%sele
      ```

    - The running example in this topic uses only one report variable (%selected_country%); however, your query may contain multiple report variables.
    - Record the names of all report variables for use when you specify the reportobjvars attribute for the second select box.

5. In the second select box, specify the reportobjvars attribute using the following format:
   $({'reportvar':*value*}).
   A valid *value* is one of the following:

   - A constant, such as 12, as in $({'reportvar':12})
   - A string, such as abc, as in $({'reportvar':'abc'})

     Note: Enclose strings in single quotation marks, as shown. Within a quoted string, if needed, use a backslash (****) as an escape character to specify a literal single quote or apostrophe. For example: $({'what\'s the status?'})

   - A JavaScript expression, such as the user's last name, as in $({'reportvar':_.user.lastName})
   - A JavaScript function of the following form: $({'reportvar':foo()})
   - Combinations of the previous values, delimited with commas, using the format shown in the following example:

     ```
     $({'reportvar':_.user.lastName,'reportvar1':'abc','reportvar2':12,'re
     ```

   In our running example, create a second select box to be populated with the states from the database, based on the country that the user selected. For the reportobjvars attribute of the state select box, specify the pre-defined JavaScript function (see page 2967) named ca_fdGetSelectedOptionValues, as follows:

   ```
   $({'selected_country':ca_fdGetSelectedOptionValues ('<form _id> ','coun
   ```

   - **form _id**
     Specifies the value of the _id attribute of the form containing the first select box. You reference this form in Step 2.
   - **country**
     Specifies the value of the _id attribute of the first select box. You create and record this value in Step 2.

6. In the first select box, set the onchange attribute to retrieve the data for the second select box as soon as the user makes a selection in the first select box. For the onchange attribute, specify the pre-defined JavaScript function named ca_fdFetchSelectData, using the following format:

   ```
   ca_fdFetchSelectData('<form _id>','<state field _id>');
   ```

   - **form _id**
     Specifies the value of the _id attribute of the form containing the second select box. You reference this form in Step 4.
   - **field_id**

Specifies the value of _id attribute of the form containing the second select box. You create and record this value in Step 4.
In our running example, set the onchange attribute for the country select box to the following:

```
ca_fdFetchSelectData('<form _id>','<state field _id>');
```

7. Test the form to verify that it works as you intended.

Use User Input for Personal Data to Pre-Populate a Select Box

You can use the first few characters provided by the user in a select box in a form to trigger an auto-complete function. A common application of this technique occurs on a form with a select box (an element of a form (see page 2916)) for the last name. For example, if the user types the letters *smit*, the field displays all valid options, such as Smittapopolous, Smitderski, Smitapunangala, and so forth. The user can select a valid value but cannot enter a custom value. This technique helps users find and specify valid data efficiently when the database is large.

Follow these steps:

1. In the Report Builder, create a data object (see page 3232) that queries the data source (such as the MDB) for the data you want. The query must return the list of all possible values and populate the select box with this list. This step is part of the process of pre-populating a combo box based on a report data object (see page 2972). For this example, do the following:

   - Create a report data object to retrieve the list of user IDs from the database. When the form appears, the report data object runs and populates the combo box with the resulting data.
   - Record the ID of the data object for later reference.
   - Verify that the variable you want to use exists and is of type *string*. If necessary, create or update the variable. For illustration, we use the last_name_prefix variable in the following example.

   For example, consider the following sample query for a data object for the MDB. This example returns the list of available last names that match the user input in the field.

   ```
   Select userid as id, last_name from ca_contact where last_name like '%la
   ```

   - **Select userid as id, last_name**
     Specifies which values to return. It returns the ID and the last name of all users that match the first few characters entered by the user.
   - **From ca_contact**
     Specifies the name of the database table.
   - **where last_name like '%last_name_prefix%%%'**
     Specifies the filter clause.
     The last_name_prefix variable filters on the last_name column (the display column of the query).
     The 'like '%last_name_prefix%%%' syntax filters the results so that the last_name starts with last_name_prefix.

2. Add the select box to the form.

   Note: When you use a data object to populate a select box, do not add any options to it, because they are ignored (not used). When the user opens the form, any options for the select box are ignored, only the data object is used.

   a. For the _id attribute, specify a meaningful value, and save the form.

   b. (Optional) Rename the default display text from the select group from "Select" to a more meaningful name, as follows: Select the element in the Component Tree and click the Rename icon at the top of the tree.

3. Specify values for the following attributes of the select box, and save the form.

   - Multi-Select: Specify False so that users can select only one option in the combo box.
   - (Optional) Title (tooltip text): Specify instructional text, such as "Click the arrow and scroll to select a last name.

     Note: You can optionally localize (see page 2987) the tooltip text or the name of the select box, if applicable.

4. Specify values for the following attributes of the select box, and save the form.

   - Report/Plug-in Id: Specify the name of the report data object that you created in Step 1.
   - Report/Plug-in Variable: Specify a JSON expression for the object that maps a key value pair, as follows:
     - The key is the variable for the report data object.
     - The value is a JavaScript expression that matches the data you want.

     For this example, specify the following:

     ```
     $({'last_name_prefix':_val})
     ```

     - last_name_prefix is a string constant, as noted in Step 1.
     - _val is a predefined variable that CA Service Catalog provides.
   - Minimum Search Characters: Specify a custom value, for example, 4 or 5. This attribute specifies the number of characters that users must type to trigger the auto-complete feature. The defaults is 4.

5. Test the form to verify that it works as you intended.

Pre-Populate Fields Based on a Report Data Object and JavaScript Functions

To pre-populate fields with data that is not accessible through JavaScript expressions (see page 2957), you can use a report data object (data object), custom JavaScript functions, and pre-defined JavaScript functions (see page 2967), especially ca_reportQuery(reportId, variables, onSuccess, onFailure). A representative case involves querying your organization's Human Resources database (not the CA MDB) for sensitive data, such as the banking account number and related information for a user.

For example, you may create a form for changing the bank account to which a user's pay check is automatically deposited. In this form, you may pre-fill fields with name of the current bank name and account number. Use later fields on the form for the user to enter the name of the new bank name and account number.

First, ca_reportQuery(reportId, variables, onSuccess, onFailure) retrieves from the data object the variables that match the fields queried by the data object. Next, the OnSuccess function is called, at which point you can use other pre-defined JavaScript functions (see page 2967) to pre-populate multiple fields in the form with the results of the query. For example, you may write a custom function that calls ca_fdSetTextFieldValue(formId, _id, text) multiple times, once for each field you want to pre-populate. This scenario is typically most suitable for pre-populating text fields, but can also be used to populate other types of fields.

Follow these steps:

1. Design and create the form (see page 2951), if you have not already done so.

2. In the Report Builder, create a data object (see page 3232) that queries the data source for the data you want (the data to be copied to the matching fields on the form).
   Record the ID of the data object for later reference.
   The following sample query for the MDB matches the example started earlier in this topic:

   ```
   SELECT bank_name,account_number FROM my_hr_db WHERE userid ='%userid%'
   ```

   CA Service Catalog processes this query as follows:

   a. "WHERE userid = '%userid% ’ specifies that a user id must be provided as input to this data object.

   b. "SELECT bank_name,account_number" specifies which values to return.

3. "FROM my_hr_db" specifies that the database is my_hr_db, a fictitious database for illustration.

4. On the form, add text fields (or other suitable form elements instead) to receive the retrieved data, as follows:

   - Add one text field for each variable queried by the data object.
     For the continuing example, add two text fields, one for bank name and one for account number.
     For the continuing example, add two text fields, specify bank_name and account_number, respectively.

- Rename each text field to have a meaningful name.
  For the continuing example, rename the fields to Bank Name and Account Number, respectively.

5. Select the form name to display the form attributes.

6. In the form attributes, in the JavaScript attribute named onload, enter the name of your function that calls ca_reportQuery. For illustration, these steps use getAcctData() as the name for this function. Substitute the name of your function if it is different.

7. Verify that getAcctData() is declared in a JavaScript file accessible by CA Service Catalog.
   For best results, use this location in the filestore: FileStore/scripts/custom_form_lib.js.

   Important! The folder name *FileStore* is case sensitive. Therefore, use the correct case in path names and all other programmatic references.

8. In the body of getAcctData, specify the call to ca_reportQuery function, to run the data object and return the results.

9. Use the results as input values to JavaScript functions such as ca_fdSetTextFieldValue to update the fields in the form.
   In this example, use the results to make two calls: one to update the bank name field and another to update the account number field.

10. Customize ca_reportQuery(reportId, variables, onSuccess, onFailure) to meet your requirements. This step uses the continuing example for illustration.

    - For reportId, specify the data object that you created earlier.

    - For variables, specify the JavaScript map with the variable names and values.
      For the continuing example, specify: {“userid”:_.user.id}.
      These variables *must* match the ones that you query in the data object, but they do not need to be ordered in the same sequence.

    - For onSuccess, specify the custom JavaScript function to run when the query returns successfully. The onSuccess function must take one operand. This operand is set with an array of maps, each representing a row, returned by the query. Within your custom onSuccess function, use ca_fdSetTextFieldValue(formId, _id, text) to return the results of each field, one at a time.
      For the continuing example, specify the following:

```
function updateFields(result) {
   if (result.length == 1) {
   ca_fdSetTextFieldValue(formId, 'bank_name', result[0].['bank_name'

   ca_fdSetTextFieldValue(formId,'account_number',result[0].['account

   } else {
      alert('could not find your bank account information')
   }
}
```

- For onFailure, specify the JavaScript function to run if the query fails.
  For the continuing example, specify the following:

  ```
  function onGetAcctDataFail() { alert("can't find your account");}
  ```

11. Finish creating the form to meet your requirements.

12. Test the form to verify that it works as you intended.

Validate User Input

You can configure Form Designer forms to verify that users entered the following types of data in the correct format: credit card numbers, social security numbers, email addresses, phone numbers, postal (zip) codes, and decimal numbers with two fractional digits.

This process does *not* guarantee that the data entered by the user is authentic but does assist in the validation process by verifying that the user entered the data in the correct format.

You can thus use the Form Designer to verify that the data you want and is recorded in the format that you want. For example, you can verify that phone number fields accept only numeric input, that date fields accept only your company's standard date format, and that credit card fields accept only numbers that are entered in the correct format for the credit card type specified.

Additionally, you can specify maximum length, minimum length, and other attributes used to validate user input.

Choose the task you want to perform:

- Use regular expressions to validate numeric and address data (see page 2980). In this case, you use regular expressions in the HTML attribute (see page 2928) named pattern to validate the format of credit card numbers, social security numbers, email addresses, phone numbers, IP addresses, postal codes, dates, and decimal numbers with two fractional digits.

- Use JavaScript functions to validate the format of credit card numbers. For example, you use the pre-defined JavaScript function (see page 2967) named ca_fdValidateCC(credit card number, credit card type) in a JavaScript attribute (see page 2940) such as onValidate to verify the credit card formats. Alternatively, you can create your own custom JavaScript function.

Use Regular Expressions to Validate Numeric and Address Data

This topic explains how to use regular expressions to configure Form Designer forms to verify that users entered the following types of data in the correct format: credit card numbers, social security numbers, email addresses, IP addresses, phone numbers, postal (zip) codes, and decimal numbers with two fractional digits. .

To verify the types of user input mentioned earlier, follow these steps. These steps use a continuing example for illustration.

1. Design and create the form (see page 2951), if you have not already done so.

2. For each type of user input, add a text field.

3. Rename each text field from Text Field to a meaningful name, such as Social Security Number, Credit Card Number, and so forth.

4. For the value of the HTML Attribute (see page 2928) named pattern, specify the regular expression for the type of data being validated, and save the form. Valid values follow:

   - Social security number: ^([0-6]\d{2}|7[0-6]\d|77[0-2])([\\d{2})\2(\d{4})$
   - Decimal number with two fractional digits: ^[1-9]\d*(\.\d{2})$
   - E-mail address: ^([0-9a-zA-Z]+([_.-]?[0-9a-zA-Z]+)*@[0-9a-zA-Z]+[0-9,a-z,A-Z,.,-]*(.){1}[a-zA-Z]{2,4})+$
   - IP Address: ^((25[0-5]|2[0-4][0-9]|1[0-9]{2}|[0-9]{1,2})\.){3}(25[0-5]|2[0-4][0-9]|1[0-9]{2}|[0-9]{1,2})$
   - Telephone number: ^(([0-9]{1})*[- .(]*([0-9a-zA-Z]{3})*[- .)]*[0-9a-zA-Z]{3}[- .]*[0-9a-zA-Z]{4})+$
   - URL: ^(http[s]?://|ftp://)?(www\.)?[a-zA-Z0-9-\.]+\.(com|org|net|mil|edu|ca|co.uk|com.au|gov)$
   - Postal Code (CAD): ^([A-Z][0-9]){3}$
   - For additional values, or to create your own expression, see your reference for regular expressions, such as www.regular-expressions.info or www.regexlib.com.

5. For the value of the HTML Attribute (see page 2928) named patternMessage, specify an error message to appear when the user input violates the pattern attribute.

   Note: You can optionally localize (see page 2987) this error message.

6. Finish creating the form to meet your requirements.

7. Test the form to verify that it works as you intended.

Use a JavaScript Function to Validate the Format of Credit Card Numbers

This topic explains how to configure Form Designer forms to use a JavaScript function to verify that users entered a credit card number in the correct format for the credit card type that they specified.

This topic explains how to present two credit card types: Master Card and Visa. For each type, you create a radio group option and a text field for the account number. Each account number field is disabled by design but is enabled if the user selects the matching credit card type.

You use the pre-defined JavaScript function (see page 2967) named ca_fdValidateCC(*number*, '*type*') to validate the format of the credit card number entered by the user, based on the credit card type that the user selected. This JavaScript function verifies the format according to the specifications set by the company issuing the credit card. Each company sets its own standard format.

To verify the credit card numbers entered by users, follow these steps. These steps use a continuing example for illustration.

1. Design and create the form (see page 2951), if you have not already done so.

2. Verify that the value of the form's HTML Attribute (see page 2928) named _id specifies a meaningful name, such as ccValdtnForm1.

3. Add a radio group; it is one of the elements of a form (see page 2916).

    a. For the value of the _id attribute of the radio group, specify a meaningful name, such as rgCCVal, and save the form.

    b. Rename "Radio Group" to a meaningful name or phrase, such as Select a Credit Card or Credit Card Type.

4. Add the first radio group option; these options are elements of a form (see page 2916) that apply only to radio groups.

    a. For the _id attribute, specify a meaningful name, such as mcard (signifying Master Card radio group option), and save the form.

    b. Rename "Radio" to a meaningful name, such as Master Card.

5. Add the second radio group option.

    a. For the _id attribute, specify a meaningful name, such as visa (signifying Visa radio group option), and save the form.

    b. Rename "Radio" to a meaningful name, such as Visa.

6. Add a text field onto the form

    a. For the _id attribute, specify a meaningful name, such as ccf.

    b. For the value of the JavaScript attribute (see page 2940) named onvalidate, specify cc_val(_val).

7. Use the Script dialog (see page 2969) to add the following function definition:

```
function cc_val(value) {
                var ccname = '';
                if (ca_fdIsSelectRadio('ccValdtnForm1', 'rgCCVal', 'mca

                                ccname = 'master';
                else
                                ccname = 'visa';
                ca_fdValidateCC(value, ccname);
}
```

    As a best practice, use the Script dialog on each form to create and maintain the custom JavaScript functions for the form.

8. Finish creating the form to meet your requirements.

9. Test the form to verify that it works as you intended.

Link Fields in Two Forms for Simultaneous Updates

You can optionally specify JavaScript functions to link two fields in two Form Designer forms. When a user updates a field in one form, the linked field is updated in the second form simultaneously. This technique essentially creates an automatic cross-reference between the fields in both forms.

Follow these steps:

1. Verify that the forms are in the same service option.

   Important! The forms *must* be in same service option.

2. Decide which fields in which forms you want to link. For example, you may want to ensure that a name, date, item, or phone number field has the same value in both forms in each request.

3. Specify the same exact function in both forms *except* that you switch the form IDs in each JavaScript function, as follows:

   - In the JavaScript function in Form 1, you specify the ID for Form 2.
   - In the JavaScript function in Form 2, you specify the ID for Form 1.
   - For ease of maintenance, use the same field name and same JavaScript attribute in each form.
     For example, you may decide to name the field Address in both forms and specify the JavaScript function in the onclick attribute in each form.

Important! Do *not* re-use either form in a different service. If one of the forms is re-used in a different service, the fields become un-linked. Consequently, both fields function correctly individually but are no longer cross-referenced. Therefore, they are no longer configured for simultaneous updates.

Example

This example illustrates how to use JavaScript functions to link two fields in two Form Designer forms for simultaneous updates.

In Form AA, whose form ID is form_aa, specify the following for the linked field:

- Name: Item Requested
- JavaScript function in the onclick attribute: ca_fdSetTextFieldValue ('form_bb','item_requested','New Laptop')

In Form BB, whose form ID is form_bb, specify the following for the linked field:

- Name: Item Requested
- JavaScript function in the onclick attribute: ca_fdSetTextFieldValue ('form_aa','item_requested','New Laptop')

Administer Forms

This article contains the following topics:

Understand Access Level Rules

Authorized users can access forms. Authorized users are users with the following roles: Super Business Unit Administrator, Catalog Administrator, Service Manager, and Service Delivery Administrator. Here, *access forms* means that the users can view, create, edit, copy, and delete forms, unless noted otherwise.

To configure access rights to forms, configure these Use Service Provider Catalog Only and Pass Through Catalog settings. Accept or change the default settings, as follows:

- By default, the *Use Service Provider Catalog Only* setting is No. Authorized users can access the forms in the current business unit and its child business units *only*. Authorized users can add forms to services and can delete forms from services in the current business unit and its child business units *only*.
  If the *Use Service Provider Catalog Only* is Yes, then authorized users can view and copy forms in the Service Provider business unit. They cannot perform any other actions on these forms. Similarly, authorized users cannot add forms to services and cannot delete forms from services in the Service Provider business unit.

- By default, the *Pass Through Catalog* setting is No. Authorized users can access forms in the current business unit and its child business units *only*. Authorized users can add forms to services and can delete forms from services in the current business unit and its child business units *only*.
  If the *Pass Through Catalog* is Yes, then authorized users can view and copy forms in the parent business unit. They cannot perform any other actions on these forms. Similarly, authorized users cannot add forms to services and cannot delete forms from services in the Service Provider business unit.

- If both the *Use Service Provider Catalog Only* and *Pass Through Catalog* settings are Yes, then the former setting takes precedence. Authorized users can view and copy forms in the Service Provider business unit, but not in any parent business unit. Similarly, authorized users cannot add forms to services and cannot delete forms from services in the Service Provider business unit.

To configure access rights to forms, proceed as follows:

- To configure the *Use Service Provider Catalog Only* setting, log in to the root (highest level) business unit as a Service Delivery administrator. Select Catalog, Configuration, System Configuration.

- To configure the *Pass Through Catalog* setting, log in to the business unit of interest as an authorized user. Select Catalog, Configuration, Catalog Configuration.

Note: Users cannot access forms in sibling business units under any circumstances.

Create and Maintain Forms

You can create forms in the Form Designer.

Follow these steps:

1. Verify that you have administrator rights to each folder that you want to access, in each affected business unit. To copy or move a form from one business unit to another, you must be an administrator in both business units. If you are an administrator in a parent business unit, then you are automatically an administrator in all its children business units.

   Note: You cannot create, copy, move, or delete any forms or elements within the System folder.

2. Use caution when modifying an existing form. If the form is included in an *active* request, you receive a warning message.
   Do *not* update the form (except trivial changes) if you receive this warning message. When you no longer receive this message, proceed with your change. To make important changes to the form, create a new version with the changes and use the new form.

3. Use extreme caution when deleting an existing form or moving an existing form from one business unit to another. If the form is included in an *active* request, you receive a warning message. Do *not* complete the move or delete operation if you receive this warning message. When you no longer receive this message, proceed with your change.

   Important! When you delete a form, all elements under it are also deleted. If you want to save the elements, store them in another form before deleting this form.

4. Click Catalog, Forms.

5. Click the icon next to the Forms folder in the Component Tree.

6. Create the form (see page 2951), if applicable.

7. Click the Associations tab to display the list of service offerings and service option groups that are associated with the selected form. It also provides the ability to view where a particular form has been used in the current Business Unit and also the capability to assess the impact of modifying or deleting a form. This functionality is also available in the Form Chooser UI when attaching a form to a Service Option.

   Note: The Associations tab is available only if you have installed the CA Service Catalog 14.1.01 patch updates available on CA Support.The form level associations are shown only for the selected Business Unit level.

8. Edit a form, as follows:

   a. Open the folder that contains the form you want to edit.

   b. Open the form to display its existing elements.

   c. Add, modify, and configure elements on the form (see page 2951).
   You can rename, move, copy, or delete a form.

      Note: The copied form, including all its elements, now belong to the business unit of the destination folder. The name of the copied form must be unique within the business unit. The form is copied, and its new name is "copy of *original name.*" The copied elements under the copied form are *not* renamed.

(Optional) Create and Maintain Folders

Create and maintain folders to organize your forms according to groups, categories, or business units. For example, you create and name folders that correspond to each business unit, department, owner, or service.

- If you delete a folder, all sub folders, forms, and elements under it are also deleted.
- If you move a folder from one business unit to another, the moved folder now belongs to the business unit of the destination folder. The names of each folder, form, and element must be unique within their new business unit.
- If you copy a folder from one business unit to another, the pasted folder now belongs to the business unit of the destination folder. However, the sub folders, forms, and elements under it are *not* renamed.
- If you want to delete a folder, first delete any sub folders or forms under it.

Import and Export of Forms

You can use the Import Export utility to perform the following tasks:

- Import and export Form Designer forms by themselves, without related services or service option elements.
- Import and export Form Designer forms associated to service option elements.

Localize Forms

You can use the Localization Editor to localize the element names and selected attributes in forms. You can do so for the supported languages.

When you edit the form in the Form Designer, you see localized names and values only if you are using the Localization Editor. However, when a localized form appears in a request, it displays all localized values. If no localized values exist, the form displays the default values for the form name, element names, and selected attributes.

For more information about how to set the Localization Attributes for a Form, see Localize a Single Service (see page 3031) section.

Manage Services

A service consists of hardware, software, or other resources that users request from the catalog. Administrators *manage* services to meet the needs of their users and organization. Here, *manage* means to create or update services, or to perform other tasks to manage services, as explained in the following steps.

Administrators (typically service designers) group one or more service option groups together as a single service. You can create services for several purposes, including requesting hardware or software, on boarding new employees, and reserving physical or virtual resources. You can optionally use Service Accounting Component to specify charges for each service.

You create and maintain services in folders in a service catalog. You make the catalog available either to all business units or only to a specific business unit. You can have multiple catalogs for multiple business units.

1. Verify that you are logged in to the correct business unit. If your role permits, you can change to another business unit to access its catalog instead of the catalog of your current business unit as follows:

    a. Click **Catalog**, **Service Offerings**.
    The Services page appears and displays the folders containing services, organized hierarchically according to category.

    b. Click **Change Business Unit**.
    The **Search Business Units** window appears.

c. Use the Expand and Collapse icons to navigate the business unit tree or search to locate the required business unit.

> **Note:** The list includes only the business units that the role of the user permits.

d. Select the business unit name in the tree.
The window closes and the catalog for that business unit is displayed. You have changed business units.

2. Click Catalog, Service Offerings.

3. Expand the tree and select the folder in which you want to manage services.

4. (Optional) Create a Simple Service (see page 2988).

5. (Optional) Add or Update a Service (see page 2996).
This task optionally includes specifying inheritance, setting featured and related services, and defining dependencies between services.

6. Perform Other Tasks to Manage Services (see page 3004):

   - Setting thresholds for quality-of-service (QoS) SLAs for services
   - Managing the folders that store services

As part of managing services, you Manage Service Option Groups (see page 3011) and Manage Service Options and Service Option Elements (see page 3017). You can also Localize a Single Service (see page 3031) or Localize Multiple Services (see page 3035).

Create a Simple Service

This scenario illustrates how service design managers create a simple service by copying predefined service option groups and forms and customizing the copied objects. Creating a service in this manner is more efficient than creating and configuring the objects that comprise the service. You can use this scenario *as a model* to create a simple service.

This scenario focuses on the onboarding of a new employee into the Field Services group in your organization. For a use case other than new hire onboarding, search the catalog for the service that most closely matches the service that you want to create. For example, to create a service for reserving a virtual machine using Reservation Manager, review services in the Reservation Services folder.

The predefined service in this scenario is a simple, on-premise enterprise service named New Hire Onboarding. You use it to create a similar service for the Field Services group. In this scenario, you optionally configure default options so that users can request the service with little to no effort or input. Creating simple services in this manner reduces user errors and increases efficiency, especially for users submitting requests from mobile devices.

Important! If you already have multiple forms with the same _id value, do not associate such forms to a single Service Option. Having multiple forms with the same _id value in a single Service Option can cause validation errors.

Follow these steps:

Step 1 - Create the Service Option Group for the Form

As a best practice, copy predefined objects and customize the copies, rather than changing predefined objects.

Follow these steps:

1. Click **Catalog**, **Service Offerings**.
2. Click the **Option Group** tab.
3. Select the group **New Hire Onboarding** and perform the following actions:
    a. Click the Copy icon.
    b. Click the Paste icon (*not* the Paste as Inherited icon).
    c. Specify New Hire Onboarding for Field Services Only in the prompt for the name of the new option group.
4. Select the copy of the service option group and perform the following actions:
    a. Click the Definition tab.
    b. Click the Delete icon to delete this form from the service option group.
    This action deletes the form from this service option group *only*. The form still exists in any other service option groups that include it, and in the Form Designer folder.

Step 2 - Review and Copy the Form

All services include at least one predefined or custom form to record and process essential information from the user requesting the service. In this scenario, you review and copy the predefined form included with the standard New Hire Onboarding service. Afterwards, you modify the copied form for use in the New Hire Onboarding for Field Services Only service.

Follow these steps:

1. Copy the New Hire Onboarding form, as follows:
    a. Click **Catalog**, **Forms**.
    b. Expand the **Forms**, **CA Catalog Content** folder in the Component Tree.
    c. Select the **New Hire Onboarding** form.
    d. Click the Copy icon.
2. Select the top level of the Forms folder and complete these actions:
    a. Click Add and create a subfolder named Custom.
    b. Select the Custom folder and click Paste.
    The new form appears; its name includes the "copy of" prefix. The copied elements under the copied form are *not* renamed.

    > **Note:** When you copy the form from one business unit to another, the pasted form, including all elements under it, belong to the business unit of the destination folder.

    c. Select the form and click Rename.
    d. Enter the new name as New Hire Onboarding for Field Services Only. Click OK. The name must be unique within its business unit.

Step 3 - Modify the Form

Modify the form that you copied by adding a unique field for Field Services.

Follow these steps:

1. Expand the New Hire Onboarding for Field Services Only form.
2. Copy the Additional Info field, as follows:
    a. Select the Additional Info field in the tree, and click the Copy icon. The Copy icon appears near the top left of the screen, in the row of form tools under the main menu and tab names.
    b. Select the name of the New Hire Onboarding for Field Services Only form in the tree. Click Paste.
    c. Enter a unique ID (for example, field_services_group_id) in the _id field in the right pane.

d. Click Save.

3. Rename the new field, as follows:

   a. Select the field and click Rename.

   b. Enter the new name as Field Services Group ID. Click OK.

The new field is renamed. The Field Services managers can use this field to assign new employees to a group in the organization.

Step 4 - Add the Form to the Service Option Group

Add the new, modified form to the New Hire Onboarding for Field Services Only service option group. Later, you add this service option group to the New Hire Onboarding for Field Services service.

Follow these steps:

1. Click **Catalog**, **Service Offerings**.

2. Click the **Options Group** tab.

3. Select the group named New Hire Onboarding for Field Services Only. Perform the following actions:

   a. Click the Definition tab.

   b. Click **Add Option**.
   The Service Option Details tab appears and lists the service option elements in the group.

   c. Enter a meaningful name for the service option. Example: New Hire Onboarding Form for Field Services Only.

4. Scroll to the Form field and click Add.

5. Complete the fields in the Service Option Element Definition, as follows:

   a. Specify meaningful text In the Display Text field. Describe the purpose of this form. This text appears to the user as a description for the form when administrators view this service option group in the catalog.

   b. Click the Search icon in the Form Name field.

   c. Navigate through this form tree and select the New Hire Onboarding for Field Services Only form.

   d. Click the Select Form button.

6. Click Update.
   The Service Option Element Definition dialog closes. You return to the Service Option Details tab.

7. Scroll to the bottom of the tab and click Save.

8. Scroll to the top of the tab and click Return to Service Option Group.

Step 5 - Create the Service and Customize the Details

You create a service to contain one or more service option groups. Specify the details of how and when catalog users can request the service. In this scenario, you create and configure a service to contain the service option group that you created previously (New Hire Onboarding for Field Services Only).

Follow these steps:

1. Click **Catalog**, **Service Offerings**.

2. Expand the **Personnel Services** folder in the tree and select the **New Hire Onboarding** service.

3. Click the Definition tab to view the service option groups. In this scenario, you use the same service option groups in your new service.

4. Select the **Personnel Services** folder, and click **Add**, **Offering**.

5. Enter the name of the new service as New Hire Onboarding for Field Services Only.

6. Complete the following fields on the Details tab of the new service, and click Save:

   - For Description, specify Onboards new employees in the Field Services group.

   - Complete the fields in the Availability section, and click Save.
     The service becomes visible and users can request it only on the date that you specify in the Available On field.

7. Complete the following fields as shown, and click Save:

   - For User Request Method, verify that One-Click Submit is selected.
     This setting lets users request the service quickly, without using a cart. This setting is ideal for simple services.

   - Select the option named Available from mobile device.

   - For the Approval Process drop-down list, either select No Approval or verify your selection with the catalog administrator. Catalog administrators typically configure either the Workflow driven approval process or the Policy driven approval process.

   - Accept the default values for the other fields.

8. Click the **Definition** tab, and perform the following actions:

   a. Click the Edit icon for the Overview field.

   b. Specify the following (or similar) text for the Overview, and click the Save icon:
      For onboarding new employees in the Field Services group only

Step 6 - Add and Customize the Service Option Groups

You can add several service option groups for onboarding Field staff. As you add each group, if applicable, you customize it for the Field staff by including only the deluxe option.

Note: The customizations in these steps affect this service *only*. You do not modify the service option groups or their service options. Instead, you customize this service to include only the service options that you select from each service option group.

Follow these steps:

1. Click the Edit Offering Selection button on the Definition tab for the New Hire Onboarding for Field Only service.
2. Scroll to the service option group named Business Cards. Perform the following actions:
    a. Click the Include checkbox.
    b. Select Order Business Cards - Embossed, and select the options for Include and Default. Leave both options *unchecked* for the service option named Order Business Cards - Standard.

    This action adds embossed business cards to the service and includes them by default.
3. Scroll to the service option group named Mobile Phone, and perform these actions:
    a. Click the Include checkbox.
    b. Select Mobile Phone- Deluxe, and select the option for Default.

    This action adds a deluxe mobile phone to the service and includes it by default.
4. Scroll to the service option group named Mobile Phone Accessories, and perform these actions:
    a. Click the Include checkbox.
    b. Select all the options for Include and Default.

    This action adds all mobile phone accessories to the service and includes them by default.
5. Scroll to the service option group named New Hire Onboarding for Field Services Only, and perform these actions:
    a. Click the Include checkbox.
    b. Select the options for Include and Default.

    This action adds the form that you created earlier to the service and includes it by default.

6. Scroll to the service option group named Procure Laptop, and perform these actions:

    a. Click the Include checkbox.

    b. Select Laptop - Deluxe, and select the options for Include and Default.

    This action adds a deluxe laptop to the service and includes it by default.

7. Scroll to the bottom of the dialog and click Save.
   The Catalog system adds the service option groups to the service, with your customizations.

Step 7 - Specify Automatically Chosen Selections

You can specify the service option groups that you added to the service as automatically selected (default). This technique helps to verify that Field Services personnel can see and request all required equipment efficiently, especially from mobile devices.

Follow these steps:

1. Perform the following actions on the Definition tab for the New Hire Onboarding for Field Only service:

    a. Click the Edit icon for the first service option group, Business Cards.

    > **Note:** When you mouse-over this Edit icon, the help text is "Edit Service Option Group." Other Edit icons for the header text and for the service option also appear near this Edit icon, but each one has different help text when you mouse over it.

    The Details tab for the service option group appears.

    b. Specify Automatically Chosen as the Selection Type. Click Save.
    This service option group is automatically included when the service is requested or subscribed to. This service option group contains one service option, embossed business cards. The embossed business cards option is automatically selected for Field Services staff, and is the only option for them.

    c. Click the Back button on the browser to return to the Details tab for the service.

    d. Click the Definition tab for the service.
    You return to the Definition tab for the New Hire Onboarding for Field Only service. The list of service option groups in the service appears.

2. Perform the following actions:

    a. Click the Edit icon for the next service option group, Mobile Phone.

b. Specify Automatically Chosen as the Selection Type. Click Save.
This service option group is automatically included when the service is requested or subscribed to. This service option group contains one service option, the deluxe mobile phone. The deluxe mobile phone option is automatically selected for Field Services staff, and is the only option for them.

c. Click the Back button on the browser to return to the Details tab for the service.

d. Click the Definition tab for the service.
You return to the list of service option groups on the Definition tab.

3. Use the previous steps as a model to edit the definitions for the following service option groups and to specify Automatically Chosen as the Selection Type:

   - Mobile Phone Accessories
   - New Hire Onboarding for Field Services Only
   - Procure Laptop

   These service option groups also contain a single, deluxe service option that is automatically included for Field Services staff.

Step 8 - Set the Permissions

You can optionally set the permissions for the service so that only specified roles or groups can request it. If a role or group has permission to access the service, the associated users can perform the following actions.

- View the service in the catalog.
- View, request, and subscribe to the service
- Access the service through searches and web service calls

Conversely, if a role or group does not have permission to access the service, the associated users do not have these rights.

Follow these steps:

1. Click the **Permissions** tab of the service named New Hire Onboarding for Field Only.
2. Clear the check box named **Grant All Access to All Roles in All Business Units**.
3. Select the Request/Subscribe box for Catalog User, and click Save.
This selection lets all Field staff request this service. In this scenario, all Field staff have the catalog user role. In your organization, another role may be more suitable.

Note: You can optionally define a user group for Field staff in CA EEM and use the Groups tab to restrict the permissions for the service to that group.

Add or Update Services

This article contains the following topics:

Service designers create or update services. They do so by grouping service option groups together as a single service that users can request from the catalog.

Follow these steps:

1. Click Catalog, Service Offerings.
2. Expand the tree and select the folder in which you want to manage services.

   Note: To add a folder at the top level (root folder), click Add and name the new folder.

3. Perform one of the following actions in the selected folder:
   - Create a service by clicking Add and naming the new service.
   - Edit a service by selecting it and updating its fields.
4. Complete the fields on the Details tab (see page 2997) for the service.

   Note: This step and the remaining steps apply *only* if you are adding or updating a service.

5. Define the service (see page 3001).
6. Click the Permissions tab, and set permissions for the service.
   Each role and group (if applicable) receives the access rights that you specify to the new service.
   Only if a role or group has permission to access the folder, the associated users can perform the following actions:
   - View the service in the catalog.
   - View, request, and subscribe to the service.

- Access this service through searches and web service calls.

7. (Optional) Click the Related Offerings tab, and perform the following tasks:
   - Review Service and folder inheritance (see page 3002). Specify other services to inherit (include) with this service.
   - Define dependencies (see page 3005) for this service, if applicable.
8. (Optional) Set Featured and Related Services (see page 3003).

Service Details Tab

When you add or edit a service, you complete the fields on the Details tab for the service.

The following fields on the Details tab for a service require explanation.

- **Image**
  Assigns an image to a service.
  To select the new image from the USM_HOME\FileStore\images\offerings folder, click the existing image.

  Important! The folder name *FileStore* is case-sensitive. Therefore, use the correct case in path names and all other programmatic references.

  The recommended size for an image is no larger than 48 x 48 pixels. However, the size of an image for a featured service is fixed at 32 x 32 pixels. So, the image is reduced or enlarged to 32 x 32 pixels, regardless of its original size.
  If you make this service a featured service, verify that the image is legible when viewed at 32 x 32 pixels. If you add images to several services in the same folder, verify that the sizes of the images are compatible. Verify that the images blend together to form a balanced layout that aligns with the Featured Item header.

- **Service ID**
  (read-only) Specifies the object ID of the service.

  Note: As part of importing or exporting objects using IXUtil or content packs, you specify the Service ID explicitly.

- **Name *and* Description fields**
  Specifies the name and description of the service for catalog users. You can optionally localize these fields for use in a multilingual catalog.

- **Code**
  Specifies the text value to represent the product code, subscription code, SKU number, or any other applicable value.

- **URL Info**
  Specifies an external URL for more information about the service. For example, a service for a new laptop can include the URL to the manufacturer specifications page for the laptop.

- **Date fields**
  The dates and times that you view and specify are based on the time zone on the CA Service Catalog server. These values can be different from your local time zone.
  The dates that you enter in any of the following fields affect the availability of the service to catalog users:

  - Available On
  - Unavailable After
  - Canceled After fields

  The changes that you make to these fields take effect immediately.
  The following date fields require further explanation:

  - **Unavailable After**
    Specifies the date when catalog users can *no longer* request or subscribe to the service.
  - **Canceled After**
    Specifies the cancellation date for all requests for this service and all accounts with subscriptions to this service.
    On this date, these subscriptions and requests are canceled. Requests and subscriptions that are in progress are canceled immediately.

- **Business Hour**
  Specifies the business hours for the service. The business hours are the regularly scheduled days and times of service. For example, Monday-Friday, 9:00 am to 5:00 pm. Business hours apply only when you use request SLAs to help measure the availability of a service.

- **Outage Calendar**
  Specifies the outage calendar for the service. The outage calendar specifies days, dates, and times when the service is not available. For example, weekends, holidays, and one-time outages. Outage calendars apply only when you use request SLAs to help measure the availability of a service.

- **User Request Method**
  Specifies whether users request the service by using the one-click submit method or by using a shopping cart.

  - **One-Click Submit**
    Allows users to request the service, using one click, without a shopping cart. This method submits a stand-alone request for the service.
    The one-click submit method is appropriate for the internal business and personnel services that are *not* related to shopping. Examples: Services for onboarding new employees and for setting up or accessing virtual computers.
    When you use this method for a service, users cannot include it in the same request as other services.

- **Shopping Cart**
  Allows users to request this service by adding it to a shopping cart. The cart can include multiple services. The user finishes shopping, verifies the cart, and submits it. This method is appropriate for services that are related to internet shopping, typically procurement requests. Example: Requests for new hardware or software.
  A catalog user who has added services to a shopping cart without submitting it can request a one-click submit service. The request for the one-click submit service is submitted immediately as a separate stand-alone request. The shopping cart is not affected.

- **Available from mobile devices**
  Enable the checkbox to raise a service request from the mobile application.

- **Display SOG Name**

  Note: This capability is available only if you have installed the CA Service Catalog 14.1.01 patch updates available on CA Support.

  Check or uncheck the checkbox to hide or display the Service Option Group name that has single or multiple options associated in an offering. This option is enabled only when you have a single Service Option Group in an offering. In case of multiple service option groups in an offering, this option is disabled or greyed out by default. Checking or unchecking this option will not alter the offering Preview.

- **Approval Process**
  Specifies the approval process to use for the service when a user requests it. This Approval Process setting does *not* apply to subscriptions.
  Select *one* of the following options:

  - **System approval process**
    To determine whether the request for a service requires further approval, the System approval process uses the following options:

    - The authorization level of the user requesting the service
    - The approval level of the service

    If the authorization level of the user is less than the approval level of the service, the request requires further approval. In that case, the Catalog system performs the following tasks:

    - Assigns the manager of the user to approve the request
    - Places the request in the Requests Pending Action queue of that manager

    This process repeats until the authorization level of the approver is at least equal to the approval level for the service.

  - **No approval process**
    Approves the service automatically.

- **Workflow Driven Approval Process**
  Uses a CA Process Automation process to determine the approval process.
  The process includes the business logic to determine the approver and the number of approval levels. CA Service Catalog provides sample processes for a single level of manager approval.
  For any service, if you use this approval process with a CA Process Automation process, you can optionally use policies. In that case, the approval process proceeds the same as with Policy driven approval process, except as follows:

  - The Workflow driven approval process uses the CA Process Automation workflow engine to evaluate and implement policies.

  - Policy driven approval process uses the Catalog Policy Engine to evaluate and implement policies. This option is typically more efficient for an approval process that uses policies, because this engine is internal.

  Verify that the rules and actions are enabled (see page) for the option that you specify.

- **Policy driven approval process**
  Uses policies to determine the approval process for requests. In policies, you specify conditions that are based on the attributes of service options, services, requested items, and users. If a policy is active and a submitted request meets the condition in the policy, then the following event occurs: The assignees in the policy receive a request pending action to approve, reject, or fulfill a service option, service, or request. Policy driven approval and system approval use a few common terms. Example: The *level of approval* refers to the authority of an approver in numeric terms. The higher the number, the greater the authority of the approver. However, in policy driven approval, the administrator assigns each approver and authority level uniquely, with no relation to system approval. If a policy does not apply to a request, the Catalog system uses the approval flow that is defined in the workflow driven approval process. Example: You are using the predefined workflow approval process and no predefined sample policy applies to a request pending action. In that case, the Catalog system assigns the request pending action to the manager of the Requested For user. If the user has no manager, then the system assigns the request pending action to the Default User for Request Actions. This user is specified in the Request Management Configuration.

- **Approval Level**
  Specifies the approver Authorization Level that is required for the service. Specify these values logically and consistently to verify proper approval operations in your organization. This setting applies *only* if you specify System approval process or Workflow driven approval process in the Approval Process field.

- **Status on Approval**
  Specifies the status of the request items in the service once the service is approved. Select *one* of the following options:

  - Fulfilled

  - Pending Fulfillment.
    Using Pending Fulfillment enables you to specify workflow processes that assign any additional tasks to fulfill the request, if necessary.

This setting applies *only* if you specify System approval process or No approval process in the Approval Process field.

- **Sort By**
  Arranges the service option groups to appear to the user according to the category you select. Categories include Name, Selection Type, Code, Date Created, and None. You can also select Custom - use Sort Number. This option uses the Sort Number field in the service option group details.

- **Sort Number**
  Sorts the service according to the value you specify.
  This field applies *only* when the parent folder uses a value of Custom - use Sort Number in the Sort By field.

Define a Service

After you create a service, define it. *Defining* a service primarily means adding one or more service option groups and specifying which service options to include.

Follow these steps:

1. Click Catalog, Service Offerings.
2. Expand the tree and display the service of interest and click the Definition tab.
3. Click Edit Offering Selection.
   - If no service option groups are already associated with this service, all service option groups appear.
     To add service options from a group to a service, select the group, expand it. Select the service options that you want to include.
   - If one or more service option groups are already associated with this service, the service options from those groups appear.
     - Expand the associated service option groups and select or remove service options for this service.
     - Click Show All to display all service option groups. Select the group that you want, and include the service options that you want in the service.
   - Verify that you have completed the following actions, as applicable:
     - Select the service options that are included in the service *by default*. To do so, select the check box for the service option in the Default column.
     - Select the service options that are *required* in the service. To do so, select the check box for the service option in the Include column.
     - Exclude any groups or service options that you do *not* want in the service.
4. Save your changes and close the Service Offering Selection dialog.

You can set thresholds for QoS SLAs for request fulfillment reports. You can also set permissions as part of managing the service.

Service and Folder Inheritance

You can configure the inheritance folders and services, as follows:

- Inherit folders and services from the catalog of one business unit to the catalog of another business unit.
- Inherit folders and services from one part of the catalog hierarchy to another.
- Copy a service or folder and paste it as inherited.

After you create the inherited folder or service, you can update both the parent and child (inherited) objects. The following tables list:

- The changes to the parent that the child inherits
- The changes to either the parent or child that break inheritance

Parent Object	Change	Change Inherited?	Breaks Inheritance?
Folder or Service	Update settings on the Details tab	Y*	N
Folder	Add subfolders or services	N	N
Folder or Service	Delete services or subfolders--Not permitted directly. To delete the service or subfolder, first break the inheritance by deleting the inherited service or subfolder. You can also break inheritance for a service by editing or deleting an inherited service option group or service option.	N	N
Service Option Group	Update settings on the Details tab	N	N
Service Option Group	Add a service option	N	N
Service Option Group	Delete a service option--Not permitted directly. To delete the service option, first break the inheritance by editing or deleting the inherited service option.	N	N
Service Option	Update a service option element**	Y	N
Service Option	Add a service option element	N	N
Service Option	Delete a service option element	N	N

*Your updates in the parent folder override any existing values (including any custom values) in the child folder. The only exceptions are as follows:

- For child folders, the folder name is not changed.
- For child services, the service name, dates, and status are not changed.

