Suppose that you configure the Network Area to assign configuration item-based auto assignments using the network_contact_uuid attribute as the Assignable CI Attribute value. Tickets that are opened for the Network Area are assigned automatically to the group that is specified for Network Operations in the corresponding CI. If no CI is associated with the ticket, the Network Operations value of the CI is blank, or a group is not specified, the ticket is not assigned. In such cases, the system acts in accordance with the Option Manager option, Area Defaults, and assigns the ticket using the Group and Assignee fields of the Category.

How Configuration Item-Based Auto Assignment Works

Request/Incident/Problem tickets must specify the following for configuration item-based auto assignment to occur:

- A configuration item and an Area.
- The Area must have the Auto Assignment option set to Configuration Item Based.

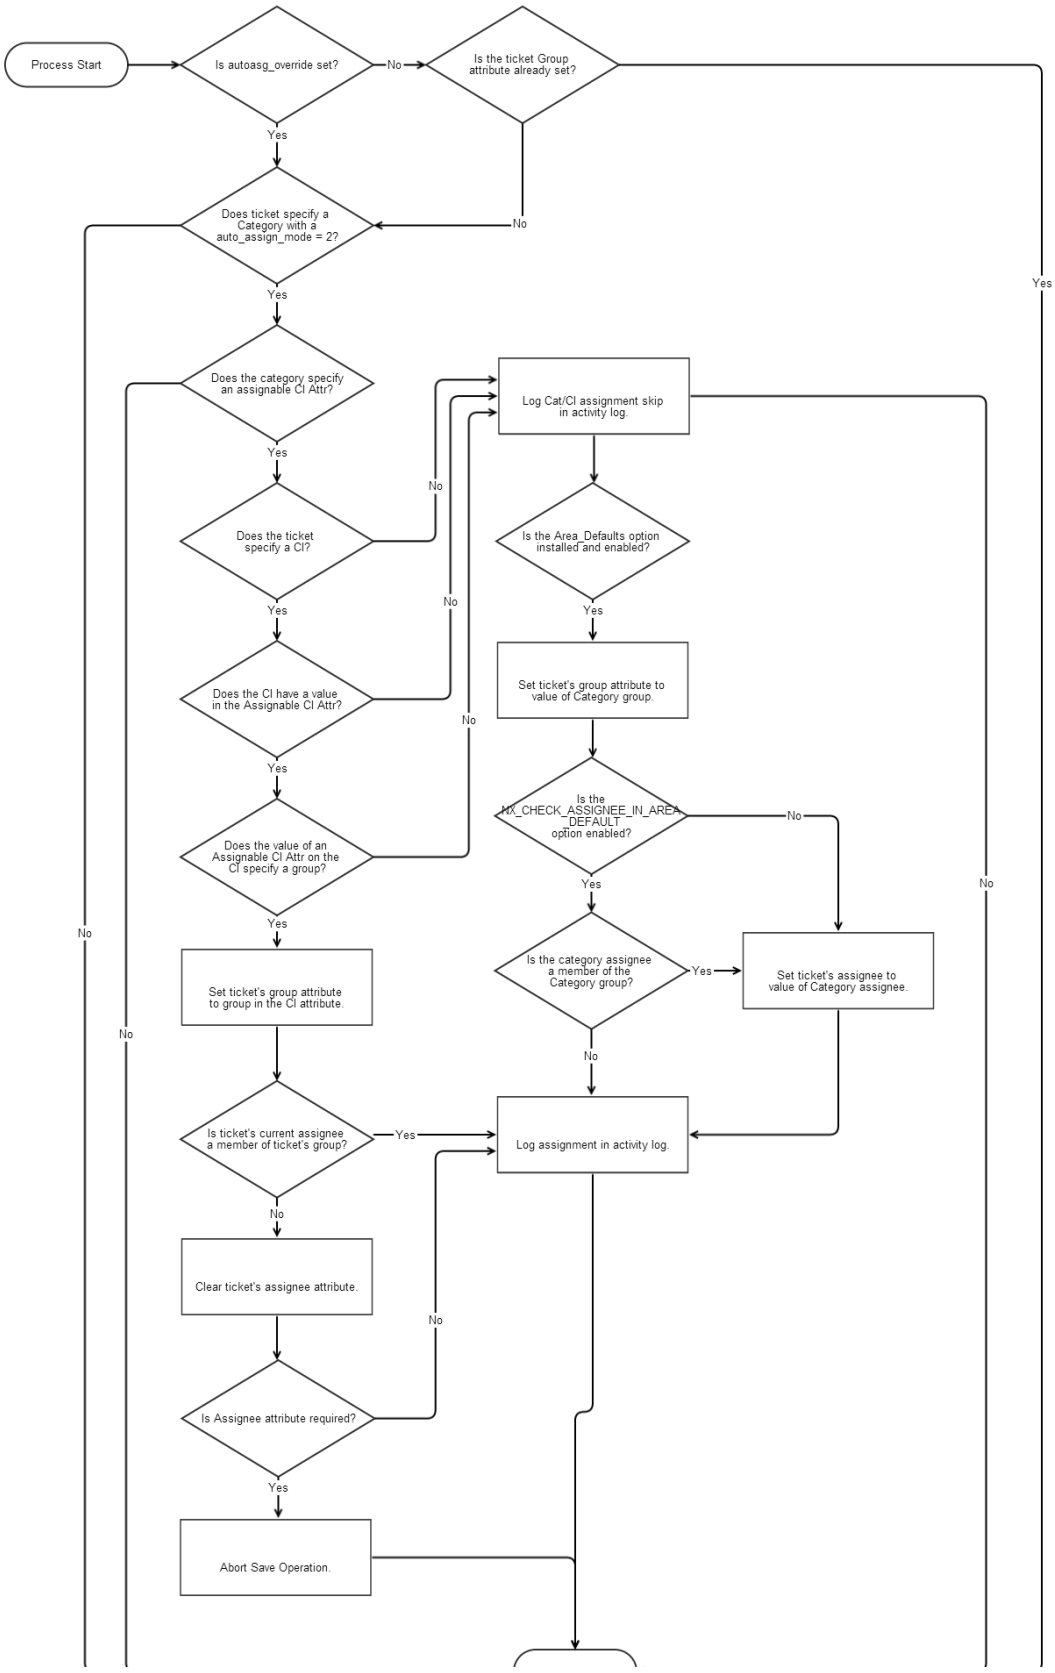
When an analyst creates and assigns a ticket to this Area, or changes the Area on an existing ticket, CA SDM examines the Assignable CI Attribute field of the Area. CA SDM uses the value of Assignable CI Attribute as the name of an attribute and then attempts to find an identically named attribute on the configuration item that is associated with the ticket. If the attribute on the configuration item includes a group, the ticket is assigned to that group.

The following diagram describes the process for configuration item-based auto assignment in more detail:

1. CA SDM checks for the following:
    a. Is the autoasg_override option set?
    b. Does a ticket specify an Area with its Auto Assignment auto_assign_mode=2?
    c. Does the category specify an assignable CI attribute?
    d. Does the ticket specify a configuration item?
    e. Does the configuration item have an assignable CI attribute value?
    f. Does the value specify a group in the CI attribute?
    g. Is the assignee of the ticket a member of the ticket group?
2. When the answers are positive for all questions in the previous step, CA SDM sets the group attribute of the ticket to the group attribute of the CI, and logs the assignment in the activity log.

Note: The diagram shows how Configuration Item-Based Auto Assignment uses the NX_CHECK_ASSIGNEE_IN_AREA_DEFAULTS variable to determine if the Area option is enabled. NX_CHECK_ASSIGNEE_IN_AREA_DEFAULTS is a variable in the NX.env file, which is located in the $NX_ROOT\ directory.

3. CA SDM assigns the ticket to the group.



Process Start
Is autoasg_override set?
No
Is the ticket Group attribute already set?
Yes
Does ticket specify a Category with a auto_assign_mode = 2?
No
Yes
Does the category specify an assignable CI Attr?
Yes
Log Cat/CI assignment skip in activity log.
Does the ticket specify a CI?
No
Yes
Is the Area_Defaults option installed and enabled?
Yes
Does the CI have a value in the Assignable CI Attr?
No
Yes
Set ticket's group attribute to value of Category group.
Does the value of an Assignable CI Attr on the CI specify a group?
No
Yes
Is the NX_CHECK_ASSIGNEE_IN_AREA_DEFAULT option enabled?
No
Yes
Set ticket's group attribute to group in the CI attribute.
Is the category assignee a member of the Category group?
Yes
Set ticket's assignee to value of Category assignee.
No
Is ticket's current assignee a member of ticket's group?
Yes
Log assignment in activity log.
No
Clear ticket's assignee attribute.
Is Assignee attribute required?
No
Yes
Abort Save Operation.
No
No
No
Yes

Enable Configuration Item-Based Auto Assignments

Configuration item-based auto assignment lets you create group-specific assignments that apply to specific scenarios. You can specify that for Request/Incident/Problem tickets opened for a particular Area, the value of an attribute of the configuration item associated with the ticket controls its assignment. Configuration item-based auto assignment reassigns tickets whenever the Request /Incident/Problem Area of a ticket or configuration item changes.

Note: The Options Manager autoasg_override option controls the circumstances under which auto assignment takes place. When you set this option to 1, CA SDM ignores any existing assignee and group settings and auto assigns tickets in all cases. If you want CA SDM to auto assign tickets only if they are not already assigned, set the option value to 0.

Follow these steps:

1. On the Administration tab, browse to Service Desk, Request/Incident/Problems, Areas.
   The Request/Incident/Problem Area List appears.

2. Click the area to edit.
   The Area Detail page appears.

3. Click Edit.
   The Update Area page appears.

4. Select the Auto Assignment tab, and complete the fields as follows:

   - **Auto Assignment Mode**
     Specifies how auto-assignment occurs. You use the Configuration Item Based option to base the auto assignment on the CI Assignable Attribute value.

   - **Assignable CI Attribute**
     Specifies the configuration item attribute to use for the group assignment. You can enter a value directly or click the magnifier to search for an attribute.

   Click Save.
   Auto assignment is enabled. CA SDM performs configuration item-based auto assignments using the attribute that you specified in the Assignable CI Attribute field.

Activity Logging

Auto assignment logs information as events in the ticket's activity log. The success or failure of auto assignment is logged, and any anomalies that may have occurred during processing.

Enable Activity Logging for Additional Attributes

Activity logs display changes attribute values of objects. Objects such as all ticket types, classic workflow tasks, Surveys, Contacts, and Configuration Items feature activity logging. You can enable activity logging for additional attributes In WSP.

Note: You can view activity log simple attributes, including strings, integers, date, duration, and SREL types. You cannot view activity logs for list types, such as QRELs and BRELs.

Follow these steps:

1. Open WSP and start the Schema Designer.
2. Select the table that you want to modify, and add additional attributes.
3. For each attribute, add +AUDITLOG() to the site-defined UI_INFO field.

   Important! When you add the AUDITLOG flag, you *must* also remove the val_fieldupdate_site() function to prevent duplicate activity logs.

4. Save and publish the schema
5. Open WSP again and add the new attributes to the appropriate detail forms.
6. Open CA SDM and define an Activity Association for the additional attributes.
7. Test your changes.
   For example, open a previously-saved instance of the object and modify the affected attributes to verify that the appropriate activity logs appear.

Auto Assignment Tracing

In a complex auto assignment implementation, auto assignment may not make the decisions that were expected. Tracing can be enabled to help you understand the processing flow. Tracing is normally turned off but when turned on, numerous messages are written to the stdlog files in $NX_ROOT\log that describe the various decisions made by auto assignment.