** A service option element is a part of a service option. Examples include forms, reservations, and rate elements. Service option elements appear as fields on the Service Option Details tab. When you update these fields, the Service Option Element dialog opens.

Child Object	Change	Breaks Inheritance?
Folder or Service	Update settings on the Details tab	Y or N*
Folder	Add subfolders or services	N
Folder	Delete subfolders or services	N
Service Option Group	Update settings on the Details tab	N
Service Option Group	Add a service option	N
Service Option Group	Delete a service option	N
Service Option	Update a service option element	Y**
Service Option	Add a service option element	Y**
Service Option	Delete a service option element	Y**

* For child folders, you can change the name without breaking inheritance. For child services, you can change the name, dates, and status without breaking inheritance. Any other change breaks inheritance of the folder or service details *only*. Inheritance of service options and service option elements is not broken.

** The inheritance of the service option is broken. Inheritance of the folder and service details remains.

Note: Inheritance applies only to the changes listed in the tables.

Set Featured and Related Services

For folders, you can specify *featured* services. Similarly, for services, you can specify *related* services. These specifications are helpful when the user viewing a service or folder considers requesting a featured or related service. **Example:** When you create an "onboarding" service for new employees, you can specify services for laptops and cell phones as related services. When new employees access the onboarding service in the catalog, they see summaries and links for these related services.

Follow these steps:

1. Click Catalog, Service Offerings.

2. Expand the tree. Perform one of the following actions for the service or folder of interest:
   - Select the folder and click the Featured Offerings tab.
   - Select the service and click the Related Offerings tab.
3. Expand the Catalog Tree and specify one or more services, as follows:
   a. On the left side of the tree, select the box next to the service name.
   b. Next to the Selected Offerings box, click the right arrow to add the selected service to the box.
   c. (Optional) Include the children (inherited services) with the featured service. You can specify this setting individually for each featured service.
4. Verify and save your updates.
5. Verify that the catalog is configured to display related services, as follows:
   a. Select Catalog, Configuration, Request Management Configuration.
   b. For the Browse Catalog Layout option, specify Request View.
   c. For the *Access Control: Show General Information* option, specify the roles that you want to see featured services.
   d. For the *Access Control: Show General Information* and *Selections in Catalog Item Details* option, specify the same roles that you specified in the previous step.

Perform Other Tasks to Manage Services

This article contains the following topics:

Administrators (typically service designers) can copy, cut and paste, delete, and cancel services. They can use a service as a template. Administrators can also manage the folders that store services, define dependencies, and set thresholds for quality-of-service (QoS) SLAs.

Perform or skip any of the following tasks, as needed.

1. Use a service as a template (see page 3006).
2. Copy a service *with or without* inheritance (see page 3002), as follows:

a. Select the service and click Copy.

b. Specify which *one* of the following options you want to include in the copy:

- All associated service option groups (preferred)
- Only the service, *without* the service option groups (primarily for backward compatibility with earlier releases of the product)

c. Expand the tree and select the folder to which you want to paste the copied service.

d. Click the Paste icon or the Paste as Inherited icon.
The folder (and its child folders and services) or service is pasted to the new location. The inherited services are named "Inherited from *parent service*." When the parent service is updated, the same updates occur in the child service automatically.

3. Cut and paste a service, as follows: Select the service and click Cut. Expand the tree to the new location and click Paste.

4. Delete a service by selecting it and clicking the Delete icon. Before you confirm the deletion, review the effects of deleting a service (see page 3007).

> **Important!** Deletion is permanent.

5. Cancel a service by selecting it and setting the Canceled After field on the Details tab. Before you confirm the cancellation, review the effects of deleting a service (see page 3007). Canceling a service has the same effects as deleting a service on the related subscriptions and requests.

6. Review thresholds for QoS SLAs (see page 3008) and set (see page 3009) them.

7. Manage the folders (see page 3009) that store services in the catalog.

Define Service Dependencies

A dependency in the catalog allows a service state to change depending on the state of another service. You can also set the availability of a service to a user based on the business unit of that user.

The ability to define dependencies of services allows you to define how one service behaves based on how you select or clear another service. For example, if you are subscribing to Service A, the following events can occur for Service B:

- Service B can become disabled. The selection check box is inactive and cannot be selected or cleared.
- Service B can become subscribed to. The check box displays selection whether it is enabled or disabled.
- Service B can become unsubscribed to. The check box is cleared whether it is enabled or disabled.

Follow these steps:

1. Click Catalog, Service Offerings.
2. Click Change Business Unit, if necessary, and select the business unit whose service dependencies you want to define.
3. Click Define Dependencies.
4. Select one of the following options, and click Save Dependency.
   - **Business Unit to Service Assignment**
     Specifies which services appear in the catalog of the child business unit.
   - **Service to Business Unit Assignment**
     Specifies which services appear in the catalog of the child business unit.
   - **Subscribe Services**
     Specifies which services are included automatically in a subscription to another service. When a user subscribes to the selected service, the Catalog system subscribes the user to the services that you specify.
   - **Un-subscribe Services**
     Specifies which subscribed services are canceled automatically with the cancelation of another service. When a user cancels the selected service, the Catalog system cancels the subscription (of this user) to the services that you specify.
   - **Disable Services**
     Specifies which services are made *unavailable* (disabled) automatically as a result of a subscription to another service. When a user subscribes to the selected service, the Catalog system disables (for this user) the services that you specify.
5. Click the Close icon.

Use a Service as a Template

You can create a service to use as a template for creating all services in your catalog. Creating a template service helps ensure that all services in your catalog have a consistent look-and-feel. To create a template service, follow this process:

1. Add a service, using the following guidelines:
   - Include the word "template" in the name.
   - Mark the service as unavailable by setting the Unavailable After date to the current date.
   - Select the service option groups that you want to be in the template service.
2. Inform other administrators about the template service. Tell them to follow the remaining steps to use it to add a new service:
   a. Copy and paste the template service to an appropriate "holding" folder.

b. Rename the service each time that you copy it to a different folder.

c. Add new service option groups to the service, if necessary.

d. Remove existing service option groups from the service, if necessary.

3. Perform one of the following steps to modify a service option group in a service that is created from your template service:

   - To apply your changes to all services that use the service option group, edit the service option group definition directly.
   - To apply your changes only to the new service that you are creating from the template service:

     a. Copy and rename the service option group.

     b. Modify the new service option group as required.

     c. Add the new service option group to your new service.

     d. Remove the original service option group from the service.

   Note: When you copy a service, specify whether the new service includes copies of the original service option groups or links to them. If you specify links, any changes to a linked service option group apply to all services that include it. That is, the original service, the new service that you copied, and any other service in the Catalog system that includes the link.

4. Define a service option element in a service option group, or update it, if necessary.

Effects of Deleting a Service

Deleting folders or services affects the subscriptions and requests for the deleted services, as follows:

- **Subscriptions**
  The account that is subscribed to the service being deleted no longer contains or lists that service.
- **Requests**
  The status of requested service options for the account change that is based on their original status, as follows:

Original Status	New Status
Not Submitted	The service is deleted from the request.
Submitted. An approval status, a fulfillment status, Pending Resource Assignment, or Resource Assignment	The service and its service options are set to Cancelled.
Completed	

Original Status	New Status
	The default cancellation status (Pending Cancelation or Cancel) if Service Accounting Component is installed. Cancelled if Service Accounting Component is not installed.
Pending Cancelation or Canceled	Same as original status.

Thresholds for QoS SLAs

Request Service Level Agreements (SLAs) are a feature of CA Service Catalog. Quality of Service (QoS) SLAs are available only if CA Service Catalog is integrated with CA Business Service Insight.

You can establish thresholds for QoS SLAs for use with Request Fulfillment reports. An SLA threshold specifies the following data:

- Starting status
- Ending status
- Duration (days, hours, and minutes) for warning status
- Duration for a violation status

If the request for the service option takes longer than the SLA duration, then the request reaches a warning or violation status.

The Request Fulfillment reports use the SLA threshold specification. By default, the report includes the following phases:

- The approval phase
- The fulfillment phase
- The combination of approval and fulfillment phases

The following table shows summary data for these items:

Starting Status	Numeric Value	Ending Status	Numeric Value
Submitted	200	Approval Done	999
Approval Done	999	Completed	2
Submitted	200	Completed	2

You can also configure the reports to display the following data:

- The time for the status of a service option to move from the starting to the ending phase.
- The average time in each phase.
- The violation time for the SLA phases.

- The color code of warnings and violations for the service options for which SLA thresholds have been set.

If you report on different SLA thresholds, alter the STATUS_RANGES values for the Request Fulfillment reports.

The SLA violation duration for the Submitted to Completed phase is used for the “estimated time to fulfill” value. This value appears in the catalog in the “fulfillment details” for a service option.

Set Thresholds for QoS SLAs

You can establish thresholds for QoS SLAs for use with Request Fulfillment reports. Doing so is an optional task when you define a service.

Follow these steps:

1. Select Catalog, Services Offerings.
2. Expand the tree, locate the service of interest, and click its Definition tab.
3. Select the service option of interest and click its SLA icon.
4. Click Add, specify the following parameters for the new SLA, and click OK:
   - The starting status
   - The ending status
   - The warning and violation thresholds

Manage Folders

Services exist in a folder structure. You can *manage* the predefined folder structure to meet your needs. *Manage* here means create, copy, delete, and move.

Follow these steps:

1. Click Catalog, Service Offerings.
2. Expand the tree and select the folder of interest.

   Note: To add a folder at the top level (root folder), click Add and name the new folder.

3. Perform one of the following steps in the selected folder:
   - Copy a folder *with or without* inheritance (see page 3002), as follows:
     Select the folder and click Copy.
     Specify which *one* of the following you want to include in the copy:

- All associated service option groups
- Links to these service option groups

Expand the tree and select the folder to which you want to paste the copied folder.
Click the Paste icon or the Paste as Inherited icon.
The folder (and its child folders and services) or service is pasted to the new location.
Inherited folders are named "Inherited from *parent folder*." When the parent folders or services are updated, the same updates occur in the child folders or services automatically.

- Delete a folder by selecting it and clicking the Delete icon.

Important! Deletion is permanent. Deleted folders *cannot* be recovered.

Deleting the folder deletes all services in it. Before you confirm the deletion, review the effects of deleting a service (see page 3007).
Do one of the following actions *if* the folder that you want to delete contains inherited services.

- Delete the child, inherited service.
- Break the inheritance by editing the child, inherited service.

4. Complete the fields on the Details tab (see page 3011) for the folder.

Note: This step and the remaining steps apply only if you are creating or updating a folder.

5. Click the Permissions tab, and set permissions for the folder.
   Each role and group (if applicable) receives the access rights that you specify to the new folder.
   Only if a role or group has permission to access the folder, the associated users can perform the following actions:
   - View the folders and its subfolders in the catalog.
   - View, request, and subscribe to the services in the folder and its subfolders.
   - Access this folder, its subfolders, and associated services through searches and web service calls
6. (Optional) Review featured services (see page 3003). Specify any services in this folder to feature in the catalog.
   (Optional) Review service and folder inheritance (see page 3002). Specify other services to inherit with this folder.

Details Tab for a Folder

When you add or edit a folder, you complete the fields on the Folder Details tab.

The following fields on the Folder Details tab require explanation.

- **URL**
  Specifies a URL that supplies more information about the services in the folder. For example, a URL to a manufacturer web site.

- **Display Subfolders**
  Specifies whether the top-level subfolders under this catalog folder appear in the Browse section of the Requests page. Select *one* of the following options:

  - **Use System Setting**
    Use the system or "global" setting to show or hide the subfolders that are specified in the Browse Catalog: Show Subfolders parameter in the Request Management Configuration section of the Configuration page of the Catalog tab.
    If the value of the Browse Catalog: Show Subfolders parameter changes, all catalog folders that use the system setting are automatically updated accordingly.

  - **Show Subfolder**
    Specifies that this catalog folder *always* displays its subfolders in the Browse section of the Requests page, regardless of the value of the system setting.

  - **Hide Subfolder**
    Specifies that this catalog folder *never* displays its subfolders in the Browse section of the Requests page, regardless of the value of the system setting.
    Hiding these subfolders is often helpful when the number of them is so high that the following condition exists: Users must scroll through the Browse Catalog several times to view them all or to see the remaining folders and subfolders

Default: Use System Setting

Manage Service Option Groups

This article contains the following topics:

Administrators (typically service designers) create, update, and otherwise manage service option groups, which are the main components of services. Here, *manage* means create, update, copy, edit, delete, and so forth. A service option group consists of hardware, software, or other resources that you can include in a service. Service option groups are bundled groups of service options (see page 3017). Each service option consists of individual service option elements. You can use the same service option group in multiple services. Each business unit can have its own set of service option groups.

Follow this process:

1. Click Catalog, Service Offerings.
2. Click the Option Groups tab and perform one of the following actions:
   - View the details (see page 3013) of a service option group by selecting it.
   - Edit a service option group by selecting it and updating its fields. Go to the next step.
   - Create a service option group by clicking the + sign below the Option groups tab and name it. The details page for the new service option group appears. Go to the next step.
   - Copy a service option group *with or without* inheritance (see page 3015), as follows:
     a. Select the service option group in the tree and click Copy.
     b. Specify a unique name for the new service option group.
     c. Click the Paste icon or the Paste as Inherited icon.
     On the service option group tree, the inherited options appear in green.
   - Delete a service option group by selecting it and clicking the Delete icon. Before you confirm the deletion, review the effects of deleting a service option group (see page 3016).

     Important! Deletion is permanent. Deleted service option groups *cannot* be recovered.

     Perform one of the following actions *if* the service option group that you want to delete contains inherited service option groups. Otherwise, skip to the next step.
     - Delete the child, inherited service option group.
     - Break the inheritance by editing the child, inherited service option group. You cannot delete a folder or service that contains inherited service option groups.
3. Complete the fields on the Details Tab for the service option group.

   Note: This step and the remaining steps apply only if you are adding or updating a service option group.

4. You can optionally use a tiered service option group (see page 3014).
5. Define the service option group by clicking the Definition tab and performing one of the following actions:
   - Create service options and add them to the group.
   - Edit a service option in the group.

- Delete a service option from the group.
- Copy a service option in the group, with or without inheritance.
- Organize the service options in the group.

After you define the service option group, you can add it to services that users can request from the catalog.

6. Publish a report layout (see page 3016) for a service option group.
7. Associate a CA APM model with a service option, if you have integrated with CA APM.

Service Option Group Details Tab

The following fields on the Details tab for a service option group require explanation:

- **Id**
  (Read-only) Specifies the object ID of the service option group. At times, you specify object IDs explicitly. For example, as part of importing or exporting objects using IXUtil or content packs.

- **Date fields**
  The dates and times that you view and specify are based on the time zone of the CA Service Catalog server, which can be different from your local time zone.
  The following date fields require further explanation:

  - **Available On**
    Specifies the date when this service option group becomes available for catalog administrators to include in a service when they define the service. The change that you make to this field take effect immediately.

  - **Unavailable After**
    Specifies the date when catalog users can *no longer* request or subscribe to the service option group. Catalog administrators can no longer include this service option group in a service when they define the service. The change that you make to this field take effect immediately.

- **Name *and* Description fields**
  Specify the name and description of the service option group for catalog users. You can optionally localize these fields for use in a multilingual catalog.

- **Type**
  Specifies the type of service option group. This value determines how you can include this service option group within other service option groups as a characteristic of a service option element. Select one of the following options:

  - Fixed - A fixed service option group presumes a fixed cost or a variable cost that is based on usage.

  - Tiered - A tiered service option group (see page 3014) presumes a variable cost value.

  Default: Fixed

- **Selection Type**
  Specifies how catalog users select the options in the service option group while requesting a service that includes the service option group.

- **Code**
  Specifies a text value for a code of your choice. Examples include the product code, subscription code, and SKU number.

- **Sort Number**
  Specifies how to sort this service option group when a service that includes it uses a Sort By setting of Custom - use Sort Number.

- **Offering Dependencies**
  Specifies the names and statuses (for example, Available) of the services that include this service option group.

- **Account Dependencies**
  Specifies the following data:

  - The names of the accounts that are subscribed to services that include this service option group. The accounts subscribe to the service option group by subscribing to the service.

  - The names and statuses of the services to which these accounts are subscribed.

Tiered Service Option Group

A tier is a single row in a tiered service option group. You can use a tiered service option group to produce a variable cost according to a lookup value. The lookup value from the referencing service option group is matched with the tier values in the tiered service option group.

An association into a tiered service option group starts at the first row and works its way down: The first tier has the lowest tier values. When an applicable tier is identified and the Quantity Specification is set to System Specified, this event occurs: The lookup value is multiplied by the rates in other service option elements in the tier row to determine the invoice amount. If the Quantity Specification is not set to System Specified, other rates apply.

When a service option element is associated with a tiered service option group, the tier type value determines how the tiered service option group is used. The following tier types are available, depending on the referencing service option element:

- **Lookup**
  Use the first tier that matches the value being passed to the tiered service option group.

- **Lookup Multiple**
  Use each tier that matches the value being passed to the tiered service option group.

- **Variable Lookup**
  Use each tier up to and including the tier that exactly matches the value being passed to the tiered service option group.

- **Fixed**
  Use the first tier that matches the value being passed to the tiered service option group. Once in that tier the tier is fixed and cannot change.

- **Fixed Incremental**
  Use the first tier that matches the value being passed to the tiered service option group. Increment to the next tier only if the value passed in exceeds the previously used tier. That is, a certain tier level is used; a lower tier level can never be used.

- **Variable Fixed**
  Is a merger between variable lookup and fixed tier types. Use each tier up to and including the tier that exactly matches the value being passed to the tiered service option group. Once in the tier that exactly matches, that tier is fixed and cannot change.

- **Variable Fixed Incremental**
  Is a merger between variable lookup and fixed incremental. Use each tier up to and including the tier that exactly matches the value being passed to the tiered service option group. Increment to the next tier only if the value passed in exceeds the previously used tier.

Inheritance of Service Option Groups

You can copy a service option group and paste it as an inherited service option group. The inherited service option group has the same characteristics as the parent service option group from which it was created. The Catalog system shows the inheritance in the inherited service option group, as follows:

- On the Details tab, a note indicates that the service options in this group are inherited.
- On the Definition tab, the inherited service options appear in green.
- If you click the Edit icon of an inherited service option, the Service Option Details tab includes the following information:
  - Text that the option is inherited.
  - A link to the parent service option.
- If you click the Edit icon of an inherited service option element on the Service Option Details tab, the resulting dialog includes:
  - Text that the service option element is inherited.
  - The ID of the parent service option element.

The following rules apply to the inheritance relationship:

- If you update a service option element in the parent service option group, the Catalog system automatically makes the same updates to the inherited service option element in the child service option group. The updated values of the parent replace the existing values in the child.
- If you make either of the following updates to the parent service option, the updates do not apply to the child service option:

- Adding a service option element
- Deleting a service option element

- If you make either of the following updates to the child service option, you break the inheritance relationship. If this relationship breaks, then changes to the parent no longer propagate automatically to the child.
  - Adding a service option element
  - Deleting a service option element
  - Editing a service option element

When you manually update an inherited service option element, the green color disappears. The color disappearance indicates that the element was changed after it was inherited.

Effects of Deleting a Service Option Group

Deleting a service option group affects the subscriptions and requests for the deleted service option groups, as follows:

- **Subscriptions**
  The account that is subscribed to the service option group being deleted no longer contains or lists that service option group.

- **Requests**
  The statuses of requested service options in the service option group being deleted change, as follows:

Original Status	New Status
Not Submitted	The service option group and its service options are deleted from the request.
Submitted. An approval status, a fulfillment status, Pending Resource Assignment, or Resource Assignment	The service option group and its service options are set to Canceled.
Completed	The default cancellation status (Pending Cancellation or Cancel) if Service Accounting Component is installed. Cancelled if Service Accounting Component is not installed.
Pending Cancellation or Canceled	Same as original status.

Publish a Report Layout

You can publish a report layout that appears as a service option in a special service option group. This service option group is created the first time that a report is published. This service option group is named *Published Reports*. You can manage it as you manage other service option groups.

Follow these steps:

1. Select Administration, Report Builder, Layouts.

2. Expand the folders and select the report of interest.

3. Click the Publish Layout to the Catalog icon in the Actions column.
   A new service option for the report layout is added to the Published Reports service option group. The new service option has a default cost of 0.
   The service option representing the published report contains the following data:

   - Two Text type service option elements that display the report name and comment values.
   - A Rate Type service option element that holds the report cost.

   You can edit this service option and can include it in services.

Note: You can remove a published report from the catalog, as follows: De-select the service option from a service that includes it, or remove the service option from the service option group.

Manage Service Options and Service Option Elements

This article contains the following topics:

Administrators (typically service designers) create, update, and otherwise manage service options, which are the building blocks of a service option group. A service option group must contain at least one service option. Similarly, each service option contains one or more service option elements.

Each service option element adds value to the service. Examples include an item that the user can request or a function to complete the request lifecycle. Examples include these elements:

- A form element provides a form that the user completes to customize the request and to obtain fulfillment.
- A rate element provides billing specifications for a service option.
- A reservation element helps provide required data in a service for reserving physical or virtual computers.

Service option elements can have the following characteristics:

- **Static**
  Provides fixed information about the service option.

- **Actionable**
  Specifies that a request, service, or service option follows a specific approval process, fulfillment process, or both.

- **Financial**
  Specifies fixed, tiered, or usage-based rates. You can optionally link these rates to budget and planning functions.

You create, edit, and delete service options as part of managing service option groups.

When you create or edit a service option, you complete the fields on the following tabs, as applicable:

- Policies & Actions (see page 3018)
- Options (see page 3019)
- Details (see page 3021)

After you finish creating a service option, click the Preview tab to see how it appears to users in the catalog. If necessary, update the service option after you preview it to achieve the results you want.

Policies and Actions Tab

You create *global* policies and global actions for general use with any service. In contrast, you create *attached* policies and actions for use with one or more specific service options only. You attach these policies and actions to each service option individually. You can create an attached policy or action *only* from the Policies & Actions tab of that service option. After you create an attached policy or action for that service option, you can optionally attach that policy or action to another service option. However, you cannot change an attached policy or action into a global policy or action. Similarly, you cannot change a global policy or action into an attached policy or action.

Note: On the Policies and Actions tab, you can use the link to access CA Process Automation.

By default, CA Service Catalog evaluates all global policies and all events, rules, and actions (see page 3040) (global actions only) for every requested *service*. However, for individual service options, you can replace this default behavior. From the Policies & Actions tab of a service option, you can specify that the Catalog system apply the following specifications to that service option:

- For policies, one of the following options:
  - Global policies only
  - Attached policies only

- Both global and attached policies

- For actions, one of the following options:
  - Global actions only
  - Attached actions only
  - Both global and attached actions

Important! Applying policies or actions at both the service and service option levels could produce conflicting, unintended, or unpredictable results. Use attached actions and policies *only* if you are using a discrete request life cycle (see page 2120) that includes discrete approval of service options. This precaution helps avoid the unintended application of policies and actions at *both* the service and service option levels.

Service Option Element Options Window--Options Tab

Several fields appear on the Options tab of the Service Option Element Definition dialog. These fields apply to all service option elements.

- **Change to Take Effect**
  Applies *only* if the Catalog Configuration item named **Default Effect of Service Option Element Changes** is set to *Allow User to Choose*. For more information about Catalog Configuration settings, see the Catalog Configuration (see page 1449) section.
  If applicable, this option appears when you create or update service options in a service option group that is already defined in a service (see page 3001). The setting for this field applies to *all* updates that you make to other fields on this tab.
  Select an option from the following list and specify when the changes take effect for existing subscribers or requesters:
  - **Beginning of Accounts' Current Billing Period - No Audit Trail**
    The change takes effect retroactively to the beginning of the current billing period for existing subscribers or requesters.
  - **Beginning of Accounts' Current Billing Period**
    The change takes effect retroactively to the beginning of the current billing period for existing subscribers or requesters.
  - **Beginning of Accounts' Next Billing Period**
    The change takes effect at to the beginning of the next billing period for existing subscribers or requesters.
  - **Immediately during Accounts' Billing Period**
    The change takes effect immediately for existing subscribers or requesters.
  - **Specify a Future Effective Date**
    The change takes effect for existing subscribers or requesters on the date specified.

- **Code**
  Specifies user-specified text value to represent the product code, subscription code, SKU # or any other applicable code.

- **URL Info**
  Displays a clickable URL with the service option element to the requesting or subscribing user.

- **Display Type**
  Specifies how the service option element appears in the request, subscription, and invoice (if Service Accounting Component is installed). This setting allows you to hide the service option element from view in special cases. Select an option from the following list:

  - Include in Request/Subscription and Invoice
  - Include in Request/Subscription, Exclude from Invoice
  - Exclude from Request/Subscription and Invoice

- **Include in services (offerings)**
  Applies only when you create a service option element in a service option that belongs to a service option group that is already defined in a service (see page 3001). In other words, one or more services already include this service option group.
  Select from the following list:

  - **Do not include**
    Specifies that the new service option element is not included in any existing (defined) services. However, newly defined services that include this service option do include the new service option element.

  - **That have this service option**
    Updates all existing services that include this service option to include the new service option element.
    The updated service definition includes the new service option element.

  - **That have this Service Option Group**
    Updates all existing services that include this service option group to include the new service option element, as follows:
    Did the original service definition include the service option that you updated by adding the new service option element?
    If yes, the updated service definition includes the new service option element in that service option.
    If no, the updated service definition includes a new service option that contains only the new service option element.

  If you select the second or third option, the following subscription (see page 3120) prompt appears
  Select from the following list:

  - **Do not subscribe**
    The new service option element is not included in any existing subscriptions.
    However, new subscriptions for this service that include this service option do include the new service option element.

- **That have this service option**
  Updates all existing subscriptions for services that include this service option to include the new service option element.

- **That have this Service Option Group**
  Updates all existing subscriptions for services that include this service option group to include the new service option element, as follows:
  Did the original service definition include the service option that you updated by adding the new service option element?
  If yes, the updated subscription to the service includes the new service option element in that service option.
  If no, the updated subscription to the service includes a new service option that contains only the new service option element.

Service Option Details Tab

Use this tab to add the service option elements that you want to this service option.

To add an element, click the Add icon and supply the following data. To update an element, click the Edit icon and update the following data.

- Fields that apply to all service option elements (see page 3019)

- Fields that apply to the element only.

Basic Information

- **Name *and* Description fields**
  Specify the name and description of the service option for catalog users. You can optionally localize these fields for use in a multilingual catalog.

- **Attachment Mandatory**
  Requires the user requesting the service to add an attachment for this service option. If the user does not add the attachment, the user cannot submit the request. Use this option to collect documents (such as certifications or proof of identity) or data that you cannot collect in a form. If selected, this option is activated *only* when the Allow Attachments at Service Option Level parameter is set to Yes. To set this parameter, select Catalog, Configuration, and click Request Management Configuration.

Reservation

- **Reservation Service Option**
  Associates a Reservation Manager reservation of a physical or virtual resource.
  This option and the related fields apply *only* if Reservation Manager or an external reservation system is installed and integrated with CA Service Catalog. The related fields are as follows: Reservation Display Text, Operation, Reservation Ready Status, Reservation Failure Status, and Reservation System

Form

- **Form**
  Associates the form or forms that you select with this service option. In the catalog, the form appears under the service option. Users complete the form when they request this service option.

This form is a service option element within this service option.
Complete the fields for Form Designer form elements (see page 3025).
You can create, customize, and use forms (see page 2950) with the Form Designer (the preferred method).

Contract

- **CA Business Service Insight Contract**
  Associates a CA Business Service Insight service level agreement (SLA).
  This option applies only if CA Business Service Insight is installed and integrated with CA Service Catalog.

Categorization

- **Category**
  Specifies the major category of the service option element from a list of categories.
  The Category value helps determine which rule actions execute approval and fulfillment business processes for a request for a service including this service option element.
  In addition, this value is used to determine the asset type for assigning an asset.
  If CA APM is installed and you select Track as an Asset, the following option applies: You can use the CA APM Assign Asset dialog to associate a request item with a software asset or other type of asset.

- **Category Class**
  Specifies a value from the list to categorize the class of this element within the selected category.

- **Category Subclass**
  Specifies a value from the list to categorize the subclass of this element within the selected class.

- **Keywords**
  Specifies a list of comma-separated list of keywords that are referenced during a catalog search.

- **External ID**
  A user-specified text value to represent the product code, subscription code, SKU # or any other applicable code.

- **Track as an Asset**
  Identifies whether the service option element is eligible to be associated with an asset.
  If CA APM is installed and you select Track as an Asset, the following option applies: You can use the CA APM Assign Asset dialog to associate a request item with a software asset or other type of asset.

- **Information Service Option Only**
  Indicates that this service option is for information only and cannot be subscribed to or requested.

Cost & Pricing

- **Rate**
  Associates a rate (price or cost) service option element with this service option. This price or cost is fixed; it is *not* based on application usage.
  Complete the fields for rate elements (see page 3025).

- **Adjustment**
  Adjusts the charge of an associated service option element. It can be a fixed value or a specified multiplier of the value of the associated service option element.
  Complete the fields for adjustment elements (see page 3029).

- **Usage Based Price**
  Specifies the charges for a service option or other item according to usage.
  Complete the fields for usage based costs elements (see page 3029).

Additional Elements

- **Text**
  Specifies the text and optional image file that appear to users when they select the associated service option.
  An example text string follows: Estimate: one week to complete the request. A sample image file is a detailed photograph of the item being ordered.
  You can optionally upload an image file and specify a text value for the image.

  - **Associate Service Option Group**
    Indicates that a service option group is associated with this service option element.
    Select this field to display a list of tiered service option groups. Associate a service option group and tier type.

  - **Rich Display Text**
    Converts the Display Text field to a rich text field, so that you can add images and special formatting to the Display Text field.
    The recommended size for a Service Option Element image is no larger than 48 x 48 pixels.

  - **Information Service Option Only**
    (Read-only) This field is automatically assigned the same value as the Information Service Option Only field on the Service Option Details tab.

- **Numerics**
  Specifies either a fixed numeric value or a numeric value that is entered by the user requesting the service that contains this service option element.
  Complete the fields for numeric elements (see page 3030).

- **Booleans**
  Specifies a true or false value.
  Note that some fields apply only if Service Accounting Component is installed.

  - **Display Text**
    Specifies the additional text that appears for this service option element.

  - **Boolean Value**
    Determines the value of the service option element. Select from: False or True.

  - **Associate Service Option Group**
    Indicates that a service option group is associated with this service option element.
    Select this field to display a list of tiered service option groups. Associate a service option group and tier type.

- **Date**
  Specifies the date values used with a service option.

  - **Date Type**
    Specifies the type of date. Select from the following list:

    - Specify Value - The Administrator specifies the date value that appears in the catalog. This setting displays the following field:

    - Date Value: The date value for the catalog.

    - Subscription Date - The system sets this value to the date of the request or subscription.

    - Invoice Date - The system sets this value to the date of the invoice if Service Accounting Component is installed.

  - **Associate Service Option Group**
    Specifies that a service option group is associated with this service option element.
    Select this field to display a list of tiered service option groups. Associate a service option group and tier type.

- **Day of Billing**
  Similar to a rate element but also allows a day of the week for weekly charges or a day of the month for monthly charges.
  A Day of Billing element specifies one of the following options:

  - For weekly charges: the day of the week on which to bill the item

  - For monthly charges: the day of the month on which to bill the item

  This element applies only if Service Accounting Component is installed.
  Most of the fields for a Day of Billing element have the same meaning as the fields for rate elements (see page 3025).

- **Numeric Range**
  Specifies a numeric range entered by the user requesting the service that contains this service option element.
  This element applies to tiered service option groups (see page 3014)*only*.
  Complete the fields for numeric range elements (see page 3031).

- **Date Range**
  Specifies a date entered by the user requesting the service that contains this service option element.
  This element applies to tiered service option groups (see page 3014)*only*.

  - **Lower Bound**
    Specifies the numeric value of the lower bound for matches when this service option group is referenced.

  - **Upper Bound**
    Specifies the numeric value of the upper bound for matches when this service option group is referenced.

- **Infinite Upper Bound**
  Specifies that the Catalog system uses this service option element for matches when the lookup value exceeds the value of the lower bound.

Fields for Form Elements

- **Display Text**
  Specifies the descriptive text to display for this form to administrators browsing the list of forms.

- **Form Name**
  Specifies the name of the Form Designer form that you want to define as a service option element for this service. Use the Search icon to view the list of forms and select one.

- **Hidden and Disabled fields**
  If you do not want to hide or disable the entire form under any conditions, leave the Hidden and Disabled fields empty.
  If you do want to hide or disable the entire form, enter the corresponding JavaScript expression in the Hidden or Disabled field. You can hide or disable the form according to the request status, the user role or business unit, or other criteria. Use the following format: $(_.object.property). The expression must return a value of true or false.
  You can specify JavaScript expressions (see page 2957) in the Hidden field, the Disabled field, or both. Examples follow:

  - To hide or disable the form when the request status is Pending Approval, enter the following JavaScript expression in the Hidden or Disabled field: $(_.request.status == 400).
  - To hide or disable the form for the end user roles only, enter $(_.user.role == ‘enduser’).
  - To hide or disable the form from all business units except ca.com, enter $(_.bu.id != ‘ca.com’).
  - To disable the form when the request status is Fulfilled, enter $(_.request.status == 2000).

  When an entire form is disabled, it is disabled but visible during all stages of the request lifecycle. The exception is checkout, when the form is both disabled and hidden.

- **Display Form Name**

  Note: This capability is available only if you have installed the CA Service Catalog 14.1.01 patch updates available on CA Support.

  Check or uncheck to show or hide the Form name. The **Display Form Name** option is also dependent on the System Configuration settings. If the administrator has disabled the form name display option at the System Configuration level, the form name is not displayed, even if the the **Form Name Display** option is checked.

Fields for Rate Elements

- **Cost Type**
  Specifies the type of cost for the Service Option Element. Select from the following list:

- **Specify Value**
  The Administrator specifies the cost value that appears in the catalog and the requesting or subscribing user cannot change the value.
  This setting displays the following field:
  - Unit Cost: The cost value that is to appear in the catalog.
- **User Specified**
  The Administrator specifies the default cost value that appears in the catalog. The requesting or subscribing user can change the value.
  This setting displays the following fields:
  - Default Unit Cost: The default cost value that is to appear in the catalog.
- **Allocate Cost**
  The cost is determined by using values that are associated to a Set as established in Accounting, Budgeting, and Planning worksheets. This setting applies only if you have Service Accounting Component installed.
  This setting displays the following fields:
  - Default Unit Cost: This value in this field is set to 0, as the cost is determined from the worksheet value for the associated set with the selected Allocation Method.
  - Set: List of Accounting Budgeting and Planning sets available for this cost type.
  - Allocation Method: The list of possible methods of allocating the cost that is tied to the service option element.
  - Assign: Use the value in the set for the total cost of this service option element for every subscription or request.
  - Distribute by Subscribed Account: Use the value in the set for this service option element that is divided by the number of accounts that are subscribed to this service option element.
  - Distribute by Subscription: Use the value in the set for this service option element that is divided by the number of subscriptions to this Service Option Element.
  - Weighted Distribution: Use the value in the set for this service option element that is allocated according to actual usage by the account.
- **Standard Cost**
  The unit cost is determined by pulling values that are associated to a Set value as established in Budgeting and Planning worksheets. This setting applies only if Service Accounting Component is installed.
  This setting displays the following fields:
  - Default Unit Cost: This value in this field is set to 0, as the cost is determined from the worksheet value for the associated set with the selected Allocation Method.
  - Set: List of Accounting Budgeting and Planning sets available for this cost type.

- Allocation Method: The list of possible methods of allocating the unit cost that is tied to the service option element.

- Assign: Use the value in the set for the unit cost of this service option element.

- **Display Unit Type**
  Specifies a text value that appears with the cost value.

- **Charge Type**
  Indicates whether cost value must appear as a Charge or a Credit on an Accounting invoice.

- **Budget**
  Indicates whether the service option element appears in the Budget and Planning worksheet.
  If Service Accounting Component is not installed, this field serves as additional categorization for the service option element.

- **Billing Cycle**
  Indicates how the cost value is applied to an invoice if Service Accounting Component is installed.
  Select from the following list:

  - One-Time - The charge is applied one time.

  - Installments - Cost is applied on an installment plan.
    This setting displays the following fields:

    - Periodic Type: The type of interval to be used when applying the cost: Daily, Weekly, Monthly, or N/A.

    - Periodic Type Interval: The frequency of the interval in Periodic Type field for determining the billing interval of the cost.

    - Number of Installments: The number of times the cost must be applied before no longer applying the cost.

  - **Periodic**
    This setting displays the following fields:

    - Periodic Type: The type of interval to be used when applying the cost: Daily, Weekly, Monthly, or N/A.

    - Periodic Type Interval: The frequency of the interval in Periodic Type field for determining the billing interval of the cost.

- **Quantity Specification**
  Indicates how a quantity value must be applied. Select from the following list:

  - **Flat Rate**
    The cost is applied as a flat rate without alteration.
    This setting displays the following fields:

    - Default Quantity Value: The multiplier for the cost value.

- **Specify Quantity**
  The cost is multiplied by the value in the Quantity field.
  This setting displays the following fields:
  - Quantity: The multiplier for the cost value.
  - Show Quantity: Indicates whether the Quantity value must be shown in the catalog.
- **Lookup Admin Specified Quantity**
  The cost is applied according to an associated service option group.
  This setting displays the following fields:
  - Service Option Group: Displays the associated service option group from the list of tiered Service Option Groups in the list or None.
  - Service Option Element: List of service option elements in the tiered service option group which must be associated with this service option element.
  - Show Quantity: Indicates whether the Quantity value must be shown in the catalog.
- **Lookup User Specified Quantity**
  The cost is applied according to a service option element in a service.
  This setting displays the following fields:
  - Service: List of services or None.
  - Service Option Group: List of service option groups for the selected service in the list or None.
  - Service Option Element: List of service option elements in the selected service option group which must be associated with this service option element.
  - Show Quantity: Indicates whether the Quantity value must be shown in the catalog.
- **User Specified**
  The cost is multiplied by the value in the quantity field.
  This setting displays the following fields:
  - Default Quantity Value: The multiplier for the cost value. The user can set this value.
  - Show Quantity: Indicates whether the Quantity value must be shown in the catalog.
- **System Specified**
  The Catalog system applies the cost based on a usage quantity.
- **Form Specified**
  The Catalog system applies the cost based on a form field.
  If you select this option, complete the additional related fields that appear for the related form.
  The Charge Effective From Form Field provides the date field on the form that specifies when billing starts.

Fields for Adjustment Elements

Note that some fields apply only if Service Accounting Component is installed. Adjustments appear on Accounting invoices.

- **Adjustment Value**
  Displays the numeric value of the adjustment to the Accounting invoice.

- **Charge Type**
  Indicates whether cost value must appear as a Charge or a Credit on an Accounting invoice.

- **Adjustment Type**
  Indicates how the Adjustment Value is applied to an invoice if Service Accounting Component is installed. Select from the following list:

  - Applied Amount - The actual amount of the associated service option element is applied.

  - Multiplier - A multiplier of the associated service option element is applied.

- **Service**
  Specifies the service to which the adjustment applies.

- **Service Option Group**
  Specifies the service option group (of the selected service) to which the adjustment applies.

- **Service Option Element**
  Specifies the service option element (of the selected service option group) to which the adjustment applies.

Usage Based Costs Element Fields

Note that some fields apply only if Service Accounting Component is installed.

- **Pricing Structure**
  Specifies the method of charging for a selected application. Select from the following list:

  - **Subscription Based**
    The cost is based on a pre-defined fixed rate. This setting structure displays the following fields:

    - Cost Type: The cost type that must be used to apply the cost of this service option element. This field has the same effect as the Cost Type field on the rate element: Depending on the Cost Type selected, additional fields appear.

    - Display Unit Type: Text value that appears with the cost value

    - Charge Type: Indicates whether cost value must appear as a Charge or a Credit on an Accounting invoice.

  - **Tier Based**
    The cost is derived from an associated tiered service option group according to a lookup value. This setting displays the following fields:

- Service Option Group: The list of tiered service option groups, allowing the Administrator to select an associated service option group.
- Tier Type: The list of available tier types for the selected service option group.

The options that appear in tier type drop-down have the same meaning as the options for tiered service option groups (see page 3014).

- **Usage Based**
  The cost is based on the usage information from data mediation.

  Note: For Service Accounting Component to assign costs correctly, the fiscal period of the Budgeting and Planning Set that is used and the account Billing Cycle must be aligned. For example, if monthly fiscal periods are defined in the set, the billing cycles of associated accounts must also be set to monthly. The Period Start and Period End dates for the Accounting Profile must be aligned. The period start date and period end dates for the account period must have an end date one day later than the fiscal period end date.

  This setting displays the following fields:

  - Cost Type: The cost type that must be used to apply the cost of this service option element. This field has the same effect as the Cost Type field on the rate element: Depending on the Cost Type selected, additional fields appear.
  - Display Unit Type: Text value that appears with the cost value
  - Charge Type: Indicates whether cost value must appear as a Charge or a Credit on an Accounting invoice.

- Show Metric Result
  Shows the metric results on an Accounting invoice and provides a link to a report representing this data.
- Application
  The list of available applications appears in the list.
- Metric
  The list of metrics available for the selected Application is shown.

Fields for Numeric Elements

- **Numeric Specification**
  Specifies whether the subscriber or requester can change the numeric value of the service option element. Select from the following list:

  - Specify Value - The Administrator sets the value of the service option element. This setting displays the following field:
    Numeric Value: The numeric value of the service option element.

- User Specified - The Administrator sets the default value of the service option element which the subscribing or requesting user can change. This setting displays the following field:
  Default Value: The default numeric value of the service option element.

- **Show Numeric Value**
  Determines whether the value of the service option element is shown to the user.

- **Associate Service Option Group**
  Indicates that a service option group is associated with this service option element.
  Select this field to display a list of tiered service option groups. Associate a service option group and tier type.

Fields for Numeric Range Elements

- **Lower Bound**
  Specifies the numeric value of the lower bound for matches when this service option group is referenced.

- **Upper Bound**
  Specifies the numeric value of the upper bound for matches when this service option group is referenced.

- **Infinite Upper Bound**
  Specifies that the Catalog system uses this service option element for matches when the lookup value exceeds the value of the lower bound.

- **Specify Median**
  Exposes the following field:

  - **Median Value**
    Specifies that when determining the tier to be used, the value to compare is the lookup value from the usage data. The value of the multiplier for any rate elements for the tier is the absolute value of the difference between the lookup value and the median value.

Localize a Single Service

Service Managers can specify localization attributes to make a single service available in multiple languages. The service appears in the catalog with localized names, descriptions, and forms. This feature lets a multilingual organization maintain one service in a single catalog for *all* supported languages. Multiple versions of a service or multiple catalogs are *not* required.

For efficiency, localize your *custom* services *only.* CA Service Catalog automatically localizes the predefined services when you install a language pack for a localized language. For example, after you install the French language pack, the predefined services appear in the catalog in French if you set your browser language to French.

Follow these steps:

- Step 1 - Review the Best Practices and Limitations (see page 3032)
- Step 2 - Set the Localization Attributes for the Folder (see page 3033)
- Step 3 - Set the Localization Attributes for the Service (see page 3033)
- Step 4 - Set the Localization Attributes for the Service Option Group (see page 3034)

Step 1 - Review the Best Practices and Limitations

The following best practices apply when you localize a single service:

- Before you localize services and the following related objects, verify that they are completed in the original language:
  - Service option groups
  - Service options
  - Service option elements
  - Forms (if applicable)
  - Folders
- If you update these objects in the original language after you localize them, update the localization attributes accordingly. Otherwise, your catalog could contain localized services and related objects that do not completely match the original-language versions.
- You can copy or inherit a service that includes localization attributes. But, the copied or inherited service retains the localization attributes of the original service.

To make a service available in the catalog, define the service as you define a service without localization attributes.