Use caution when implementing this in a high-volume installation, as the number of messages generated could cause the log files to grow and eventually wrap. On very active systems, performance degradation may occur. Tracing is controlled with the pdm_logstat utility. The parameters used by this utility are case-sensitive. Be sure to enter them as shown.

To turn tracing on, run the following command on each CA SDM the server:

```
pdm_logstat  -f auto.pm milestone
```

To turn off tracing, run the following command on each CA SDM the server:

```
pdm_logstat  -f auto.pm
```

Create a Stored Query

CA SDM supports use of stored queries to produce two kinds of data:

- Scoreboard Queries let you configure the web interface scoreboard by adding counter fields for items of interest.
- KPI Queries let you retrieve historical information for a specified time period on the value of a counter for use in web-based reporting.

Stored queries apply to all service desk models. Stored queries are not intended to bring users to a new page.

Administrators define the stored queries that are available to users. You can use the predefined stored queries that are installed with CA SDM, or define your own. You can define stored queries by using the administrative function of the web interface.

Consider the following information about stored query definitions:

- A valid stored query clause is integrated into an appropriate SELECT statement and passed to the underlying DBMS engine for processing. To develop the SELECT statements, see the object definition files in the following directories:
  - Windows: installation-directory\bopcfg\majic directory
  - UNIX: $NX_ROOT/bopcfg/majic directory
- Stored queries use the object and attributes statements for building the SQL WHERE clause instead of the field names at the database level.
- CA SDM does not support Cartesian product joins for stored queries. To help ensure that your stored query does not produce a Cartesian product join, enter the following command appropriate for your system.
  - Windows: bop_cmd -f *installation-directory*\bopcfg\interp\bop_diag.frg "check_queries()"
  - UNIX: bop_cmd -f $NX_ROOT/bopcfg/interp/bop_diag.frg "check_queries()"

  Update any queries that are flagged as a result to avoid Cartesian product joins.
- The URL stored query is an option offered while creating stored queries. The URL stored query runs a query and returns numerical results that only work with Knowledge Management.

Stored queries are supported for the following:

- **Scoreboard Queries** -- Allow you to configure the Web Interface scoreboard by adding counter fields to monitor items of interest.
- **KPI Queries** -- Allow you to retrieve historical information for a specified time period on the value of a counter for use in web-based reporting.

- **Automated Policy Queries** -- Allow you to retrieve information about the documents that are flagged for correction and promoted to publication or retirement during the various stages of the document lifecycle.

You can create stored queries for use in configuring the Scoreboard, or defining KPIs, or both.

Note: When you save a stored query, validation testing is performed on parameters. If you attempt to save a stored query with an invalid parameter (for example, datespan @cnt, @root) the save fails and an error message appears.

Follow these steps:

1. Click CA SDM, Application Data, Stored Queries on the Administration tab.
   The Stored Query List appears.

2. Click Create New.
   The Create New Stored Query page appears.

3. Complete the stored query fields (see page) as appropriate.

4. Click Save.
   The Create Stored Query Detail page displays your entries.

Stored Query Fields

You can use the fields on the Stored Query pages to define and edit query definitions.

Note: If you are using multi-tenancy, a tenant column appears on the list page.

The following fields require explanation:

- **Code**
  Defines a unique identifier for the stored query.

- **Scoreboard Usage**
  Specifies whether the query is available for configuring the Scoreboard.

- **KPI Usage**
  Specifies whether the query is available for configuring a KPI

- **Record Status**
  Specifies whether the stored query is active or inactive.

- **Type**
  Specifies the type of CA SDM object for which the stored query produces data (Contact, Request, Change Order, and so on).

- **Label**
  Defines the text string to be displayed on the Stored Query List page.

- **Where Clause**
  The SQL WHERE clause for the query. A WHERE clause includes a comparison predicate, which restricts the number of rows returned by the query.

Manage Roles

Contents

Roles are the primary records that control CA SDM security and user interface navigation. Each role defines a focused view of the system by exposing only the functionality necessary for users to perform the tasks typically assigned to the role they perform within their business organization.

A user's default role determines the system view that is presented upon login. Users with multiple role assignments can switch from one role to another to see different views of the system without having to log out and log back in again.

Predefined Roles

You can use the predefined roles in their default configuration, modify them to meet your business requirements, or create new roles.

The following table describes the predefined roles installed with CA SDM. These roles are designed to align with ITIL v3 best practices, and thereby reduce the amount of site-specific modifications required to bring your IT organization into ITIL compliance.

CA SDM only supports ITIL, and the CA SDM documentation is ITIL-oriented. For more information, see ITIL Configuration.

Role Type	Role Name	Description
End Users	Configuration Viewer	Performs basic CI viewing and research tasks from inside your organization.
	Customer	Performs basic self-service tasks from outside your organization.
	Employee	Performs basic self-service tasks from inside your organization.

Role Type	Role Name	Description
Analysts	Configuration Analyst	Performs tasks within the configuration item life cycle process and second-line CMDB support within your organization.
	Customer Service Representative	Supports users external to your organization, most often customers.
	Knowledge Analyst	Performs tasks within the knowledge management life cycle process.
	Level 1 Analyst	Provides first-line support within your organization.
	Level 2 Analyst	Provides second-line support within your organization, which requires more advanced subject matter expertise.
	Support Automation Analyst	Provides first-line support within your live assistance environment.
	Vendor Analyst	Supports a limited segment of your IT environment from outside your organization, such as vendor-specific hardware.
Managers	Change Manager	Manages the change order process, but typically not the analysts who work on change order tickets.
	Customer Service Manager	Manages Customer Service Representatives and the external support process.
	Incident Manager	Manages the incident process, but typically not the analysts who work on incident tickets.
	Knowledge Manager	Supervises Knowledge Analysts, knowledge document reassignments and escalations, and day-to-day knowledge administration.
	Problem Manager	Manages the problem process, but typically not the analysts who work on problem tickets.
	Service Desk Manager	Handles escalations and supervises Level 1 Analysts. Also may manage overall service desk operations.
Administrators	Administrator	Performs administrative tasks throughout your CA SDM and Knowledge Management implementation. This role typically installs, configures, and integrates the products.
	Configuration Administrator	Performs administrative tasks related to your CA CMDB implementation. This role typically administers CMDB and configuration item infrastructure and data structures.
	Knowledge Management Administrator	Configures and monitors knowledge management settings.
	Service Desk Administrator	Performs administrative tasks on data and processes, such as creating and updating categories, contacts, service types, root causes, and so on.
	Support Automation Administrator	Performs administrative tasks related to your Support Automation environment, such as configuring queues and analyst tool permissions.

Role Type	Role Name	Description
	System Administrator	Performs administrative tasks related to your CA SDM implementation, configuration and adaptation, such as setting options, configuring integrations and modifying web forms.
	Tenant Administrator	Performs multi-tenancy administrative tasks specific to a particular tenant or supporting organization.

Create a Role

Roles are the primary records that control security and user interface navigation. Each role defines a focused view of the system by exposing only the functionality necessary for users to perform the tasks typically assigned to the role they perform within their business organization.

Predefined roles are provided that are designed to align with ITIL v3 Best Practices and thereby reduce the amount of site-specific customization required to bring your IT organization into ITIL compliance. You can use the predefined roles in their default configuration, modify them to meet your business requirements, or create new roles.

Administrators can create roles to meet site-specific business requirements.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Security and Role Management, Role Management, Role List on the Administration tab.
2. Click Create New.
3. Complete the following fields:
   - **Code**
     Specifies the code that identifies the role to the system.

     Note: After you save the record, this field value cannot be changed.

   - **Record Status**
     Indicates whether the role is Active or Inactive.
   - **Default?**
     Indicates whether this role is the default role.
   - **Customization Form Group**
     Specifies a predefined or custom form group.

- **Preferred Document**
  Specifies the document used by this role for entering tickets into the system.

Click Save.
The role definition is saved and the Role Detail page appears.