The following limitations apply when you localize a single service:

- Once all the fields are localized the localized values are seen in end user view only, in Request page. In Service Designer page the definition remains in original language itself.
- Only the fields that you localize appear in the local language in the catalog.
- You can set *one* currency unit (for example, dollars) that applies to *all* local languages.
- You can localize attributes *only* for the languages in which CA Service Catalog is localized for this release.

Note: You can optionally replace the default icon at *USM_HOME* \view\webapps\usm\images\localization_16.png with another icon.

Step 2 - Set the Localization Attributes for the Folder

After you set the Folder attributes, they appear in the local language when users view the folder in the catalog.

Follow these steps:

1. Click Catalog, Service Offerings. Expand the folders and open the folder that you want to localize.
2. Click the Localization icon  for the Name field and specify the text.
3. Save your changes and close the Localization Values dialog.
4. Click the Localization icon for the Description field and specify the text
5. Save your changes to the folder.

You have set the localization attributes for the folder.

Step 3 - Set the Localization Attributes for the Service

After you set the Service attributes, they appear in the local language when users view the service in the catalog.

Follow these steps:

1. Click Catalog, Service Offerings. Expand the folders and open the service that you want to localize.
2. Click the Localization icon  for the Name field and specify the text.
3. Save your changes and close the Localization Values dialog.
4. Click the Localization icon  for the Description field and specify the text.
5. Save your changes and close the Localization Values dialog.
6. (Optional) Click the Definition tab to see the Overview text. Click the Localization icon  , specify localized overview text in the Localization Values dialog, and save your changes.
7. Save your changes on the Overview dialog.

You have set the localization attributes for the service.

Step 4 - Set the Localization Attributes for the Service Option Group

To set the Service Option Group attributes, click the Localization icon for the Name field and Description fields of the Service Option Group you want to localize. Provide the information and save your changes.

Next, you set the localization elements for its service options and its service option elements, including forms.

Step 5 - Set the Localization Attributes for the Service Option

To set the Service Option attributes, click the Localization icon for the Name field and Description fields of the Service Option you want to localize. The Description field includes several options for rich text, including pictures, links, colors, formatting, and highlighting. You can optionally use these options for any language, including all languages on the Localization Values dialog.

You have set the localization attributes for the service options.

Step 6 - Set the Localization Attributes for the Form

You use the Form Designer to create and localize custom forms: You can localize the element names and selected attributes in forms, using the Localization Editor.

While editing the form in the Form Designer, you see localized names and values only when you are using the Localization Editor. However, when a localized form is used in a request, it displays all localized values. If no localized values exist, the form displays the default values for the selected attributes.

Localized system forms are applied *automatically* when you install the CA Service Catalog language pack for your language.

Follow these steps:

1. Select the form name in the Component Tree and click the Localize button.

2. Select a language from the Language drop-down list. Specify local values for the following attributes, for each element in the Localization Editor. Some attributes do not apply to all elements. When an attribute does not apply to an element, the attribute is omitted. *Only* the following attributes can be localized.

   - **Empty Text**
     Provides more description of a field to the user.
     The value that you specify for this attribute appears inside the field when the user opens the form. This text disappears when the user begins entering a value in the field. A sample value follows, for a password field: AAbb1234

   - **Hint**
     Specifies text to help users complete the field correctly. This text *always* appears below the field, regardless of the position of the mouse.
     For example, for a password field, you can specify the following hint: "Passwords must be six to eight characters and must include both letters and numbers."

- **Label**
  Specifies the name of the element. This text is used as the name of the field when the user displays the form in a request. For example, you can specify Name, Address, City, or State.

- **Pattern Message**
  Applies to text fields and text areas *only*, and only when the HTML attribute (see page 2928 named pattern is also used.
  Specifies the error message to appear when the user input violates the *pattern* attribute. In the value for the pattern attribute, you specify regular expressions to validate numeric and address data (see page 2980). Examples include credit card numbers, social security numbers, email addresses, IP addresses, and telephone numbers.

- **Tool Tip**
  Specifies the Tool Tip text, if applicable. Only certain elements use this attribute.

- **Value**
  Specifies the value of the element; this text is the default value for the field when the user displays the form in a request.
  For example, you can leave the value blank for an element whose name (label) is Name or Address, because each user must specify a custom value.

3. Click Save after you enter a localized value.

4. Continue specifying local values for attributes.

You have set the localization attributes for forms.

Step 7 - Test the Localized Services

To verify that the localized services appear as intended in the catalog**,** set your Web browser to the localized language and access the localized services in the catalog. Ensure that the localized elements and attributes appear correctly in folders and services, including its forms.

Localize Multiple Services

Service Managers can localize multiple service offerings (services), including forms, to be available in the catalog in multiple languages. You use IXUtil commands, a localization properties file, and a localization agency. This process lets a multilingual organization maintain one service in a single catalog for *all* supported languages. Multiple versions of a service or multiple catalogs are *not* required.

For efficiency, localize your *custom* services *only.* CA Service Catalog automatically localizes the predefined services when you install a language pack for a localized language. For example, consider the predefined services that appear in English when you install CA Service Catalog. After you install the French language pack, these predefined services appear in the French catalog if your browser language is set to French.

Follow these steps:

- Step 1 - Review the Best Practices and Considerations (see page 3036)
- Step 2 - Export the Services and Forms to an XML File (see page 3036)
- Step 3 - Send the Default Localization Properties File to the Localization Agency (see page 3038)

Step 1 - Review the Best Practices and Considerations

The following best practices apply when you localize multiple services:

- Before you localize services and the following related objects, verify that they are completed in the original language:
  - Service option groups
  - Service options
  - Service option elements
  - Forms (if applicable)
  - Folders
- After you export these objects to an XML file, (see page) make only critical updates to the objects. Otherwise, your catalog can contain localized services and related objects that do not completely match the original-language versions. When you merge the completed localization properties files (see page), any existing objects with the same IDs are overwritten. Thus, any changes that you make to these objects using the UI are also overwritten.

  Important! If you update these objects, apply the updates again after you merge the completed file.
- You can copy or inherit a service that includes localization attributes. But the copied or inherited service retains the localization attributes of the original service.

To make a service available in the catalog, define the service as you define for a service without localization attributes.

The following considerations apply when you localize multiple services:

- Fields appear with localized attributes in the catalog only. In all other components of the product, for example, in Catalog Component, fields appear in the original language.
- You can set *one* currency unit (for example, dollars) that applies to *all* local languages.
- You can localize attributes *only* for the languages in which CA Service Catalog is localized for this release.

Step 2 - Export the Services and Forms to an XML File

The export creates both the XML file and a default localization properties file. The default localization properties file includes the attributes of the exported objects, for the default (original) language *only*.

Follow these steps:

1. Open a CA Service Catalog command prompt.

2. Navigate to the *USM_HOME*\scripts folder.

3. (If you have access to the Catalog system and you are working individually)

   Enter the following command to export services and related data to an XML file. The XML file includes all services that you specified and the objects that comprise the services. This command also extracts the default translatable strings from the XML file into a default localization properties file.
   To export services *with* forms, use the following command:

   ```
   ixutil export service  - f filename.xml -include_forms -include_translation
   object-specific parameters
   ```

   To export services *only*, use the following command:

   ```
   ixutil export service  - f filename.xml -include_translation object-specific
   parameters
   ```

   ***filename*.xml**

   Specifies an intuitive name of your choice for the exported objects. Enclose the *filename*.xml in quotation marks if it contains one or more spaces.

   -include_translation

   Creates a default localization properties file. This file contains default localization parameters. You send this file to the localization agency, which supplies the language-specific attributes and completes the file. The file name is *xml-filename*_default.properties. For example, if you specify PersonnelServices.xml as the XML file name, then this file name is PersonnelServices_default.properties.

   object-specific parameters

   Specifies the parameters for a specific object. For example, a business unit or folder, as shown in the examples that follow this procedure.

4. (If you do not have access to the Catalog system or if you are working in a team)

   a. The first person or team exports the services to one or more XML files. Use the following command:

      ```
      ixutil export service  - f filename.xml -include_forms object-spec
      ```

   b. The second person or team receives the XML file or files and then extracts the default translatable strings from each XML file into a default localization properties file. Use the following command:

      ```
      ixutil export service  - f filename.xml -extract_translation
      ```

Examples

These sample commands show how to export services, with or without forms, using a single command. All single-command operations must specify the -include_translation option to create the localization properties file. If you are using two teams and two commands, use the following examples to help construct your first export command.

```
ixutil export service  - f AllServicesAndForms.xml -include_forms -include_translation
```

This command creates the AllServicesAndForms.xml file and the AllServicesAndForms_default.properties file.

The following command exports all services in the business unit that is named SaoPaulo25, and does not include forms:

```
ixutil export service  - f SaoPaulo25.xml  - domain "SaoPaulo25" -include_translation
```

This command creates the SaoPaulo25.xml file and the SaoPaulo25_default.properties file.

The following command exports the services and forms in the folder Folder 1 in the business unit named CA:

```
ixutil export service  - f CA-Folder1.xml  - folder "Folder 1"  - domain "CA" -
include_forms -include_translation
```

This command creates the CA-Folder1.xml file and the CA-Folder1_default.properties file.

Step 3 - Send the Default Localization Properties File to the Localization Agency

The agency completes the default localization properties file by adding localization attributes for the languages that you require.

Follow these steps:

1. Send the default localization properties file to the localization agency.
2. Instruct the agency to provide one new properties file for each required language. An example for the file naming convention is *filename*_pt_BR.properties for Brazilian Portuguese. Or *filename*_fr_FR.properties for French.

Important! Instruct the agency to save each file with the UTF-8 encoding. This encoding is required for the file to function properly.

You have sent the default localization properties file to a localization agency.

Step 4 - Merge the Completed Localization Properties Files

When the localization agency returns the completed localization properties file for each language, you merge these files into the catalog. After the merge, the services are available to catalog users in the localized languages.

Follow these steps:

1. Review each completed localization properties file that the localization agency returned to you. Verify that the localization attributes appear for services and forms (if applicable) in the required languages.

2. Copy the completed localization properties files to the same folder as the XML file that you exported (see page) originally.

   Important! This XML file and the properties files *must* reside in the same folder. Otherwise, the merge does not occur.

3. Open a CA Service Catalog command prompt and navigate to the *USM_HOME*\scripts folder.

4. (If you have access to the Catalog system and you are working individually)

   Enter the following command to import the completed localization properties files into an XML file. This command also imports the updated XML file into the Catalog system. Merge the completed localization properties files into the Catalog system, using the IXUtil import command.
   To import services *with* forms, use the following command:

   ```
   ixutil import service  - f filename.xml -include_translation -include_f
   ```

   To import services only, use the following command:

   ```
   ixutil import service  - f filename.xml -include_translation object-spe
   ```

   ***filename*.xml**

   Specifies the name of the XML file that you exported originally. Enclose the *filename*.xml in quotation marks if it contains one or more spaces. Specify the complete path name. Enclose the complete path name in quotation marks if it contains one or more spaces.

   -include_translation

   Merges the localization attributes from the completed localization properties files into the exported XML file. Also inserts the objects from this XML file into the Catalog system.

   object-specific parameters

   Specifies the parameters for a specific object. For example, a business unit or form.

5. (If you do not have access to the Catalog system or you are working in a team)

   a. The first person or team imports the completed localization properties files into one or more XML files. Use the following command:

      ```
      ixutil import service  - f filename.xml -merge_translation
      ```

   b. The second person or team imports each updated XML file into the Catalog system after receiving it from the first person or team. This command merges the completed localization attributes from the localization properties files into the corresponding

objects in the XML file. Next, the command inserts these objects into the Catalog system. The updated objects from the XML file overwrite any existing objects with the same ID in the system. Use the following command:

```
ixutil import  - f filename.xml -include_forms object-specific par
```

Examples

These examples show how to import services, with or without forms, using a single command. If you are using two teams and two commands, use these examples to help construct your first import command.

The following command imports all services and forms from the AllServicesAndForms.xml file into the catalog:

```
ixutil import service  - f AllServicesAndForms.xml -include_translation -include_forms
```

The following command imports all services (without forms) from the SaoPaulo25.xml file into the business unit that is named Sao_Paulo25:

```
ixutil import service  - f LocalizationSaoPaulo25.xml -include_translation  - domain
"Sao_Paulo25"
```

Step 5 - Test the Localized Services

Verify that the localized services appear as intended in the catalog.

Follow these steps:

1. Set your Web browser to the localized language and access the localized services in the catalog.
2. Verify that the localized elements and attributes appear correctly in folders and services, including its forms.
3. If necessary, correct any errors. Also, if necessary, synchronize changes between the original language and the localization attributes.

You have tested the localized services to verify that they appear as intended in the catalog.

Manage Events-Rules-Actions

As a CA Service Catalog administrator, you can use events, rules, and actions for automating the requests, users, and accounts process in the system as following:

- Events (see page 3041)
- Rules (see page 3041)
- Actions (see page 3042)

Events

Events are installed automatically when you install or upgrade CA Service Catalog.

- *Events* represent changes that occur within CA Service Catalog. Several *standard* events typically occur in various components. For example, the User Create event occurs when an administrator adds new user, by using either the user interface or the createUser web service method. You can also add *custom* events.
- Events can have *rules* that are associated with them. Rules can have a set of filter conditions that define when the rule applies. When the filter conditions are satisfied and the rule is enabled, the rule *actions* are launched.
- A rule can have one of more *actions that are associated* with it. When an event occurs and a rule filter is satisfied, the associated rule actions are executed, if the rule is enabled.

Perform one of the following actions when a *custom* event occurs:

- Use one of the postEvent web service methods for the event type
- Use a URL to post the event

To manage rules, select Administration, Events-Rules-Actions. The page displays the event types and provides access to the rules and actions that are associated with each event type. You can perform the following actions:

- Use Event Parameters
- Add a Custom Event Type
- Manage Rules
- Manage Actions
- Post an Event

Rules

All rules are initially disabled. A rule must be enabled to be used. In addition, for some of the rules, there are two mutually exclusive actions, one for use with CA Service Desk Manager and one for use without CA Service Desk Manager. By default, the actions which interface with CA Service Desk Manager are disabled.

The rule conditions that are shipped with CA Service Catalog may not completely match your business processes. They are generic and must be examined for applicability to your environment. In addition, some rules overlap in functionality. When activating rules, be careful to understand the full implications of your changes.

A rule can have one of more actions associated. When an event occurs and a rule filter is satisfied, the associated rule actions are executed. A rule action causes some task to be executed. A rule action can perform one of several action types such as run a command line command, send an email, start a CA Process Automation process, or run a Java plug-in.

The When Status is Submitted and Approval Process is Driven by Workflow rule handles the approval process. The rest of the rules handle the fulfillment process.

Actions

Actions are invoked when a condition in a rule is satisfied. Actions include running a command line command, starting a Java process, sending an email, and starting a CA Process Automation process. For more information about actions, see the descriptions of the rules.

Add a Custom Event Type

Administrators can create *custom* events by adding a new event type. You typically do so to address a need in your organization that the predefined event types do not meet.

Follow these steps:

1. Select Administration, Events-Rules-Actions.
2. Click Add.
3. Complete the fields on the page, and click OK.
   The following fields require explanation:

- **Event Source**
  Specifies that the event source is *physical.* A physical event is based on an update to a database table.
- **Audit Trail Level**
  Specifies the level of detail to log in an event log table.
- **Transaction Name**
  Specifies the name of the database table.
- **Transaction Type**
  Specifies the transaction type: Added, Modified, or Deleted.
  This type represents the general behavior of the custom event. The Transaction Type together with the Event Type Name and Event Source make a unique combination.

  Note: The event type name is not required to be unique. However, we recommend that you specify a unique name.

Event Parameters

Events represent changes that occur in components. Each standard event occurs when it is caused by an action. For example, the User Create event occurs when a new user is added using the Add User user interface or the createUser web service method. You can optionally add custom events.

Each event type may have parameters associated with it. When an event occurs, the parameter values reflect the context of the event. For example, when the User Create event occurs, the associated parameter named $user_id$ contains the User ID value for the new user just created. Event parameter values can be used in rule filters and rule actions.

Administrators can use event parameters as conditions to determine whether rules or actions are triggered. Each event type has parameters that reflect the context of the event. **Example:** The $user_id$ parameter of the User Create event contains the User ID value for the new user.

Most parameters for event types are intuitive. However, the parameters in the following sections require explanation:

Request Create Event and Change Event

These event types occur when the request header information is modified.

Note: You must have CA Service Catalog installed to use this event type.

Event Parameter	Meaning	Example
$completion_date$	Date the request is completed.	
$created_date$	Date the request is created.	
$desired_date$	Date required	
$domain$	Business unit name for the requested for user or account.	ABC Corp Sales
$modified_date$	Date the request was last modified.	
$name$	Request name	My new laptop
$priority$	Numeric value for request priority	3
$req_by_account_id$	Internal ID for Requested By user	10018

Event Parameter	Meaning	Example
$req_by_user_id$	User ID for Requested By user	ABCUser
$req_for_account_id$	Internal ID for an account that is associated with Requested For user or account.	10054
$req_for_user_id$	User ID for Requested For user	ABCUser - for a request for a user NIL - for a request for an account
$request_id$	Internal ID for request	10023
$status$	Numeric value of status of the request, for example: 400=Pending Approval800=Approved	400
all	Name=value pairs of all available event parameters including additional data not available as event parameters. Also includes variables containing old data before the save causing the event to occur.	comments='My laptop for travel' comments_eventdatatype='String' comments_old='NIL'

Request Item Form Element Create Event and Change Event

These event types occur when a field in a form that is associated with a request item is changed.

Note: Install Catalog Service Accounting component to use this event type.

Event Parameter	Meaning	Example
$form_elem_name$	Label for the field as it appears on the displayed form.	Employee Title
$form_elem_value$	Value for field on the form **Note**: This value is the HTML “value” field which is different from the choice list “label” field displayed.	Vice President (for an input type field) 1 (for a select list type field)
$subscription_detail_id$	Unique internal ID for this request item	10012
all	Name=value pairs of all available event parameters including additional data not available as event parameters. Also includes variables containing old data before the save causing the event to occur.	

Event Parameter	Meaning	Example
		form_elem_label='Employee Title' form_elem_label_eventdatatype='String' form_elem_label_old='NIL' form_elem_name='emp_title' form_elem_name_eventdatatype='String' etc

Request Pending Action Change

The following parameters apply to the Request Pending Action Change event type and any new event types that you create based on it.

Parameter	Value
rpa_action_type	0=Default1=System2 =CA Workflow3=CA Process Automation4=Policy
rpa_id	The request_pending_action_id entry in the usm_request_pending_action table in the MDB
rpa_object_type	1=Service Offering (service)2 =Request Item
$rpa_reassigned_id$	The reassigned value of the request_pending_action_id entry in the usm_request_pending_action table in the MDB
rpa_status	0=deleted1=active2=completed by assigned user3=completed by other user4=transferred5=delegated6=terminated
$rpa_users_or_groups$	The user_id or group_id entry in the usm_request_pending_action table (mdb)

Request/Subscription Item Create Event and Change Event

These event types occur when a request or subscription item is modified. The modification is generally a change to the status of the item.

Note: Requests or subscriptions are for service options. Service options are comprised of service option elements. When the status of a service option that is part of a request or subscription changes, this event occurs for each service option element in the service option.

Event Parameter	Meaning	Example
$account_label$	The account name for the Requested For user	ABC Corp:ABCUser (for a request for a user) Sales (for a request for an account)
$account_no$	Internal ID for the account in $account_label$	10002

$approval_level$	Numeric value for the approval level for service	10
$approval_process$	Numeric value for the approval process, as follows: 0=No approval1=System approval process2=Workflow driven approval process	2
$category$	Numeric value for requested item category, for example: 0=Software1=Hardware	0
$category_class$	Numeric value for requested item class within category, for example: For category 0 (Software), class 10 may be “Office”.	10
$category_subclass$	Numeric valued for requested item subclass within class within category, for example: For category 0 (Software), class 10 (Office), subclass 10 may be “Microsoft”.	10
$charge$	Numeric value indicating whether associated amounts are a charge or credit for use by Service Accounting Component where: 0=credit 1=charge	1
$charge_date$	Date the item is first charged for by Service Accounting Component.	
$code$	Code for the service option element	My Element Code
$domain$	Business Unit Name for the Requested For user or account	ABC Corp Sales
$enum_1$ through $enum_5$	Vary depending on service option element type.	
$external_id$	Service option element External ID	My Element External ID
$group_id$	Numeric value indicating the occurrence of the service in a request (in case a request includes more than one copy of a service)	1 NIL (for a subscription)
$form_data_sd$ - for the Request/Subscription Item Change Event only	If this service option includes a form, then this parameter lists the details of the form in JSON structure. To apply rules to subscription items whose type is form, append the following condition to the event filter: “AND form_data_sd <> 'NIL'”	See Sample Data for $form_data_sd$ (after this table)
$form_data_sd_row$ for the Request/Subscription Item Change Event only	If multiple forms exist in a service option, this parameter lists the details of all these forms in JSON structure.	See Sample Data for $form_data_sd_row$ (after this table)
id	Unique internal ID for this request item	10012

Event Parameter	Meaning	Example
$installments$	Numeric value indicating the number of installments for associated amounts for use by Service Accounting Component	0
$instance_name$	Optional value that is assigned when subscribing an account to a service.	My instance
$item_id$	Internal ID for requested service option element	9981
$last_charge_date$	Date the item was last charged for by Service Accounting Component.	
$numeric_1$ and $numeric_2$	Vary depending on service option element type.	
$offering_id$	Internal ID for requested service	10002
$offering_name$	Name of the service offering (service)	Standard Laptop Bundle
$rate_item_col$	Numeric value (zero-based) indicating the associated service option element's column position in the service option row	0
$rate_item_name$	Service option element Display Text	Standard Laptop
$rate_item_row$	Numeric value (one-based) indicating the associated service option element's row position in the service option group	1
$rate_item_text_1$	Additional text that is associated with the service option element. For example, for a Text type service option element, this is Text Value and for a Rate type service option element, this is Display Unit Type.	/month
$rate_item_type$	Numeric value for the associated service option element where: 0=Text1=Header2=Numeric Range 3=Rate4=Application5=Agreement6=Numeric7=Boolean 8=Adjustment9=Date10=Date Range11=Day12=Allocation13=Form	3
$rate_plan_id$	Internal ID for associated service option group	10035
$rate_plan_name$	Associated service option group name	Standard Laptop Accessories
$req_by_user_id$	User ID for Requested By user	ABCUser NIL (for a subscription)
$req_for_user_id$	User ID for Requested For user	

Event Parameter	Meaning	Example
		ABCUser(for a request for a user) NIL (for a request for an account) NIL (for a subscription)
$request_id$	Internal ID for request	10023 (for a request) NIL (for a subscription)
$request_name$	Request Name	My new laptop NIL (for a subscription)
$request_priority$	Numeric value for request Priority	3 NIL (for a subscription)
sd_row	Numeric value (one-based) for the service option containing this service option element relative to all the service options selected with the service.	1
$status$	Numeric value of status of the requested item, for example: 400=Pending Approval800=Approved	400
$subscribed_date$	Date the item was included in a request or subscription.	
$subscription_type$	Numeric value indicating the type of item where: 0=Other1=Application2=Agreement3=Adjustment4=Form	0
$text_1$ - $text_7$	Vary depending on service option element type.	
$tiered_item_id$	Internal ID of the tiered service option group of the associated service option element where: -1=Not associated with a tiered service option group	-1
$tiered_last_date$	Date the item was last charged for by Service Accounting Component. Applicable only if the related service option element is part of a tiered service option group.	
$track_as_asset$	Numeric value indicating whether this request item must be tracked as an asset where: 0=No1=Yes	1
$unsubscribed_date$	Date the item is cancelled or unsubscribed.	NIL
all	Name=value pairs of all available event parameters including additional data not available as event parameters. Also includes variables containing old data before the save causing the event to occur.	account_label='Sales 'account_label_eventdatatype='String' etc

Sample Data for $form_data_sd$

The following sample data lists the details of one form:

```
{"name" : "dept",
"value" : "001|Human Resources",
"type" : "9"},
{"name" : "empid",
"value" : "spadmin",
"type" : "5"},
{"name" : "empName",
"value" : "Administrator, Service Delivery",
"type" : "5"},
{"name" : "reason",
"value" : "0",
"type" : "12"}
```

Sample Data for $form_data_sd_row$

The following sample data lists the details of two forms (10246 and 10245) in the same service option. Form 10245 includes the form type subscription ids.

```
{
"10246" : [
{"name" : "dept",
"value" : "001|Human Resources",
"type" : "9"},
{"name" : "empid",
"value" : "spadmin",
"type" : "5"},
{"name" : "empName",
"value" : "Administrator, Service Delivery",
 "type" : "5"},
{"name" : "reason",
"value" : "0",
"type" : "12"}],
"10245" : [
{"name" : "accesstype",
"value" : "0",
"type" : "12"},
{"name" : "buildingcode",
"value" : "1|Building1",
"type" : "9"},
{"name" : "date",
"value" : "",
"type" : "14"},
{"name" : "date_fdms$$",
"value" : "",
"type" : null},
{"name" : "device_code",
"value" : "device access code value",
"type" : "5"},
{"name" : "empid",
```

```
"value" : "spadmin",
"type" : "5"},
{"name" : "empname",
"value" : "Administrator, Service Delivery",
"type" : "5"},
{"name" : "purpose",
"value" : "purpose value",
"type" : "8"}]
}
```

Notes Create and Notes Change

The Notes Create and Notes Change event types are described as follows:

Notes Create

This event type occurs when a note is created for a CA Service Catalog request. Rules associated with this event type are as follows:

- **When a note is added to a CA Service Catalog request**: When note is added to a CA Service Catalog request, email notifications are sent.
- **When notes are added to a CA Service Catalog request**: When a note is added to a CA Service Catalog request, it is also synchronized with the corresponding CA Service Desk Manager ticket.
- **When a CA Service Desk Manager note is synchronized to a CA Service Catalog request**: When CA Service Desk Manager (CA SDM) note is synchronized to CA Service Catalog request, email notifications are sent.

Notes Change

This event type occur when a Note is changed or modified for a request. The following rules are associated with this event type:

- **When note with attachment(s) is edited in a CA Service Catalog request**: When a note with attachment(s) is edited in CA Service Catalog request, E-Mail notifications are sent.
- **When note without attachment(s) is edited in a CA Service Catalog request**: When a note without attachment(s) is edited in CA Service Catalog request, E-Mail notifications are sent.

The following event parameters associated with these event types require explanation:

Event Parameter	Meaning	Example
$source_id$	The request ID of the corresponding Note.	10510
$note_text$	Description of the note.	
$ignore_notification$	Value will be true in the following cases: ▪ on submission of request that has note(s). ▪ When a note event is triggered for a comment with notes and attachments posted in Widgets.	

Attachment Create and Attachment Change

The Attachment Create and Attachment Change event types are described with associated rules:

Attachment Create

This event type occurs when an attachment is created for a request. Rules associated with this event type are as follows:

- **When attachment is added to CA Service Catalog request**: When an attachment is added to a CA Service Catalog request, it is added as a link to the corresponding CA Service Desk Manager ticket.
- **When attachment is added to a CA Service Catalog request:** When an attachment is added to a CA Service Catalog request, email notification is sent.
- **When note and attachment(s) are added to a CA Service Catalog request**: When note (s) and attachment(s) are added to a CA Service Catalog request from Widgets, email notifications are sent.
- **When a CA Service Desk Manager attachment is synchronized to a CA Service Catalog request**: When a CA Service Desk Manager attachment is synchronized to CA Service Catalog request, email notifications are sent.

Attachment Change

This event type occurs when an attachment is changed for a CA Service Catalog request. Following rule is associated with this event type:

- **When attachment associated with a CA Service Catalog request is edited**: When an attachment associated with a CA Service Catalog request is edited, email notifications are sent.

The following event parameters associated with these event types require explanation:

Event Parameter	Meaning	Example
$object_id$	Request ID of the corresponding attachment.	10510
$ignore_notification$	Value will be true in the following cases: ▪ on submission of request that has attachment(s). ▪ for the first *n-1* attachments when a comment with *n* attachments is posted in Widgets.	For example, if a comment in Widgets has 1 note and 5 attachments, so for the first four attachments (n-1=4), the value will be true.
$attachment_url$	Specifies the URL(s) of the uploaded attachment(s).	

Manage Actions

Administrators can configure actions in in several ways, to trigger the response you want for specific rules.

Example: You can create and configure a rule to trigger an automatic email notification when a fulfiller fulfills a request.

Follow these steps:

1. Select Administration, Events-Rules-Actions.
2. Click the event that contains the rule and action of interest.
3. Click the name of the rule and modify the actions associated with the rule.
4. (Optional) Retry failed action if required.

You create *global* policies and global actions for general use with any service. In contrast, you create *attached* actions and attached policies for use with a specific service option only. You can create an attached action or policy *only* from the Policies & Actions tab of that service option.

Note: You can perform significant edits on custom actions *only*. The predefined actions permit only limited editing. Similarly, you can delete custom actions *only*. You *cannot* delete predefined (built-in) actions.

If the predefined actions and existing custom actions do not meet your needs, you can add a new action to a rule. You can *add* new actions (create custom actions) in both custom rules and predefined (built-in) rules. When required, you can edit a custom action to meet a need in your organization more closely. For example, you can edit a custom action to refine the request email that the action sends.

Note: After you create, save, and close a custom action, you can edit its parameters. But you *cannot* change the Type field. To specify a different type for the action, copy and rename it. If you do so, update the related rule to trigger the renamed action.

Parameters

You can specify the several parameters for a *custom* action when you add or edit it. The following parameters are not self-explanatory:

- **Type**
  Specifies the type of action that must be used. To disable a rule action, select DISABLED. Based on the type you select, more fields are exposed. The add icon can be used to add an event parameter to the field used for each action type.

- **Command line**
  Specifies a command that must be run.

- **HTTP Post**
  Specifies the URL that must be posted.

- **Java**
  Specifies the Java Class and parameters that must be passed.

- **Email**
  Notifies users (typically administrators) about system activities that are not related to requests. Examples include the addition of new users or a new business unit, or a data mediation load.

- **Request Email**
  Notifies stakeholders about a request and optionally includes request details.
  The following parameters require explanation:
  Include Request Details - Specifies whether to add the details of the request to the text of the message body in the request email.
  Specify Yes to add these details or No to omit them.
  Type - Applies *only* when you use the $pending_action_users_or_groups$ variable.
  Specifies the Type: Request, Service, or Service Option.
  This parameter retrieves the list of pending action users or groups applicable to the selected Type. This parameter also assigns the retrieved list to the $pending_action_users_or_groups$ variable.
  Request ID - Specifies the ID (not the name) of the request, which must be a numeric value or variable.
  Request Item ID - Applies only when the selected Type is Service or Service Option.
  Specifies the ID of the subscription detail object, which must be a non-numeric value or variable. This value is used to retrieve the list of pending action users or groups applicable to the selected Type. The selected type can be Service or Service Option.
  From Email - Specifies the email address from which to send request emails.
  From Name - Specifies the name of the email address from which to send request emails.
  If you do not specify a value for From Email or From Name, the Catalog system assigns the following value: the value that is specified in the Catalog, Request Management configuration options of the business unit of the request.
  To - Specifies one or more primary recipients for the email.
  You can use specific email addresses, user IDs, and requested for user-related variables.
  To send an email to specific users or groups automatically, specify the matching variables, as follows:

  - For the requested for user, specify $req_for_user_id$
  - For the requested by user, specify $req_by_user_id$
  - For the pending action user, specify $pending_action_users_or_groups$

  To specify more than one value, separate the entries with a semi-colon (;).
  You can select these variables and other variables from the list that appears when you click the list icon next to the field.
  CC and BCC - Specifies more recipients for the email. Use the same syntax as the To field.
  A commonly used variable in the Subject and Message Body is $server_url$. You can optionally use it to direct the recipient to the request detail page.

- **CA Process Automation**
  Specifies the start request form (SRF) (for CA Process Automation) to invoke.
  Use the Find Start Request Form icon (for CA Process Automation).
  Specify the parameter values for the SRF, if applicable.

- **CA Automation Suites Reservation Manager**
  Specifies a parameter that must be passed to Reservation Manager.

- **Execution Mode**
  Specifies whether the action runs asynchronously or synchronously.
  Administrators *cannot* set the order in which actions run.

- **Timeout**
  Specifies the number of seconds the action must run before a user can cancel it.
  A value of 0 means no timeout applies.

Parameters That Accept Multiple Values

For some events, some parameters can have multiple values. For such parameters, use a delimiter to separate multiple values. For each parameter that can have multiple values, you can specify the separator to use when that event occurs. If the Multiple Values check box is selected, the rule action is executed for each value for the parameter indicated in the Parameter field.

Note: The only standard event with multiple values parameters is the Catalog Subscription Change event. This event provides multiple values for the $new_offerings$, $new_subscriptions$, $old_offerings$ and $old_subscriptions$ parameters. You can use multiple value parameters with custom event. However, the event posting logic must provide the multiple parameter values.

Retry Failed Actions

When a rule action fails to launch its associated CA Process Automation process, a system alert is created. Possible causes for the failure include the related service either not running, or being too busy to accept more work, or connectivity between CA Service Catalog and CA Process Automation is not established. Service Delivery administrators can retry failed actions of these types.

Follow these steps:

1. Select Home, Messages, Alerts from the Messages menu.
   The Alert Messages lists all the alert types appears.

2. Click **List All Failed Actions**.

3. Use **Filter Alerts** to display the list of alerts that include the failed actions you want to retry.

4. Click **Change Business Unit**, if the failed action is in another business unit,

5. Select the alerts in the that you want to retry, and click **Retry Failed Actions**.
   For example, if you have retried an alert of type ITPAM_QUEUE_FAILURE, then it appears as a separate alert message for that request on the Alerts page.
   You have retried the failed actions.

Manage Rules

Administrators can configure rules in several ways, to trigger the actions you want under the conditions you want. For example, you can create and configure a rule to trigger an action when a user, service, business unit, or account is created or updated.

You can perform the following actions to manage rules:

- Add a Rule (see page 3055)
- Add an Event Filter (see page 3055)

Add a Rule

Administrators can add a new rule for several reasons. **Example:** Create a rule to trigger an action, such as an email notification, when an approver approves or rejects a request pending action.

Follow these steps:

1. Select Administration, Events-Rules-Actions.
2. Click the event to which you want to add the rule and click Add.
3. Complete the fields, following these guidelines:
   - Specify a unique rule name.
   - Click the Add Filter icon and create or edit an event filter.
4. Click OK.
   The rule is saved. The Event Type Details page appears, and it includes the new rule.

Add an Event Filter

Specify the conditions for invoking the rule and triggering its actions by adding an event filter. Otherwise, the rule and actions are invoked whenever the event occurs.

The properties available to a rule condition depend on the event type of the rule. You can specify both *old* and *new* (or *before* and *after*) values for each event property in the condition.

Follow these steps:

1. Select Administration, Tools, Events-Rules-Actions.
2. Click the event that contains the rule for which you want to add/edit a filter.
3. Click the Add icon next to the Event Filter field.

Note: You can add or update event filters in custom rules *only*, not predefined (built-in) rules. The predefined rules permit limited editing. You can copy a predefined rule and can save it with a new name as a custom rule.

4. Specify the values for the property, operator, and constant of your new condition in the Condition Builder section.

5. Click the Add Condition arrow and add your new condition to the Current Conditions section. The Condition appears in the Current Conditions field. The condition is translated into a conditional SQL-style expression that the rule engine can process. You can add as many conditions as required.

6. Click OK.
   The Event Filter appears in the Rule Information section of the Edit Rule page for the selected rule.

7. Click OK.
   The system saves the rule, including the event filter.

You have added the event filter.

Post an Event

Administrators can post an event as an automated way to mimic an action by a user. **Example:** A catalog user submitting a request or a catalog administrator updating the details of a user or business unit. In both cases (posted event or user action), when the event occurs, its rules are evaluated. If the conditions for a rule are met, the rule actions are executed.

Posting an event is useful for performing such tasks using automation and with specific values and actions. **Example:** You can post events to specify custom values for the integration between CA Service Catalog and another CA product. This topic explains how to post a CA Service Catalog event through HTTP URL. You can also use this URL in rule actions whose type is HTTP Post.

Important! If you post an event, test it thoroughly before moving it to a production environment. Verify that the event does *not* run cyclically if the action is triggered.

Follow these steps:

1. Gather the data from the event and construct the HTTP URL.

2. Specify the HTTP URL. This topic uses a URL example to illustrate how to post an event.

> **Note:** You can also post events using web services. Both techniques produce the same results.

3. Verify that the event is posted.

Gather the Data from the Event to Construct the HTTP URL

Gather the following values from the event definition for the URL.

This example uses the Data Mediation Aggregation event on the Tools, Events-Rules-Actions page. Click the event name. You see the following details of the event. Use these details to help specify the HTTP URL, as illustrated in the following text:

- Event Type: Data Mediation Aggregation
- Event Type Name: Data Mediation Aggregation
- Event Source: Logical
- Audit Trail Level: System Default
- Transaction Name: DATA_MEDIATION_AGGREGATION
- Transaction Type: Modified
- Event Type Parameters: end_date, $start_date$, $status$, $status_date$
- Description: When Data Mediation Aggregation Status is changed

Specify the HTTP URL

To specify the HTTP URL to post an event to the system, use the following syntax:

> **Note:** In the following line and in the example that follows, the line breaks are for readability *only*. In the product UI, enter this code as a single continuous line.

```
http://hostname:port/usm/wpf?Node=icguinode.postevent
&username=userid&pass=password&domain=businessunit
&Args=eventsource&Args=nsppath&Args=transactionname&Args=eventtypename
&Args=transactiontype&Args=eventdescription&Args=associatedobjectid
&Args=false&Args=param1|oldvalue1!param#|oldvalue#!
&Args=param1|newvalue1!param#|newvalue#!
```

An example URL follows:

```
http://hostname:port/usm/wpf?Node=icguinode.postevent
&username=spadmin&pass=spadmin&domain=ca.com&Args=LOGICAL
```

```
&Args=DATA_MEDIATION_AGGREGATION:MODIFIED
&Args=DATA_MEDIATION_AGGREGATION&Args=MODIFIED&
Args=LOGICAL&Args=Modified&Args=$id$&Args=false
&Args=end_date|abc!start_date|abc!status|123!status_date|abc!
&Args=end_date|abd!start_date|abd!status|124!status_date|abd!
```

Note: When you post an event using a URL from Java or some other tools, encode the URL by replacing unsupported characters with codes. **Example:** Replace the ampersand (&) with %26 or replace a single blank space with %20.

Note: The Catalog system uses both old and new values when it evaluates rule filters for event rules.

The following parameters require explanation:

- ***userid* and *password***
  Specifies login credentials for authentication.

- ***businessunit***
  Specifies the business unit for the role of the user ID.

- ***eventsource***
  Specifies the Event Source from the event details: LOGICAL, PHYSICAL, CommonDB.
  In this example, the value is LOGICAL.

- ***nsppath***
  Specifies the namespace path, a placeholder value only. The Catalog system does not use the actual value but requires a placeholder value.
  Use the following format:
  <Transaction Name>-<Transaction Type>
  <Transaction Type> - MODIFIED, ADDED, or DELETED.
  <Transaction Name> - As displayed in event details
  In this example, the value is DATA_MEDIATION_AGGREGATION:MODIFIED.

- ***transactionname***
  Specifies the transaction name for the event.
  As shown in the event details, in this example, the value is DATA_MEDIATION_AGGREGATION.

- ***eventtypename***
  Specifies the name of the event type: MODIFIED, ADDED, or DELETED.
  In this example, the value is MODIFIED.

- ***transactiontype***
  Specifies the transaction type for the event.
  This value is the same as the value of the eventsource parameter.
  In this example, the value is LOGICAL.

- ***eventdescription***
  (Optional for web service) Specifies a description for the event.
  Specify the Transaction Type as displayed in event details.
  In this example, the value is Modified.

- ***associatedobjectid***
  Specifies the ID of an object to associate with this event.
  You can optionally specify one of the event parameters for this value. This value is used to associate the alert that was logged in Change Events.
  This example uses a dummy value: id.

- **ispartial**
  Specifies whether this event is partial; This value is always false.

- ***param#*|*oldvalue#***
  Specifies the parameter name and the *old* value. Delimit the name and value with a vertical bar. Separate each name and value pair with an exclamation point.
  In this example, the value is as follows:

```
end_date|abc!start_date|abc!status|123!status_date|abc!
```

  Note: This example uses dummy values for event attributes. Do *not* specify a value for the all attribute, because it reads *all* values.

- ***param#*|*newvalue#***
  Specifies the parameter name and *new* value. Delimit the name and value with a vertical bar. Separate each name and value pair with an exclamation point.
  In this example, the value is as follows:

```
end_date|abd!start_date|abd!status|124!status_date|abd!
```

  The note for the previous parameter also applies to this parameter.

Verify that the Event is Posted

To verify that an event is posted, follow these steps:

1. Disable all the rules for the event that you are posting.
2. Enable only one rule with no filter and one command-line action, as follows:

   ```
   cmd /c echo Posted Event: $all$ >> C:\PostEventCheck.txt
   ```

3. Verify that the PostEventCheck.txt file is created on the C:\ drive of the application server for CA Service Catalog.

Note: You can also post an event using one of the postEvent Administration web service methods.

Manage Dashboards

Administrators and other users use the Dashboard Builder to manage dashboards and their content elements (dash items). Administrators can create shared dashboards and manage the dashboard library. Other users can create personal dashboards and can access the shared dashboards to which they have access in the following ways:

- Add a Dashboard (see page 3060)
- Configure Content Elements (see page 3061)
- Administer Dashboards (see page 3063)

Add a Dashboard

You add personal or shared dashboards to provide access to information and to frequently used features of CA Service Catalog.

Follow these steps:

1. Click Home, Dashboards.

2. Click the << icon at the top right part of the page, and click Add Dashboard.

3. Name the dashboard, configure the options, and click Add.
   The following fields require explanation. Click the Help (question mark) icon for further assistance.

   - **Shared Dashboard**
     Creates a shared dashboard.
     Administrators use shared dashboards to publish information to users. If this option does not appear or if you do not select it, then this dashboard is available to you *only*.
     You can create a personal dashboard and can share it later.
     When you select Shared Dashboard, several other fields appear. These fields are mutually exclusive. Select one of the following options:

     - Accessible by Sub Business Units - Shares this dashboard with users in your business unit and its child business units.

     - Accessible by Role - Shares this dashboard with users who have the roles you specify. Only those roles can access the dashboard. If you do not specify your own role, you cannot access the dashboard after you create it.

   - **Default Dashboard**
     Sets the dashboard as the default dashboard.

   - **Full Screen**
     Configures the dashboard to open in full-screen mode when users select it.

   - **Open in New Window**
     Configures the dashboard to open in a new window when users select it.

- **Disable Session Timeout**
  Disables the session timeout feature. Users are not logged out if they are inactive longer than the session timeout value.

- **Auto Arrange**
  Arranges the dashboard items automatically.

- **Make Item Snappable**
  Creates an invisible grid on the Dashboard, which lets you position and resize the Dashboard items.
  You set the Grid Height and Grid Width properties of each cell in the grid. Each Dashboard item "snaps" to this grid when it is positioned or resized.
  This option applies only if Auto Arrange is *not* selected.

- **Lock Down Items**
  Fixes the location of the dash items so that other users cannot move them.

The new dashboard appears in the dashboard menu and is selected. The rest of the window is blank, because a new dashboard has no dash items.

4. Add dash items as follows:

   a. Verify that the new dashboard is selected. Click the << icon at the top right part of the page, and click Show Library.

   b. Navigate the Library tree and locate the elements that you want to use on the dashboard.

   c. Drag the content elements to the place where you want them on the dashboard. The elements become the dash items.

   d. Adjust the size of the dash items as needed.

5. Set the properties of the dash items by clicking the Edit icon on the dash item heading.

6. Click Save Layout.

Configure Content Elements

You configure content elements in dashboards to customize them to meet the needs of your organization.

Follow these steps:

1. Click Administration, Dashboard Builder.

2. Expand the folders and subfolders and select a content element.
   The details of the element appear in the Content Preview and Content Properties panes.

3. Configure the fields on the Content Properties pane, and click Save.
   The following fields require explanation:

- **ACL Settings**
  Specifies the access control list (ACL) settings.
  Use these settings to specify the level of access for each role to the content element.

- **Content Type**
  Specifies the type of content element, as explained in the next section.

Type of Content Element

- **Folder**
  Configures the content element as a folder.

- **External Web Content**
  Configures the content element as a web page URL.