4. Update the information in the role tabs (see page).

Role Tabs

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

The following tabs are available on the Role Detail and Update Role pages:

- **Authorization**
  Allows you to define the authorization level assigned to the role. Complete the following fields as appropriate:

  - **Grant Level**
    Specifies the access permission that users assigned to this role can grant to others. The grant level is used to determine which access types a user can grant to another user. You can assign an access type to the contact record of another user only if the access level of the access type you are attempting to assign is ranked the same as or lower than the grant level for your own access type. These levels are ranked as follows:

    - Admin (highest)
    - Analyst
    - Cust/Emp
    - None (lowest)

  - **View Internal Logs?**
    Allows users assigned to this role to view internal log files.

  - **Data Partition Name**
    The name of the data partition assigned to this role. Data partitions are subsets of the database with restricted access to data records, based on their content. You restrict that access by defining a set of constraints for each data partition.
    Enter the data partition name directly into the field, or click the search icon to search for a data partition name.

  - **Override Contact Data Partition?**
    Select this option if you want the data partition defined for the access type to override the data partition defined on the contact record. This option can help prevent conflicts from arising between data partitions specified on the contact records and data partitions specified on the role record.

- **Multi-Tenancy Settings**
  The following options apply to systems where multi-tenancy is enabled:
  Update Public (Service Provider only)
  Select this option if you want users that are assigned to this role to update data for all tenants and non-tenanted data.
  Tenant Access
  Select the tenant or tenant group that you want users assigned to this role to be able to read. If you select Single Tenant, you can enter the name of the tenant that you want this role to read. You can assign the following associations to roles:

  - **Same As Tenant Access (Tenant Write Access Only)**
    Sets Tenant Write Access to be the same as the Tenant Access setting. Default for Tenant Write Access and only valid for Tenant Write Access.

  - **All Tenants**
    Removes tenant restrictions. CA SDM allows a user in a role with this access to view any object in the database (read access) or create and update (write access) any tenanted object in the database. When users with All Tenant access create an object, CA SDM requires that they select the tenant of the new object.

  - **Single Tenant**
    Sets a role's tenant access to a named tenant. When this option is selected, a second field appears on the web UI that allows selection of a specific tenant. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects associated with the named tenant. This selection is valid for either Tenant Access or Tenant Write Access.

  - **Tenant Group**
    Sets a role's tenant access to a user-defined or system-maintained tenant group. When the Tenant Group option is selected, a second field appears on the web UI that allows selection of a specific tenant group. CA SDM restricts a user with the role to view (read access) or create and update (write access) only those objects associated with one of the tenants in the group. When a user with tenant group access creates an object, CA SDM requires that they select the tenant for the new object. This selection is valid for either Tenant Access or Tenant Write Access.

  - **Contact's Tenant**
    Sets a role's tenant access to the tenant of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects associated with their own tenant. This selection is valid for either Tenant Access or Tenant Write Access.

  - **Contact's Tenant Group (Analyst Only)**
    Sets an analyst's role access to the tenant group that the analyst works with, as specified on the analyst's contact record. If the user with the role is not an analyst, this selection has the same effect as Contact's Tenant. It is valid for either Tenant Access or Tenant Write Access.

  - **Contact's Subtenant Group**
    Sets a role's tenant access to the Subtenant group of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects associated with their own Subtenant group. This selection is valid for either Tenant Access or Tenant Write Access.

- **Contact's Supertenant Group**
  Sets a role's tenant access to the Supertenant group of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects associated with their own Supertenant group. This selection is valid for either Tenant Access or Tenant Write Access.

- **Contact's Related Tenant Group**
  Sets a role's tenant access to the Related Tenants Group of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects associated with their own Related Tenants Group. This selection is valid for either Tenant Access or Tenant Write Access.

All users can view public data, regardless of their current role's access rights. The Update Public check box controls whether a service provider user in the role has the authorization to create or update public data. Tenant users (users belonging to a tenant other than the service provider) cannot update public data, regardless of their role.