- **External XML Source**
  Configures the content element as an external web reference in XML format. If access to the XML content requires authentication, the web publishing framework automates the authentication login to gain access.
  The web publishing framework can use Web Services to transform the information to meet the needs of the user. You can view the XML directly. Alternatively, you can supply a custom XSL instead.
  If you use XSL, you can embed it as part of the published data definition or can obtain it through a URL.

- **Embedded HTML**
  Configures the content element to include the HTML to display.
  You supply the information in HTML format. The information is stored with the metadata in the Dashboard Library. Embedding HTML enables you to integrate with application data accessible through web controls and Java applets, such as Microsoft Outlook.

- **Embedded XML**
  Configures the content element to include the XML to display.
  You supply the information in XML format. The information is stored with the metadata in the Dashboard Library. Embedding XML enables you to view it directly. Alternatively, you can optionally supply a custom XSL instead of XML.

- **GUINode**
  Configures the content element to reference a CA Service Catalog page.
  Specify the page as a Graphical User Interface (GUI) node.

- **GUINode XML**
  Configures the content element to reference internal CA Service Catalog data that you obtain through a GUI Node.
  This setting enables you to define custom views of information without modifying back-end methods and customizing XSL style sheets.
  Alternatively, you can optionally supply a custom XSL instead of XML.
  Access to the published data requires access to the GUI Node.

- **Managed Document**
  Configures the content element as a document maintained in CA Service Catalog.
  Specify the path in the Filename field. This document must be in the same location on all Catalog Component servers if you are using multiple Catalog Component servers.

Administer Dashboards

You administer dashboards to meet the needs of your organization.

Follow these steps:

1. Click Administration, Dashboard Builder.
   The Dashboard Library folders appear and display the dashboards that you have permission to access.

2. Expand the library tree and display the category for which you want to administer dashboards.

3. Install ActiveX components, if you are prompted to do so.

4. Select an option from the Action drop-down list and click Go. The options vary, according to the category that you select in the library tree.

5. Repeat these steps as needed for more dashboards.

Manage Outage Calendars

You can create and Maintain Outages, outage groups, outage calendars, create business hours, and associate outage calendars and business hours to a service in the following ways:

- Create and Maintain Outages (see page 3063)
- Create and Maintain Outage Groups (see page 3064)
- Create and Maintain Outage Calendars (see page 3064)
- Create Business Hours (see page 3065)
- Associate Outage Calendars and Business Hours to a Service (see page 3066)
- (Optional) Specify Default Outage Calendar and Business Hours (see page 3066)

Before you perform these tasks, verify that you have completed the tasks to manage request SLAs.

Create and Maintain Outages

You create a scheduled outage to specify a single occurrence when a service is not available. Reasons for such outages include holidays, maintenance periods, disaster recovery activities, one-time events such as major hardware or software changes. Both outages and outage groups are independent entities that can be reused in multiple outage calendars. During the outage periods that the outage calendars define, the monitoring of time for a request SLA is stopped.

Follow these steps:

1. Click Catalog, Service Hours.

Check the business unit identification message under the main menu. Verify that you want to create this outage for the current business unit.

- Click Add to create a new outage.
- Complete all required fields and add or edit an SLA.
- Click Save.

This outage can be used in an outage group or outage calendar.

Create and Maintain Outage Groups

Outage groups are logical sets of related outage events, such as holidays or annual maintenance days. These outage groups typically recur annually. As an administrator, you combine individual outages into outage groups. Outages and outage groups are the major ingredients of an outage calendar. Both outages and outage groups are independent entities that can be reused in several different outage calendars.

Follow these steps:

1. Click Catalog, Service Hours.
2. Check the business unit identification message under the main menu. Verify that you want to create this outage for the current business unit.
3. Click Add to create a new outage group.
4. Complete all required fields and add or edit an SLA. For existing outage groups, any outages that are already included in the group appear in the Associated Outages box.
5. Click Save.
6. Click Associate Outages to add an outage to the current outage group.

This outage group is ready to be used in an outage calendar.

Create and Maintain Outage Calendars

As an administrator, you use outages and outage groups to create *outage calendars*. For each business unit, you can optionally apply *one* outage calendar to a service. You cannot apply outages or outage groups to a service directly; they must be associated to a calendar. The criteria that you use for determining the outages, outage groups, and calendars for each service in a business unit are based on different groupings. Examples of such groupings are geographical areas, departments, time zones, and other customer-related considerations. Both outages and outage groups are independent entities that can be reused in several different outage calendars.

Follow these steps:

1. Click Catalog, Service Hours.

Check the business unit identification message under the main menu. Verify that you want to create this outage for the current business unit.

- Click Add to create a new outage calendar.
- Complete all required fields and add or edit an SLA. For an existing outage calendar, outages and outage groups that are already in the calendar appear in the Associated Outages box. For outage groups, the Group Name column is completed; for outages, the Group Name column is empty.
- Click Save.
- Click Associate Outages to add one or more outages to the current outage calendar.
- Click Associate Outage Groups to add one or more outage groups to the current outage calendar.

After selecting the outages and outage groups for your outage calendar, you can associate the calendar to a service.

Create Business Hours

Business hours specify the regularly scheduled days and times of service. The service provider sets the business hours. But for best customer relations, business hours are geared towards the typical business schedule of all requestors.

As an administrator, you can optionally apply *one* outage calendar and *one* business hours specification to a service. The criteria that you use for determining the business hours for each service in a business unit can be based on different grouping.

During the time periods that the business hours define, time is monitored for the request SLA attached to a service. During the outages that the outage calendar of the service specifies, the time in not monitored.

Follow these steps:

1. Click Catalog, Service Hours.
2. In that Menu, click Business Hours.
3. Check the business unit identification message under the main menu. Verify that you want to create this outage for the current business unit.
4. Click Add to create a new Business Hours specification.
5. Complete all required fields and add or edit the Business Hours.
6. Click Save.

After you select and save your business hours specification, you can associate it to a service.

Associate Outage Calendars and Business Hours to a Service

The outage calendar and business hours that are associated to a service work together to specify the time periods during which the service is expected to be available. During these periods, the time is monitored for the Request SLAs attached to the service.

You are not required to associate an outage calendar and business hours object to a service at the same time. However, we recommend that you do so. When you associate an outage calendar and business hours object to a service at the same time, it ensures the expected up time and down time govern the Request SLAs attached to the service. **Example:** Suppose that you attach a Request SLA to a service without specifying either an outage calendar or business hours. The clients then expect that the service is to be available 24 hours per day and 365 days per year.

Follow these steps:

1. Click Catalog, Service Offerings.
2. Expand the tree and access the service you want.
3. Follow these steps to associate an outage calendar to a service.
    a. Click the Not Specified link for the business hours.
    b. Click Search in the Associate Business Hours dialog. The currently associated object (if applicable) is selected.
    c. Select the objects that you want and click Associate.
    The list of available objects disappears, and the object that you selected appears in the Associated Business Hours field.
4. Follow these steps to associate business hours to a service.
    a. Click the Not Specified link for the business hours.
    b. Click Search in the Associate Business Hours dialog. The currently associated object (if applicable) is selected.
    c. Select the objects that you want and click Associate.
    The list of available objects disappears, and the object that you selected appears in the Associated Business Hours field.

(Optional) Specify Default Outage Calendar and Business Hours

Business unit administrators can optionally specify a default outage calendar and default business hours for all services in their business units. Doing so helps verify consistency in the days and hours that services are available throughout the business unit.

If a service is associated to a different outage calendar, you can assign the default outage calendar by clicking the Use Default button of the calendar. If a service is associated to a non-default business hours, you can assign the default business hours by clicking the Use Default button of the business hours.

If the business unit administrator assigns no default outage calendar and if the administrator for a service does not associate a custom outage calendar to the service, then time is tracked for SLAs associated to the service *every day of the year*. Similarly, if the business unit administrator assigns no default business hours and if the administrator for a service does not associate custom business hours to the service, then time is tracked for SLAs associated to the service *every hour of the day*.

Therefore, as a best practice, business unit administrators and administrators of individual services work together. Together, they verify that the default outage calendar and default business hours for the business unit are reasonable and achievable. Otherwise, avoidable SLA warnings and violations are issued for such services.

Follow these steps:

1. Review the outage calendars and business hours that you have created already. Identify the ones that you want to use as defaults. Verify that your selections meet your requirements for all services in the business unit. If no suitable options exist yet, create suitable outage calendars and create suitable business hours.

2. Click Catalog, Service Offerings.

3. Check the business unit identification message under the main menu. Verify that you want to create this outage for the current business unit.

4. Click the root folder, which is also the name of the business unit that you selected in the previous step.

5. Click Not Specified in the Default Business Hours field and select the business hours.

6. Click Not Specified in the Default Outage Calendar field and select the outage calendar.

7. (Optional) Specify the default outage calendar and default business hours for each child business unit.

Note: You set the default outage calendar and default business hours for each business unit *individually*. Child business units do *not* inherit these default settings from their parent business unit.

Review SLA reports for the affected services to verify that the default settings meet your requirements for the business unit.

Manage News, Change Events, and Alerts

Administrators can manage news, change events, and alerts from the Home, Messages tab.

News is any announcement for the user community. Administrators can perform the following tasks to manage news messages:

- Add a news message for other users or roles in the same business unit.

- Delete news messages from themselves and from other users.

Change Events are automatically generated when either the system or users (especially administrators) perform significant actions. For example, if you add a user, your action appears as a change event message on the Change Events page. Administrators can view and delete change events.

Alerts represent failed change events. Typically, CA Service Catalog components issue alert messages when a system action fails or a user action fails. For example, failed actions and alerts can result from an administrator specifying an incorrect email address for a user. In such cases, actions that use the email address can fail. An attempt by a request manager to perform email-based approval of a request from that user can fail, resulting in the "REQEMAILACTION_FAILED" alert. Administrators can view and delete system alerts and also retry failed actions.

Manage the Scheduler

Administrators can use the Scheduler to schedule tasks that you want to run one or multiple times. Scheduling is especially useful for recurring tasks, so that you do not have to repeat them manually. To manage scheduled tasks, Click Administration, Tools, Scheduler. You can:

- View the list of scheduled tasks.
- Add or edit a scheduled task.
- Delete a scheduled task.
- View Scheduler-related system alerts.

Note: For optimum scheduling capabilities, use CA Process Automation to schedule tasks. For more information, see the CA Process Automation documentation.

Follow these steps:

1. Click Administration, Tools, Scheduler.
2. Click the Add button and create a scheduled task.
3. Complete the fields and click OK.
   The following options for the *Category* field require explanation:

- **Valid Until**
  Specifies the date when the scheduled task stops running. If this field left blank, the scheduled task continues to run indefinitely.
- **Action Type**
  Depending on the Action Type, other fields appear to help further define the action.

- **Execute Command Line**
  Specifies a command that runs on the server.

- **Execute Scheduler Plugin**
  Specifies an option for system use *only.*
  If you have scheduled data mediation tasks, you can view this option.

- **Missed Actions**
  Specifies the action to perform when a scheduled task cannot run, as follows:

  - *Ignore* skips all missed scheduled tasks.

  - *System Alert* posts a system alert when a scheduled task is missed.

  - *Execute All* runs all missed scheduled tasks as soon as possible.

Manage Content Packs

A content pack is a collection of CA Service Catalog objects, such as services, forms, policies, events, report data objects, and CA Process Automation processes. This article contains the following topics:

Who Creates, Exports, or Imports Content Packs

Both customers and CA Technologies can create content packs, as follows:

- CA Technologies typically creates content packs that include new objects or updated versions of existing objects, including sample objects and fixes.

- Customers typically create content packs that include objects that are customized to meet specific organizational requirements.

- Customers can optionally copy content packs from CA Technologies. They can then customize the content packs before they apply them across their implementations.

- You can export and import multiple content packs for a single business unit. Similarly, you can export and import multiple content packs for all business units. If a conflict occurs between the existing content pack and the one you are activating, the new content pack automatically overrides the old one.

- As a producer or designer, create and export content packs to package customized versions of the CA Service Catalog objects.

- As a consumer or adopter, import content packs and use the customized objects without having to perform the same customization processes.

Typically, the customizations in a content pack are focused to configure CA Service Catalog system for the optimal use of a specific feature, service, or environment. Content packs enable you to repeat the customizations efficiently and accurately from one system to another, multiple times.

Service Management Content Pack

Demo Content

The Demo Content (Demo) content pack contains several model services for common requests throughout an enterprise. Some services require CA Process Automation processes and integration with underlying systems to function as intended.

An example service is the **Smartphone Selector service.** This service lets catalog users select a smartphone and accessories by guiding them through several nested levels of choices. This service uses JavaScript programs in forms for this purpose. To copy and customize this service, you must have advanced knowledge of the Form Designer and a working knowledge of JavaScript.

For the complete list of services in the Demo content pack, import it and view the Import Report. Then view the services in the CA Service Catalog Demo Content folder in the catalog. You can import the Demo content pack file from this location: USM_HOME\Filestore\contentpacks.

Overview of Content Configuration Form

This article contains the following topics:

You can create a content configuration form (see page 3071) to specify any custom configuration information and then use your content pack. These forms are typically not required but can be helpful, especially under the following circumstances:

- The imported objects require configuration before you can use them.
- The administrator who imports the content pack did not export it.
- You require custom values for variables in API plug-ins or CA Process Automation processes. Instead of hard-coding specific values, you can retrieve values from fields on content configuration forms (see page 3072). **Example:** The values can change and cause the API plug-ins or CA Process Automation processes to fail, leading to system downtime. **Example:** A server URL that can change during a migration from a low-security to high-security environment.

Content configuration forms can be helpful when your imported content requires a custom configuration for:

- CA Process Automation processes and plug-ins that require configuration data.
- A plug-in that needs access to an external data source (not the MDB), such as web service or database.
  An example is an Active Directory query that supplies CA EEM. The configuration form can list a *server name=field-name* field. The Active Directory query references this field in the form, rather than a hard-coded server name.
- Organization-specific requirements, such as user names and passwords that change both at regular intervals and intermittently as-needed.

Content configuration forms are specific to the business unit for which you create them. Parent business units have access to the forms of their child business units.

Administrators of each business unit can define their own configuration forms in the same way as they define request forms. Catalog, Configuration, Content Configuration page includes the Change Business Unit button. This button opens a dialog that lets you select another business unit that you are authorized to access. If you change business units, the list of configuration forms on the left pane of the page updates to display the forms of the current business unit.

Create the Content Configuration Form

To create a content configuration form, follow this process:

Note: For more information about creating forms using the Form Designer, see the section Manage Forms (see page 2914).

1. Decide the purpose of the configuration form. Examples include specifying custom *parameter*=*value* expressions for API plug-ins or CA Process Automation processes.

   Note: These custom expressions are *not* the same as the parameters on the Administration Configuration page, the Accounting Configuration page, or the CA Service Catalog Configuration page. Moreover, these expressions are *not* the same as any other parameters on the CA Service Catalog GUI. Custom parameters can *complement* the GUI parameters, but they are not required to do so.

2. Determine the fields that are required on the form. Create the fields that require user input and determine configuration data that the Catalog system saves and uses.
   Examples include the following fields, which supply database parameters:

   - Server name or URL
   - User name
   - Password
   - Port number

   Note: This form applies to your business unit *only*. Queries to the fields on the form from API plug-ins or CA Process Automation processes must specify the business unit.

3. Create the form in the Form Designer. Follow these guidelines:

- For the Form attributes (see page 2927), specify a value of configuration for the Form Type attribute.
- Create *unique* configuration forms, especially if you use multiple configuration packs. A unique configuration form has unique value for the _id attribute in the Form attributes. Verify that no other configuration form in your business unit has the same value for that attribute.

4. Open the form on the Catalog, Configuration, Content Configuration page and specify the values that you want in each field. Follow these guidelines:
   - Specify default values that can help run the content pack successfully without the user changing any data. Doing so is helpful if the user creating or exporting the content pack is not familiar with it.
   - Optionally specify _.bu and _.user JSON objects as values. You *cannot* specify any other JSON objects as values.
5. Save the form.

Note: If you import configuration forms using content packs, the values for the form fields are available only when you save them on this page. This page is the Catalog, Configuration, Content Configuration page that you opened previously.

Retrieve Values from Fields on Content Configuration Forms

You can have custom values for variables in API plug-ins or CA Process Automation processes.

Important! The values on a content configuration form can have a maximum length of 4,000 characters for single-byte languages. **Example:** English.

The values can have a maximum length of 2,000 characters for double-byte languages. **Example:** Chinese or Japanese. For example, a select box with many options can exceed this limit and cause errors.

Follow these steps:

1. (API plug-in) Locate the com.ca.usm.plugins.apis.PluginContext object. In that object, use one of the following methods to retrieve values from fields on a content configuration form:
   - **Object getCatalogConfigValue(String configGroup, String tenantId, String configName);**
     Queries *one* field on the form. This method returns the value of the configuration parameter.
     Specify the values for the following parameters:
     configName specifies the value of the _id attribute of the field on the form.

configGroup specifies the literal value "ca_cc_" followed by the value of the _id attribute of the form. An example is ca_cc_form1.
tenantId specifies the business unit ID, for example, ca.com.

- **Map<String, Object> getCatalogConfigValues(String configGroup, String tenantId);**
  Queries *all* fields on the form. This method returns the map of key value pairs. The keys are the values of the _id attributes of the form fields.
  For configGroup and tenantId, the same values apply as for the previous method, Object getCatalogConfigValue.

2. (CA Process Automation) Link the process to one of the following methods in the CA Service Catalog web services. You link the process and the method so that you can retrieve values from fields on a content configuration form:

   - **public String getConfigurationValue(String sessionId, String configGroup, String tenantId, String configName)**

   - **public Map<String, Object> getConfigurationValues(String sessionId, String configGroup, String tenantId)**
     The parameter explanations are the same as for the methods in the previous step, except session ID.
     session ID uniquely identifies the session. This parameter is required and the client uses the value for the remaining web service calls.

     Note: For more information about web services and examples, see the Plug-in Documentation. To access the Plug-in Documentation, log in to CA Service Catalog and click Administration, Tools, Links, Plug-in Documentation.

You have retrieved values from the form fields.

Implement the Content Packs

Implementing the content packs enables you to do *both* of the following tasks:

- As a producer or designer of content packs, package a library of objects including your updates and customizations in a single location.

- As a consumer or adopter of content packs, import the customized objects programmatically in a single operation, as many times as necessary.

You do not have to repeat individual operations for each object type. Content packs provide an efficient method of packaging and applying such updates and customizations, especially when you move from one implementation to another. For example:

- Test-to-production migrations and other same-release migrations

- Replacement of a decommissioned computer

- Restoration of CA Service Catalog customizations after upgrades

To manage the content packs, perform the following tasks:

Step 1 - Complete the Prerequisites

- If you are using CA Process Automation as your process automation tool, verify that you have:
  - Installed and configured CA Process Automation.
  - Integrated CA Service Catalog with CA Process Automation.
- If you use content packs to import CA Process Automation objects and if *both* CA Process Automation and CA Service Catalog are using secure socket layer (SSL), verify that you have completed all applicable tasks for configuring CA Service Catalog to use SSL. As part of that process, you configure CA Process Automation to communicate with CA Service Catalog using SSL.

Step 2 - Create and Export the Content Pack

You create content packs to record (export) customizations so that you can reuse them in another implementation. Using content packs provides greater efficiency and accuracy than repeating multiple customization processes manually.

Follow these steps:

1. Decide and record the objects that you want to include in the content pack.
   You can include any or all of the following categories:
   - API plug-ins
   - CA Process Automation processes
   - Events, including rules, and actions
   - Form Designer forms
   - Policies
   - Report data objects
   - Services, including service hours and request SLAs

   For each category that you select, decide and record which objects to include, as follows:
   - All objects in your implementation; that is, all objects in all business units (domains).

- All objects from one or more specific business units only.
- Only the objects that you specify by object names, for example, in a comma-separated list.
- Only the objects that you specify by object-specific criteria.
  For example, for services, you can specify the last modified date.

Events, rules, actions, and report data objects (including API plug-ins) are *not* specific to any business units. That is, they always apply to *all* business units. The exception is *attached* actions. The attached actions apply *only* to the individual service options that you specify explicitly. Attached actions are service option elements of the service option for which they were created.

2. Select **Start**, **Programs**, **CA**, **CA Service Catalog**, **Service Catalog Command Prompt** on the source computer.
3. Run the following command at this command prompt:

   ```
   ant create-contentpack
   ```

   The Catalog system creates the folder structure for the content pack.
   The Catalog system also prompts you to specify the following information:

   - Simple identification data for the content pack, such as a name, author, and description.
   - The message with which to prompt the user during an import.

   We recommend that you name the *folder* to include the name, version, and locale (language) of the content pack.
   The ant command creates the content pack folder named *USM_HOME* \FileStore\contentpacks*folder-name*. This folder includes the contentpack.properties file. This file stores the identification data for the content pack. This folder also contains several subfolders, including Forms, Policies, Reports, and Services.
4. Answer the prompt about whether to export the objects into this content pack now or later, as follows:

   - If you specify Yes, skip to the next step.
   - If you specify No, run the following command on the source computer:

     ```
     ant export-to-contentpack
     ```
5. Answer the prompts about which objects must be exported, and their attributes.
   The ant command performs the following functions:

   - An XML file for each object is created, using the attributes that you specified.
   - In most cases, copies the XML file to the appropriate subfolder.

   For example, if you exported services, the ant command performs the following functions:

   - A services.xml file is created using the attributes that you specified.

- Copies the services.xml file to the Services subfolder of the content pack folder

The ant command copies some (but not all) categories of objects to their subfolders. Therefore, you copy the remaining categories of objects to their folders manually, as explained in the next step.

6. When prompted, copy the objects that you want to include (if any) to the following subfolders of the content pack folder:

   - **Processes**
     Stores CA Process Automation processes.
   - **Images\Offerings**
     Stores images for the services that you have included the Services subfolder.
   - **Images\RatePlans**
     Stores images for the service option groups that you have included in the Services subfolder.
   - **Prescripts**
     Stores custom scripts to run *before* you import the content pack. Examples include scripts, required to unzip files that are needed for the import or scripts to display the critical information.
   - **Postscripts**
     Stores custom scripts to run *after* you import the content pack. Examples include scripts that load data into the Catalog system or that prompt the user for configuration specifications.
   - **Plug-ins**
     Stores custom API plug-ins.

You have created and exported the content pack on the source computer. You are now ready to import it on the target computer.

Step 3 - Import Content Packs

You import content packs so that you can reuse customizations that you (or another administrator) previously exported from another implementation.

Note: As a best practice, use scheduled down time. Verify that no users are active on CA Service Catalog before you import, enable, or disable content packs.

You can import the content packs using one of the following methods:

- Import Content Packs using the Ant Scripts (see page 3077)
- Import Content Packs from the GUI (see page 3078)

Import Content Packs Using the Ant Scripts

This section describes importing the content packs using the ant scripts.

Follow these steps:

1. Copy the content pack folder (*USM_HOME**FileStore**contentpacks**folder-name* folder) from the source computer to a location on the target computer. Record the location for reference.
2. Select **Start**, **Programs**, **CA**, **CA Service Catalog**, Service Catalog Command Prompt on the target computer.
3. Run the following command at this command prompt:

   ```
   ant import-contentpack
   ```

4. Enter the complete path name of the folder that stores the content pack to import.
5. Perform the following steps:
   a. Confirm that you want to continue the import.
   b. Enter the business unit ID for the content pack. You can specify any business unit, including the root business unit.
   c. Answer the object-specific prompts. When applicable, consider carefully whether to import objects as disabled.
   For example, you import a new rule action that affects the emails that the Catalogs system sends. Before you enable the new rule action, you likely want to update the configuration of your mail server.

   Note: If you import objects as disabled, manually enable them before you can use them.

6. Restart the Windows service named CA Service Catalog if the content pack includes events, rules, or actions. Restart this service on all Catalog Component computers in your environment.

   Important! If you do not restart the CA Service Catalog service as directed, unpredictable results can occur.

You have imported the content pack using the ant scripts. All imported objects are either read-only or permit only limited editing.

Import Content Packs from the GUI

This section describes how you can import the content packs from the GUI.

Follow these steps:

1. Click **Catalog**, **Configuration** in CA Service Catalog UI.
2. Click **Content Packs** in the left menu.
3. Click **Import** tab.
4. Specify the folder where the content pack is stored. Select the content pack zip file and click Open.
5. Clear the **Continue import with default values** check box if you want to import the Content Pack without the default values.
6. Click **Start Import**.
   If the Content Pack includes any CA Process Automation Objects in it, the following three options appear:
   - Set imported version of CA Process Automation objects as the current version:
     - If the option is selected, the imported version of CA Process Automation objects and the current version is same.
     - If the option is not selected, the imported version of CA Process Automation objects and current version is different.
   - Make imported custom operators or sensors available:
     - If the option is selected the operators or sensors that are imported are in Available status in CA Process Automation.
     - If the option is not selected, the operators or sensors are imported as it is present in the content pack.
   - Enter the name of CA Process Automation configuration and import the process definitions to specific CA Process Automation instance.
7. If the content pack includes events, rules, or actions, the Import rules, actions in a disabled state option appears. If the option is selected, the events, rules, or actions in the content pack are imported in disabled state irrespective of the content pack status.
8. Restart the Windows service that is named CA Service Catalog on *all* Catalog Component computers in your environment.

Important! If you do not restart the CA Service Catalog Windows service as directed, unpredictable results can occur.

For example, you import a new rule action that affects the emails that the Catalog system sends. Before you enable the new rule action, update the configuration of your mail server.

Note: Enable the objects manually if you import the objects as disabled.

9. If the content pack includes policies, the Import policies in a disabled state option appear. If the option is selected, the policies in the content pack are imported in disabled state irrespective of the content pack status.

10. Click Continue Import.
The content pack import is successful.

Note: The import of the content packs is blocked with the availability of any .bat or .cmd files in the content packs. Ant scripts are used import the content packs containing .bat or .cmd files.

You have imported the content pack in CA Service Catalog UI. All imported objects are either read-only or permit only limited editing.

When the import of the content pack is complete, the images of the services are copied to the *USM_HOME**Filestore**Images* folder. The Plug-ins are copied to the *USM_HOME**Filestore**Plugins* folder.

Step 4 - Verify the Content Packs

After you import the content packs in CA Service Catalog, you can verify if the content packs were imported successfully in CA Service Catalog.

Follow these steps:

1. Click **Catalog**, **Configuration**, **Content Configuration**.

2. Select the content pack that you imported.

3. Verify the following criteria:

   - The Content Pack Details section lists the details that you specified when you created the content pack, for example, the name, version, and status.

   - The Content section lists the object that you specified, according to the criteria that you specified.

4. Verify that the user interface menus include the imported objects, for example:

- Select **CA Service Catalog**, **Service Offerings**, **Offerings**, **Services**. Verify that the list of services includes any services that you imported.

- Select **Administration**, **Events**. Verify that the list of events includes any services that you imported.

Step 5 - Enable or Disable the Content Packs

You can enable and disable either an entire content pack or individual objects (if applicable) in the content pack. You enable objects in a content pack so that the Catalog system can use the objects. Enabling the imported objects and setting permissions on them work together to let users view and use the imported objects. After you enable objects in a content pack you can disable them, for example, if a problem occurs.

Note: As a best practice, use scheduled down time, verify that no users are active on CA Service Catalog to import, enable, or disable content packs.

Follow these steps:

1. Log in to the business unit that contains the content pack that you want to enable or disable.
2. Click **Catalog**, **Configuration**, **Content Packs**.
3. Click the content pack that you want and enable.
4. Enable or disable objects in the list, as follows:

   - Activate *all objects* in the content pack by clicking the Enable button for the entire content pack. This button appears on the Content Pack Details bar.

     Important! Use this option with caution. The content pack contains rules, action, or policies that perform redundant or conflicting tasks, causing unpredictable results. Therefore, if you are not certain regarding the purpose or goal of the content pack, then enable each object individually.

   - Conversely, deactivate *all objects* in the content pack by clicking the Disable button for the entire content pack.

   - Enable or disable individual objects within a category by clicking the Enable or Disable button for the object.
     You can enable or disable objects in any or all of the following categories:

     - **Services**
       Enabling a service activates its Date Available setting: The service uses its Date Available setting to determine whether and when it is available to users.

- **Service Option Groups**
  Enabling a service option group activates its Date Available setting: The service option group uses its Date Available setting to determine whether and when it is available to users.
  Enabling a service or service option group sets its status to System Object--Available (6). Similarly, disabling a service or service option group sets its status to System Object--Unavailable (7).

- **Policies**
  You enable a policy to set its status to Active, and disable a policy to set its status to Inactive.
  You can make only limited updates to imported polices that you have enabled. To make more updates to such policies, copy and modify them.

- **Rules**
  You enable or disable rules individually, without affecting the status of any other rules in the same event.
  Enabling or disabling a rule does not automatically enable or disable the actions in the rule. The actions remain in the original status.

- **Actions**
  You enable or disable actions individually, without affecting the status of any other actions in the same rule. Similarly, enabling or disabling an action does not affect the status of the rule that contains the action.

Enabling and disabling does not apply to the following objects: Events, forms, reports, images, and CA Process Automation processes. You specified during the import process whether to make CA Process Automation processes active or inactive.

5. Click **Done**.

6. (Optional) Verify that the object is enabled (active) or disabled (inactive) by viewing its status. For example, select Services, *folder-name*, and open a service that you enabled. Verify that its status is System Object--Available. Also verify that its Date Available meets your requirements.

You have enabled or disabled objects in the content pack. All objects that you enabled are available in the Catalog system.

Note: If you copy and customize an object from a content pack, the customized object is *not* affected by enabling or disabling the content pack.

Step 6 - Modify the Imported Objects

The actions that you can perform on the objects that are imported from a content pack vary by object. When applicable, you perform certain actions on certain imported objects so that users can view and use the objects. The following table shows which actions apply to which objects.

Object	Enable or Disable	Set Permissions	Limited Editing
Services	Y	Y	Y
Service Option Groups	Y	Y	Y
Policies	Y	Y	Y
Events	N	Y	N
Rules	Y	Y	N
Actions	Y	Y	N
Forms	N	Y	N
Report Data Objects	N	Y	N
Images	N	N	N

The actions are as follows:

- **Enable or disable**
  You enable objects so that users and the Catalog system can use them. For example, suppose that your content pack includes policies. You enable these policies so that the Catalog system can use them and manages requests. Similarly, your content pack includes services and you enable these services for the users to view and request the services. For any reason, such as a problem occurring, you can disable any objects that you have enabled.

- **Set permissions**
  To set permissions for each Catalog role on an imported object, use the portion of the UI that stores and maintains the object. For example, to set permissions for services, select Catalog, Service Offerings, Services, Permission, and edit the service details.
  Edit limited attributes
  Typically, imported objects are read-only. You can perform only limited editing on certain imported objects, as follows:

  - For services and service options, you can change the date available and date unavailable.
  - For policies, you can add or remove approvers, change the priority, and set the status as active or inactive.

  Otherwise, to customize an imported object, copy, and modify it. For example, to customize an imported report data object, copy and modify it.

Step 7 - Customize the Imported Objects

To customize an imported object, copy and modify it. For example, to add a field to an imported form, copy the form, rename it, and add the field.

You can customize a service, service option group, or a form. The common customizations are as follows:

- Adding, deleting, and modifying the service option groups or the image in the service.
- Setting the dates that the service is available or unavailable.

Note: For more information about performing these tasks, see the Manage Services (see page 2987), Manage Service Option Groups (see page 3011), Manage Service Options and Service Option Elements, (see page 3017) or Manage Forms (see page 2914) sections.

Important! If you copy and customize an object that you imported in a content pack, copy and customize all *parent* objects that include the original object. This requirement exists because forms, services, and service option groups allow only limited editing.

Follow this process to copy a form, customize the copy, and include the form in a service option group and service that are based on the original service option group and service in the content pack:

1. Copy Form A and modify the copy, creating Form B.
   Service Option Group A (SOG A) contains Form A. You cannot modify SOG A to replace Form A with Form B, because SOG A allows only limited editing. So, you perform the next steps.
2. Copy SOG A to create SOG B.
3. Update SOG B by deleting Form A and adding Form B.
   Service A contains SOG A. You cannot modify Service A to replace SOG A with SOG B, because Service A allows only limited editing. Therefore, you perform the next steps.
4. Copy Service A to create Service B.
5. Update Service B by deleting SOG A and adding SOG B.
6. Copy Folder A to create Folder B.
7. Update Folder B by deleting Service A and adding Service B.

The following table lists the parent objects that you must copy and customize if you copy and customize a child object.

Child	Parent
Form	Service Option Group
Service Option Group	Service
Service	Folder
Folder	Parent Folder

Use CA Service Catalog Content Packs

This content pack contains a folder named Service Management with a subfolder named Asset Services for the business unit in which you import the content pack.

The Asset Services folder (available in Catalog, Service Offerings, IT Support Services, Service Management) stores the services for *Request a Hardware Asset* and *Request a Hardware Asset (for mobile users)*. The other services are available in Catalog, Service Offerings, IT Support Services, Service Management folder.

Services

The content pack provides the following service offerings:

- **My Resources**
  Lets business users view all the devices, software, and applications that are assigned to them. For example, the resources can be computers, mobile phones, or software that is installed on the devices. Business users can access this service and the items that it includes through a mobile device, laptop, desktop, or a server.
  The My Resources service does not require any approval process. This service offering is of type informational service.

- **Problem with My Resource**
  Lets business users report an issue with the resources that are assigned to them and are listed under My Resources. The Problem with My Resource service is used only with the My Resources service. When business users use this service, the application displays the information corresponding to the selected resource.
  The Problem with My Resource service does not require any approval process.

- **Reset Application Password**
  Lets business users reset the password of any application that they have subscribed to. Typically, an application is a software program that is not installed on your computer. For example, a web-based defect tracking tool is an application. You may not have installed the tool on your computer, but you access it using a web browser.
  The Reset Application Password service is a self-service feature. It helps business users reset their passwords without having to raise Service Desk tickets. The service and the items that it includes can be accessed through a mobile device, laptop, desktop, or a server.
  The Reset Application service does not require any approval process. This service offering is only an informational service.

- **Reset User Password**
  Lets business users reset their domain passwords. The service is an example of automating the procedure to reset a user password in Active Directory.
  This service offering does not require any approval process.

- **Report an Issue**
  Lets business users report an issue (incident) in CA Service Desk Manager. For example, a CA Service Catalog user can use this service to report a broken laptop in CA Service Desk Manager and arrange for a repair or replacement.
  Business users can access this service and the items that it includes through a mobile device, laptop, desktop, or a server.
  The Report an Issue service has no approval process, because the service is only for reporting an issue. When the request reaches Pending Fulfillment status, the incident is created in CA Service Desk Manager. After this incident is created, the request reaches Request Opened status. The incident IDs are attached to the request, and notes and attachments are synchronized between CA Service Catalog and CA Service Desk Manager.

- **Request a Hardware Asset**
  Lets catalog users select and request a hardware asset.

- **Request a Hardware Asset (for mobile users)**
  Lets catalog users request a hardware asset from a mobile device.

The following table provides the details of the Option Groups available for the services:

Service	Option Group	Option	Items in the Option Group
My Resources	My Resources	My Resources	My Resources form
Reset Application Password	Reset Application Password	Reset Application Password	Reset Application Password form
Reset User Password	Reset User Password	Reset User Password	Reset User Password form
Report an Issue	Report an Issue	Report an Issue	Report an Issue form
Request a Hardware Asset	Request a Hardware Asset	Request a Hardware Asset	Request a Hardware Asset
Request a Hardware Asset (for mobile users)	Request a Hardware Asset (for mobile users)	Request a Hardware Asset (for mobile users)	Request a Hardware Asset (for mobile users)

Note: All the Service Option Groups are available in Catalog, Service Offerings, Option Groups.

Forms

The content pack provides the following forms:

- **My Resources Configuration**
  Lets administrators configure the options that display the resources assigned to a user.

- **SAM Configuration**
  Lets administrators configure the CA Software Asset Manager server details. This enables retrieving the software and displaying it in My Resource for business users.

- **Reset Password Configuration**
  Lets administrators map applications with their knowledge documents. This helps end-users know the procedure to reset their passwords for applications.

- **Reset User Password**
  Lets catalog users configure the fields that are displayed for end-users to reset their domain passwords.

- **Reset Application Password**
  Lets administrators configure the fields that are displayed for end-users. These fields help end-users reset the password for the applications they have access to.

- **Report an Issue service**
  This service includes a service option group named Report an Issue, which includes a form named Issue Details. This form lets catalog users provide details for an issue to the service desk and request help. Users enter a description and assign the issue to a CA Service Desk Manager category. This form is the only form that catalog users see.

- **SDM Incident Configuration**
  Lets administrators define settings or attributes that CA Service Catalog creates in CA Service Desk Manager. This form is also used to define settings or attributes that CA Service Desk Manager creates in CA Service Catalog.

- **Issue Details**
  Lets catalog users use this form to provide details of an issue to the service desk and request help. Users enter a description and assign the issue to a CA Service Desk Manager category.

- **Request a Hardware Asset**
  Lets catalog users select and request a hardware asset.

- **Request a Hardware Asset (for mobile users)**
  Lets catalog users request a hardware asset from a mobile device.

The *Request a Hardware Asset* and *Request a Hardware Asset (for mobile users)* are available in Catalog, Forms, CA Catalog Content, Service Management Forms, Asset Service. All the other forms are available in Catalog, Forms, Forms folder, CA Catalog Content, Service Management Forms

Plug-ins and Default Locations

The plug-ins that are available in the content pack also include the source code. You can copy the code and can customize it to suit your requirements. To customize the code, copy the Java files into any folder of your choice and modify as required. Ensure that the plugin_class attribute in the plugin.properties file includes the modified folder path.

To view the plug-ins, go to Administration, Tools, Plug-ins. The following plug-ins are available in the content pack:

Imported Object	Plug-in
My Resources	USM_HOME\filestore\plugins\ ca.catalog.content.resource-plugin
Reset Application Password	USM_HOME\filestore\plugins\ ca.catalog.fetchallservicedeskapplicationareas.plugin USM_HOME\filestore\plugins\ ca.catalog.fetchkbapplications.select-plugin USM_HOME\filestore\plugins\ ca.catalog.fetchkbdocument.select-plugin

Imported Object	Plug-in
	USM_HOME\filestore\plugins\ ca.catalog.fetchservicedeskapplicationareas.plugin
Reset User Password	USM_HOME\filestore\plugins\ ca.catalog.updateactivedirectoryuserpassword.select-plugin
Common	USM_HOME\filestore\plugins\ ca.catalog.samples.configurationreader-plugin
Plug-in for fetching incident areas from CA Service Desk Manager	ca.catalog.servicedesk-select-plugin

Events, Rules, and Life Cycle

The following table lists the action that apply to the Request/Subscription Item Change event:

Event	Status	Action
Request/Item Subscription Change	Not Applicable	When a Note or an Attachment is added to CA Service Catalog, this event triggers CA Process Automation process to synchronize with CA Service Desk Manager.

The following table lists the action that applies to the different rules:

Rule	Status	Action
When Category is Service Management Content	Canceled	Cancel Incident
When Category is Service Management Content	Completed	Close Incident
When Category is Service Management Content	Pending Fulfillment	Create Incident

Typically, you do not need to customize these rules and actions.

Verify the General Prerequisites

To verify that you can use the content packs as intended, complete the prerequisites. For more information about the prerequisites for individual offerings and services, see the corresponding section.

Software Prerequisites:

This content pack requires integrations with other applications. Ensure that you install the following components:

- CA Service Desk Manager 12.9 or higher
- CA Asset Portfolio Management 12.9 or higher
- CA Software Asset Manager 12.9 or higher
- Microsoft Active Directory 2008 R2

General Prerequisites:

The following prerequisites apply to all content packs:

- Restart the CA Service Catalog Service.
- Have a working knowledge of content packs, including how to import and verify the import, and how to enable and disable the objects in the content pack. For more information about importing a content pack, watch this video.
- Understand that you can edit only limited attributes of the objects that you import from the content pack. To make further changes, copy the objects and customize the copies. You must have a working knowledge of how to copy and modify any object that you want to modify, and all its parent objects. For more information about how to customize the content, watch this video.
- Follow these steps to update the Problem with My Resource offering ID, Reset User Password offering Id, and Report an Issue offering Id in the Content Configuration page.

  Note: Ensure that you update these IDs before using the My Resources and Reset Password service offerings.

  1. Log into CA Service Catalog as an administrator.
  2. Go to **Catalog**, **Service Offerings**, **IT Support Services**, **Service Management**.
  3. Select the ID from the required service offering.
  4. Use this ID value to update the existing value in the Content Configuration page (**Catalog**, **Configuration**, **Content Configuration**).
  5. Click **Save** after you update the configuration details.
     The offering ID has been updated.

Use My Resources Service

The *My Resources* offering lets business users view all the devices, software, and applications that are assigned to them. For example, the resources can be computers, mobile phones, or software that is installed on the devices.

Prerequisites:

Before going through this topic, ensure that you verify the general prerequisites (see page 3087).

The following prerequisites apply for using the *My Resources* offering:

- CA Service Catalog is integrated with CA Service Desk Manager and CA Asset Portfolio Management.
- CA Software Asset Manager configuration and My Resources configuration details are updated under **Catalog**, **Configuration**, **Content Configuration**.

The following video demonstrates how to use the My Resources offering:

Use Reset Password Service

The Reset Password offering consists of two parts:

- Reset Application Password
- Reset User Password

Prerequisites:
Before going through this topic, ensure that you verify the general prerequisites (see page 3087).
The following prerequisites apply for using the Reset Password offering:

- The Active Directory server is installed and configured.
- The alternate email address is added to Active Directory.
- Ensure that the Active Directory Certificate Services are installed.
- The reset password offering ID is mentioned in the Reset Password Configuration form.

Add the alternate email address to Active Directory

To add an alternate email address to Active Directory, you must first add the custom attribute Alternate Email to the Active Directory User class. To add a custom attribute, you modify the Active Directory schema. Adding custom attribute requires that the modifying user be a member of the Schema Administrators and Enterprise Administrators groups.

Follow these steps to add a custom attribute to the user object:

1. Register the schema snap-in.
2. Create a custom attribute.
3. Add the custom attribute to the user class.
4. Restart the Active Directory Domain Services.

Follow these steps to register the schema snap-in:

1. Press Windows + R on your keyboard.
2. Type RegSvr32 SchmMgmt.dll and click OK.
   When the schema snap-in is registered, a confirmation message appears.

Follow these steps to create a custom attribute:

1. Press Windows + R on your keyboard.
2. Type mmc.exe and click OK.

3. Click File, Add/Remove snap-in, or simply press Ctrl + M.

4. Select the snap-in Active Directory Schema, click Add >, and then click OK.

5. Expand the Active Directory Schema root node, right-click the node Attributes, click Create Attribute.

6. If the Schema Object Creation warning message appears, click Continue.

7. Create the custom attribute Alternateemail. Complete the following fields:

   - Common Name: Enter Alternate Email
   - LDAP Display Name: Enter alternateemail
   - Unique X500 Object ID: Enter the object ID that is applicable for your domain.
   - Syntax: Select Unicode String

8. Click OK.
   The new custom attribute Alternateemail is created and displayed in child node of Attributes.

Follow these steps to add the custom attribute to the user class:

1. Navigate to the node Active Directory Schema, Classes, and select the class User.

2. Right-click the User class and click Properties. Go to the Attributes tab and click Add.

3. Select the schema object alternateemail and click OK.
   This adds alternateemail as an optional attribute for the User class.

4. Click Apply.
   You have successfully added the alternate email attribute to the User class.

Restart the Active Directory Domain Services

After you have created the custom attribute and added it to the User class, you must restart the Active Directory domain service to apply the schema change.

Follow these steps:

1. Press Windows + R on your keyboard.

2. Type services.msc and click OK.

3. Right-click Active Directory Domain Services and click Restart, and then click Yes.
   All the related services are restarted.

Follow these steps to create the Active Directory Certificate and use it:

1. Create an Active Directory Certificate File on the computer where Active Directory is hosted.

2. Register the certificate in CA Service Catalog.

Follow these steps to create the Active Directory Certificate:

1. Log in to a computer where Active Directory is installed.
2. Open a Command Prompt window using the Run as Administrator option.
3. Type MMC and press Enter.
   The Microsoft Management Console opens.
4. Click File, Add/Remove Snap-in.
5. Select Certificate in the Available snap-ins section, click Add to move it to the Selected snap-ins section, and then click OK.
6. Select Computer account and click Next.
7. Select Local computer: (the computer this console is running on), and click Finish.
   The Add or Remove Snap ins page opens. The Certifications (Local Computer) is added to Selected snap-ins.
8. Click OK.
   The Add or Remove Snap-ins wizard closes.
9. Expand Certificates (Local Computer) in the Console and then expand Personal.
10. Right-click Certificates, select All Tasks, and then select Request New Certificate.
    The Certificate Enrollment wizard opens.
11. Read the instructions and click Next.
    The Select Certificate Enrollment Policy page opens.
12. Verify that Active Directory Enrollment Policy is selected, and click Next.
    The Request Certificates page opens.
13. Select Domain Controller, Domain Controller Authentication, and click Enroll.
    The Certificate Installation Results page opens.
14. Verify that the status is Succeeded for both policies, and click Finish.
15. Verify that there are three certificates under Certificates, in the Console.
16. Right-click the certificate with the Intended Purpose of <All>.
17. Select All Tasks and Export.
    The Certificate Export Wizard opens.
18. Click Next.
    Select the option No, do not export the private key, and click Next.
19. Select DER encoded binary X.509 (.CER), and click Next.
20. Browse and create a folder called Certificate (\Certificate).

21. Name the certificate file to identify it (for example, ITSM-AD.cer) and click Next.
    The Completing the Certificate Export page opens.

22. Verify the Certification Export information and click Finish. Click OK.

23. Close the Microsoft Management Console.

24. Click Yes and Save to save the Console.
    A Certification File (for example, ITSM-AD.cer) is created in the Certification folder on the Domain Controller.

25. Copy the Certification File (ITSM-AD.cer) to the computer where CA Service Catalog is installed.

Follow these steps to register the certificate in CA Service Catalog:

1. Log in to a computer where CA Service Catalog is installed.

2. Go to [USM_Home]\view\conf and open the viewService.conf file.

3. Find the Djavax.net.ssl.trustStore parameter under Java Additional Parameters, and get the value of the parameter. Identify the keystore.
   For example, if the key store value is "C:/Program Files (x86)/Java/jdk1.7.0_40/jre/lib/security /cacerts", navigate to the directory C:\Program Files (x86)\Java\jdk1.7.0_40\jre\bin.

4. Run the following command where ITSM-AD.cer is the name of the file from your Active Directory server:
   keytool -import -keystore ..\lib\security\cacerts -alias ADCertificateRegistration -file C:\ITSM-AD.cer

5. Enter the keytool password, which is available in the 'Djavax.net.ssl.trustPass' parameter value in the viewService.conf file.
   The message Trust this certificate? [no]: appears.

6. Enter yes and confirm the key import.

Change the Reset Password Offering ID

If you want to modify the Reset User Password form and include other details, change the Reset Password Offering ID.
Follow these steps:

1. Log in into CA Service Catalog as Service Delivery Administrator or Catalog Administrator.

2. Specify the new Reset Password Offering ID in the Reset Password Configuration form. Click Save.

Note: The new offering ID is generated when you copy the default Reset Password offering and create a custom form.

3. Log in into EEM using the CA Service Catalog instance.
4. Click Manage Access Policies and click the offering.
5. Click ACL_Guest_Offering.
6. Remove all resources except "_preventWildcardMatch__ACL_Guest_Offering".
7. Add the resource "offering__<new reset password offering id>".

> **Note:** This offering ID is generated when you copy the default Reset Password offering and create a custom form.

8. (Optional) To find the offering ID, log in to CA Service Catalog and click the new Reset Password Service offering. The Id is displayed in the Details tab.
   For example suppose that the offering is under ca.com (Id = 10001), IT Support Services (Id = 10013), Service Management (Id = 10048). When you click a service offering or a folder, the offering ID is displayed in the Details tab. Per the example, add the following resources to the ACL_Guest_Offering policy:
   - offering__10001
   - offering__10013
   - offering__10048
9. Click Save. Click Configure, Session, Synchronize Cache.
10. Restart CA service Catalog.

The following video demonstrates how to use the Reset Password offering:

Use Report an Issue Service

The *Report an Issue* service creates an incident in a predefined (default) implementation of CA Service Desk Manager. If you have customized CA Service Desk Manager to match your business needs, copy and customize the service to match your implementation.

Before going through this topic, ensure that you verify the general prerequisites (see page 3087).

Follow these steps:

1. Understand how the Catalog system creates and populates a CA Service Desk Manager incident.
2. Include custom attributes in the CA Service Desk Manager incident.
3. Customize status codes, attribute prefixes, and other details for the CA Service Desk Manager incident.

4. Review the guidelines and limitations for the Report an Issue service and your custom versions of it.

5. Follow the guidelines for using and customizing rules and actions.

The following video demonstrates how to use the Report an Issue service:

Retry Failed Attempts to Create CA Service Desk Manager Incidents

At times, a catalog user submits a request for the Report an Issue service. But the attempt to create the incident in CA Service Desk Manager fails. In such cases, the Catalog system reports the failed attempts as alert messages (alerts). The system issues one alert per incident. For example, if a service contains two service options that create an incident, the system issues two alerts. A common reason for failed attempts is a temporary network problem that makes CA Service Catalog inaccessible to CA Service Desk Manager. After the problem is resolved, retry the failed attempts.

Follow these steps:

1. Log in to CA Service Catalog as Service Delivery Administrator.

2. Click **Home**, **Messages**, **Alerts**.

3. Click **List All Failed Actions**, and proceed as follows:

    a. If necessary, click Change Business Unit to display the list of alerts that include the failed actions you want to retry.

    b. Retry all Incident Creation Failures of the following type: INCIDENT_CREATION_FAILED.

4. Select five or fewer rows and click **Retry Failed Actions**.
   If the retry fails, the Catalog system marks the alert as Retried, and issues a new failure alert that you can retry again later.
   If the retry succeeds also, the Catalog system marks the alert as Retried. You can view the request and its corresponding ticket in CA Service Desk Manager.

Synchronize Attachments and Notes between CA Service Catalog and CA Service Desk Manager

You can synchronize notes and attachments between CA Service Catalog and CA Service Desk Manager.

Follow these steps:

1. Log in to CA Service Catalog as Service Delivery Administrator.

2. Click **Administration**, **Event-Rules-Actions**.

    a. Open the **Document Create** event type.

    b. Select the **When attachment is added to Service Catalog request** rule and click **Enable** .

    c. Enable the Launch PAM SRF to sync Attachments action.

This action synchronizes the attachments between service options and tickets after the ticket is created. That is, if a business user adds an attachment to a service option after submitting the request, this action passes the attachment to the related ticket.

3. Follow these steps to synchronize notes:

    a. Open the **Notes Create** event type.

    b. Select the **When note is added to Service Catalog request** rule and click Enable.

    c. Enable the Launch PAM SRF to sync notes action.

    This action synchronizes notes between service options and tickets after the ticket is created. That is, if business user adds a note to a service option after submitting the request, this action passes the note to the related ticket.

Use Asset Services

To use the *Asset Services* offering, follow these processes.

Before going through this topic, ensure that you verify the general prerequisites (see page 3087).

Request a Hardware Asset Service

Follow this process to create a custom service for requesting a hardware asset from CA Asset Portfolio Management. In this process, you copy the Request a Hardware Asset service and customize the copied objects.

1. Select **Administration**, **Events-Rules-Actions**, and perform these actions:

    a. Open the event named **Request/Subscription Item Change**.

    b. Enable and open the rule named **When Category is Hardware and Status is Pending Fulfillment**.

    c. Enable the action named **Auto assign the selected asset to the user**.
    After all approvals are supplied and the request reaches Pending Fulfillment status, this action automatically assigns the CA Asset Portfolio Management asset to the Requested For user. If this action is not enabled, an administrator must fulfill the request manually, using gold brick icon.

    Note: You perform this step only once per business unit. Unlike the remaining steps, you do not perform this step each time that you create a service.

2. Create a folder and copy the Request a Hardware Asset service from the content pack to the new folder.

Note: Copy all objects in the service.

3. Rename the folder, service, service option group, service option, and form to intuitive names. An example is Request a Hardware Asset--custom-V1.

4. Meet the following requirements:

   - Assign models to a service option.
   - Verify that this service option is included in a service option group in the service.
   - Understand that the Request a Hardware Asset form uses a hidden field named Selected Assets' Id to store the UUID of the IT Asset Manager asset that the user selects.

     Important! Do not modify or replace this field. If you decide to modify or replace this field for any reason, the new or modified field must use the same value for the _id attribute as the original field: ca_itam_attr_asset_id. Otherwise, the selected asset is not assigned properly.

   - When the request for the selected asset is approved, the Assign Asset action from the content pack (or your custom version of that action) assigns that UUID to the Requested For user specified in the request.

5. Verify the following requirements for using the report data object (data object) from the content pack:

   - The catalog user and the assets must have the same location.
   - The assets must not have been assigned to any user.
   - The assets must be active in status.

6. (Optional) If the CA Service Catalog database runs on SQL Server, you can optionally create and use a custom query that removes one or more of the restrictions in the predefined data object for requesting a hardware asset.
   This topic illustrates the process to remove the restriction that users and assets have the same location. You can use this topic as a model to make similar customization to your queries. Follow this process:

   a. **Create a data object with your custom query:**

      i. Click **Administration**, **Report Builder**, **Data Objects**.

      ii. Expand **Catalog**.

      iii. Open the data object named **Fetch Hardware Assets to Assign - Table Provider** .

      iv. Copy the fields of this report data object to a Notepad file. The fields include Database, Table, Fields, and Query.

v. Create a data object. Specify an intuitive name, for example, Fetch Hardware Assets--Custom-version1.

vi. Copy and paste the text from the Notepad file to each field of the new data object.

vii. Update the query in the new data object to remove the location requirement. The updated query appears as follows:

```
SELECT cc.resource_name AS ca_itam_attr_asset_name,cc.host_name AS
ca_itam_attr_host_name,cs.name AS ca_itam_attr_resource_family,
cv.name AS ca_itam_attr_resource_class,lc.name AS
ca_itam_attr_lifecycle_status,sc.name AS ca_itam_attr_cost_center,
bb.location_name AS ca_itam_attr_location_name,cc.resource_name,
CONVERT(CHAR(100),own_resource_uuid,1) AS
ca_itam_attr_asset_id_temp
FROM ca_owned_resource cc
JOIN ca_model_def cl ON cc.model_uuid = cl.model_uuid
JOIN usm_link_rateitem_model lrm ON cl.model_uuid=lrm.model_uuid
JOIN usm_rate_definition r ON lrm.rate_item_id=r.item_id
JOIN usm_offering_ratedef_inclusion ori ON r.item_id=ori.child_id
JOIN usm_offering o ON ori.parent_id=o.offering_id
JOIN ca_resource_family cs ON cc.resource_family = cs.id
JOIN ca_resource_class cv ON cc.resource_class = cv.id
LEFT OUTER JOIN ca_asset_lifecycle_status lc ON cc.
lifecycle_status = lc.id
LEFT OUTER JOIN ca_resource_cost_center sc ON cc.cost_center = sc.
id
LEFT OUTER JOIN ca_location bb ON cc.location_uuid = bb.
location_uuid
WHERE cc.resource_contact_uuid IS NULL AND cc.inactive='0' AND cl.
name=(SELECT cl.name WHERE cl.inactive='0' AND cl.family_id='%
family_id%' AND o.offering_id='%offeringid%')
```

viii. Copy the ID of this new report data object to a Notepad file. You use this information in the next procedure

b. **Copy and customize the form to accommodate the new object**

i. Select **Catalog**, **Forms**.

ii. Expand **Forms**, **CA Catalog Content**, **Service Management Forms**, **Asset Services**, **Request a Hardware Asset** and review the value of the Report/Plug-in Variables attribute in the original form

iii. Select the **Select An Asset** field and review the value of the Report/Plug-in Variables attribute.
The original value of the attribute follows:
$({'offeringid':_.service.id,'family_id':'600','location':_.user.location.uuid})

iv. Copy the form. Specify an intuitive name, for example, Request a Hardware Asset--Custom-version1.

v. Update the following attributes of the Select An Asset field:

vi. Report/Plug-in Id: Replace the existing value with the ID of the new report data object that you created in the previous procedure.

vii. Report/Plug-in Variables: Remove the location requirement.
The updated value appears as follows:
$({'offeringid':_.service.id,'family_id':'600'})

7. (Oracle Users Only) Replace the SQL Server query in the content.
The predefined queries in the data objects in the content pack are for SQL Server only. Therefore, if the CA Service Catalog database runs on Oracle, create a custom query for Oracle that performs the same functions as the predefined query.

   - Create an Oracle query for requesting hardware assets (see page 3098).
   - Create an Oracle query for requesting hardware assets (for mobile users) (see page 3099).

8. You can use the predefined or custom approval process of your choice.

Create an Oracle Query for Requesting Hardware Assets

Create an Oracle query for requesting hardware assets, for use in a service that users submit from a laptop or desktop computer (not a mobile device).

Follow this process:

- Step 1 - Create a data object with your custom query (see page 3098)
- Step 2 - Copy and customize the form (see page 3099)

Step 1 - Create a data object with your custom query

1. Select **Administration**, **Report Builder**, **Data Objects**.

2. Create a data object. Specify an intuitive name, for example, Fetch Hardware Assets–RequestedFromLaptop.

3. Configure the new data object to perform the same functions for Oracle as the original data object for SQL Server.
Use this query as a model to create your query. This query includes the location requirement. Remove it if you do not want it.

```
Database: mdb
Fields: ca_itam_attr_asset_name,ca_itam_attr_host_name,
ca_itam_attr_resource_family,ca_itam_attr_resource_class,
ca_itam_attr_lifecycle_status, ca_itam_attr_location_name,
ca_itam_attr_cost_center,resource_name,item_id,ca_itam_attr_model_name,
ca_itam_attr_location_uuid,ca_itam_attr_asset_id_temp
Query: SELECT cc.resource_name AS ca_itam_attr_asset_name,cc.host_name AS
ca_itam_attr_host_name,cs.name AS ca_itam_attr_resource_family, cv.name AS
ca_itam_attr_resource_class,lc.name AS ca_itam_attr_lifecycle_status,sc.name AS
ca_itam_attr_cost_center,bb.location_name AS ca_itam_attr_location_name,cc.
resource_name, CAST(own_resource_uuid AS CHAR(100)) AS
ca_itam_attr_asset_id_temp FROM ca_owned_resource cc
JOIN ca_model_def cl ON cc.model_uuid = cl.model_uuid
JOIN usm_link_rateitem_model lrm ON cl.model_uuid=lrm.model_uuid
JOIN usm_rate_definition r ON  lrm.rate_item_id=r.item_id
JOIN usm_offering_ratedef_inclusion ori ON r.item_id=ori.child_id
JOIN usm_offering o ON ori.parent_id=o.offering_id
JOIN ca_resource_family cs ON cc.resource_family = cs.id
JOIN ca_resource_class cv ON cc.resource_class = cv.id
LEFT OUTER JOIN ca_asset_lifecycle_status lc ON cc.lifecycle_status = lc.
id
LEFT OUTER JOIN ca_resource_cost_center sc ON cc.cost_center = sc.
```

```
id
LEFT OUTER JOIN ca_location bb ON cc.location_uuid = bb.
location_uuid
WHERE cc.resource_contact_uuid IS NULL AND cc.inactive='0' AND CAST(cc.
location_uuid AS CHAR(100))='0x' + '%location%' AND cl.name=(SELECT cl.name
FROM ca_model_def cl WHERE cl.inactive='0' AND cl.family_id='%family_id%' AND o.
offering_id='%offeringid%')
```

4. Copy the ID of this new report data object to a Notepad file. You use this information in the next procedure.

Step 2 - Copy and customize the form

1. Review the value of the Report/Plug-in Variables attribute in the original form in the content pack, as follows:

   a. Select **Catalog**, **Forms**.

   b. Expand **Forms**.Select **CA Catalog Content**, **Service Management Forms**, **Asset Services**, **Request a Hardware Asset**.

   c. Click the **Select An Asset** field and review the value of the Report/Plug-in Variables attribute.
   The original value of the attribute follows:
   $({'offeringid':_.service.id,'family_id':'600','location':_.user.location.uuid})

2. Copy the form. Specify an intuitive name, for example, Request a Hardware Asset--From a Laptop.

3. Update the Report/Plug-in Id attribute of the Select An Asset field: Replace the existing value with the ID of the new report data object that you created in the previous procedure.

Create an Oracle Query for Requesting Hardware Assets (for Mobile Users)

Create an Oracle query for requesting hardware assets, for use in a service that users submit from a mobile device.

Follow this process:

- Step 1 - Create a data object with your custom query (see page 3099)
- Step 2 - Copy and customize the form (see page 3100)

Step 1 - Create a data object with your custom query

1. Select **Administration**, **Report Builder**, **Data Objects**.

2. Create a data object. Specify an intuitive name, for example, Fetch Hardware Assets–RequestedFromMobile.

3. Configure the new data object to perform the same functions for Oracle as the original data object for SQL Server.
   Use this query as a model to create your query. Test your query thoroughly before making the service that includes it available to catalog users. This query includes the location requirement. Remove it if you do not want it.

```
Database: mdb
Fields: ca_itam_attr_asset_id,ca_itam_attr_asset_name,ca_itam_attr_host_name,
ca_itam_attr_resource_family,ca_itam_attr_resource_class,
ca_itam_attr_lifecycle_status,ca_itam_attr_location_name,
ca_itam_attr_cost_center,resource_name,item_id,ca_itam_attr_model_name,
ca_itam_attr_location_uuid
Query: SELECT CAST(own_resource_uuid AS CHAR(100)) AS ca_itam_attr_asset_id,cc.
resource_name + ', ' + cl.name AS ca_itam_attr_asset_name,cc.host_name AS
ca_itam_attr_host_name,cs.name (http://cs.name) AS ca_itam_attr_resource_family,
cv.name AS ca_itam_attr_resource_class,lc.name AS ca_itam_attr_lifecycle_status,
sc.name AS ca_itam_attr_cost_center,bb.location_name AS
ca_itam_attr_location_name,cc.resource_name
FROM ca_owned_resource cc
JOIN ca_model_def cl ON cc.model_uuid = cl.model_uuid
JOIN usm_link_rateitem_model lrm ON cl.model_uuid=lrm.model_uuid
JOIN usm_rate_definition r ON  lrm.rate_item_id=r.item_id
JOIN usm_offering_ratedef_inclusion ori ON r.item_id=ori.child_id
JOIN usm_offering o ON ori.parent_id=o.offering_id
JOIN ca_resource_family cs ON cc.resource_family = cs.id
JOIN ca_resource_class cv ON cc.resource_class = cv.id
LEFT OUTER JOIN ca_asset_lifecycle_status lc ON cc.lifecycle_status = lc.
id
LEFT OUTER JOIN ca_resource_cost_center sc ON cc.cost_center = sc.
id
LEFT OUTER JOIN ca_location bb ON cc.location_uuid = bb.
location_uuid
WHERE cc.resource_contact_uuid IS NULL AND cc.inactive='0' AND CAST(cc.
location_uuid AS CHAR(100))='0x' + '%location%' AND cl.name=(SELECT cl.name
FROM ca_model_def cl WHERE cl.inactive='0' AND cl.family_id='%family_id%' AND o.
offering_id='%offeringid%')
```

4. Copy the ID of this new report data object to a Notepad file. You use this information in the next procedure.

Step 2 - Copy and customize the form

1. Review the value of the Report/Plug-in Variables attribute in the original form in the content pack, as follows:

    a. Select **Catalog**, **Forms**.

    b. Expand **Forms**. Select **CA Catalog Content**, **Service Management Forms**, **Asset Services** , **Request a Hardware Asset (for Mobile Users)**.

    c. Click the **Select An Asset** field and review the value of the Report/Plug-in Variables attribute.
    The original value of the attribute follows:
    $({'offeringid':_.service.id,'family_id':'600','location':_.user.location.uuid})

2. Copy the form. Specify an intuitive name, for example, Request a Hardware Asset--From Mobile Devices.

3. Update the Report/Plug-in Id attribute of the Select An Asset field: Replace the existing value with the ID of the new report data object that you created in the previous procedure.

Best Practices for Service Catalog Management

IT organizations have focused on technology without clear accountability for adding business value, while their customers have focused on costs. Increased competition in the marketplace and increased dependence on high technology demand that IT organizations:

- Build a stronger understanding of the customers they serve.
- Work in a close partnership with them to deliver true value.

These business alignment initiatives require:

- A clear definition of the services that the IT organization provides.
- An understanding of the components and resources that constitute the services.
- An identification of the costs of the associated services.

With centralization of IT services and movement toward a utility model, implementing a service catalog becomes an increasingly important necessity. Using a service catalog leads to better IT service alignment with business goals and improved internal customer satisfaction. It also leads to standardized processes to achieve greater operational efficiency.

The ITIL™ (IT Infrastructure Library) framework stipulates that IT organizations start their process enhancement initiatives by developing a service catalog to:

- List all the services being provided
- Summarize the details of the services, customers, service designers, and service administrators.

Many IT groups produce a service catalog as part of their ITIL Service Level Management deployment. Others view the opportunity to leverage the service catalog as the focal point for communication between IT and the business.

Benefits

CA Service Catalog enables you to load catalog content and to enable related business process automation through CA Process Automation. The goal of this initiative is not to create a complete and comprehensive list of services. Instead, the goal is to help you get started in building your own catalog.

As the foundation for aligning IT with the business, service catalog represents a crucial element of success in ITIL initiatives. By using a service catalog, IT organizations can:

- Create clear service definitions.
- Define service levels and costs.
- Deliver usage and performance data in business terms.
- Track user subscriptions and service requests.

- Provide a fast, consistent, and more effective access to IT services.
- Publish or review service reports.

Developing a service catalog can provide the following improvements to drive down costs while still achieving high levels of service:

- Improved efficiencies in handling incoming requests.
- Eliminate service redundancies.
- Increased IT staff productivity.
- Better allocation of resources.
- Reduced calls to the help desk.

Guidelines for Collecting Data

The following guidelines are for using staff interviews to collect data regarding the services and service levels currently existing in your organization. These guidelines are developed based on ITIL Methodology and CobiT™ Principles. These guidelines consist of the following activities for collecting and analyzing data, in sequential order:

- Review of the purpose of the staff interviews. (see page 3102)
- Use of the suggested questions (see page 3103) and any related questions of your own to conduct the staff interviews. (see page 3103)
- Analysis of service-related documents. (see page 3103)
- Review and benchmark activities (see page 3104) for existing services.
- Collation the results of staff interviews. (see page 3104)
- Organization of the newly determined information into service specifications that include detailed descriptions of each service.

Purpose of the Staff Interviews

The purpose of the interviewing the staff is to obtain and understand organization-wide policies and procedures relating to provider-to-user relationships. Examples follow:

- IT policies and procedures:
  - Service level agreements
  - Operational reporting content, timing, and distribution
  - Performance tracking methods
  - Corrective action activities

- IT documentation:
  - Service level performance reports
  - Service budget and costing procedures
  - Charge-back algorithms and methodology for calculating charges
  - Service improvement programs
  - Recourse resulting from nonperformance
  - Service level agreements with internal and external users and providers of services

Questions for Staff Interviews

The staff interviews can include the following questions:

- Who delivers which services where, to which organization or organizational groups, and at what cost?
- Who requests which services from which IT group and at what volume?
- What level of service is in place within the organization?
- Who are the stakeholders?
- How can we use the template catalog?

Staff Interviews

The staff whom you Interview include the following personnel:

- Chief Information Officer
- IT senior management
- IT Contract Administrator
- Service Level Administrator
- IT Operations management
- User management

Documents to Analyze

You review and analyze the following documents:

- Service level agreement process
- Definitions of responsibilities of users and providers

- Management reports on the achievement of the specified service performance criteria and all problems encountered

The purpose of analyzing the documents is to verify whether:

- Users understand service level agreement processes and procedures.
- The level of user satisfaction with the service level process and service level agreements is sufficient.
- Service fulfillment data is available to track performance.
- A performance improvement program exists.
- The accuracy of actual charges matches agreement content.
- A comparison of historical performance and prior service improvement commitments is tracked.
- Managers appropriately use reports on service performance.

Review and Benchmark Activities

The review and benchmark activities are as follows:

- Benchmarking of service level agreements against similar organizations or appropriate international standards and recognized industry best practices.
- Review of service level agreements to determine qualitative and quantitative provisions confirming obligations are defined and being met.
- Review of selected service level agreements to confirm compliance and resolution procedures for problems, specifically nonperformance.

Results of Staff Interviews

The results of the staff interviews help the organization identify the:

- Adequacy of the provisions describing, coordinating, and communicating the relationship between the providers and the users of information services.
- Incorrect calculations for selected categories of information.
- Ongoing review and corrective action by management of service level reporting.
- Adequacy of proposed service improvements in comparison with cost-benefit analysis.
- Adequacy of the ability of providers to meet commitments for improvements.

Best Practices Foundation

This article contains the following topics:

- Service Catalog Logical Structure (see page 3106)
- Customer-Focused Documentation (see page 3107)

Request and Fulfillment Automation with CA Process Automation

A key characteristic of the predefined foundation content is the automation of approvals and notifications for actions that complete the service fulfillment process. This automation makes the services "actionable." Service designers accomplish this goal through the workflow capabilities included with CA Process Automation.

All services in the predefined foundation content invoke the workflow-driven approval process. This process sends an email to the manager of the requestor, indicating the requiring approval for the request. The email includes a link to the approval page in CA Service Catalog to streamline the approval process. You can use a different approval process for individual services. To do so, select a different approval mechanism for those services through the Service Builder.

After a service request has been approved, the requested items in the service option group then follow a fulfillment workflow. The category that is specified for the requested component determines the workflow. The predefined service option groups contain components that belong to one of these categories: Hardware, Software, or Service.

The event rules for each category control the notifications that are generated as the components of the request move through the stages of fulfillment. The foundation content, as delivered, follows the predefined rules for each category. You can customize these rules to address your specific requirements.

The predefined foundation content provides a category-class-subclass structure (see page 3105) for your use.

Category-Class-Subclass Structure

The predefined foundation content provides a category-class-subclass structure. You can use the class and subclass designations within each category to customize the workflow process. The default structure contains the following top-level categories:

- None
- Hardware
- Reservation Manager
- Service
- Service Offering Management
- Software
- Other

Multiple classes exist within each category, and in most cases multiple subclasses within each class.

To view and optionally update the complete detailed structure of category classes and subclasses, edit the category.xml file.

Note: You can add categories to meet your specific requirements. However, you cannot change the internal numeric values of the default categories. This field is used for logic in other portions of the product.

Service Catalog Logical Structure

You can use a table or spreadsheet to design the full logical structure of the catalog before its actual implementation. This approach facilitates communication between stakeholders and end users regarding the service catalog structure and content required.

We recommend that you agree on the general service catalog content and structure first and the details next. As the catalog and its use mature within an organization, some restructuring and fine-tuning are likely to occur.

IT Support Services						
Folder	**Service**	**Service Option**	**Category**	**Class**	**Subclass**	**Description**
Data Security						
	Virus Protection / Remediation Plan SLA					
		Bronze	Service	IT	SLA	Bronze SLA for Virus Protection /Remediation
		Silver	Service	IT	SLA	Silver SLA for Virus Protection /Remediation
		Gold	Service	IT	SLA	Gold SLA for Virus Protection /Remediation
	VPN Access					
		Request VPN Access	Service	IT	Security	Request VPN access for remote user
	Proxy Access					
		Subscribe to Proxy	Service	IT	Security	Request proxy access (security request)
	Pre-Production Security Scans					
		Security Scan	Service	IT	Security	Request Security Scan before production status
Data Management						
	Backup Data					
				IT	Data	

	Backup Production Server Data	Service	Backup Services for Production Server Data.
	Backup Local PC / Laptop Data	Service	IT Data Backup Services for Local PC / Laptop Data.
Restore Data			Services to restore production or local data.
	Restore Production Server Data	Service	IT Data Restore data on a production server from backup files.
	Restore Local PC / Laptop Data	Service	IT Data Restore data on a local PC from backup files.

We recommend limiting the number of levels that users navigate to reach specific services in your catalog. As an example, consider an IT Support Services category such as Hardware and Software Procurement. For ease of use, divide it into two separate categories. Examples include Hardware Procurement and Software Procurement. This approach is more efficient than using subfolders, for example, under Hardware and Software Procurement.

You can customize the structure of the provided content to meet the needs of your organization. For example, you can divide a single-Server service into the following services: Blade Server, Standard Server, and Mainframe Server. In this case, create a folder that is named Server to contain the other thee services. Each service contains descriptions and service option group items to assist users in their selection.

Customer-Focused Documentation

Prepare customer-focused documentation for the service catalog and make it available to all potential users. Sample contents follow:

- Forward from the IT Director
- Table of Contents
- IT Service Provider profile
- Version number, date created, date amended
- Changes from last published Catalog
- Service times and accessibility of the IT Service Provider
- Overview of Services and Products
- Customer-focused Service and Product descriptions
- Specifications of Services
- Deliverables
- Service Times

- Maintenance Times
- Support Times
- Delivery Times
- Quality Target (availability, reliability, usability, priority)
- Requirements
- Request and Change procedures
- Contingency policy
- Pricing and Charging
- Index and definitions

Service Accounting

Service Accounting lets you manage your invoicing and financial reports, accounts, subscriptions, exchange rates, budgets and plans, and so on. You can search and view all invoices for an account for a certain period. It offers you a consolidated view of all invoices for a selected group. Financial reports provide insight and visibility about account details, adjustment details, invoice details, and payment details. An Administrator can manage invoices for an account using the available options. Accounting configuration enables you to prorate the online as well as batch processes. You can generate an invoice for charges as per the usage rate. Administrators can schedule the on-demand invoice to produce instant current invoice for an account.

This section contains the following articles:

Manage Invoicing and Financial Reporting

This article contains the following topics:

Invoice History

The Invoice history feature enables you to search for and view all invoices for a certain period for any account. Ensure that you have access to the accounts for which you want to view the invoices. Invoice History Records offer a consolidated view of all invoices for a given group. Information that is displayed includes the Invoice group and the status (successful or unsuccessful). Invoices can be viewed in HTML, CSV, or XML format, and provides the facility to email these invoices.

Invoicing and Financial Reporting

Once services are tied to accounts through a subscription, you can schedule these accounts for batch invoicing. You can process any rates, adjustments (general or SLA violation), and payments posted for the current billing period. An invoice group with global settings can be established to bill an associated list of accounts together in one instance at a scheduled future date. This list can be assembled at the time the group is created or determined dynamically during invoice execution. At the scheduled time, the invoice engine kicks off. The group is then placed into a queue for the accounting service to pick up for processing. Once selected, the engine queries the accounts that are associated with the invoice group. The engine then proceeds to generate an invoice for each of accounts.

The invoice states and justifies charges to users and business owners. These charges can be rolled up by a Business Unit organization. The stakeholders, at each level, can be given access to their IT cost information. Once processed, organizations can provide each Business Unit Web access to real time and historical chargeback invoice information. Business Units can also see detailed IT usage reports. IT owners can view actual spending versus budget and can determine the actual cost by business function. Providing such visibility into IT costs enables providing an organization with the necessary data for setting budgets and business planning.

Financial Reports

Several reports are available to help provide insight and visibility into IT. These reports include:

- Accounting Details - shows the accounting profile details for all accounts given the filter specification.

- Adjustment Details - displays details pertaining to any defined adjustments.
- Invoice Details - shows information that is related to invoicing such as dates, balance, and number of violations.
- Payment Details - provides a listing of payments posted against account balances.

Invoice Criteria for Accounts

For the invoice engine to process the account, the account must be:

- Included in the Account List associated to an active invoice group.
- Have the Billing Date field (in the Accounting profile) specified earlier than the date of the bill run.
- Have the status field (in the Accounting profile) specified.
- Have the Automatic Invoicing field (in the Accounting profile) set to Yes.
- Subscribed to a service under a valid state if the configuration is set for *Allow No Activity Invoices*.

Invoice Criteria for Subscriptions

A subscription must meet the following criteria before showing on an invoice:

- Chargeable items such as one time, daily, weekly, monthly, and installment appear when those periods for those charges are recognized.
- An element in the service option groups of a service is not specified to be Excluded From Invoice.
- Usage and transaction based charges appear when there have been metrics that are collected to represent use or transactions.
- Agreement and contract charges as defined through CA Business Service Insight appear on an invoice. The subscription is being charged as a one time, periodic or installment charge.

Invoice Groups

Administrators can create invoice groups. An Invoice Group provides the capability for grouping and scheduling accounts for future invoicing. When the invoicing process initiates, each group enters a queue to provide the accounting service the facility to retrieve and process the list of accounts in the group. This account list can be assembled and maintained manually or dynamically depending on the group type. The invoice groups generate invoices on a schedule or on demand and facilitate financial reporting.

Add a Static Invoice Group

Static Invoice Groups contain an account list that is comprised of accounts that have been manually assigned to it. Accounts assigned to a static invoice group cannot be assigned to any other group. Any accounts that are assigned to an invoice group remain unless explicitly removed or deleted from the system. You can further expand the account list for active groups by directly selecting and adding accounts to it.

Follow these steps:

1. Click Accounting, Invoices, Groups.

2. Click the Add button.

3. Complete the Invoice Group information:

   Note: Do not select Dynamic for this procedure because groups are static by default.

4. Complete the Accounting Profile information

   - Billing Cycle
     Determines the cycle when an account is invoiced.

   - Billing Cycle Interval
     Indicates the number of billing cycles that must elapse before an account is invoiced. This parameter is used with Billing Cycle.
     For example, to specify a quarterly billed account, select a monthly billing cycle, and specify 3 as the billing cycle interval.

   - Period Start Date
     Indicates when the accounting profile billing period begins. Choices include:

     - The date when department was created.

     - The date when the account was opened.

     - The current date that the accounting profile is created.

   - Period End Date
     Indicates when the accounting profile billing period ends.

   - Days Due Default
     Calculates the number of days past the date of the invoice that payment is due.

   Review the information on the Group Confirmation window. Click Next to confirm the information.

5. Click Add Accounts and use the shuttle box to move any accounts you wish to include in the account list. Verify that all selected accounts appear in the Accounts to Save column, and click OK.

6. Click Next and apply the appropriate Scheduler settings giving the billing date and the time zone.

7. Set the status to Active and click Finish.
   The Invoice Groups window appears, reflecting your newly created group.

Add a Dynamic Invoice Group

With Dynamic Invoice Groups, account lists are generated dynamically given a specified criteria that is stored as a Data Object. As new accounts are added and fall within that criteria, they are included in the account lists in that group. In essence, Invoice Groups can now be set to maintain and manage their own account lists.

Follow these steps:

1. Click Accounting, Invoices, Groups.
2. Click the Add button.
3. Complete the Invoice Group information and select Dynamic.
4. Review the Accounting Profile information and change the fields as necessary.
5. Review the information on the Group Confirmation window.
6. The Account List window appears empty since there are no associated criteria to assemble this list. Click Define Criteria and use the Account Criteria Builder to create a query to generate a list.
7. Click the Create Criteria button.
   - Save Last Executed Search
     Saves the last search that the Account Criteria search account mechanism executes.
   - Advanced Custom Search
     Enables the user to specify directly the where clause in SQL.
8. Once a criteria type is selected, two more fields are present:
   - Name
     Specifies the name to be associated to this query. (This value is stored as a Report Data Object.)
   - Comments
     Provides a field for more information.
9. Click Save when complete.
10. Click Next.
11. Apply the appropriate Scheduler settings giving the billing date and the time zone.
12. Set the status to Active.
13. Click Finish.
    The Dynamic Invoice Group has been created and is reflected in the Invoice Groups window. Click View Accounting Tasks to view the scheduled task.

Specify the Output Location

The default locations where invoices are saved to the hard drive are as follows:

- Accounts that receive invoices through email have a copy of their invoices that are stored in %ACC_HOME%\outbox\email.
- Accounts that receive invoices through regular postal mail have a copy of their invoices that are stored in %ACC_HOME%\outbox\postal.
- Accounts that receive invoices through fax have a copy of their invoices that are stored in %ACC_HOME%\outbox\fax.
- Accounts that the administrator wants to print internally have a copy of account invoices that are stored in %ACC_HOME%\outbox\printer.

Note: Specify \\ as a folder separator on Windows.

Instead of emailing a business unit an invoice directly, you can also to print or fax it. You can store the files in a directory on your hard drive. To do so, set the **Invoice Method** in the accounting profiles of all your customer accounts to *Postal* by default.

Manage Invoices

An administrator has several options to manage invoices that have already been generated for an account.

Follow these steps:

1. Click Accounting, Account Management.
2. Search for and select an account.
3. Click the Invoices tab.
4. Manage invoices, as follows:
   - View the invoice history
   - Edit an invoice (see page)
   - Perform an invoice on-demand (see page 3114)
   - View an invoice online (see page 3114)
   - Rollback an invoice (see page)

An invoice can be edited and line items can be added, modified, or removed. These line items include text, charges, adjustments, and payments.

Proration

Prorating is the process of dividing the cost of a subscription over the billing cycle period of an account. For example, Suppose that a monthly charge is $3000.00, and an account is on a Monthly billing cycle. An invoice is generated one day into the billing cycle with 30 days that are left in that month. The charge on the invoice is $100.00 and a description that specifies that the charge is for one day.

The accounting configuration enables you to specify that both online and batch process invoices are prorated:

- Only online invoices are prorated.
- Only invoices that are generated during the batch process are prorated.
- Or neither are prorated.

By default, both online invoices and batch invoices are configured to prorate charges.

Generate Invoice

An invoice can be generated to show the charges that are computed against the usage. If User Usage-Based billing was employed, the charges come from all users who are associated to the invoiced account.

Invoice On-Demand

On-demand invoicing enables an administrator to bypass the scheduled invoicing and instantaneously produce the current standing invoice for an account.

Performing an invoice on-demand produces the same results as if it had been processed as a scheduled bill run. A new invoice is generated for the current billing period and the accounting profile is updated.

Invoice Online

Online invoicing enables you to view your charges in real time with a web browser. An online invoice displays charges that an account has incurred since its last billing period, up to and including the current date. All the charges are computed in real time. Because these values can change, the invoice does not get persisted until the end of the billing cycle when the invoicing process runs.

Similar to on-demand invoicing, online invoices do not have to go through the same account query and verification: an invoice is requested to be viewed for that account regardless of the account status, billing cycle, or automatic invoicing. The criteria still apply for choosing or selecting which subscriptions show up on the invoice as charges, as with the invoice process.

You can enable or disable prorating charges when viewing your invoice online. Set the **Pro Rate Online** to Yes in the **Invoice Engine Configuration** of Accounting Configuration.

View Invoice Status

As the Invoice Engine processes the invoices, it logs alerts to the CA Service Catalog database. These alerts can be viewed by clicking Messages from the main menu.

Your Alert messages are listed in a table displaying the following parameters:

- Date/Time
- Type
- Source
- Computer
- Message

If a failure occurs during any one of the phases, the Invoice Engine logs a critical severity alert. The Invoice Engine then displays a message.

Rollback Invoice and Rollback Invoices Utility

Rollback invoicing enables you to invoice accounts from a previously billed period. This sequential rollback of invoices can reprocess an invoice to reflect any changes that are made to charges. To roll back to a previous invoice period, select the invoices to roll back from the Invoice History window of the account. Click Rollback. The period date, bill date, and account balance for the accounting profile is updated up to the period, invoices were rolled back. These Invoices and their associated transactions are permanently deleted from the system once the rollback is complete. Invoice On-demand can be used to regenerate any or all the invoices whenever necessary.

Note: The rollback works *only* for invoices that a successful invoice bill creates.

The syntax for using the rollback.bat (Windows) command follows.

rollback -g *groupname* -b *businessunitid*

- **-g *groupname***
  Specifies the name of the invoice group that defines the accounts whose most recent invoices you want to roll back. This parameter is required.

- **-b *businessunitid***

  Specifies the business unit ID of the accounts--in the named invoice group--whose most recent invoices are being rolled back. For Windows, the rollback.bat file is located in the USM_HOME\accounting\scripts folder.

Examples

The following command rolls back the most recent invoices for all accounts in the InternationalAccounts invoice group, in *all* business units:

```
rollback -g InternationalAccounts
```

The following command rolls back the most recent invoices for only the accounts in the InternationalAccounts invoice group that belong to the ForwardInc business unit:

```
rollback -g InternationalAccounts -b ForwardInc
```

Batch Printing

Service Accounting Component offers a Batch Printing option. You can create print jobs and print invoices individually or as a whole. A print job is a collection of invoices that have been grouped according to the specified credentials. After it has been created, the collection remains unchanged and its invoices can be printed as a whole or individually.

Follow these steps:

1. Click Accounting, Invoices, Batch Printing.
2. Click Add Print Job.
3. Enter the Name and Description.
4. Select the appropriate Invoice Group.
   An Invoice group is a set of accounts that you can run together in one instance. With the Batch Printing feature, invoice groups serve as an invoice filter. Only those invoices that are associated with the accounts in the selected invoice groups are included in this print job.
5. Select Services. Select all Services (the default) or further refine your number of invoices by filtering by Service name.
6. Select Billing Cycles.
   By including specific types of billing cycles, the number of invoices in the collection is once again decreased. This billing cycle is for the account, not at the Invoice Group.
7. Click Add.
   Once a print job has been added, the Batch Printing user interface can be used to manage them. Clicking a print job changes its details on the right. You can delete the selected print job or can reuse it.

Note: You can return the invoices in reverse order or filter the invoices by selecting a specific Item Status.

By default, 50 invoices are returned for each page. To adjust this number, specify the desired amount and click Refresh. Clicking an invoice launches it into a new window serving as a print preview tool. This tool can also check all invoices by item status. By clicking the Reverse Order check box, the checked invoices on the current page is printed in ascending order.

After each print item is completed, the status for each item is updated. The print job status appears at the top.

Manage Accounts

This article contains the following topics:

Administrators manage the accounts for a business unit. An *account* represents a corporate unit, a regional office, an individual user, or a logical group of them. CA Service Catalog applies charges to accounts.

If a user requests a service from the catalog, the product automatically creates an account for the user. The product also subscribes the account to the requested service.

Note: In Accounting Component, two digits appear after the decimal point for all supported currency units, including the Japanese yen. If your organization uses the yen, decide how to process the two digits after the decimal point because Yen is processed in whole numbers only. For example, you can decide to ignore the two digits after the decimal point or round them up or down to the nearest whole number.

Add or Edit Accounts

You can add an account so that you can bill it for services that it has requested or subscribed to. Typically, administrators edit accounts periodically as part of standard business unit operations.

Follow these steps:

1. Select Administration, Business Units from the main menu.
2. Expand the business unit tree and find the business unit that you want.
3. Click:
   - Add Account.
   - Account name of interest and edit it.
4. Complete or update the fields.

When you add an account, the Add a New Account page appears. You complete the fields on this page to configure the new account to meet the needs of your organization.

- **Opened Date**
  Specifies the date when the account becomes part of your organizational structure, in local time.

- **Status**
  Specifies whether the account is open or it is closed.

- **Primary Contact Information**
  Specifies the user ID of the primary contact for the account.

- **Location Information**
  Specifies information about the location of the account.

  Note: All CA products using the same MDB share location data. Therefore, be careful when you edit location information.

- **Account Settings**
  Specifies the list of users who are associated with this account. Usage-based billing references these users.

  Note: When a user creates a request for the first time, the Catalog system creates a request-related account for the user.

Close and Delete Accounts

Closing an account is typically a required task as you create and maintain accounts in your business unit over time. If the status of an account is Closed, you cannot:

- Enter a subscription for the account.
- Generate the invoices.
- Edit the Accounting Profile.

If you close an account, the associated accounting profile handles any residual accounting functions before the status is Closed. The status field moves from “Close Requested” to “Closed” once the outstanding charges and credits are processed for that period.

Follow these steps:

1. Review the effects of closing or deleting an account and verify that you want to proceed.
2. Run the final invoicing (see page 3109) for the account, if necessary.
3. Select Administration, Business Units, and expand the tree to display the business unit that contains the account that you want.
4. Click the account name.

5. Edit the account profile and change the status to Closed.

6. Delete the account. You can optionally close an account without deleting it.

Effects of Deleting or Closing an Account

Deleting or closing an account affects the subscriptions and requests for the account, as follows:

- **Subscriptions**
  The status of subscriptions for the account change to the default cancellation status (Pending Cancellation or Cancel).

- **Requests**
  The status of requested service options for the account change that is based on their original status as follows:

Original Status	New Status
Not Submitted	None. Request is deleted.
Submitted. An approval status, a fulfillment status, Pending Resource Assignment, or Resource Assigned	Cancelled
Completed	Default cancellation status (Pending Cancellation or Cancel) if Service Accounting Component is installed. Cancelled if Service Accounting Component is not installed.
Pending Cancellation or Cancelled	Same as Original Status.