- **Tenant Write Access**
  Select the tenant or tenant group that you want users assigned to this role to be able to create and update. If you select Single Tenant, an additional field displays where you can enter the name of the tenant you want this role to access.

  Note: Either the Tenant Access or Tenant Write Access fields can be set to Contact's Tenant Group to reference the Analyst's Tenant Group on the Contact Detail page. If a user that is not an Analyst, or an Analyst with no Analyst's Tenant Group defined, uses a role with this access, their access is Contact's Tenant.

- **Support Automation Access**
  Defines the appropriate Support Automation access for this role.

- **Function Access**
  Allows you to define the role's access to each functional area.

- **Web Interface**
  Allows you to configure the web interface for the role by defining the web pages and online help content the users can access. Complete the following fields as appropriate:

  - **Web User Interface Type**
    The kind of Web Interface that used to present the product features. Most of the predefined roles use the Analyst interface. The Customer and Employee roles are assigned a restricted interface type because they are not allowed access to analyst, management, and administrative functionality.

  - **Web Initial Form**
    The initial web form that appears for this role.

    Important! This must be set to menu_frames_role.htmpl in order for role-based functionality to be active. Changing the name of this form to anything else negates the role-based functionality.

- **Help View**
  The name of the help set that appears for this role. Enter the name of the help set directly or click the search icon to select the help set from a list.

  Note: The list of available help sets is based on the web user interface type selected in the role. Only active help sets belonging to that interface type are available for selection. If you do not select the web user interface type before selecting the help view, no help sets are available for selection.

- **Knowledge Management**
  Allows you to specify the Knowledge Management privileges for the role. Fill in the following fields as appropriate:

  - **Open Issue/Request**
    Allows the role to open an issue and request.
  - **Open Issue/Request based on Document**
    Allows the role to open an issue and request based on a Knowledge Document.
  - **Bypass Approval Process**
    Allows the role to bypass the knowledge approval process.
  - **Change Approval Process Template**
    Allows the role to change the approval process template.
  - **Add, Edit, Copy and Paste Categories**
    Allows the role to manage Knowledge Categories.
  - **Delete Multiple Categories and Documents**
    Allows the role to delete parents and child categories and documents.
  - **Delete Category**
    Allows the role to delete a Knowledge Category.
  - **Create Document**
    Allows the role to Create a Knowledge Document.
  - **Create Document with Attachments**
    Allows the role to create a document with attachments.

    Note: If this option is disabled, the Attach File and Attach File from Library buttons do not appear for that role.

  - **Delete Knowledge**
    Allows the role to delete knowledge documents, forums and files.

- **View Forum**
  Allows the role to view forums.
- **Create Forum**
  Allows the role to create a forum.
- **Reply Forum**
  Allows the role to reply to a forum.
- **Edit Forum**
  Allows the role to edit a forum.
- **View File**
  Allows the role to view files.
- **Edit File**
  Allows the role to edit files.
- **View External Repository**
  Allows the role to view the external repository.
- **View Related Tickets**
  Allows the role to view related support tickets.
- **Add Bookmark**
  Allows the role to add bookmark to My Bookmarks.
- **Use Preferences**
  Allows the role to use preferences.
- **Allow Export**
  Allows the role to export knowledge packages.
- **Allow Import**
  Allows the role to import knowledge packages.

- **KT Document Visibility**
  Allows you to specify which document statuses the role is allowed to view (for example, draft, retired, and published).
- **Tabs**
  Allows you to define the tabs that appear when a user assigned to this role is logged in.

Important! Include *only* tabs that contain forms that are in the form group assigned to the role you are creating or editing. For example, assigning the Customer tab or Employee tab to the Administrator role causes an error when users attempt to access that tab. Including more tabs than your browser window can display causes some tabs to be inaccessible to the user.

Note: The role's form group is specified in the Customization Form Group field on the Role Detail page, and is also displayed in the Form Group column on the Role List page.

- **Report Web Forms**
  Allows you to define the report web forms that are available to this role.