Aggregation of Accounts

A business unit can designate an account to aggregate the charges and account balances for all other accounts within its scope. To do so, configure the accounting profiles for a set of accounts appropriately. Set the Aggregate option in the Accounting Profile to Aggregating Account to select the accounts for this consolidation. The aggregating account includes all accounts in the business unit hierarchy. Even sibling accounts whose Aggregate option is set to Yes are included in the aggregating account.

When the aggregating account is used to maintain the account balances of all accounts included in its aggregation, the aggregated accounts are typically zero balancing accounts. Set the Account Type option to Zero Balance in its Accounting Profile.

Post a Payment to an Account

Payments can be posted for an account to settle any outstanding balances.

Follow these steps:

1. Click Accounting, Account Management.

2. Click the Make Payment icon for the account for which you are posting the payment.

3. The Payments List and Payment Details page appears. From this window, you can perform the following actions:
   - Add payments to the Payments List by completing the payment details and clicking the Add to List button.
   - Modify Payments in the Payments List by selecting the payment, making your modifications and clicking the Update Payment button.
   - Delete Payments in the Payments List by selecting the payment and clicking the Delete Payment button.
4. The Business Unit, Account Name, and Account Balance are populated in the Payment Details window.
5. Complete the mandatory Payment Details and any optional fields.
6. Click Submit Payment.
   The payment is processed.

Manage Subscriptions

This article contains the following topics:

A *subscription* is a Service Accounting Component to identify the assignment of a service by an administrator to an account. Once the service is activated for the account and the subscription is active, the charges are calculated for each invoice period. If a subscription is cancelled, the service is deactivated as soon as all outstanding charges are processed. In addition, subscriptions can be suspended for any amount of time, during which no charges are incurred.

Subscription Types

Subscriptions are possible *only* when Service Accounting Component is installed.

Accounts can have *physical* subscriptions, *data mediation logical* subscriptions, or both types of subscriptions.

- A physical subscription includes one or more service options in a service. A physical subscription results from one of the following conditions:
  - When a service that a user explicitly requests is completed or a request that is only submitted but not completed. When a service is completed, it results in *request-based* subscription.

- The business unit administrator assigns subscriptions to accounts, which are based on certain criteria, such as business needs. Such subscriptions are *account-based* subscriptions.

- A data mediation logical subscription is virtual; it includes no physical subscription records. Rather, it is a logical mapping and an aggregation mapping. This type results from an administrator using the Data Mediation component to aggregate usage data. In the Invoice component, the usage cost for this subscription is shown when data is aggregated. Considering data mediation logical subscriptions is important when you implement usage-based billing.

A single account can have one or more subscriptions of either type or both types. If an account has both a physical subscription and a data mediation subscription, the physical subscription *always* overrides the data mediation subscription.

On the Existing Subscriptions window, each applicable subscription type appears in the Currently Subscribed column. However, data mediation logical subscriptions appear *only* if no physical subscription exists.

Subscription types are cancelled when:

- A physical subscription (S) is canceled when you cancel the subscription for an account.
- A request subscription (R) is canceled when you cancel the request for an account.
- A Data Mediation logical subscription (D) is not shown when an administrator unloads or aggregates usage data again.

Administrators manage subscriptions by selecting Accounting, Account Management, clicking an account name, and clicking the Subscriptions tab. The subscription process is primarily an administrator task. But end users are given read access to active subscriptions for their accounts.

The Administration, Configuration, Subscription Configuration menu option enables Administrators to change the way future subscriptions of an account are handled.

Create a Physical Subscription

You can create a physical subscription.

Follow these steps:

1. Select Accounting, Account Management.
2. Click the account name for which you want to add a subscription.
3. Click the Subscriptions tab.
4. Select the service to which you want to subscribe.
5. Click the Subscribe link.
6. Click Yes.
   The physical subscription is added.

Enable Notes in Physical Subscriptions

To add notes to a physical subscription, you first enable the related notes feature.

Follow these steps:

1. Click Accounting, Configuration.
2. Click Subscription Configuration.
3. Click the Edit icon.
4. Check "Enable Subscription Notes."
5. Click Update Configuration.

The feature has been enabled and you can add notes to a physical subscription.

Add Notes to a Physical Subscription

After you have enabled notes in physical subscriptions, you can add notes to physical subscriptions.

Follow these steps:

1. Click Accounting, Account Management.
2. Click the account name for which you want to add notes.
3. Click the Subscriptions tab.
4. Click the Existing Subscriptions button.
5. Locate and expand the subscription for which you want to add notes.
6. Click the Notes link for the item of interest.
7. Click Save Notes.

The notes are added to the selected physical subscription for the selected account.

Suspend a Physical Subscription

You can *suspend* a physical subscription (see page 3120) only for rate items that have a periodic billing cycle. You can cancel a physical subscription (see page 3123) for all other rate items.

Follow these steps:

1. Click Accounting, Account Management.
2. Click the account name for which you want to suspend the subscription.
3. Click the Subscriptions tab.

4. Click the Existing Subscriptions button.
5. Locate and expand the subscription that you want to suspend.
6. Click Suspensions.
7. Enter the start and end dates for the suspension or select "Indefinite Suspension."
8. Click Add New.
9. Click Close.

The physical subscription is suspended for the selected account for the period indicated.

Cancel a Physical Subscription

You can *cancel* a physical subscription (see page 3120) for all rate items except ones that have a periodic billing cycle. For such rate items, you can suspend a physical subscription (see page 3122).

Follow these steps:

1. Click Accounting, Account Management.
2. Click the account name for which you want to cancel a subscription.
3. Click the Subscriptions tab.
4. Click Existing Subscriptions.
5. Remove the subscription for the service.
6. Click Save.
   A message appears asking you to confirm the subscription changes.
7. Confirm or cancel the changes.
8. Verify that the physical subscriptions were successfully updated.

You can set subscription options that apply to services, service option groups, and service option elements. By default, these settings apply to all accounts. In addition, however, you can specify custom settings for one or more selected accounts.

Follow these steps:

1. Click Accounting, Configuration.
   The Accounting Configuration page appears. On the left, in the Menu under the main menu, Options is selected by default. On the right, links appear for each category (subset) of the accounting configuration options.
2. Review the name of the current business unit. To manage subscription options for a different business unit, change the business unit.

3. Click Subscription Management in the Menu on the left under the main menu.
   The Subscription Decision Tree appears on the right, replacing the links for the accounting configuration categories.

4. Decide whether to update subscription options for all accounts in the business unit or only one more selected account. In either case, decide whether to update subscription options for a specific service, service option group, or service option element.
   To help you decide, review the following order of precedence:

   - A setting for a service option element overrides the setting for the service option group to which it belongs.
   - A setting for a service option group overrides the setting for the service to which it belongs.
   - A setting for a specific account overrides the corresponding setting under "All Accounts."

5. Perform *one* of the following actions:

   - Click All Accounts to apply your updates to every account in the business unit.
     The Services and Service Option Groups nodes appear, under all accounts.
   - Click Apply to Individual Account to apply the updates to only one or more selected accounts in the business unit.
     The Select Accounts dialog appears. Select the account or accounts you want and click OK.
     The Services and Service Option Groups nodes appear, under the selected accounts.

6. Click the Service or Services node (whichever you want to update), under either All Accounts or a selected account.

7. Drill down the Services and Service Option Group node to reach the subscription management options (see page 3125) of interest. You can update the options for services, service option groups, and service option elements.

   Note: Optionally specify *no* value for Bill In Advance field or the Effective Dates And Bill Dates field when you create an account. In that case, the system applies default settings. So, the account does *not* appear in the Subscription Decision tree. For information about creating accounts, see the Manage Accounts (see page 3117) section.

8. Update these options as needed and save your changes.

You have managed subscriptions. These settings apply to any sub business units of the business unit that you are updating. If a business unit has sub business units, it has its own configuration settings.

Subscription Management Options

To manage subscriptions (see page 3120), you specify the subscription management options, using the Subscription Decision Tree. Specify separate settings that apply to all either *all* accounts in the business unit or to selected accounts *only*. In both cases, use the tree to set the following options for individual services, service option groups, or service option elements:

- **Effective Dates and Bill Dates**
  Specifies when billing begins after an account subscribes to a service option element. Select *one* of the following options:
  - **Bill Date begins on the Effective Date**
    Begins billing the account on the date the subscription is made.
  - **Specify a Bill Date separate from the Effective Date**
    Begins billing the account on a specific date, regardless of the subscription date.
  - **Specify a Bill Date relative to the Effective Date**
    Begins billing the account that is based on the *complex* option you specify, relative to the subscription date. An example is “the first day of the month of the subscription.”
  - **Specify a Bill Date offset from the Effective Date**
    Begins billing the account that is based on the "before and after" option you specify, relative to the subscription date. An example is “two months after the subscription date.”
- **Bill in Advance**
  Specifies whether a subscribing account is charged in advance of a service being rendered. Select *one* of the following options:
  - **Do not bill in advance**
    Bills the account when the service is rendered.
  - **Specify how far in advance the charge should be billed**
    Bills the account the specified number of periods in advance.

  The billing period is the billing period of the service option element being subscribe*d to*. For example, suppose that a service option element specifies a Unit Cost of $10 with a Billing Cycle of Periodic, a Periodic Type of Monthly, and a Periodic Type Interval of 1. If this setting is 3, then a subscribing account is billed $30 on the first invoice and each interval invoice, rather than $10 per month.

Manage Exchange Rates

Service Accounting Component supplies the Accounting, Configuration, Exchange Rates table. By default, this table displays exchange rates for the current time period. You can also view any previously defined exchange rates for earlier or future periods.

Using this table, you manage exchange rates for the currencies that are used in your implementation. The exchange rates are relative to the US dollar. The Catalog system uses these exchange rates to produce invoices for each account. The invoices are produced in the currency of the business unit to which the account belongs.

All exchange rates are relative to the US dollar. When you convert from one currency type to another, the system first converts the catalog amount to US dollars. Next, the system converts the amount to the currency type of the account.

By default, the exchange rates for all currency types are set to 1.0. This setting means that the exchange rate for each currency type relative to the US dollar is 1.0.

Updates to exchange rates apply to the *entire* system. You *cannot* specify different exchange rates for different business units.

You can update exchange rates in Service Accounting Component when the official exchange rates change. Updates to exchange rates apply to the *entire* system. You *cannot* specify different exchange rates for different business units.

Follow these steps:

1. Click Accounting, Configuration.

2. Click Exchange Rates in the Menu on the left under the main menu.
   The Exchange Rates table for the current date range appears on the right. The table lists the currency name, symbol, date, exchange rate, and so forth. By default, The table for the current time period (the previous month) appears.

3. View the exchange rates for the currency that is defined in your system.

4. (Optional) Edit exchange rates for the current time period to provide a regularly scheduled update.

5. (Optional) Delete an exchange rate for a date range.

   Important! Deleting *all* exchange rate entries for a currency name deletes that currency name from the Exchange Rates table completely! You *cannot* use the GUI to restore a deleted currency name. Therefore, use caution when deleting exchange rates from the table.

6. (Optional) Delete a currency name from the exchange rate table if your implementation does not need the currency.

   Note: Delete currency names with caution, because you *cannot* use the GUI to add a missing or deleted currency name.

7. (Optional) Add an exchange rate for a date range to provide a periodic update or to prepare for the start of the next billing period.

> **Note:** You *cannot* add a new exchange rate that overlaps the same date range as any existing exchange rate.

Manage Budgets and Plans

This article contains the following topics:

Implementing a successful budgeting process is a primary key to achieve organizational business objectives. Budgets help IT managers evaluate the performance of a business unit though comparison analysis of actual expenditures against budgeted amounts. These findings can aid in justifying IT costs or identifying why expectations have not been met. In addition, this information can be used to establish new goals and discovering the means to reach them through planning.

Through the Budget and Planning module, a financial manager can set up period budgets for business units and their services. At the end of each fiscal period, a variance report evaluates the differences between actual and budgeted costs. This information can be then used to help identify the root cause for areas of inefficiency.

Manage Fiscal Periods

Fiscal Periods can be user-defined for any time period to represent an accounting period. Service Accounting Component allows for the definition of monthly, quarterly, or yearly fiscal periods. Once defined, these periods are used in Budget and Planning worksheets when defining budgets or setting costs for services. These periods are also used for data mediation when selecting a period for aggregation.

By default, you create monthly fiscal periods for the current year, which is based on your installation date. You also use fiscal periods to view Data Mediation aggregations and to manage budgeting and planning.

You cannot create different fiscal periods for different business units. *Only one* set of fiscal periods applies to all business units.

Use Worksheets

Worksheets are used to capture budget and cost totals for services. A Service Worksheet can be used to set budgets, unit cost, or total cost for services across fiscal periods. Costs can also be pooled. Then, use the Service Worksheet to set service costs by tracing pooled activities to the services that consume them. A Pool Worksheet is used to establish these pooled costs. A cost pool is comprised of contributing cost elements whose sum makes up the total cost of the pooled activity. A percentage of this total can then be allocated among the services in the Service Worksheet.

Follow these steps:

1. Click Accounting, Budget and Planning, Worksheets.
2. Click Change Business Unit and select a different business unit, if necessary.
3. Complete the Worksheet Options:
4. Click View Worksheet.

The services that are presented in the worksheet contain any chargeable service option group elements whose Budget option is selected. For the elements that employ a Cost Type of either *Allocated Cost* or *Standard Cost*, the values that are entered in the worksheet determine the cost of the service element.

For the *Allocated Cost* setting, the value represents the total cost of the service element to be allocated back to Business Unit accounts. The associated Allocation Method specification determines the distribution of that cost. For example, suppose that the method is set to Distribute by Subscription. Then, the total cost of the chargeable element is divided by the number of subscriptions to it.

The *Standard Cost* option, is used to define a predetermined unit cost for the service option group element. This cost can be used to assign a rate to a service that can vary from period to period, or as the expected costs defined in a budget. For example, suppose that you have to pre-define a set of unit costs for a particular period and then change. Worksheets are tools that enable these service rates to change over time. Worksheets allow the definition of budgets for service during specified fiscal periods. The values that are defined in this instance are not used in the cost calculation of a service option group element. But these values are used instead in reporting variance between budgeted and actual amounts.

Create a Set

Sets enable you to define related financial and quantitative values. For example, you can use sets to represent various types of budgets, especially when you are initially creating these budgets. You can also link costs to services. Sets can be defined to represent a unit cost or total cost of a service. These types of sets are typically associated with a service during service definition when you employ a Cost Type of *Allocated Cost* or *Standard Cost.*

Follow these steps:

1. Click Accounting, Budget and Planning and click Sets.
2. Click the Add Set button.

3. Complete the following information:

   - **Name**
     Specifies the set name.

   - **Description**
     Indicates the optional text area for a description.

   - **Status**
     Specifies whether the associated worksheet values can be modified. Choices include Locked or Unlocked. Once a set is locked, values are read-only in the worksheets until the Status is changed to Unlocked.

   - **Source**
     Provides for further classification of the associated values. Choices include:

     - Allocated Cost - used when defining the total cost of a chargeable service. Once this type of set is bound to a service, an associated Allocation Method can be selected to employ a means of distributing the cost.

     - Standard Cost - used when defining the total unit cost of a chargeable service. Once this type of set is bound to a service, a predetermined service cost can be set for each period.

     - Actual Units - used to attribute unit quantities to services.

4. Click Add New Set.

Create a Cost Element

A Cost Element is a resource that is used to subdivide costs corresponding to the consumption of a particular service. The amount is paid for a resource that an activity consumes and is included in a cost pool.

Follow these steps:

1. Click Accounting, Budget and Planning, Cost Elements.

2. Click the Add Cost Element button.

3. Complete the fields for this cost element.

4. Click the Update button.

You have created a cost element.

Create a Cost Pool

A Cost Pool is the grouping of all cost elements that are associated with an activity carried out by an entity. The cost pool can be used to identify the cost of any main activities in providing a service.

Follow these steps:

1. Click Accounting, Budget and Planning and click Cost Pools.
2. Click the Add Cost Pool Button.
3. Complete the fields on the dialog:
   - **Name**
     Specifies the cost pool name.
   - **Type**
     Specifies how Cost Pool totals apply to service costs.
4. Click Add New Pool button.

Assign Cost Elements to Cost Pools

Once the main cost pools have been defined, a total cost of each cost pool can be calculated. First, the activities that are related to each cost pool are identified and assigned to the appropriate cost pool. To trace the expenses to each cost pool, identify the cost drivers for each cost element.

Follow these steps:

1. Go to Accounting, Budget and Planning, Cost Elements.
2. Select the Cost Elements to assign to a cost pool.
3. Click the Assign to Cost Pools button.
4. Assign the pools with cost elements by selecting the corresponding check-box.
5. Click the Save Assignments button.

Assign Activity Based Costing to Services

Activity Based Costing (ABC) is a process of assigning costs to services and is used as a tool for planning. The method aims initially to identify and categorize the main operating activities within an organization. Once defined, the costs attributable to these activities are assigned to cost pools. The cost pools are then allocated back to services based on how the service consumes the activity. The steps that follow outline the ABC process:

- Typically, an organization can be broken down into a set of succinct activities that accomplish business processes. The cost pools are created to assemble all cost elements that are related to each of these activities.
- Once the activities have been identified, the principle causes of the costs for each activity are identified. These expenses are categorized by establishing cost elements.
- Add the cost elements. Then, ensure that the cost elements are related to their corresponding cost pools through cost pool assignment.
- The Pool Worksheet applies values to the cost pools based on the expense attributed to each associated cost element. Go to Accounting, Budget and Planning, Worksheets and use the Pool Worksheet option. Then apply these values.

- The Service Worksheet is used as activities are traced to services. The associated pooled costs are allocated to services based on their level of consumption of activities. The Service Worksheet is used to capture these amounts, which can be fixed or a percentage of the pool total.

- Only services that contain chargeable service option group elements are eligible to appear on the Service Worksheet. Check the Budget properly in the service option group element definition dialog when defining a service. In addition to having the worksheet values applied in invoicing calculations, a cost type of *Allocated Cost* or *Standard Cost* must be selected for the service element.

- Invoices are generated for accounts that are subscribed to these services. These invoices show an expandable breakdown of services by cost pools and cost elements.

Manage General Adjustments

Adjustments are credits or debits applied to services, individual charges of a service option group or service option element, and SLA violations. These adjustments are a fixed dollar amount or a percentage. Applying an adjustment to a business unit applies to all accounts within the selected business unit.

The General Adjustment properties appear on the Adjustment Information window.

- **Adjustment For**
  Specifies the account number of the account being adjusted.

- **Adjustment Type**
  Specifies whether the adjustment is a fixed amount or a percentage. More fields appear depending on the option you select in **Adjustment Type**.

Administrators can apply general adjustments either globally to all accounts or individually to a specific account. Applying general adjustments globally are required when a general adjustment applies to all accounts. For example, global credit to all accounts to cover an accidental overcharge of a specific fee in an earlier bill.

Follow these steps:

1. Select Accounting, Adjustments.
2. Select General from the side menu.
3. Click the Add General Adjustment button.
4. Complete the fields.
5. Click OK.

If only one account requires general adjustments, use the following procedure to apply the adjustments to the account.

Follow these steps:

1. Select Accounting, Account Management.
   Click the Add Adjustments icon (+/-) associated with the account.

2. Complete the fields.

3. Click OK.

Manage QoS SLA Violation Adjustments

Request Service Level Agreements (SLAs) are a feature of CA Service Catalog. Quality of Service (QoS) SLAs are available only if CA Service Catalog is integrated with CA Business Service Insight. The terms request SLA and QoS SLA are used to distinguish between the two types of SLAs.

Administrators can apply violation adjustments for QoS SLAs either globally to all accounts or individually to a specific account.

Note: To use SLA violation adjustments, CA Service Catalog must be integrated with CA Business Service Insight. For more information, see the Integrate CA Service Catalog with CA Business Service Insight (see page 3441) section.

You specify the QoS SLA Violation Adjustment properties on the Add SLA Violation Adjustment window.

- **Adjustment For**
  Specifies the account number of the account being adjusted.

- **Adjustment Type**
  Specifies whether the adjustment is a fixed amount or a lookup. A lookup refers to a tiered service option group based on the total violations of an SLA package, agreement, or agreement value.

- **Lookup Service Option Group**
  Specifies the tiered service option group to use with the lookup adjustment types. The selected item is used to help calculate the adjustment amount.

- **Per Violation**
  Specifies the fixed amount to adjust for each violation.
  This option applies *only* when the Adjustment Type is Fixed Amount.

- **Aggregate Violations on Invoice**
  Specifies that each violation appears as one line item on the invoice.
  This option applies *only* when the Adjustment Type is Fixed Amount.

- **Tier Type**
  Specifies the type of lookup into the tiered service option group, as follows:

- **Lookup**
  Selects the first matching tier.

- **Variable Lookup**
  Selects all tiers up to and including the matching tier.

Applying QoS SLA violation adjustments globally is required when an SLA violation affects all accounts. For example, a system-wide outage resulting in no services to all accounts for a period that exceeds the downtime that an SLA allows.

Follow these steps:

1. Select Accounting, Adjustments.
2. Select SLA Violation.
3. Click the Add SLA Violation Adjustment button.
4. Complete the fields as required.
5. Click OK.

If only one account requires QoS SLA violation adjustments, use the following procedure to apply the adjustments to the account.

Follow these steps:

1. Select Accounting, Adjustments.
2. Select SLA Violation.
3. Click the Add SLA Violation Adjustment button.
4. Complete the fields on this window as required.
5. Click OK.

Manage Data Mediation

This article contains the following topics:

- Repository Agent (see page 3138)
- Data Import Frequency (see page 3139)

Data Mediation lets you import usage event data from various external sources. Data Mediation uses the process of ETL (Extraction, Transform, and Load). You can use this process to transform operational data into event data to support billing, and reporting. After the data has been imported, other CA Service Catalog components can use this data. Data Mediation is useful when batch operational data from a source other than CA Service Catalog is available. Also, the requirements allow for historical rather than real-time data.

Data Mediation supports the following types of data feeds:

- Delimiter Separated File
- Fixed-Length File
- Database Import includes Database Table Import and Advanced Database Import.

When the external usage data is imported through Data Mediation as File Type data feeds, it is transformed into a flat file. The file is uploaded to the \datamediation subdirectory of the filestore location. By default, the filestore location is the USM_HOME\FileStore\ directory of the Catalog Component computer that you are using. To view the location of the imported flat files, select Administration, Configuration, File Store Information. Use the filestore location to find and view the flat files in the datamediation subdirectory. The value can be a local directory, or it a directory on another Catalog Component computer.

Important! The folder name *FileStore* is case-sensitive. Therefore, use the correct case in path names and all other programmatic references.

Depending on the completeness of the usage data, the data is loaded into the database into a *reference table*, a *temporary data table, or* a Data Mediation *event table*. Define the mapping between external data feed fields to database field types before importing data. The field definitions also contain the Driver Validation Rules which are enforced upon data import and filter irrelevant data.

Data Summary

During Data Mediation design, determine where to summarize data. For example, if your business objective is to measure average CPU usage over a month for reporting. If the data source system has running information and can determine the average over the period, then use a single, summarized data point rather than a data series of five-second samplings over the same time period. This data point serves to use computer and human resources (CPU, bandwidth, maintenance) efficiently. The best practice is to summarize information early in the process.

Data Aggregation

Data Aggregation is the gathering and expressing of data in a summary form. Data from the reference tables or temporary data tables are normalized into a set of Data Mediation event tables.

Aggregation processes one event at a time. Normalization or initial aggregation is customized using a SQL query and is specified in the Data Mediation profile. Data that is stored in Data Mediation event tables represents complete usage event data. All data from Data Mediation event tables is aggregated. The results are loaded into the set of metric-based result tables. These metric requests are processed for the Service Accounting Component rating engine. Budgeting information and billing transactions are created based on the resulting data that is contained within the metric result tables.

Imported usage data by defined profiles is processed for Service Accounting Component through Data Aggregation. The usage data is imported using the Metric Data Profile. Before usage data is aggregated, the data must be normalized into a common format. The common format consists of fields that are known as Server Mandatory fields. Five Default Server Mandatory Fields are required in every record to qualify as complete event usage data.

Service Accounting Component creates billing transactions that are based on the event results. The data that is imported through Data Mediation is aggregated based on the fiscal period. The data can be aggregated for a defined fiscal period or for all fiscal periods. Aggregation produces results by server mandatory fields, for example, by account, service offering, metric, and fiscal period.

When an aggregation is run for a defined fiscal period, the transactions of the previous aggregation are deleted. Then, new transactions are created to reflect the data being imported. This result is due to the transactions being rolled back on re-aggregation. The new transactions are created as part of the aggregating again. Therefore, regenerate the invoices to capture these new transactions, and show the associated charges.

Note: You can use Invoice groups and then generate your invoices in batch mode. You can also bill for two different data sets that are imported at two different times. You can do an aggregation after the first one is imported and then aggregate again after the second data imported. Generate the invoices *after* you verify that all the data for that fiscal period is valid.

The Data Mediation component aggregates data as follows:

- Generates usm_mr_itemp_XXXXXX data from the external files and databases.
- Generates usm_mr_ievent_XXXXXX data from the usm_mr_itemp_XXXXXX data based on the SQL aggregation specified in the Data Mediation profile. The XXXXXX values are sequential numbers that the system generates.
- Generates usm_mr_iresult_YYYY data from the usm_mr_ievent_XXXXXX table that is based on the built-in aggregation logic. The YYYY is the internal metric ID for the event that is specified by the aggregation.
- Generates transactions for the accounts that are based on the usm_mr_iresult_YYYY data that is created.

You can run the aggregation process any number of times for a fiscal period to reflect the latest imported data.

Custom Fields

You can use custom fields to facilitate aggregation logic. For example, business rules can indicate that the processing of rows in a data set varies based on external value.

You can also use custom fields to maintain legacy information as part of a user interface customization. For example, a charge can have a value in an external system that is used to perform cross referencing.

Aggregation Status

The possible data aggregation status values are as follows:

- Load files only -- New data has been imported since the last aggregation. Aggregation is not currently occurring.
  Numeric code: 0
- Importing -- Data is being imported and initial aggregation logic in profiles is being executed. In this phase, any data in reference tables or temporary data tables is being placed into Data Mediation event tables.
  Numeric code: 1
- Aggregating -- Aggregation is being performed. DC Importer is performing aggregation. In this phase, the data in Data Mediation event tables is being stored into the metric results tables.
  Numeric code: 6
- Profile Error -- An error occurred while executing initial aggregation logic contained in profiles. Aggregation is stopped. Go to Profile Management to locate profiles that are in error. Profiles in error are denoted with Error in the Import Status column.
  Numeric code: 8
- Profiles Pending -- A profile has not been defined. Aggregation is stopped. Profiles containing usage event data must be defined.
  Numeric code: 7
- Waiting for CA Service Accounting -- The Service Accounting Component rating engine is creating billing transactions.
  Numeric code: 5
- Aggregation Error -- A severe error occurred during aggregation.
  Numeric code: 4
- Aggregation Complete -- Aggregation completed successfully.
  Numeric code: 3

Data Management

Data Management lets administrators manage data sets imported into the CA Service Catalog by using the following functions:

- **Unload Checked**
  Unloads (removes) the data from the data mediation tables. The associated charges are removed the next time aggregation occurs.

  Note: You do not need to roll back the invoices that used the data that this data set provides before unloading and aggregating again,

- **Re-import Checked**
  Reloads imported data sets and effectively resets the aggregation flag of the imported data set to "not aggregated." The associated charges are recalculated the next time aggregation occurs.

- **Archive Checked**
  Archives the selected data set. The status of the data set is changed to Archived.

  Note: Archived data sets cannot be unloaded or re-imported after archiving. Use archiving only if required.

Note: Aggregation results for a period appear on the Aggregation Status page, although data for that period has been unloaded and aggregated again.

Reference Data

Reference data is often required to facilitate the transformation process. An example is the need to translate account codes from a legacy system to match accounts in CA Service Catalog. In such a case, you can match accounts in the following ways:

- You can customize the user interface to add a field for the legacy account code in CA Service Catalog. This option is best to use when the mapping information is static and can be maintained through data entry.
- You can use a reference table. This option is required if the mapping data is dynamic and it is maintained outside of CA Service Catalog.

Data Import

After creating a data mediation profile and defining the data feed and structure of the external data, import the data. You can import database profiles as needed and can schedule them to occur later.

You can import data from a file or from an Ingres, SQL Server, or Oracle database table. Data is loaded into database tables when imported.

The database tables that the Data Mediation creates include the following types:

- **Reference tables**
  Contains reference data to be used as lookup tables (usm_mr_iref).

- **Temporary tables**
  Contains partial usage event data, meaning that all server mandatory fields are not present, implying that normalization is necessary (usm_mr_itemp).

- **Event tables**
  Contains complete usage event data (usm_mr_ievent).

- **Metric result tables**
  Contains aggregated event data (usm_mr_iresult).

Data Profiles

Every data profile has one data source. The data profile contains a definition of the data feed of the external data. The profile also contains the initial aggregation logic in the form of a SQL statement. This initial aggregation logic is specified during profile definition. A data source can consist of an ASCII file (fixed-length, or delimited) or a database query. For database queries, multiple physical database resources (tables, databases) can be combined into a single result set. The resulting set is considered a single data source.

One set of fields exist per profile. Consider the size of the returned dataset. Determine how to deal with portions of the total data so that you can perform loads, unloads, and aggregations in smaller sets.

Unique initial aggregation logic (normalizing and aggregating raw data) indicates a unique profile. However, given the same data source and fields you can copy an existing profile to create a profile. You do not have to redefine the source information. For example, consider the situation when given a single data source, aggregation logic varies based on some field value.

The types of profiles for Data Mediation are as follows:

- Metric Data -- Usage event data for the cost allocation process of Service Accounting Component. This type of profile loads data into temporary or event tables that are based on the completeness of the usage event data.

- Reference Lookup Data -- Data contains reference data for lookup purposes. Data is loaded into reference tables.

If necessary, usage event data can be normalized or aggregated, preparing it for the aggregation process and cost allocation process. To do so, use an SQL query or procedure that is defined in the profile.

Repository Agent

The CA Service Repository Agent automates the process of importing usage data. The usage data is stored in Delimiter Separated File or Fixed-Length File format. The CA Service Repository Agent is also known as Data Mediation Data Repository Agent. The repository agent is installed as a service named CA Service Repository Agent during the installation of Catalog Component.

The Repository Agent imports usage data files into the database in the following ways:

- The agent can be configured to read files from an FTP server. The files are automatically copied from the FTP server locally and processed based on associated Data Mediation profiles.
- An external system can locally copy the usage data files. The usage data files are then processed based on associated Data Mediation profiles.
- A Data Mediation profile can be generated externally as an XML file. The XML file can then automatically be loaded and used to process a corresponding data file where both the profile definition XML file and the data file are copied locally by an external system.

Note: The integration with CA NeuMICS uses this technique.

Data Import Frequency

Decide the frequency of data imports. To determine the frequency, consider your reporting requirements.

For example, consider the following situations:

- If an invoice, an SLA report, a metric report, or a custom report is run daily, then the Data Mediation feed frequency must also be daily.
- If the data is required for a monthly bill run, then a monthly feed can be appropriate.
- If millions of records are loaded monthly, import subsets daily to spread the processing. You can also minimize the end-of-month window. Another benefit of this approach is to avoid having to unload and reload larger data sets when changes are necessary. The size of the data set does not affect the commit size in the database tables. The best practice is to perform commits in small batches, rather than after the entire data set. This approach minimizes lock contention and log file growth.

Implement Data Mediation

This article contains the following topics:

Administrators use data mediation functions to import, aggregate, and summarize data from external sources. Administrators use the results to help calculate costs for usage-based billing and to generate reports.

Important! As a prerequisite, verify that your fiscal period has been defined to fit your business model.

Step 1 - Define Data Fields

Define the Extraneous fields from an external data feed to map the external data feed field to a database field type. You can also define field definitions when creating a profile. When creating a profile, you use field definitions to define the structure of the external data.

When usage data is imported, it is uploaded into the database. During data import, data validation checks are performed. The invalid records are not uploaded into the database. Before data is imported into the database, you can apply rules to filter out erroneous or irrelevant data. The field definitions hold the definition of these validation rules, specifying a validation rule on each column of data imported.

Follow these steps:

1. Select Accounting, Data Mediation.
2. Click Add to define a new field.
3. Specify the information in the Define a Field window. The following fields need explanation:
   - **Mandatory Types**
     - None - indicates that both the server and the client are not mandatory.
     - Server Mandatory - indicates that the field is required for data mediation aggregation to occur. The absence of these fields results in a profile error.

     Client Mandatory - includes the field in profile definitions.
   - Both - indicates that both the server and client are mandatory.
   - **Default:** Server Mandatory
4. **Check type**
   Specifies the check type, if applicable.
   - **Default:** No check
5. (Optional) Specify a driver validation rule:

- **Not Empty**
  Specifies that the field value must not be empty.

- **Range**
  Specifies that the field value falls within the specified range.

- **Lookup**
  Specifies that a field value exists in a database table field.

- **Lookup Replace**
  Specifies a replacement value, if the value in the field exists in the specified database table field.

These validation rules are enforced when usage data is imported. If the driver validation rules are violated upon import, a kickoff report is generated. The report is available through the Data Management user interface.

6. Click Submit.
   The data fields are defined.

Default Server Mandatory Fields

Normalize the usage data into a common format that data mediation can understand before it is aggregated. The aggregation results in an error if the following server mandatory fields are not included:

- **CA Service Account Number**
  Associates a data record to a Service Accounting Component account ID.

- **Event ID**
  Associates a data record to an event (Event ID).

- **Event Time**
  Associates a data record to a fiscal period (Time Stamp).

- **Metric Value**
  Associates a data record with a metric value.

- **Service Code**
  Associates a data record with a service offering (Service Offering ID).

Note: Formatting data to include all server mandatory fields before data import is unnecessary. Data Mediation features complex data mapping mechanisms, such as validation and normalization, which help the administrator include server mandatory fields.

Step 2 - Create a Profile

Profile management is a definition of the data feed of the external data. The profile also contains the initial aggregation logic in the form of an SQL statement.

If necessary, usage event data can be normalized or aggregated, preparing it for the Data Mediation's aggregation and cost allocation processes through a SQL query or procedure defined in the profile. This profile feature helps normalize the data to a common format understood by Data Mediation.

You can create a profile to define the data feed of the external data.

Follow these steps:

1. Click Accounting, Data Mediation, Profile Management.
2. Click Add New Profile.
3. Select the Data Type:
   - **Metric Data**
     Specifies the usage event data for the cost allocation process. This type of profile loads data into temporary or event tables based on the completeness of the usage event data.
   - **Reference Lookup Data**
     Data contains reference data for lookup purposes. Data is loaded into the reference tables for data mediation.
4. Select the Import Format.
5. Click the Define Fields button.
   A profile template window appears for field definitions.
6. Enter a unique name for the profile you are creating. Define the fields for the profile.
7. Click Save.
   The profile is created.

Note: You can optionally edit or delete profiles. But you cannot edit profiles after they have been aggregated. If the Import Status is “Processed,” you cannot edit the profile. You cannot delete data profiles after they have been aggregated.

Step 3 - Create an Application Metric

The Data Mediation component uses metric packages to measure usage of an application.

Follow these steps:

1. Add, edit, or delete event information, as follows:
   a. Select Accounting, Data Mediation, Application Metric, Event.
      The Event List window appears.
   b. Click Add to create an event or click Edit to modify an existing event.
      The Event Detail window appears.

c. Specify all details about the event and click Save.

2. Add, edit, or delete metric information, as follows:

   a. Select Accounting, Data Mediation, Application Metric, Metric.
   The Metric List window appears.

   b. Click Add to create a metric or click Edit to modify an existing metric.
   The Metric Detail window appears.

   c. Specify all details about the metric and click Save.

   d. Link or unlink related events, as described in the next step.

3. Link or unlink related events for a metric, as follows:

   a. Ensure that at least one event is associated with each metric.

   b. Click Associate Event.
   The Metric Name: *metric name* window appears, displaying all events that are not already associated with the metric.

   c. Select the events that you want to associate with the metric.

   d. Click Associate Event. The selected events are linked and therefore appear in the Associated Events list.

   e. Select the events that you want to disassociate and click Disassociate Event.

4. Add, edit, or delete application information, as follows:

   a. Select Accounting, Data Mediation, Application Metric, Application.
   The Application Detail window appears.

   b. Click Add to create an application or click Edit to modify an existing application.
   The Application Detail window appears.

   c. Specify all details about the application and click Save.

   d. Link or unlink related metrics, as described in the next step.

5. Link or unlink related metrics for an application, as follows:

   a. Ensure that at least one metric is associated with each application.

   b. Click Associate Metric.
   The Application Name: *application name* window appears, displaying all metrics that are not already associated with the application.

   c. Select the metrics that you want to associate with the application.

   d. Click Associate Metric. The selected metrics are linked and therefore appear in the Associated Metrics list.

e. Select the metrics that you want to disassociate and click Disassociate Metric. The selected metrics are unlinked and therefore no longer appear in the Associated Metrics list.

6. Click Done.

The application metric is created.

Step 4 - Import the Data

You can import data by using Data Mediation.

Follow these steps:

1. Click Accounting, Data Mediation, Data Management.
2. Click Import Data.
3. Select the appropriate Data Type of the profile.
4. Select the import format.
5. Select the appropriate import profile for the data to be imported.

> **Note:** You can specify a filter and description.

6. Click Import Now.
7. (Optional) Click Schedule Import to automate the process of importing usage data.
   The scheduling information is already populated. The administrator only schedules the task by entering an optional Comment and the required fields. Do not modify fields other than Comment and the required fields.

> **Note:** To edit a scheduled database import, go through the Scheduler user interface and click View Scheduled Tasks.

Configure the CA Service Repository Agent

You can configure the CA Service Repository Agent by modifying the settings in the configuration file USM_HOME\repagent\config\repagent.cfg. Use the CA Service Repository Agent to automate the import of usage data that is stored in Delimiter Separated File or Fixed-Length File format

The repagent.cfg file uses the following parameters:

- **usm.url**
  Specifies the Catalog Component URL.

- **init.pause.ms**
  Specifies the pause time (for initialization) in milliseconds when the repository agent starts up.

- **repeat.interval.ms**
  Specifies the polling interval in milliseconds. The Repository Agent polls the FTP server for any new files that are based on this value. This value also determines the polling interval for processing local files.

- **upload.list.file**
  Specifies the profile configuration file name.

- **history.file**
  Specifies the repository agent upload history log file name. The repository agent keeps a log of all files that are imported to the database.

- **ftp.host**
  Specifies the FTP host name.

- **ftp.user**
  Specifies the FTP user name.

- **ftp.password**
  Specifies the FTP password name

Automatic Profile Load with Data Load

If the profile to be used is not already in the database, the repository agent can automatically load the profile and can load the associated data. This approach requires a pair of files in the USM_HOME\repagent\data folder with the same file name except for the extension. The file with the extension of .xml contains the profile definition. The file with the extension of .txt contains the usage data. For example, suppose a profile definition that is named abc.xml exists. The repository agent loads that profile into the database and uses it to process an associated usage data file abc.txt.

The profile definition XML file must follow a certain format. If integrated with CA NeuMICS, CA NeuMICS automatically generates this profile definition. For loading other usage data from other systems, generate the profile XML file according to the supported format.

Profile XML File Format

To generate a profile from an external source, use the format in the sample profile XML file. This file resides in the USM_HOME\repagent\data\samples folder.

The profile XML file that the repository agent uses to create a Data Mediation profile contains two sections:

Profile section
Contains information about the data mediation profile. Only one profile section can exist for each XML file.

- profile_name - the profile name (mandatory).

- profile_type - the profile type where 0=reference, 1=metric (default is 0).

- import_format - the format of the data source where 0=delimiter-separated file, 1=fixed-length file (default is 0).

- field_separator - the delimiter between fields in the usage file. The valid values are either the character itself or the ASCII numeric value for the following characters: ampersand (&), asterisk (*), at sign (@), comma (,), dollar sign ($), exclamation mark (!), percent (%), period (.), pipe (|), or space ( ). The ASCII numeric value for a tab can be used.

Field section
Contains information about each column of the data file. You can use this section to create the fields in the Data Mediation profile. Each XML file can contain many field sections.

- field_name - database table column name (mandatory)

- display_name - display name of the field

- mandatory - mandatory status

  - 0 - both server and client are not mandatory.

  - 1 - server mandatory

  - 2 - client mandatory

  - 3 - both client and server mandatory

- data_type - data type

  - 0 - string

  - 1 - integer

  - 2 - float

  - 3 - date

  - 4 - decimal

  - 5 - double
    A data type of “double” is converted to “float” during import.

  - 6 - binary

- data_length - the length of this field

- data_format - the format of date data (only if data_type =3).
  A dash (-) can replace a slash (/)in the following formats: The separator between the date and time portion can be a slash (/), dash (-) or space. Upper or lower case letters can be used. For example, YYYY-MM-DD hh24:mi:ss is a valid format.

  - MM/DD/YY

  - MM/DD/YYYY

- MM/DD/YYYY HH:MI:SS
- MM/DD/YYYY HH24:MI:SS
- MM/DD/YYYY HH:MI:SS.MSS
- MM/DD/YYYY HH24:MI:SS.MSS
- DD/MM/YY
- DD/MM/YYYY
- DD/MM/YYYY HH:MI:SS
- DD/MM/YYYY HH24:MI:SS
- DD/MM/YYYY HH:MI:SS.MSS
- DD/MM/YYYY HH24:MI:SS.MSS
- YY/MM/DD
- YYYY/MM/DD
- YYYY/MM/DD HH:MI:SS
- YYYY/MM/DD HH24:MI:SS
- YYYY/MM/DD HH:MI:SS.MSS
- YYYY/MM/DD HH24:MI:SS.MSS

- default_value - the value for this field. The Catalog system uses this value, not the input record.
- start_position - if import_format=1 (fixed-length file), start_position is the starting position of the field in each record, starting at 1. If import_format=0 (delimiter-separated file), it is the field position starting with 1.
  For example:
  - For a fixed-length file, a record contains “abc001” and this field is the numeric portion. Therefore, the start_position is 3, and the end_position is 6.
  - For a delimiter-separated file, a record contains “abc,001” and this field is the numeric portion. Therefore, the start_position is 2, because this field is the second field. Also, the end_position is blank.
- end_position - required only when import_format=1. It is the ending position of a field in each record.
- status - status of the field (default is 1)
  - 0 - system (cannot delete)

- 1 - active
- 2 - inactive

Profile List

When a profile is created and the repository agent must process the usage data, the agent must be made aware of the new profile. The profile information is specified in the Profile List file that is named in the upload.list.file setting. This file is located in the USM_HOME\repagent\config folder.

The format of each record in the Profile List file is as follows:

```
profile_table_id, usage_file_name
```

- ***profile_table_id***
  Specifies the numeric ID value from the Data Mediation profile Source Table column, without the leading zeroes. For example, if the Source Table column contains entry usm_mr_itemp_001012, the *profile_table_id* entry in the Profile List file for this profile is 1012.

- ***usage_file_name***
  Specifies the full path and file name for the usage file corresponding to the profile referenced in the first parameter, for example, C:\Program Files\CA\Service Delivery\repagent\data\my_usage_data.txt.

Step 5 - Aggregate the Data

You can aggregate the data.

Follow these steps:

1. Select Accounting, Data Mediation.
2. Select Aggregation Status.
3. Complete the window options:
   - **Use selected period for aggregation**
     Aggregates data that is contained within a specific fiscal period (suggested). Only data falling within the specified date range is aggregated. Not selecting this option aggregates data for all fiscal periods.
   - **Advanced Option**
     Specifies multiple fiscal periods.
4. Click Start Aggregation.
5. (Optional) Click Refresh to check the Aggregation Status during data aggregation.
   The data is aggregated. To view the details, including history, for an invoice, navigate the Aggregation Summary pages for the account of interest. Alternatively, click Accounting, Account Management and click the action icon that is named View Invoice History for account name.

Data Mediation Aggregation Utility

You can start a data mediation aggregation using a command-line utility. For Windows, the startDMAggregation.bat file is located in the USM_HOME\scripts folder.

The syntax for using the startDMAggregation.bat (Windows) command is as follows:

```
startDMAggregation.bat [startdate] [enddate]
```

Specify the start date and end date in MM/DD/YYYY format.

Define Aggregation Logic

You can define the initial aggregation logic in the form of an SQL statement.

Follow these steps:

1. Click Accounting, Data Mediation, Profile Management.
   If the target table column is empty and the configuration status is “pending,” the initial aggregation logic for the profile is not yet defined. The presence of a target table entry and a configuration status of “Defined” indicate that the profile has been defined.

   Note: The Target Table column is visible when the Show more columns double arrow icon is clicked.

2. Click the Define Aggregation Logic icon.

3. Drag-and-drop each field from the data source into the target table field to define the logic to be used during aggregation.

4. Click Generate Query to generate the SQL Expression.

   Note: You can define the initial aggregation logic by using a SQL statement or procedure. Specify the initial aggregation logic to prepare the imported event usage data to include all of the server mandatory fields for the aggregation and cost allocation process. For example, suppose that you have usage data for each host in temporary tables for data mediation. You want to map the hosts to accounts using the data mediation reference tables. In that case, perform a join of these tables in the SQL procedure to prepare the event table.

5. Click Save.
   The aggregation logic is defined.

Define Multiple Aggregation

Data that is imported from an external source can be aggregated in multiple ways. To fulfill this requirement, you can define multiple profiles that are based on the same data set. This definition lets you use one set of external source data. You can then aggregate the external data in different ways to meet your business requirements.

Follow these steps:

1. Go to Accounting, Data Mediation, Profile Management.
2. Click Copy for the profile for which you want to define a new profile and different aggregation logic.
   A copy of the profile using the same name is created using the same source. The SQL Expression is not copied.
3. Click the new profile and define the alternate aggregation logic for this data source. Click Save.
   A different target table entry is created.

When data aggregation is called, the SQL query or procedure runs, resulting in two separate event tables. If the data in both tables is normalized properly, both data sets are aggregated successfully.

Note: The initial aggregation logic for a profile is run without regard to sequential order.

Step 6 - Generate Invoices

You can use data aggregation to generate invoices in Service Accounting Component. If you generate an invoice after an aggregation and again aggregate the data for the same fiscal period, the previously generated invoice has zero charges. These zero charges are due to the transactions being rolled back on aggregating again. You regenerate invoices to capture the new transactions. You can use invoice groups and can create invoices in batch mode. If two different data sets are involved at two different times, you can aggregate when the first data set is imported and again aggregate after the second data set is imported. You then generate invoices after all the data for that fiscal period has been received and verified.

Follow these steps:

1. Create profiles for each data set to mediate and then aggregate.
2. Import the data (files and external database) for the associated profile.
3. Define fiscal periods depending on the business model.
4. Aggregate data so that the metric result tables and the Service Accounting Component transactions are created. Repeat the aggregation process if any new data is imported or changed for that fiscal period.
5. After all the data is received and is aggregated, generate the invoices that reflect the aggregated data.

Data Mediation Reports

Several Data Mediation report data views are available:

Data Mediation - Profile List
Displays a list of Data Mediation profiles, including the following associated parameters:

- Index ID
- Profile Name
- Status
- Temp Table
- Event Table
- Data Import Type
- Profile Owner
- Description
- ID

Data Mediation - Rating Engine Queue Items
Displays rating engine queue items by the specified runtime variables. Enter the start and end date and times. The report displays the Data Mediation Rating Engine Queue items, along with the following associated fields:

- Index
- Group ID
- Queue Item ID
- Created Time
- Status
- Start Time
- Finish Time
- Metric Result ID
- Metric Result Table Name

Manage Chargeback and Pricing Models

This article contains the following topics:

Chargeback

Enterprises can define their services to allocate costs internally for budgeting and chargeback or to charge customers for them. Service Accounting Component supports various chargeback methodologies. Charges can be per transaction, or per session, and can vary by resource. The rates that are used can vary by service package and activity level. When CA Business Service Insight is integrated, the invoices that are based on real-time usage data can be generated. Adjustments can then be applied automatically to reflect any SLA violations.

Under most circumstances, the cost that is charged to a business unit is not disputed. The cost can be directly attributed to IT services that have a role in supporting its business operations. The primary focus is on whether or not the provided services and the corresponding costs are at the levels anticipated. In essence, business units want to be certain that they are getting everything that they are paying for. Business Units want to know how to distribute the burden of cost and how to lower it. Conversely, an organization must verify that all costs are recovered regardless of whether or not resources are fully utilized. The process of distributing the cost must be easily managed. The system that is put into place influences business unit behavior and demands.

Administrators can configure Service Accounting Component to specify chargeback and to use one or more of the following pricing models:

- Subscription-based Pricing (see page 3152)
- Usage-based Pricing (see page 3153)
- Tiered-based Pricing (see page 3153)
- Combined Approach (see page 3154)

Subscription-Based Pricing

Chargeback can be done regardless of actual consumption, but on a fixed basis using a specific unit of measure and unit cost. This method is known as subscription-based pricing. This strategy can be implemented by using any chargeable type service option element when defining services for a Business Unit. This element type allows for the specification of a unit cost, billing cycle, and quantity. Examples include subscription charges, such as $500 per month or $1000 per laptop.

This method is used when the true cost driver is unknown or it is too difficult to ascertain. Because the subscription is based on a controllable unit of specification, this approach provides the Business Unit with some control over cost expectation and a clear picture of their IT-related costs. But this method fails to meet any objectives pertaining to fairness. Disparate resource use is not accounted for, as the treatment of all subscribers is equal. This decoupling of service cost and usage translates into a system that tends to fail to motivate Business Unit behavior. So, subscription-based pricing does not guarantee the recovery of cost or that profit is generated.

Usage-Based Pricing

Usage-based pricing enables IT to charge back to Business Units cost based proportionately to their consumption of resources. This strategy can be implemented by using the Application type service option element and choosing the Usage Based selection for its Pricing Structure when defining services for a Business Unit. This element type allows for the specification of a unit cost and a metric type.

Import the usage-based data into the system using data mediation. Use this metric result to calculate the total cost of that service for an account. In addition to global account charges, these usage-based amounts can be processed on a per user basis.

Implementing usage-based billing involves knowledge and decision at multiple levels within an organization such as:

- Financial decisions determine how to present and price these services.
- IT technical decisions on where and how to collect and process useful usage data and how to handle exceptional cases like adjustments and promotions.

This method assumes that the associated resources are shared among several Business Units and their unit cost is fairly static. Consumption is directly linked to the cost incurred. For example, when services are set to employ weighted distribution as the means of distributing charges, lowering usage levels of these services does not always guarantee lower cost. One Business Unit can decide to cut usage, thus expecting a relative change in the cost that it is allocated. However, if all other Business Units that contend for the same resources also decide to cut back on usage, but at a higher rate, the original Business Unit is forced to pay more than it did previously. Although control can be a problem, this model affects business unit behavior.

Tiered-Based Pricing

Tiered-based pricing enables IT to charge back to business units based on levels of service. A tiered structure can be constructed associating various rates to level ranges. This strategy can be implemented by constructing a tiered type service group to contain these ranges and corresponding rates, and defining services to draw their costing information from them based on a passed value. You can use this value to look up and select the appropriate tiers.

Consider a tiered service group that contains two columns. In the first column, various ranges can be defined, such as numeric values 1-100, 101-1000. In the second column, associated rates can be defined. You can configure several service group elements to use this tiered service group to determine their cost.

For example, an application service group element can be created to use this tiered service group. To do so, select Tiered-Based as its Pricing Structure. During the cost calculation for this element, the metric value can be used to select the matching tier and use the corresponding rates. The unit specification at that rate can be derived in a number of ways, such a predefined fixed quantity or the metric value itself. Agreement service group elements can employ tiered service groups to attribute a cost that is based on the number of violations.

Combined Approach

The combined approach creates a chargeback procedure that is tailored to the needs of a specific organization. For instance, a particular organization can implement a system that influences service objectives by using a tiered-based pricing with assurance adjustments on top of a fixed recurring subscription charge. Here the aim is to strengthen the control a Business Unit has over the quality and equitability of a service, while providing for a great deal of stability and predictability of cost.

A differentiation can exist between services that are bound to the infrastructure of that organization and those that are not. These infrastructure services can be positioned to do chargeback that is based on a specified allocation method as in a 'per subscription' basis. Chargeback for the other services can be based on actual consumption using a fixed rate.

Implement Usage-Based Billing

This article contains the following topics:

Step 1 - Verify the Requirements for Services

Administrators can set up usage-based billing to charge for services that are based on consumption. Administrators use data mediation to import usage-based data. Then this data is used to calculate the cost of a service for a business unit, user, or account.

Verify the requirements for the services for which you are implementing usage-based billing. The service option groups being billed must include a service option that is configured as follows:

- Type = Application
- Pricing Structure = Usage Based
- Cost Type = Specify Value
  Do not select User Specified for the Cost Type if you are using usage-based billing through data mediation logical mapping. If you select User Specified for the Cost Type, then users can overwrite the default unit cost. The default unit cost is defined in the original service definition. However, data mediation logical subscription is designed to use the default unit cost that is defined in the service definition.
- Unit Cost = any numeric value
- Application = any available application (for example, Operating System Platform)
- Metric = any available metric (for example, Disk Quota Used (KB) Per User).

Step 2 - Create the Users and Account

To get started implementing usage-based billing, create one or more users and associate them to an account.

> **Note:** If the service activation is to be achieved through request management, then the user is automatically associated to the account.

Step 3 - Create an Application Metric

To create an application metric, see the section "Create an Application Metric" in Implement Data Mediation (see page 3139).

Step 4 - Create Data Mediation Profile

To create a data mediation profile, see the section "Create a profile" in Implement Data Mediation (see page 3139).

Step 5 - Define Aggregation Logic

To define the aggregation logic, see the section "Define Aggregation Logic" in Implement Data Mediation (see page 3139).

Step 6 - Import the Data

You can import database profiles as needed and can schedule them to occur later.

You can import data from a file or from an Ingres, SQL Server, or Oracle database table. Data is loaded into database tables when imported.

The database tables include the following types:

- **Reference tables**
  Contains reference data to be used as lookup tables (usm_mr_iref).
- **Temporary tables**
  Contains partial usage event data, meaning that all server mandatory fields are not present, implying that normalization can be necessary (usm_mr_itemp).
- **Event tables**
  Contains complete usage event data (usm_mr_ievent).
- **Metric result tables**
  Contains aggregated event data (usm_mr_iresult).

Step 7 - Aggregate the Data

To aggregate the data, see the section "Aggregate the Data" in Implement Data Mediation (see page 3139).

Mobility

This section contains the following articles:

PDA Interface

CA SDM supports ITIL terminology for the Personal Digital Assistant (PDA) interface. This interface lets end users create Requests, Incidents, and Problems, and lets them search for the following ticket types:

- Incidents
- Problems
- Requests
- Change Orders
- Issues

Analysts can use the PDA interface. This interface honors the role present in the *PDA Role* field of the Access Type of the contact.

The PDA Interface is displayed for on any unsupported device or browser.

Look up service for searching a contact works only on PDA browsers that support multiple tabs and multiple browser windows. Multi-tenancy works similar to the browser interface, but the drop-down list to select multi-tenancy is not provided. When you create the ticket, tenancy is based on the requestor, the affected enduser, and the analyst.

Automatic Priority Calculator (APC) helps in deciding priority while creating Incident/Problem, based on the attributes, urgency, impact, request area, and affected end user.

Note: The PDA Interface does not support attachments when you create tickets.

REST Sample Mobile User Interface

The REST sample mobile user interface provides two user interfaces: Analyst and Employee. This sample also supports the Administrator, Level 1 Analyst, and Employee roles. After you log in to CA Service Desk Manager, the Administrator and Level 1 Analyst roles view the analyst interface. The Employee role views only the employee interface. If an administrator disabled Automatic Priority Calculation, the Priority field appears on create and edit pages.

Important! This functionality applies only to the sample program provided in this release of CA Service Desk Manager. It is not a design that is restricted in the REST Web Services application itself.

Fields that use auto suggest require a value selection from the auto suggestion list, such as the assignee and Incident Area. If you do not select a value, the user input for that field clears.

Note: Navigate REST interfaces with the provided buttons, instead of using the browser back and forward options. For example, select Home or Cancel to return to a previous page.

Analysts can perform the following tasks:

- View Announcements.
  Default: Sorted by Posted Date
- View Incidents that CA Service Desk Manager assigned to the Analyst.
- View Assigned and Unassigned Incidents.
- Sort Incidents.
  Default: Sorted by Open Date.
- Search for an Incident.
- Create an Incident.
- Modify the Status, Urgency, and Impact of the Incident.
- View and update the Activity Log with a comment, or specify Callback or Research.
  Default: Sorted by Activity Date.

Employees can perform the following tasks:

- View Announcements.

- View open and closed Incidents that an end user created.
- Sort Incidents, such as by Open Date.
- Create an Incident.
- Update the Activity Log with a comment.
- Search for an Incident.
- Modify the Incident status from Open to Closed, or Closed to Open.

Deploy the REST Mobile Sample User Interface

The administrator enables REST Web Services during the product configuration. The administrator then copies files on the CA Service Desk Manager computer to enable the REST mobile sample user interface. The analyst uses the mobile interface to manage incidents that end users open in CA Service Desk Manager.

Follow these steps:

- Step 1 - Configure REST Web Services (see page 3158)
- Step 2 - Enable the REST Mobile Sample UI (see page 3159)
- Step 3 - Manage Incidents from the REST Mobile Sample Interface (see page 3159)

Step 1 - Configure REST Web Services

By default, REST Web Services are enabled in the CA Service Desk Manager configuration. However, if the REST Web Services are not enabled at the time of CA Service Desk Manager installation, configure the REST Web Services.

Follow these steps:

1. Execute pdm_configure from the command-line interface. On Windows, click **Start**, **Programs**, **CA**, **Service Desk Manager**, **Configure**.
   The configuration dialog opens.
2. Confirm the configuration information for the **General Settings**, **System Accounts**, **Database**, and **Web Interface** dialogs.
   The **REST Web Services** dialog opens.
3. Enable the **Configure REST Web Services** option.
4. Specify the **REST Tomcat Port**.
   Default: 8050
5. Specify the **REST Tomcat Shutdown Port**.
   Default: 8055
6. Click **Next** and continue the CA Service Desk Manager configuration.
   The configuration completes.

Step 2 - Enable the REST Mobile Sample UI

CA Service Desk Manager disables the REST Mobile Sample user interface by default to prevent undesired access to the MDB. The administrator enables this interface manually.

Follow these steps:

1. Locate the following directory on the CA Service Desk Manager computer where REST web services is installed and configured:

   ```
   $NX_ROOT/samples/sdk/rest/mobiledemo
   ```

2. Copy this directory to the following location:

   ```
   $NX_ROOT/bopcfg/www/CATALINA_BASE_REST/webapps
   ```

   Note: You do not have to restart Tomcat.

   The REST Mobile Sample user interface is enabled.

3. (Optional) If you want to disable the REST sample user interface, remove the mobiledemo directory from /webapps.

Step 3 - Manage Incidents from the REST Mobile Sample Interface

The analyst or an employee views the REST mobile sample interface on their mobile device to manage incidents in the queue. For example, the analyst opens Incident 30 to log an internal-only comment.

The analyst or the employee can also download attachments.

Follow these steps:

1. Open the following URL on your mobile device:

   ```
   http://hostname:REST-Tomcat-port/mobiledemo/login.html
   ```

   The sample REST mobile interface login page opens.

2. Log in to CA Service Desk Manager using your credentials.
   The REST mobile analyst home page opens.

3. Select **Assigned Incidents**.

4. Select an Incident, such as Incident 30.

5. Select **Create Activity** on the detail page.

6. Select **Log Comment** from the drop-down list.

7. Select **Yes** from the **Internal** option.

8. Enter a comment and select **Save**.

CA Service Management Mobile Application

CA Service Management Mobile Application is a common interface to access some of the core features of CA Service Desk Manager and CA Service Catalog from your mobile device. The following mobile capabilities are available in CA Service Management Mobile Application:

Service Desk

The *Service Desk* capability enables the logged in user to access the following CA Service Desk Manager core features:

- View the count of the tickets from CA Service Desk Manager on the Home screen when you log in. You can view incidents, requests, problems, issues, and change orders only. The badge count on each tile shows the new and updated ticket counts since last refresh.

  Note: The Home screen does not display all the tickets from CA Service Desk Manager. By default it shows all the tickets that are assigned to all the users. This default filter can be changed.

- Tap a ticket type tile from the Home screen to view the list of tickets. Filter each ticket type to view only selected information. For example, tap the Filter icon from the Incident list and select Assigned - High Priority. The list is refreshed to show the selected incidents only.

  Note: Filters that are customized on the CA Service Desk Manager server and are displayed on the CA Service Desk Manager Scoreboard is also displayed in this capability.

- Search for ticket. Tap on the search area and enter the search keyword. The search results are displayed as you type. You can search for a ticket that is based on the ticket number or summary of the ticket.

- Tap a ticket to view the details. You can also view the attachments and activity logs (if any).

- Tap More Actions to perform actions on a ticket:

  - Escalate or update status or transfer ticket to another user.

- Add a comment to this ticket.
- Add an attachment to the ticket. Allowed size for the attachment is 3 MB or less. This capability only supports .jpeg, .jpg, and .png image formats.

- Change the refresh interval (**Default:** four minutes). Tap system menu, Settings, Preferences, Service Desk. Increase or decrease the Polling interval.
- Choose the features to be displayed in this capability. For example, the logged-in user can choose to view the incidents only. Go to the Settings screen and tap Features. Swipe to enable or disable a feature.

My Tasks

The *My Tasks* capability is used to respond to pending workflow tasks. This capability provides the mobile user with all the information required to complete the task.

The logged-in user can access the following core features of this capability:

- View the following tasks:
  - Pending tasks from the following workflow engines that are integrated with CA Service Desk Manager:
    - CA Service Desk Manager Classic Workflow
    - CA Process Automation
  - Workflow tasks that are assigned to the user. If the logged in user is part of the PAMAdmins group, the user can view and respond to any CA Process Automation tasks from the *My Tasks* capability.
  - Workflow tasks that are assigned to a group that the user belongs to.
    - For CA Service Desk Manager Classic Workflow, tasks that are assigned to the CA Service Desk Manager group are not displayed. Only tasks that are assigned to individuals are displayed.
    - If the logged-in user is part of the PAMAdmins group,the user can view and respond to any CA Process Automation tasks from the *My Tasks* capability.
  - Workflow tasks for which the user is requested to respond, regardless of the CA Service Desk Manager ticket assignee or requester. For example, a user who is not directly involved with CA Service Desk Manager performs a financial approval task.

Note: If a workflow engine is down and if the user is not using the related work item, *My Tasks* does not display the work items or an error message. When the workflow engine starts working, the related work items are visible to the user. But if you are already using a work item and the server goes down, then *My Tasks* displays an error report.

- View a bar chart showing the number of pending tasks that are awaiting input, as per the time the task has been pending. This bar chart allows the user to identify new tasks and identify how long they have been waiting.

- View the list of tasks that are filtered by pending time. Tap on the bar on the graph or use the pull down at the top of the screen. For example, tapping on Last Hour bar displays all the tasks that are created or modified in the last one hour and are pending for approval.

- Search for a pending task; enter the search text in the Search area. The search result is updated as you type. You can search using ticket numbers, priorities, or keywords from task descriptions.

- View the work item details by tapping on a task in the list. When you see the details, you can perform the following actions:

  - View the input form of the work item. Custom approval forms are automatically available on the mobile device without any modification. They are reformatted for rendering on the mobile device.

  - Understand more about the work item by tapping the ticket icon to view the related CA Service Desk Manager ticket information. This information can include business justifications, implementation and backout procedures, contact, assignee, information, priority, SLA, and severity.

  - Call or email the requester by tapping on the phone number or email address that is listed on the related ticket tab. This information is displayed only if the CA Service Desk Manager ticket contains this contact information.

  - Download and view attachments for the related change order ticket. Install other viewer software on your mobile device to open the downloaded document, if necessary. To view attachments from the web application of the CA Service Management, turn off the "block popups" option in the web browser.

- Respond to the work item. Enter the required information in the detail form and tap **Submit**. The next task is automatically opened for your response, if multiple tasks are pending.

- Upon request from support, enable debugging information by selecting the system menu, Settings, Preferences, My Tasks. Tap the Tracing drop-down to select an option. Choose the "on" option to enable the debugging information. Choose the "verbose" option for more detailed information. You can view the logging information in the $NX_ROOT\log\approve.log directory on the CA Service Desk Manager server. Disable the option to avoid server overhead when you have completed the support session.

- Change the date and time format by tapping the system menu, Settings, Preferences, My Tasks and by choosing a Date Time Format. The changed date and time format is only reflected once you refresh the capability.

- Refresh the current list of work items by tapping the system menu in the upper right-hand corner of the task list page and choose Refresh.

- Change the refresh time interval which specifies how often the *My Tasks* tile is updated, by changing the Polling interval found on the Preferences, *My Tasks* page.

- Enable response timeout option wherein a message is prompted to the logged in user if the capability does not respond within a specified time. As a logged in user, you can set this time (in minutes) from the system menu, Settings, Preferences, My Tasks. By default the Timeout in minutes option is set to two minutes. You can change this setting. If the capability does not respond within this scheduled timeout, an error message is displayed. After clicking OK on the message prompt, the user is directed back to the login page of the *My Tasks* capability.

Unified Self-Service

The *Unified Self-Service* capability enables the logged-in user to access the following core features of Unified Self-Service on a mobile device:

- View the count of the latest questions on the Home screen, that are posted from Unified Self-Service. The posts are categorized according to tags such as Recommended, Latest, Following. By default you view the Latest questions.
- (If Unified Self-Service is configured with CA Service Desk Manager) View the count of the tickets that you created on the Home screen. The tickets can be request or incident, as configured by the system administrator on the Unified Self-Service server.
- Tap on the question tile from the Home screen to view the related posts.
- Search for a post from all sources. Enter your search criteria in the Search text box and tap Enter to display the search results from all sources. From the drop-down, you can select Global to look from all the data sources that enabled on the Unified Self-Service server. You can also select Questions to look from the questions that are listed in this capability.
- Search for requests or incidents.
- Tap a question to view the detailed post. Tap More Actions to:
  - Reply to this post
  - Follow or unfollow this post
  - Share the post
  - Open a service desk ticket if the post does not answer your questions.

  Note: To add new fields in the request form, the system administrator has to configure the fields on the Unified Self-Service server. The same configured fields are displayed on the Unified Self-Service capability. The number of fields that can be configured on the Unified Self-Service is five. For more information about how to configure the fields, see Administering CA Self Service (see page 1679) section.

- Change the refresh interval (**Default:** four minutes). Tap system menu, Settings, Preferences, Self Service. Increase or decrease the Polling interval.

- Choose the features to be displayed in this capability. For example, the logged-in user can choose to view the Questions only. Go to the Settings screen and tap Features. Swipe to enable or disable a feature.

Create Ticket

The *Create Ticket* capability is available only for CA Service Desk Manager users. You can create a request or an incident.

Note: A Non-employee CA SDM user can use the **Affected End User** field to create a ticket on behalf of other users.

Catalog

The *Catalog* users can perform the following tasks from their mobile devices:

- Browse and search the catalog
- Complete and submit requests for service offerings (services)
- Add notes or attach images to their requests
- View the status and other details of their requests, including requests submitted from both the browser interface and the mobile application
- Cancel their requests

Request managers can perform the following tasks from their mobile devices:

- View their requests pending approval and approve or reject them
- Add note or attachments to those requests

Note: A Non-business CA Service Catalog user can use the **Affected End User** field, that is available on the Report An Issue Offering page, to create tickets on behalf of other users.

Localization Support for Mobile Application

CA Service Management Mobile Application supports the following 12 languages.

- English
- French
- Dutch

- Simplified Chinese
- Spanish
- Brazilian Portuguese
- Japanese
- Italian
- German
- Finnish
- Swedish
- Danish

If you are using CA SDM, observe the following:

- CA SDM does not support Finnish, Danish, Swedish, and Dutch locales.
- CA SDM supports the French Canadian locale but the CA Service Management Mobile Application does not support it.

When you upgrade to current release of the mobile application, the default language is set to English. You can set your preferred language. To change the language settings, navigate to **Settings**, **Preferences**, **Locale Settings**.

Some mobile application forms that are generated appear with labels based on the CA SDM server side data. In such instances, the data language depends on the CA SDM server locale set by the Administrator. For example, if CA SDM server locale is set in Japanese, and the Mobile Application locale is set in French, the forms with data labels from the CA SDM server side will appear in Japanese.

Verify the Prerequisites for CA Service Management Mobile Application

CA Service Management Mobile Application is certified for the following mobile operating systems:

- iOS
- Android

For information about the supported versions of the operating system, see the Supportability Matrix (https://wiki.ca.com/display/CASM1401/Supportability+Matrix) .

As an administrator, verify the following requirements before you configure CA Service Management Mobile Application:

- To access Unified Self-Service capability, install and configure CA Open Space 3.0 or higher to the CA Service Desk Manager server.
- To access Service Desk capability:
  - Associate the logged in users for Analyst Queue with the REST Web Service API role. Ensure that the *Administration*, *Security*, Stored Query, and *Reference* function accesses of this role are assigned with the View or Modify access levels. For more information about function access, access level and roles, see the Administering CA Service Desk Manager (see page 1302) section.
  - Install “Status_Policy_Violations” option on the CA Service Desk Manager Server with “Reject” as its value to ensure that the condition attached to the status transition rules are validated correctly.

Note: When CA Service Desk Manager users use the mobile application, they see that the status is updated even when the condition attached to the status transition rule fails. For example, consider a scenario when the “Status_Policy_Violations” is set to “Warn”, and the status transition rule states that there must be an assignee assigned to the Incident while updating from “OPEN” to “ACKNOWLEDGED”. In this scenario, the status is still updated to “ACKNOWLEDGED”, even if there is no assignee for the Incident.

To ensure that such an issue does not occur, install "Status_Policy_Violations" option on the CA SDM Server with "Reject" as its value.

- To access Catalog capability, ensure that you have deployed mobile access (see page 3166).

Deploy Mobile Access for CA Service Catalog

This article contains the following topics:

Step 1 - Verify Prerequisites for Mobile Access

Review the following prerequisites for mobile access:

- Understand the terminology in this article:
  - Services and forms that you design for catalog users and request managers to access from mobile devices are *mobile services* and *mobile forms*.
  - Services and forms that you design for catalog users and request managers to access from the web browser of a tablet, laptop, or desktop are *browser services* and *browser forms*.
- Ensure that you know how to design services and forms in CA Service Catalog.

- Familiarize yourself with how request managers approve and reject requests in CA Service Catalog.

Step 2 - Follow the Guidelines and Requirements for Creating or Updating Services

Meet the following requirements as you design your mobile services:

- Select the option that is named **Available from mobile devices**, on the Service Details tab.
- Specify *one* service option per service and you can add *one* form to that service option.
  After you add the form, save your changes and complete all other applicable fields on the Service Option Details tab. Keep in mind the following considerations and limitations:
  - You can add a reservation, and it *is visible* on a mobile device.
  - You can also add the following elements: CA Business Service Insight contracts, cost and pricing elements (such as rate elements), and additional elements (such as text elements). These elements are supported; however, they are *not visible* on a mobile device.
- If you use images, meet these requirements:
  - Use one of the following formats: BMP, PNG, JPEG, or .JPG.
  - Verify that the file size is less than 30 KB.
  - Verify that the dimensions are 50 x 50 pixels or smaller.

Guidelines for Services and Forms

Follow these guidelines as you design mobile services and mobile forms:

- Keep services and forms short and simple.
- Keep all names and descriptions short.
- Use the following predefined mobile-enabled services and their forms as models:
  - View My Assets (for Mobile Users)
    This service lets catalog users view their assets in CA APM.
    This service requires that CA Service Catalog and CA APM are integrated.
  - Report an Issue
    This service lets catalog users report an issue in CA Service Desk Manager, for example, a hardware or software problem.
    This service requires that CA Service Catalog and CA Service Desk Manager are integrated.

  To access these services, import the Service Management Content Pack. For more information about how to use this content pack, see the *Using the Service Management Content Pack* article. To access this article, log in to CA Service Catalog and select Administration, Tools, Links.
- *Only when necessary*, consider creating two forms and two services: one service and form for browser access and another service and form for mobile access. *When necessary* means that the browser service and form contain multiple or complex elements that are not supported on

mobile. For example, the browser service contains multiple service options and the browser form contains a table.
For examples, see the View My Assets and View My Assets (for Mobile Users) services in the content pack.

(Optional) Specify the Order in which Services Appear

You can optionally use the Sort Number field on the Service Details tab to specify the order in which services appear. The order of appearance is sequential, from lowest to highest. For example, three services with sort numbers of 1-3 are the first three services that appear when a user opens the catalog from a mobile device.

Note: When users view services from a mobile device, a single sort order applies across all folders. In contrast, when users view services from a desktop, laptop, or tablet, the sort order applies to each folder individually.

Customizations That Are not Supported

Mobile services do *not* support the following customizations:

- Custom approval statuses
  Use *only* default approval statuses for mobile services.
- Tiered service option groups

Step 3 - Follow the Guidelines and Requirements for Creating or Updating Forms

Follow these requirements and guidelines when you design mobile forms.

General Guidelines

The requirements and guidelines for services (see page 3167) include general guidelines about using forms.

Guidelines for Fields

To achieve the most efficient display and maximize user productivity, automatically specify the most common options as the default options. For example, use JavaScript expressions and the user profile to pre-fill fields for user attributes, such as name, address, phone number, and so forth. Similarly, if the user location is available, pre-fill it also.

Requirements for Labels

If you use labels (see page), test them thoroughly on mobile devices. Labels appear to catalog users who view services and submit requests. However, labels do *not* appear to request managers who approve and reject requests. Therefore, use the Description field of a service option (rather than a label) to convey important information about the form or service option to request managers.

The Full Width attribute of a label is automatically set to True when a form appears on a mobile device. This automatic setting optimizes the use of space on a mobile screen.

If you use an image as the value for a label, the maximum size of the image is 50 x 50 pixels or smaller.

Elements That Do Not Apply

Do *not* use the following elements on mobile forms because they do not apply:

- All tables (Static Table (see page 2921) or Dynamic Table (see page 2923))
- Dual list (see page 2919)
- Column layout (see page)
- Lookup Field (see page 2920)

Attributes That Do Not Apply

The following attributes do not function when users display the form on a mobile device. However, you can optionally include these attributes on a form that users access from both mobile and non-mobile devices. In such cases, these attributes work as designed for non-mobile access but do not function for mobile access:

Element	HTML Attributes	JavaScript Attributes
All elements	Hint, Style, Tab index, Text direction, Tooltip	onBlur, onKeyDown, onKeyPress, onKeyUponMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp
Check box	Box label	onFocus and onClick
Date Time	Time Format	onFocus and onClick
Field set	Collapsed and Label Width	Not Applicable
Radio group	Orientation	Not Applicable
Radio option	Not Applicable	onFocus and onClick
Select box	Minimum Search, Multi-Select, Page Size, List Width, and Height	onFocus and onClick
Slider	Message	onFocus and onClick
Spinner	Number Format	onFocus and onClick

Form Attributes That Do Not Apply

The following form attribute does not apply: CSS class.

Date Formats

Mobile services and forms support the date formats available for the business unit.

Mobile services and forms support custom JavaScript functions that set the value and format of the date.

Custom JavaScript

Important! Mobile applications typically provide access to more personal data than web browsers on a tablet, laptop, or desktop. Mobile applications also typically have more security concerns. Exercise caution when you use custom JavaScript in forms for services that users access through mobile devices. Verify that all custom JavaScript is safe and secure and does not violate the privacy of any users.

Mobile forms do not support custom JavaScript that uses either of the following techniques:

- JQUERY
- Communication between the form and CA Service Catalog web DOM elements

Approval Process

When request managers use a mobile device to view requests pending approval in their queues, the following fields and forms do not appear on the requests:

- Fields to specify data, either by entering text or selecting a value
  Examples include fields for specifying a cost or for selecting a cost center or priority level.
- Fields or forms that include a condition
  Examples include JavaScript conditions that hide or disable fields or forms based on the request status.
- Complex forms with custom JavaScript activated during the approval process

When a form contains an element or attribute that does not apply to mobile devices, a warning message appears to the request manager. The message explains this condition and advises the request manager to view and act on the request using the web browser of a tablet, laptop, or desktop. However, the request manager can still approve or reject the request using a mobile device. Therefore, as a best practice, verify that mobile-enabled services contain *no* unsupported elements or attributes.

Step 4 - Test the Services and Forms

Test the services and forms to verify that they function correctly on mobile devices.

Follow these steps:

1. From the iTunes and Google Play Store websites, download and install the mobile application on the following devices. The mobile app is CA Service Management.

   - iPhone and iPad running iOS 6.1 or higher
   - Mobile devices running Android operating system 4.0 or higher

2. Verify that your mobile services and forms appear and function correctly on these devices. For example, verify that catalog users can browse the catalog and can submit requests. Similarly, verify that request managers can view, approve, and reject their requests pending approval.

3. Verify that you can access and update services from the mobile application on iPhones and Android phones.

(Optional) Enforce Approvals Compatibility After Upgrade

To access the *My Tasks* capability with the latest features and have a consistent user experience, set the NX_MOBILE_WFM_FORCE_CLIENTVERSION_UPGRADE to Yes.

When this option is set, users attempting to log in to the previous version of this capability are rejected. The users are instructed to upgrade this capability.

Follow these steps:

1. Log in to the CA Service Desk Manager server and open the NX.env file.
2. Add the following variable in this file:

   ```
   NX_MOBILE_WFM_FORCE_CLIENTVERSION_UPGRADE
   ```

3. Set the variable value to Yes.
4. Save the file.
5. Restart the CA Service Desk Manager server.

(Optional) Set Form Fields as Non-Mandatory

By default, all input fields in the *My Tasks* capability that are derived from the CA Process Automation workflow engine are mandatory. The system administrator can make these fields non-mandatory.

Follow these steps:

1. Log in to the CA Service Desk Manager server and open the NX.env file.
2. Add the following variable in this file:

   ```
   NX_MOBILE_WFM_ITPAM_ALL_FIELDS_ARE_REQUIRED
   ```

3. Set the variable value to No to make the fields non-mandatory.
4. Save the file.

The form fields have been set as non-mandatory.

Access the CA Service Management Mobile Application

As a user, you can install the CA Service Management Mobile Application as the *native mobile application* on your mobile device.

Follow these steps:

1. Access the Google Play (for Android) or App Store (for iOS).
2. Search for CA Service Management.
3. Install the CA Service Management application.
   The CA Service Management icon is displayed on your mobile phone after successful installation.
4. Provide the following information to CA Service Management mobile application users as per your deployment requirements based on whether you have a single CA Service Management product (either CA SDM or CA Service Catalog) or combination of these products installed at your end:

   a. **CA Service Management Integrated Environment**
   If you have installed both CA SDM and CA Service Catalog, use the Unified Self-Service (USS) URL to access the integrated product capabilities.

   > **Note:** Ensure that the data source URLs for CA Service Catalog, CA SDM REST Services, and Unified Self-Service are accessible from your mobile application.

   b. **CA Service Desk Manager Environment**
   If you have installed only CA SDM, use the CA SDM Rest Service URL *http (s)://<SDM_HostName>:<rest_port>* to access the product capabilities:

   > **Note:** Ensure that the CA SDM Rest Services URL is accessible from your mobile application.

   c. **CA Service Catalog Environment**
   If you have installed only CA Service Catalog, use the Service Catalog Web service URL to access the product capabilities.

   You have successfully deployed and are able to access from your mobile application the appropriate product capabilities.

Configure the Mobile Attributes for CA SDM Tickets

CA SDM Administrators can configure new mobile attributes on the CA SDM Server. End users can view these attributes in the mobile application UI while editing or creating a ticket. Administrators can add any mandatory or custom attributes on the CA SDM Web UI while creating a ticket and make these attributes available to mobile application users. The end users can view these attribute fields on the mobile application ticket UI and fill in the required information.

Note: Mobile attributes for CA SDM tickets is supported on CA Service Management Mobile App 3.1.3 and onwards.

For example, in the CA SDM Web UI, if the Administrator has configured a category attribute as mandatory, this will restrict mobile users to create a ticket as the category field is not available out of the box on create/edit ticket. Hence, in order to be consistent with the CA SDM Web UI, the administrator can add the same attribute as part of mobile attribute in the CA SDM server.

To create mobile attributes for CA SDM tickets, complete the following steps:

Follow these steps:

1. Log in to CA SDM as an Administrator.
2. Navigate to **Administration**, **Service Desk**, **Mobile Attributes**.
3. Click **Create New** to create a mobile attribute.
4. Select an **Object Type** from the drop-down list.
5. Select an attribute for the object type from **Select an Attribute**.
   You can also search for the object type attribute from the Activity Association List page.
6. Save the form.
   CA SDM users can view this mobile attribute while editing or creating a ticket through their mobile applications.

Restricted Object Type Attributes for Mobile Applications

Currently, few CA SDM object type attributes are not available for CA SDM mobile application users. Restricted object type attributes are as follows:

- Requests/Incidents/Problems (see page 3174)
- Change Orders (see page 3174)
- Issues (see page 3175)
- Edit CA SDM Tickets (see page 3176)

Requests/Incidents/Problems

For CA SDM requests/incidents/problems, list of object type attributes that are not displayed in mobile application UI are as follows:

- ACTIVE
- ACTIVE PREVIOUS
- Assignee Previous
- Charge back ID
- close date
- group previous
- impact previous
- incident priority
- Last Target Closed Time
- Last Target Hold Time
- Last Target Resolved Time
- Last Target Start Time
- Open Date
- Priority Previous
- Request/Incident/Problem Area Previous
- Status Previous
- Resolve Date
- Severity Previous
- Tenant
- Type
- Urgency Previous

Change Orders

For CA SDM Change Orders, list of object type attributes that are not displayed in the mobile application UI:

- ACTIVE
- ACTIVE PREVIOUS
- Assignee Previous
- Group Previous
- Impact Previous
- Last Target Closed Time
- Last Target Hold Time
- Last Target Resolved Tim
- Last Target Start Time
- Priority Previous
- Status Previous
- OPENDATE
- Resolve Date
- Tenant

Issues

For CA SDM Issues, list of object type attributes that are not displayed in the mobile application UI are as follows:

- ACTIVE
- ACTIVE PREVIOUS
- Assignee Previous
- Group Previous
- Last Target Closed Time
- Last Target Hold Time
- Last Target Resolved Tim
- Last Target Start Time
- Priority Previous
- Status Previous

- opendate
- Resolve Date
- Tenant

Edit CA SDM Tickets

While editing CA SDM tickets, list of mobile attributes that are not displayed since the user has control on these attributes from the action menu available on the CA SDM ticket page:

- assignee
- group
- priority
- status

Call Service Desk from your Mobile Device

CA SDM mobile application users can use the the Call Service Desk feature to contact the CA Service Management service desk or help desk. CA SDM Administrators can configure a phone number to contact the service desk using the CA SDM Options Manager. By default, the Call Service Desk option is kept in an enabled state. Navigate to **Administration**, **Options**, **Call Service Desk** to enable or disable this feature.

If your CA SDM setup is tenanted, Call Service Desk uses the phone number specified on the **Telephone Number** or **Alternate Phone Number** fields for a tenant. However, if these fields are empty and not having any phone numbers, the default phone number set by the Administrator is used by the Call Service Desk feature.

To enable or disable this feature and configure the phone number, the following Call Service Desk options are added to the CA SDM Options Manager:

- call_service_desk_default_phone_number
- call_service_desk_mobile_enable
- call_service_desk_tenant_phone_number_field

Note: Only CA SDM administrators can configure these options.

For more information on how you can configure these options, see the Call Service Desk Options for CA SDM Options Manager (see page 1303).

CA Service Management Mobile Application-Server Side Patch Information

CA Service Management Mobile Application-required server side patch release information is as follows:

Note: Visit CA Support to download the CA Service Management Solution and Patches as required by you.

CA Service Management Mobile Application Features	CA Service Desk Manager Release 12.7	CA Service Desk Manager Release 12.9	CA Service Desk Manager Release 14.1	CA Service Catalog 12.9	CA Service Catalog 14.1
Multi-Tenancy Support for CA SDM	▪ Windows: RO70531 ▪ Linux: RO70536 ▪ Solaris: RO71008 ▪ AIX: RO70614	▪ Windows: RO70654 ▪ Linux: RO70655 ▪ Solaris: RO70656 ▪ AIX: RO70657	Not Applicable	Not Applicable	Not Applicable

Enable or Disable Community on Mobile Devices

As a USS administrator, you can enable or disable the Community on the mobile devices.

Follow these steps:

1. Open the *US4SM\OSOP\tomcat-7.0.40\webapps\itsm\ ITSM_Configuration.json* file in edit mode.

2. Add the *disable_uss_community* property at the end of the existing properties and define either of the values:

    a. *false*, to enable Community.

    b. *true*, to disable Community.

```
{ "id": "osop",
"url": "*",
"disable_uss_community":"true"
}
```

Note: By default, Community is enabled.

3. Save the file.

Reporting

This section contains the following articles:

Reporting Using CA Service Desk Manager

Contents

CA SDM provides a variety of built-in reporting capabilities and options including the ability to do the following:

- Print forms for assets and individual change orders, issues, incidents, problems, and more.
- Generate Summary and Detail Reports (see page 3230) for lists of change orders, issues, incidents, problems, requests, configuration items.
- Generate Analysis Reports (see page 3230).

You generate reports based on the table and views (see page 2617)in your CA SDM database.

Report Methods Setup

Report methods let you specify where report results are to be sent when you select a report. Examples are the summary and detail reports available on the Reports menu and the reports available from the Analysis menu. Several predefined report methods are provided, and you can modify them.

Report Formatting

Using the dataent.fmt file found in $NX_ROOT/fig/cfg (UNIX) or installation_directory\fig\cfg (Windows) you can customize various data formats on the reports you print. You can view and modify this file using any text editor (Windows users should use WordPad to edit the file).

The following lines in the file control some of the date and time formats:

```
default_date = "long_date"
short_date = "M/D/YY// Enter a date as MM/DD/YY"
long_date = "MM/DD/YYYY// Enter a date as MM/DD/YY"
default_tod = "hour_12"
hour_12 = "h:mm:ss a(am,pm)// Enter a time of day as hh:mm:ss am/pm"
hour_24 = "HH:mm:ss// Enter a time of day as 00:00:00 - 23:59:59"
hms_12 = "h:mm:ss a(am,pm)// Enter a time of day as hh:mm:ss am/pm"
hms_24 = "HH:mm:ss// Enter a time of day as 00:00:00 - 23:59:59"
default_date_time = "date_time12"
date_time12 = "M/DD/YYYY h:mm:ss a(am,pm)// Enter a date and time as MM/DD/YY hh:mm:
ss am/pm"
date_time24 = "M/DD/YYYY HH:mm:ss// Enter a date and time as MM/DD/YY 00:00:00-23:59:
59"
```

The following code is an example of how you can change these lines to support European dates and times:

```
default_date = "long_date"
short_date = "D/M/YY// Enter a date as DD/MM/YY"
long_date = "DD/MM/YYYY// Enter a date as DD/MM/YYYY"
default_tod = "hour_24"
hour_12 = "h:mm:ss a(am,pm)// Enter a time of day as hh:mm:ss am/pm"
hour_24 = "HH:mm:ss// Enter a time of day as 00:00:00 - 23:59:59"
hms_12 = "h:mm:ss a(am,pm)// Enter a time of day as hh:mm:ss am/pm"
hms_24 = "HH:mm:ss// Enter a time of day as 00:00:00 - 23:59:59"
default_date_time = "date_time24"
date_time12 = "M/DD/YYYY h:mm:ss a(am,pm)// Enter a date and time as MM/DD/YY hh:mm:
ss am/pm"
date_time24 = "M/DD/YYYY HH:mm:ss// Enter a date and time as MM/DD/YY 00:00:00-23:59:
59"
```

Note: If you are using pdm_extract to export data from the CA SDM database to another system, and want to extract data to use the date format specified in the dataent.fmt file, use the -d flag when you invoke pdm_extract.

Data Analysis Setup

An interactive viewer provides an extensive set of tools for adjusting how the report data is viewed. You can drill to various levels of detail, such as from the group, to the assignee, or to the actual requests.

The interactive viewers lets you do the following:

- Change the appearance of the report by presenting the data in a different "block" format, such as a pie chart. For example, by right-clicking in the report and selecting "Turn table to," report presentation features appear.

- Perform different tasks, such as sorting, creating report breaks, calculating, filtering, and ranking the report.
- Share information with other users and groups.

Publish and Distribute Reports

Business Intelligence Launch Pad users can save report data in Excel, PDF or CSV format, and then distribute it to a file location, an inbox, email address, or FTP site.

When a report is approved for use within CA SDM, it is moved in to the public section making it available to authorized users. Security can be assigned to folders and documents to specify whether they can be accessed globally, by specific roles or by individuals. Security is administered in the BusinessObjects Central Management Console.

CA Business Intelligence Reports

CA Business Intelligence is a web-based component that packages Business Objects technology, integrated with CA SDM and a variety of common data sources, such as SQL Server, Oracle, and Open Database Connectivity (ODBC).

CA Business Intelligence uses BusinessObjects Enterprise as the default reporting system. Predefined reports are provided for CA SDM, Knowledge Management, and Support Automation.

With CA Business Intelligence reporting, users can do the following:

- Customize existing reports
- Drill down on Business Objects report data to show the data beneath charts and summarized groups
- Export instances of reports to different output formats
- Build ad hoc reports
- Publish new reports and distribute them to authorized users
- Schedule reports to run at specified times
- Use dashboard reporting to monitor daily operations for all CA SDM ticket types.

Access to Reporting is restricted through CA SDM Data Partitions Security.

Reporting Scenarios

CA Business Intelligence integrated with BusinessObjects Enterprise supports the following reporting scenarios:

- **Role-based reporting** -- From the CA SDM Reports tab, authorized users can view reports defined for their role, then click the Business Intelligence Launch Pad button to manage their personal reports in Business Intelligence Launch Pad. CA SDM uses the Business Intelligence Launch Pad interface to collect, organize, and present information in report formats. In Business Intelligence Launch Pad, predefined reports are grouped in public folders.

- **Web-based reporting** -- Web-based reports are predefined reports in CA SDM, Knowledge Management, CMDB, and Support Automation. They are developed with either Web Intelligence or Crystal Reports. The reports are accessed in Business Intelligence Launch Pad and can be used as models for defining site-specific reports.

- **Ad hoc reporting** -- Ad hoc reports are created and administered from Business Intelligence Launch Pad using a Web Intelligence plugin-based interface. You can store and manage reports in a personal workspace (My Folders). Ad hoc reporting is intended for users who want to create basic reports easily without writing queries.

- **Dashboard reporting** -- Dashboard reporting lets you monitor daily operations for all CA SDM ticket types (request/incident/problem, change order, or issue) in Business Intelligence Launch Pad. Each report contains analytics about the top performers working on active tickets, so you can monitor their progress. You can work with individual predefined dashboard reports or use the corporate dashboard to view all CA SDM daily operations in a single view.

- **Feature and Sample Reports** -- Feature and Sample reports that appear in the public section in Business Intelligence Launch Pad are provided by BusinessObjects Enterprise to illustrate the process of creating new reports in Web Intelligence. For more information, see *BusinessObjects* documentation.

Role-Based Reports

Contents

CA SDM presents role-based reports in two reporting frames on the Reports Tab. Each frame provides graphical views that let users drill down on report data to show the data beneath charts and summarized groups. You can manage role-based reports and display new BusinessObjects reports on the Reports tab. You can drill down

The Reports List page contains details of reports that are available for use. You click the Reports List icon that appears in the selected frame to display this page.

Define Role-Based Reports for the Role

You can manage the report web forms that display on the Reports List page when a user assigned to this role is logged into the system.

Follow these steps:

1. From the Administration tab, navigate to Security and Role Management, Role Management, Role List.
   The Role List page appears. The following default roles are available for Reporting:

   - Change Manager
   - Customer Service Manager
   - Knowledge Manager
   - Knowledge Analyst
   - Service Desk Manager
   - Incident Manager
   - Problem Manager

2. Select *one* of the Reporting roles from the list.
   The Role Detail Form page appears. This page contains the following tabs:

   - **Authorization**
     Allows you to define the authorization level assigned to the role.
   - **Function Access**
     Defines role access to each CA SDM functional area.
   - **Web Interface**
     Customizes the web interface for the role by defining the web pages and online help content the users can access.
   - **Knowledge Management**
     Specifies the Knowledge Management privileges for the role
   - **KT Document Visibility**
     Specifies which document statuses the role is allowed to view (for example, draft, retired, and published).
   - **Tabs**
     Defines the tabs that appear when a user assigned to this role is logged in to CA SDM.
   - **Report Web Forms**
     Defines the report web forms that are available to this role.

- **Go Resources**
  Specifies which record types appear in the "Go" drop-down list for the role. On the Role Detail page, select the Report Web Forms tab.

3. Click the Report Web Forms tab.
   The Reports Web Form List page appears. This page contains details of reports available for use.

4. Click Update Web Forms.

5. Enter the search criteria to display the web forms and click Search.

6. Select the web forms you want to display for this role. You can select multiple items.

7. When you have selected all the forms you want, click Select Button.

8. Click OK.
   The Role Detail page appears, with the selected web forms listed on the Report Web Forms tab.

Display New Reports on the Reports Tab

When a report is approved for use within CA SDM, it is moved in to the public section in Business Intelligence Launch Pad making it available to authorized users. To add the report to CA SDM, the administrator must perform some additional steps.

You can display new reports created in CA Business Intelligence on the CA SDM Reports tab. Use the following tools to accomplish this task:

- Web Screen Painter
- Role Management

Before you begin, do the following:

- Install and configure CA Business Intelligence so it works with CA SDM.
- Established user permissions, roles, and authentication (see page 3205) options for your reporting environment.

Step 1 - Create Two Web Form Records to Call the New Reports

By default, the Reports tab contains two reporting frames that let authorized users display new reports. In this step, you will create two web form records and define the URLs that point to the new reports.

Follow these steps:

1. From the Administration tab, navigate to Security and Role Management, Role Management, Web Forms.

2. Click Create New and click Save.

3. Fill in the following fields:

   - **Web Form Name**
     Specify a name that identifies the web form. This is a required field.
     Example: Asset List report

   - **Record Status**
     Specify active.

   - **Code**
     Specify a unique code value that identifies the web form to the system. After the code is defined, it cannot be changed.
     Example: asset_list

     > **Note**: Make a note of the value you enter in the Code field.

   - **Type**
     Select Report.

   - **Description**
     (Optional) Enter a brief description of the web form.

   - **Resource**
     Specify the URL that calls the new report.

     > **Example**: Open the Asset List web form from the Web Form list in Role Management and specify the URL that appears in this form.

     ```
     $BOServerURL?sPath=[Home],[Public+Folders],[CA+Reports],[CA+Service+Management],[CA+Service+Desk],[Asset]
     &sDocName=Asset+List&sViewer=htmlBOServerURL?sPath=[Home],[Public+Folders],[CA+Reports],[CA+Service+Desk],
     [Asset]&sDocName=Asset+List&sViewer=html
     ```

4. Repeat steps 1-3 to create a second web form record that will call the second report URL. Make a note of the value entered in the Code field.

Step 2 - Create a Mutliframe Page and Assign the New Reports

In Web Screen Painter, create a multiframe web page with two vertical frames called a Frameset. Then, assign the web form records created in step 1 to this Frameset.

> **Note**: You can create this page with any number of frames. Be aware that adding additional frames will limit visibility on the Reports tab.

Follow these steps:

1. In Web Screen Painter, select File, New.
2. Fill in the interface and form group fields as appropriate.
3. Select multiframe.template from the File Name list.
4. Click New.
5. Select Controls, Insert Frameset.
6. Do not change the default settings and click OK.
7. Right-click the left vertical frame and select Properties from the short-cut menu.
   The Properties - Frameset dialog box appears.
8. Select the blank field next to the web_form_name attribute, then click the (...) button.
   The Enter Web Form Name dialog box appears.
9. Specify the code value of the first report.
   Example: asset_list
10. After the report web form name is found, click Validate.
11. Right-click the right vertical frame, specify the code value of the second report, then validate the report.
12. Save the multiframe.htmpl page. Make a note of this file name.
    Example: report_mframe.htmpl
13. Select File, Publish.
    Publishing makes the form available to all CA SDM users. For the Analyst role, the file is available in the following location: Program Files/CA/Service Desk/Site/mods/www/htmpl /web/analyst/report_mframe.htmpl.

Note: When searching for multiframe web forms in CA SDM, navigate to Security and Role Management, Role Management, Web Forms on the Administration tab. The Code column specifies the web_form_name on the Properties tab for a multiframe form in Web Screen Painter.

Step 3 - Create a Start Page for the Reports Tab

In Role Management, create a start page to call the multiframe web page created in Step 2.

Follow these steps:

1. From the Administration tab, navigate to Security and Role Management, Role Management, Web Forms.
2. Click Create New.

3. Complete the following fields and click Save:

   - **Web Form Name**
     Specifies a name that identifies the web form. This field is required.
     Example: start page

   - **Record Status**
     Specifies active or inactive.

   - **Code**
     Specifies a unique code value that identifies the web form to the system. After the code is defined, it cannot be changed.
     Example: start_page

   - **Type**
     Specifies HTMPL.

   - **Description**
     (Optional) Specifies a brief description of the web form.

   - **Resource**
     Specifies the URL that calls the new report.
     Example: Select the Administrator Reports Multiframe record on the Web Form List page. Specify the URL that appears in this form. At the end of this path, specify the new multiframe page (report_mframe.htmpl).

     ```
     $cgi?SID=$SESSION.SID+FID=123+OP=DISPLAY_FORM+HTMPL=report_mframe.htmpl
     ```

Step 4 - Create a Reports Tab Record and Assign the Start Page

In Role Management, create a new Reports tab and specify the start page created in step 3.

Follow these steps:

1. Select Security and Role Management, Role Management, Tabs on the Administration tab.

2. Click Create New.

3. Complete the following fields and click Save:

   - **Tab Name**
     Specify the name that identifies the tab within the administrative interface. For example, the tab name appears on the Tab List page.
     Example: Reports Tab

   - **Code**
     Specify the code that identifies this tab to the system. Once the code is defined, it cannot be changed.
     Example: reports_tab

   - **Record Status**
     Specify active.

- **Display Name**
  Specify the name that appears on the tab's graphical presentation in the user interface.
  Example: Reports Tab

- **Starting Page**
  Specify the initial web form that appears in the main window when a user selects this tab.
  Example: start page

The form appears in the Web Form List page.

Step 5 - Assign the Tab Record to a Role Record

In Role Management, assign the Reports tab to the desired role listed on the Role Detail page. When a user assigned to this role logs in to the system, they will see the new Reports tab in the web interface.

Follow these steps:

1. Select Security and Role Management, Role Management, Role List on the Administration tab.

2. Select the desired role from the Role list.

3. On the bottom of this page, select Tabs, then Update Tabs.
   The new tab appears on the Tab List.

Step 6 - Create a Start Page for the Business Intelligence Launch Pad Button

You have the option of including the Business Intelligence Launch Pad button that opens Business Intelligence Launch Pad in a new window on the Reports tab. This option is controlled through the Starting Page option that appears on the Reports tab record.

Follow these steps:

1. From the Administration tab, navigate to Security and Role Management, Role Management, Web Forms.

2. Click Create New.

3. Complete the following fields and click Save:

   - **Web Form Name**
     (Required) Specifies a name that identifies the web form.
     Example: Business Intelligence Launch Pad page

   - **Record Status**
     Specifies active or inactive.

   - **Code**
     Specify a code value that identifies the web form to the system.

   - **Type**
     Specifies HTMPL.

- **Description**
  (Optional) Describes the web form.

- **Resource**
  Specifies the URL that calls the reporting frames.
  Example: Select the Administrator Business Intelligence Launch Pad record on the Web Form List page. Specify the URL that appears in this form. At the end of this path, specify the new Reports tab start page (start_page).

```
$cgi?SID=$SESSION.SID+FID=123+OP=DISPLAY_FORM+HTMPL=show_report_frames.htmpl+KEEP.report_form=start_page
```

Step 7 - Assign the Business Intelligence Launch Pad Button Start Page to the Reports Tab Record

In Role Management, assign the Business Intelligence Launch Pad button start page created in step 6 to the Reports tab record.

Follow these steps:

1. Select the new Reports Tab web form record from the Tab List page in Role Management.
2. Select Edit.
3. Specify the new Business Intelligence Launch Pad button start page in the Starting Page field.
4. Click Save.
   When a user opens the Reports tab, the Business Intelligence Launch Pad button appears in the top right corner of the form.

Work with Report Data

Reports that you access from the Reports List are developed with either BusinessObjects Web Intelligence or Crystal Reports.

Depending on the type of report that is deployed and the functions that are enabled by your administrator, you can perform a number of different activities, such as drilling and printing reports.

Note: When you work with reports in Business Intelligence Launch Pad, you can use additional features that are unique to working with Crystal Reports and Web Intelligence.

Ad Hoc Reports

Contents

Ad hoc reports are developed in Business Intelligence Launch Pad using Web Intelligence. You can create ad hoc reports. For more information about ad hoc reporting, see the BusinessObjects Enterprise documentation. To access the documentation, click the help icon in Business Intelligence Launch Pad.

Web Intelligence Interface

In Business Intelligence Launch Pad, Web Intelligence provides a custom reporting tool and it is intended for users who want to create basic reports easily without writing queries. Web Intelligence uses predefined report models and templates that manage data connections, querying, and data relationships, so you need only drag and drop data fields onto a template to create tabular or matrix reports. You can use all Business Intelligence Launch Pad features that are described in the *Business Intelligence Launch Pad User documentation*. A Web Intelligence document references a BusinessObjects object named a universe to create reports. You build new reports on BusinessObjects universes. CA Business Intelligence provides the CA SDM universe with the product.

How Ad Hoc Reporting Works

Ad hoc reporting works as follows:

1. You start the ad hoc report by first selecting the CA SDM universe in Business Intelligence Launch Pad.

2. The universe maps to the CA SDM database containing corporate business information. When you connect to a universe, Web Intelligence automatically launches the document editor selected on the Web Intelligence Document Preferences page in Business Intelligence Launch Pad.

> **Note:** For information on setting preferences, see the *Business Intelligence Launch Pad User's documentation*.

3. Using the universe, you build queries to retrieve data to use in a report from objects grouped in folders called classes. Each class can also contain one or more subclasses. Subclasses contain objects that are a further subcategory of the objects in the upper level of the class. Classes and Objects are presented in a tree structure (hierarchy) in the Data tab.

   Note: For instructions on how to build queries for Web Intelligence documents, see the BusinessObjects Enterprise documentation.

4. After you have built your query, by adding the required objects to the Result Objects pane, and defined query filter properties, you are ready to run the query. When you run a query, the universe asks the database to retrieve the data that corresponds to the demands of each of the objects in the query. You run a query by clicking Run Query on the toolbar.

   Important! When selecting objects for your query, always choose objects, measures and filters from only one universe base class and its subclasses. If you include objects, measures and filters from multiple universe base classes in a query, you might receive unexpected results and poor performance.

Before you Begin

This section provides high-level information to help you define preferences and other options. It also provides some considerations for creating new reports.

Define Web Intelligence Options

Ensure that you define Web Intelligence Document Preferences to suit your query and reporting needs before you begin creating new reports.

Follow these steps:

1. Click the Preferences button on the Business Intelligence Launch Pad toolbar.

2. Click the Web Intelligence Document Preferences tab.
   The Web Intelligence Document Preferences page appears.

3. In the "Select a report panel" area, select the report panel that you want to use when you create or edit Web Intelligence documents.

4. Select other options as appropriate.

5. Click OK.
   Business Intelligence Launch Pad displays the page you were on previously. For more information about preferences and options, see the *Business Intelligence Launch Pad User's documentation*.

Define Drill Options

You set your drill options in Business Intelligence Launch Pad. When you change your drill options, the changes are implemented the next time you start Drill mode.

Follow these steps:

1. On the Business Intelligence Launch Pad toolbar, click Preferences.
   Click the Web Intelligence Document Preferences tab.

2. The Web Intelligence Document Preferences page appears.

3. In the Select a view format section, select HTML or Interactive.

Define Query Properties

You can set properties for the query that can optimize the time taken for the query to run or the amount of data returned. Properties are grouped together in sections on the Query Properties page in the Result Objects pane.

To limit the number of rows returned to reports

1. Click Query Properties in the Query toolbar.
   The Query properties window appears.

2. Type the number of maximum rows you want to be retrieved.

To limit the run time for queries

1. Click Query Properties in the Query toolbar.
   The Query properties window appears.

2. Type a Maximum retrieval time in seconds.

Considerations for Creating a New Report

When creating a new report, the following criteria should be considered:

- The fields selected from Result Objects are the selection columns for the SQL query and reports.
- Do not mix fields of one class with another, because the reports may not work properly if you do.
- Restrict the number of columns required for the report. Choosing too many columns may degrade the report performance.

Create a Basic Report

You can create a new report for CA SDM to add new fields, queries and query filters other than the ones in the existing reports.

This section provides introductory information to help you create a new report using BusinessObjects.

Select the CA SDM Universe

You start the report by first selecting the CA SDM universe in Business Intelligence Launch Pad. The universe maps to the CA SDM database containing corporate business information. When you connect to a universe, Web Intelligence automatically launches the document editor selected on the Web Intelligence Document Preferences page in Business Intelligence Launch Pad.

Follow these steps:

1. Click New, Web Intelligence Document from the menu bar.
   The New Web Intelligence Document page appears.

2. Select the CA SDM universe in the Universe column.

   The Web Intelligence document appears along with the universe information in the left pane.

Define Data Retrieved by Queries

In the universe, objects are grouped into folders called classes. Each class can also contain one or more subclasses. Subclasses contain objects that are a further subcategory of the objects in the upper level of the class. Classes and Objects are presented in a tree structure (hierarchy) in the Data tab.

You can build one or more queries to use in your report as follows.

Follow these steps:

1. Drag and drop the objects from the Data tab (left pane) to the top right pane under Results Objects.
   The object appears in the Result Objects pane.

2. Drag and drop the fields to the bottom right panel under Query Filters.

3. (Optional) click Add Query to build a new query.

   Note: For instructions on how to use the report panel to build queries for Web Intelligence documents, see the *Building Queries Using the Web Intelligence HTML Query Panel* documentation.

Run Queries

After you have built your query, by adding the required objects to the Result Objects pane and defined query properties, you are ready to run the query. When you run a query, the universe asks the database to find the data that corresponds to the demands of each of the objects in the query. You run a query by clicking Run Queries on the toolbar.

View the SQL Generated by Queries

You can view the SQL generated by WebI for the query.

Click View SQL on the Query toolbar. The SQL Viewer window appears. In this window you can inspect the SQL behind the query that you have made.

Edit Queries In Existing Reports

You can edit the queries on which your report is based.

Follow these steps:

1. Open the document that you want to view.
   Click Document actions, and then select Edit.

2. The report appears and displays the queries that are defined for the document.

Save and Distribute Reports

You can save report data in Excel, PDF or CSV format, then distribute it to a file location, your Inbox, an email address or FTP site.

When a report is approved for use within CA SDM, it is moved to the Public section, thereby, making it available to authorized users. Security can be assigned to folders and documents to specify whether they can be accessed globally, by specific roles or by individuals. Contact your administrator for more information.

Note: For information on publishing and distributing reports, see BusinessObjects documentation.

Report Drill Analysis

Report drill analysis allows you to look deeper into the reasons behind results displayed. In Drill mode, you can:

- drill on tables
- drill on section cells
- drill on charts
- change how drilled results are filtered
- drill beyond report results
- save drilled results and ending Drill mode
- use query drill

To start analyzing reports using Drill, you need to switch to Drill mode. For more information, see BusinessObjects documentation.

Example of Ad Hoc Reports

You can work with Web Intelligence and query examples to create ad hoc reports using the default CA ServiceDesk. When you create a report, make sure that you save your report at regular intervals. If the Web Intelligence connection session times out, you will lose your report modifications.

Example - View All Open Priority 1 and 2 Requests for All Users

In this example, you specify prompt values that gather additional data before generating the report.

Follow these steps:

1. Click New, Web Intelligence Document from the menu bar.
   The New Web Intelligence Document page appears.

2. Select the CA ServiceDesk in the Universe column.
   The Web Intelligence document appears along with the universe information in the left pane.

   

   Note: To improve navigation, close the Attached Service Type folder in the left pane.

3. Locate and then expand the Request, Request Detail folders in the left pane. Use the scroll bar to locate folders.

4. Select each of the following objects, then drag and drop them from the left pane to the top right pane under Results Objects.

   - Summary
   - Priority Symbol
   - Customer Combo Name

5. Select the following objects, then drag and drop them to the bottom right panel under Query Filters. Close the Request Detail folder when you are finished.

   - Status Symbol
   - Priority Symbol

6. Expand the Request Filters folder, then drag and drop the Customer Combo Name with Userid filter to the bottom right panel under Query Filters.

7. In the Query Filters pane, click the In list arrow on the Status Symbol filter, and select the Equal to operator.

8. Select Value(s) from list from the Operand Type menu.
   The List of Values dialog box appears.

9. In the Status Symbol list, select Open, then click the green arrow.
   The value appears in the Value(s) Selected field.

10. Click OK.

11. In the Query Filters pane, click the In list dropdown on the Priority Symbol filter, and select the In List operator.

12. In the Priority Symbol list, multi-select 1 and 2, then click the green arrow.
    The values 1 and 2 appear in the Value(s) Selected field.

13. Click OK.

14. Click Run Query on the toolbar to generate the report.

> **Note**: Since the Customer Combo Name with Userid quick filter uses the Prompt function, the Prompts dialog box appears. This dialog allows you to gather additional data before the report is generated.

15. In the Prompts window, select the first option ALL, then click the green arrow button.
    All user names appear in the Select Customer list.

16. Click Run Query to generate the report.
    The report appears in a new window.

17. Double-click the report's title and type Priority 1 & 2 Open Requests for All Users in the text box. You can change the font size to 16 or other sizes.

18. To change other aspects of the report, click the Properties tab.

19. To sub-group the data by Customer Last Name, right-click any data cell in the Customer Last Name column, and select Set as Section.

20. Click Save and specify a location using the Save As option.

Example - View All Open Requests that Do Not Include a Status of Work In Progress

In this example, you specify the Count reporting function to return the total number of open requests.

Follow these steps:

1. Click New, Web Intelligence Document from the menu bar.
   The New Web Intelligence Document page appears.

2. Select the CA ServiceDesk in the Universe column.
   The Web Intelligence document appears along with the universe information in the left pane.

> **Note**: To improve navigation, close the Attached Service Type folder in the left pane.

3. Locate and then expand the Request, Request Detail folders in the left pane. (Use the scroll bar to navigate folders.)
4. Select each of the following objects, then drag and drop them from the left pane to the top right pane under Results Objects.
   - Status Symbol
   - Ref Num
   - Summary
5. Select the Status Symbol object, then drag and drop it to the bottom right panel under Query Filters. Close the Request Detail folder.
6. Expand the Request Filters folder, then drag and drop the Active filter to the bottom right panel under Query Filters.
7. In the Query Filters pane, click the In list arrow on the Status Symbol object, and select the Not Equal to operator.
8. Select Work in Progress from the Operand Type menu.
9. Click Edit Report on the main toolbar.
   The Report Viewer opens.
10. In the report, select the Ref Num column. This action enables the Insert Sum command on the Reporting toolbar.
11. Click the Insert Sum command, then select Count from the menu.
12. In the report, right-click the =[Status Symbol] cell, then select Set as Section from the context menu.
13. Click Refresh Data on the main toolbar to run the report.
14. Click Save.
    The report displays the total number (count) of requests that *do not* have a status of Work in Progress.

Example - View All Closed Requests in the Last 30 Days for Users Whose Last Name Begins with "C"

In this example, you specify prompt values for the Close Date and Customer Last Name that return all closed requests based on these values.

Follow these steps:

1. Click New, Web Intelligence Document from the menu bar.
   The New Web Intelligence Document page appears.

2. Select the CA ServiceDesk in the Universe column.
   The Web Intelligence document appears along with the universe information in the left pane.

   Note: To improve navigation, close the Attached Service Type folder in the left pane.

3. Locate and expand the Request, Request Detail folders in the left pane. Use the scroll bar to navigate folders.

4. Select each of the following objects, then drag and drop them from the left pane to the top right pane under Results Objects.

   - Ref Num
   - Close Date
   - Customer Last Name
   - Summary

5. Select each of the following objects, and drag them to the bottom right panel under Query Filters.

   - Status Symbol
   - Close Date
   - Customer Last Name

6. Click the In list arrow on the Status Symbol filter and select Value(s) from list from the Operand Type menu.
   The List of Values dialog box appears.

7. Select the following values in the Status Symbol list:

   - Closed
   - Closed-Unresolved
   - Close Requested
   - Problem-Closed
   - Problem-Fixed
   - Resolved

8. Click the green arrow.
   The values appear in the Value(s) Selected field.

9. Click OK.

10. In the Query Filters pane, click the In list arrow on the Close Date object and select the Between operator.

11. Click the In list arrow and select Prompt from the first and second Operand Type menus.

12. Click the In list arrow on the Customer Last Name object and select the Matches pattern operator.

13. Click the In list arrow and select Prompt from the Operand Type menu.

14. Click the Prompt Properties icon that appears next to the In list arrow.
    The Prompt dialog box appears.

15. In the Prompt text field, enter a pattern for Customer Last Name.

16. Click OK.

17. Click Run Query on the toolbar to generate the report.

    Note: Since the Close Date and Customer Last Name objects use the Prompt function, the Prompts dialog box appears. This dialog allows you to gather additional data before the report is generated.

18. In the Prompts window, select or type the prompt values for each prompt as follows:

    - Enter Close Date (Start): Specify a date that is 30 days earlier than today's date.
    - Enter Close Date (End): Specify today's date.
    - Enter a pattern for Customer Last Name: Specify C%.

19. Click Run Query to generate the report.
    The report appears in a new window.

20. Double-click the report's title and type View All Closed Requests in Last 30 Days for Users Whose Last Name Begins with "C" in the text box. You can change the font size to 16 or other sizes.

21. To change other aspects of the report, click the Properties tab.

22. Click Save and specify a location using the Save As option.

Dashboard Reports

You can use dashboard reporting to monitor daily operations for all CA SDM ticket types (request /incident/problem, change order, or issue), Knowledge Management, Support Automation, and CMDB in Business Intelligence Launch Pad. Each report contains analytics about the top performers working on active tickets, so you can monitor their progress.

With dashboard reporting, you can:

- View summary and detail information about active tickets by priority, analyst, category, or group.
- Find out how many tickets were resolved within a particular time frame and much more.
- Edit, print, track, and save reports in other formats, such as .xls and .pdf.

You can work with individual predefined dashboard reports or use the corporate dashboard to view all CA SDM daily operations in a single view. The corporate dashboard shares vital information about daily operations for all ticket types (request/incident/problem, change order, or request) by priority, analyst, category, or group.

Note: When you work with dashboard reporting, you can use the Business Intelligence Launch Pad features that are described in the Working with Dashboard and Analytics section of the *Business Intelligence Launch Pad User's documentation*. To access the documentation, click the help icon in Business Intelligence Launch Pad.

Web Based Reports

Contents

CA Business Intelligence installs a set of web-based, predefined reports for CA SDM and Knowledge Management. They are developed with either BusinessObjects Enterprise Web Intelligence or Crystal Reports. The reports can be used as models for defining site-specific reports.

These reports are contained in folders that are automatically deployed to the CA Business Intelligence reporting server after installation.

Security can be assigned to folders and documents to specify whether they can be accessed globally, by specific roles, or by individuals.

Business Intelligence Launch Pad includes documentation that describes how to use Business Intelligence Launch Pad. To access the documentation, click the help icon in Business Intelligence Launch Pad.

Business Intelligence Launch Pad Interface

From the CA SDM Reports Tab, analysts and managers can work with reports defined for their role or manage their personal reports by clicking the Business Intelligence Launch Pad button. From Business Intelligence Launch Pad, users can access Crystal Reports and Web Intelligence Documents, and other objects, and organize them to suit their preferences.

The features that are available in Business Intelligence Launch Pad vary by content type, but in general, the user can view information in their web browser, export it to other business applications (such as Microsoft Excel), and save it to a specified location.

Note: The folders and objects that users see in Business Intelligence Launch Pad are dependent on their group (role) assignment.

You can navigate the folders in the left-hand pane of the Business Intelligence Launch Pad window to view, schedule, modify, or run the report or to view the history and properties for a report. From the Start menu, select All Programs, CA Business Intelligence 4.1, Java Business Intelligence Launch Pad. In the left pane, navigate the folder structure-Public Folders/CA Reports/CA Service Management/CA ServiceDesk. Click the folder that corresponds to the type of report you want to view. Click the report name for the type of information you want to see.

Important! If you are using the Oracle database and want to generate All Change Impact Report, CIs Relationships Report, and Root Cause Analysis Report, then click Oracle (These Reports will work on Oracle Only) from the CMDB folder to access the reports. If you generate these reports from the SQL Server folder, the reports are not generated and an error message is displayed. Similarly, if you are using the SQL database and want to generate All Change Impact Report, CIs Relationships Report, and Root Cause Analysis Report, then click SQL Server (These Reports will work on SQL Server Only) from the CMDB folder to access the reports.

Business Intelligence Launch Pad Preferences

Users can set general preferences to specify that Business Intelligence Launch Pad should start with one of their personal dashboard pages designed with Web Intelligence's My Business Intelligence Launch Pad tool. They can also set their personal Web Intelligence and Crystal Reports viewing preferences.

Schedule Reports

Business Intelligence Launch Pad supports scheduling of reports. For ad hoc reporting, scheduled reports are stored in the My Folders section. If a report is set to "refresh on open" the system will access the database to obtain the latest information each time the end user views the report. Users can schedule reports to run at certain times.

Administrators can define calendars to reflect appropriate scheduling dates. For example, a user can select a calendar using the "When" option (for timing and frequency) that will display available business days and ignore non-working days.

Note: For more information on scheduling reports, see BusinessObjects documentation.

With scheduling, users can:

- Specify the timing and frequency of the schedule (now, hourly, daily, and weekly, for example).
- Specify the destination, such as an inbox, file location or email recipient.
- Indicate which inboxes the report should be sent to.
- Specify the output, such as Web Intelligence, Crystal Report, Microsoft Excel, and Adobe Acrobat.
- Specify caching options. By default, the document results are stored on the Output File Repository Server. Users can choose to have the system cache the report on the Web Intelligence Report Server by selecting a cache format and locale.
- Select a server group to process the request. If a defined event is selected, the object will run only when the additional condition or event occurs.

Note: If CA SDM data partitions are used to manage data restrictions in Business Intelligence Launch Pad's public folder section, scheduled reports contained in public folders must be defined for each user.

You can schedule a report to run at a specific time of the day, week, or month. You must have the appropriate authorization to perform scheduling. Right-click a report and select Schedule specify the appropriate settings and click Schedule.

Access Your Personal Folders or Inbox

You can access objects in your personal folders or inbox.

Follow these steps:

1. On the Navigation panel toolbar, click Show Folders.
   Business Intelligence Launch Pad folders are displayed in the Navigation panel. By default, My Folders and Public Folders are displayed.
2. Expand My Folders.
3. Click Favorites or Inbox.

Reporting Components

BusinessObjects Enterprise and its associated tools, coupled with BusinessObjects Crystal Reports 2013 are the backbone of the CA Business Intelligence architecture.

Although Crystal reports are delivered as the primary component of CA Business Intelligence, the report creation and maintenance tool, Crystal Reports 2013, is not delivered as part of CA Business Intelligence.

Note: Microsoft Access predefined reports are no longer developed or provided with CA SDM.

You can use the following components to administer, monitor, and configure the CA Business Intelligence reporting environment:

- **CA SDM Database/ Domsrvr / ODBC Driver --** Report data is stored in a SQL Server or Oracle CA SDM database. BusinessObjects reporting applications (Crystal Reports and Web Intelligence) access the database using an ODBC driver that connects directly with the CA SDM object engine (domsrvr). All CA SDM security, including data partition and tenancy restrictions, is automatically applied to reports, but not to your reporting environment. You can set up your reporting environment so it works with existing data partitions in CA SDM.

  Note: For information on how to establish data partitions security for your reporting environment, see How to Set Up Data Partitions Security for Reporting (see page 3205).

- **Central Management Server (CMS) --** The central repository that stores all objects used in every reporting process.

- **Central Management Console --** An administrative component that provides access to all BusinessObjects administration functions. Using the CMC, you can deploy reports and assign user access and folder permissions for Business Intelligence Launchpad. User permissions, roles, and authentication options must be established for your reporting environment using the CMC.

  Note: User permissions, roles, and authentication options must be established for your reporting environment before you use CA Business Intelligence. For more information on defining security, see Security and Authentication (see page 3205).

- **BusinessObjects Universe --** Describes the classes (tables) and objects (columns) which are used in reports. The CA SDM universe is installed and configured during the installation. At the completion of the installation, the universe connection is assigned to various groups and users in CA SDM.

- **Universe Design Tool --** A BusinessObjects component that lets you modify the CA SDM Universe, which is a metalayer between CA SDM schema, and BusinessObjects reporting tools. The Import /Export Wizard facilitates object population or extraction within the CMS.

- **Default Predefined Reports --** Predefined reports are web-based CA SDM and Knowledge Management reports developed with either Web Intelligence or Crystal Reports. The reports can be used as models for defining site-specific reports.

- **Business Intelligence Launchpad --** Business Intelligence Launchpad is a web interface that allows authorized CA SDM users to interact with web-based predefined reports by viewing, running, and scheduling report types including, but not limited to, Web Intelligence and Crystal Reports. Reports are contained in folders in the public section in Business Intelligence Launchpad.

- **Ad Hoc Reports --** Ad hoc reports let you create and administer reports using a Web Intelligence plugin-based interface. This tool is intended for users who want to create basic reports easily without writing queries.

  Note: For ad hoc reporting usage examples, see Ad Hoc Reports (see page 3190).

- **Dashboard Reports** -- Dashboard reports let you monitor daily operations for all CA SDM ticket types (request/incident/problem, change order, or issue) in Business Intelligence Launchpad. Each report contains analytics about the top performers working on active tickets, so you can monitor their progress.

- **CA SDM Reports Tab --** Authorized users can view their role-based reports on the CA SDM Reports tab, then click the Business Intelligence Launchpad button on this tab to manage their personal reports in Business Intelligence Launchpad.

  Note: For information on how to manage role-based reports and display new reports on the Reports tab, see Web-Based Reports (see page 3201).

Replicated Database for Offline Reporting

To manage potential performance issues that may affect the reporting components installed with CA SDM, you can create a replicated database for offline reporting purposes.

Note: For more information about creating a replicated database for offline reporting, see the sample documentation and scripts delivered in the NX_ROOT\samples\reporting directory.

Security and Authorization

This article contains the following topics:

The default security configuration for BusinessObjects Enterprise is performed through the CA Business Intelligence configuration. The configuration determines the security policies of folders, universes, universe connections and tools. It also provides methods for adding users and mapping them to groups, and setting some preference options.

Specifically, the CA Business Intelligence reporting configuration involves:

- Setting up security
- Deploying reports
- Deploying universes
- Configuring Web Intelligence settings

At the completion of installation, the universe connection is assigned to various groups and users in CA SDM.

The administrator can log on to the BusinessObjects CMC and modify the default settings at any time. Users are authorized access to Business Intelligence Launch Pad folders based on the CA Business Intelligence group to which they belong.

Groups and Users

The Groups listed in the following table will be added to the Central Management Server (CMS) during the CA Business Intelligence configuration. They relate to CA SDM roles with the same names. During the configuration phase, an optional check box was available to indicate whether sample users are added to the CMS. If it was selected, your default CMS configuration includes one sample user for each group. In the CMC, you can use these sample users as models when you establish user permissions and authentication options for your reporting environment.

Group Name	User Name
Change Manager	Change Manager User
Customer Service Manager	Customer Service Manager User
Knowledge Manager	Knowledge Manager User
Knowledge Analyst	Knowledge Analyst User
Service Desk Manager	Service Desk Manager User
Incident Manager	Incident Manager User
Problem Manager	Problem Manager User
Support Automation Admin	Support Automation Admin User
Support Automation Analyst	Support Automation Analyst User

CA SDM Data Partitions in Business Intelligence Launch Pad

Consider the following information about the relationships between CA SDM data partitions and Business Intelligence Launch Pad:

- The analyst connects to CA Business Intelligence through the Reports tab in CA SDM or in Business Intelligence Launch Pad with the access type of a default reporting role.
- The CA SDM login credentials *must* match the Business Intelligence Launch Pad credentials. The administrator sets an authentication method such as secLDAP or secEnterprise. CA SDM logs in to CA Business Intelligence, which then logs in to CA SDM through the ODBC.
- The CA Business Intelligence analyst login associates with the CA SDM login. CA Business Intelligence uses this CA SDM login and the reporting role associated with the access type of the login. If the analyst does not have an associated CA SDM login, CA Business Intelligence uses the system default. The system default is defined in the ODBC parameters in the Universe Designer and the reporting role of the access type.
- To restrict a user from viewing a report, the administrator can disable access to the report or the folder that contains it.

Universe and Universe Connections

The default configuration also includes the security policy for accessing the CA SDM universe and universe connections. To allow full access, all of the default groups are defined to have Full Control access.

Group Name	Access Level
Change Manager	Full Control
Customer Service Manager	Full Control
Knowledge Analyst	Full Control
Knowledge Manager	Full Control
Service Desk Manager	Full Control
Incident Manager	Full Control
Problem Manager	Full Control
Support Automation Admin	Full Control
Support Automation Analyst	Full Control

Report Folders

The default configuration comes with a set of folders containing predefined reports for CA SDM and Knowledge Management. Each CA SDM group is configured to have access to a subset of these folders.

Folder Name	Group Name	Access Level
Aggregate	Change Manager	View
	Customer Service Manager	View
	Knowledge Manager	No Access
	Knowledge Analyst	No Access
	Service Desk Manager	Full Control
	Incident Manager	View
	Problem Manager	View

Folder Name	Group Name	Access Level
Asset	Change Manager	View on Demand
	Customer Service Manager	View
	Knowledge Manager	No Access
	Knowledge Analyst	No Access
	Service Desk Manager	Full Control
	Incident Manager	View
	Problem Manager	View
Change Order (includes all sub-folders)	Change Manager	Full Control
	Customer Service Manager	No Access
	Knowledge Manager	No Access
	Knowledge Analyst	No Access
	Service Desk Manager	View
	Incident Manager	View
	Problem Manager	View
Issue (includes all sub-folders)	Change Manager	No Access
	Customer Service Manager	Full Control
	Knowledge Manager	No Access
	Knowledge Analyst	No Access
	Service Desk Manager	No Access
	Incident Manager	No Access
	Problem Manager	No Access
Request (includes all sub-folders)	Change Manager	No Access
	Customer Service Manager	No Access
	Knowledge Manager	No Access
	Knowledge Analyst	No Access
	Service Desk Manager	Full Control
	Incident Manager	View
	Problem Manager	No Access
Knowledge Management	Change Manager	No Access
	Customer Service Manager	View
	Knowledge Manager	Full Control
	Knowledge Analyst	View
	Service Desk Manager	Schedule
	Incident Manager	View
	Problem Manager	View
Survey	Change Manager	No Access
	Customer Service Manager	No Access
	Knowledge Manager	View
	Knowledge Analyst	No Access
	Service Desk Manager	Full Control
	Incident Manager	View
	Problem Manager	View
Incident and Problem Management	Change Manager	No Access
	Customer Service Manager	No Access
	Knowledge Manager	View
	Knowledge Analyst	No Access
	Service Desk Manager	Schedule
	Incident Manager	Full Control
	Problem Manager	Full Control

Access Levels

The default configuration includes the following access levels for groups and users:

- **No Access**
  Sets all permissions to Not Specified.

- **View**
  Allows the user to see the folder, report or universe. If the report contains data, the user can open and interact with it. If the report does not contain data, the user cannot refresh the report. By default, the user can edit the report and save to a personal folder and refresh it there. You can explicitly prevent users from copying corporate documents to personal folders by setting an individual right that denies "Copy Objects to another folder".

- **Schedule**
  Allows a user to schedule a report but not refresh it in real time.

- **View On Demand**
  Allows a user to refresh a report in real time. When the report is a Web Intelligence document, the user also needs View On Demand access to the Universe and Universe connection to perform the refresh.

- **Full Control**
  Allows a user to create new reports within a folder, modify existing reports or delete items.

- **Advanced**
  When the preceding access levels do not meet your needs, we provide more granular access by choosing advanced.
  When a user or group's access level is set to Advanced, more granular control of rights is available than those assigned through the selection of View, Schedule, View On Demand or Full Control.

BusinessObjects folders use inherited security. You receive the same authority in lower level folders as that of the top folder level that was assigned to you or your group, unless overriding restrictions are applied at lower levels. Default authorizations are provided at the folder level and group level. Users will inherit the rights of their group for all objects in the folder and subordinate folders.

CA Business Intelligence is installed with two groups: Administrators and Everyone. The Everyone group is assigned an Access Level of Schedule which allows scheduling and viewing of all report objects.

Point an Existing CA Business Intelligence Server to a CA SDM Server

If you have an existing CA Business Intelligence server, you can point it to a CA SDM server as follows:

1. Create 32 bit DSN and 64 bit DSN on CA Business Intelligence Server (see page).
2. Configure the Universe (see page 3211).
3. Export the Universe (see page 3211).
4. Launch Business Intelligence Launch Pad to verify the connection.

Create 32 bit DSN and 64 bit DSN on CA Business Intelligence Server

Follow these steps:

1. Launch odbcad32.exe from the following locations:
   - (for 64bit DSN) C:\Windows\System64
   - (for 32bit DSN) C:\Windows\System32
2. Select the System DSN tab and click Add.
   The Create New Data Source page appears.
3. Select CA Service Desk Manager and click Finish.
   The DataDirect OpenAccess ODBC Setup page appears.
4. Specify casd_*servername* in the ODBC Name field.
5. Click Advanced.
   The Advanced page appears.
6. Click Add.
   The Open Access Database Setup page appears.
7. Complete the following fields:
   - **Name**. Specify casd_*servername*.
   - **IP Address**. Specify the *servername* or IP address.

     Note: Ping *servername* to determine its IP address to use the IP address instead of *servername*.
   - **Port**. Specify 19987.
   - **Type**. (Optional) Specify the database used on the server. This field is only used as reference information.
8. Click OK.
9. Select casd_*servername* from the Database drop-down list.
10. Click OK.
    The ODBC data source is created.

Configure the Universe

After you create the ODBC data source, you need to configure the universe by establishing a connection between CA SDM and CA Business Intelligence. CA Business Intelligence Release 4.1 Client tools are required to configure the universe.

Follow these steps:

1. Launch Universe Design Tool and login as administrator.
2. Click File, Import.
3. Browse and select your CA SDM universe and click OK.
4. Click File, Parameters.
5. Click Edit.
6. Specify the username and password of the CA SDM privileged user, such as ServiceDesk.
7. Select casd_*servername* from datasource name and click Next.
8. Click Test Connection to verify that the CA SDM universe communicates with CA Business Intelligence.
9. Click Next, Next, Finish.
   The universe is configured.

Export the Universe

A universe is available to Web Intelligence users only when you export the universe to the repository. Commonly, you import a universe, make changes, then export the updated universe. This method ensures that the CMS (repository) version is synchronized with the file version. If you create a linked universe, you export it to the repository.

When you save a universe, you update the version in the repository file system. However, saving does not update the CMS version. When you export a universe, the update of the version in the repository file system is synchronized with the update of the universe in the CMS. The universe is then available to users.

CA Business Intelligence Release 4.1 Client Tools is required to export the universe .

Follow these steps:

1. Select File, Export, then perform one of the following actions:
   - Select a universe folder from the folder drop-down list.
   - Click the Browse button and select a universe folder in the folder browser.

   You want to export the universe to this folder.

2. (Power Users only)If you want to lock the universe, double-click the universe name.
   A locked universe appears with a padlock symbol. To unlock a universe, double-click it again.

3. (Power Users only)Click a group in the "Groups" list, which is the user group that uses the exported universe.

4. Click a universe in the "Universes" list. The "Universes" list shows the names of the active.

5. If you want to export other universes that are not open:

   a. Click the Add Universe button.

   b. Use the browser to select the other universes.

   c. Click OK.

   The universe is exported to the repository and is also available in the Universe folder that you selected.

Set Up Data Partitions Security for Reporting

This article contains the following topics:

Access to CA Business Intelligence reporting is restricted through CA SDM Data Partitions Security. All CA SDM security, including data partition and tenancy restrictions, is automatically applied to reports.

Data partition security for your specific reporting environment is not applied during the configuration phase. You set up your reporting environment so it works with existing data partitions in CA SDM.

Use the following tools to accomplish this task:

- **BusinessObjects Central Management Console** (CMC) -- Lets you administer BusinessObjects Enterprise user authentication and permissions.