- **Go Resources**
  Users can search for items in by a number, name, or ID. In the upper right-hand corner of the main window, there is a drop down list containing the searchable record types. These searchable record types are referred to as "go" resources. Allows you to specify which record types appear in the Go drop-down list for the role.

How to Implement a Custom Role

For many sites, the predefined roles are sufficient. There may be situations, however, when you want to create a custom role and tailor it to meet site-specific business needs within your organization.

The following process outlines the tasks required in implementing a new role. The example shown here describes how you might implement a role for a small group of analysts tasked with reviewing and authorizing change order tickets.

Follow these steps:

1. Create a new role record using the following field values:
   - **Role Name**
     Change Analyst
   - **Code**
     chg_anal
   - **Customization Form Group**
     Analyst
   - **Preferred Document**
     Incident
2. Select Service Desk Analyst in the Data Partition field on the Authorization tab.
3. Select the Modify in the Change Orders field on the Function Access tab.
4. Enter the following values on the Web Interface tab:
   - **Web User Interface Type**
     Analyst
   - **Help View**
     Change Analyst
5. Select the following tabs:
   - Reports tab - Change Analyst

- Service Desk tab - Change Analyst
- Change Calendar tab

6. Select the following reports on the Report Web Forms tab:
   - Active Change Orders Aging by Priority for Status
   - Active Change Orders at Weeks End
   - Change Orders by Failed Service Type for Change Categories
7. Add the Change Order resource on the Go Resources tab.
8. Create a custom help set named Change Analyst that includes all content appropriate for the new role.
   For more information, see Create and Publish a Help Set (see page).
9. Create the following custom tabs using features appropriate for the new role:
   - Reports tab - Change Analyst
   - Service Desk tab - Change Analyst
10. Create a custom menu tree that includes all nodes appropriate for the new role.
    For more information see How to Implement a Custom Menu Tree (see page 1178).

Switch Roles

Roles define the system functionality each user can access. Depending on your assigned role, a specific set of menus, tabs, and toolbar controls are presented when you log in in the Web Interface client. For example, administrative roles have access to the Administration tab, while analyst and manager roles typically do not.

Some users are allowed to access multiple roles, enabling them to switch from one view of the system to another. If you are assigned multiple roles, you can switch between them at any time without having to log out and back in again.

Follow these steps:

1. Select the desired role from the Role drop down list in the upper right corner of the main page of the Web Interface.
2. Click Set Role.

   The Web Interface and available functionality change to match the new role setting.

Create Help Sets

Help sets are the collections of online help topics available to users depending on their role assignments and current role setting. If you log in using the Administrator role, for example, you can view the online help topics included in the Administrator help set. If you switch to the Employee role, you can view the Employee help set.

Each predefined role has a corresponding predefined help set. You can create custom help sets for any custom roles you might define.

You can create custom help sets for any custom roles you might define.

Follow these steps:

1. Select Security and Role Management, Role Management, Help Sets on the Administration tab.

2. Click Create New.

3. Complete the following fields:

   - **Help Set Name**
     The unique name of this help set.

   - **Interface Type**
     The interface type of the help set (such as Analyst, Employee, or Customer).

   - **Record Status**
     Indicates whether the help set is Active or Inactive.

   - **File Name Prefix**
     The prefix you want to attach to the help files generated for this help set. Do not include spaces in the name.

     Note: Assign a prefix that allows you to identify the files belonging to this help set. For example, you may want to use ANAL for an analyst's help set prefix.

   - **Internal**
     This is automatically set to NO for user-defined help sets. The value in this field cannot be changed.

4. Click Save.

5. Click Define Content and select the content you want to include in the help set.

6. **Important!** Some topics are required, and are included in your new help set regardless of whether you select them. For example, the CA SDM home page and other front matter topics are always included. Also, nested topics are dependent on their container topics. Container topics are included automatically if you include any of their nested topics. For example, if you select the "Use the Scoreboard"

topic, the container topic "Navigate CA SDM" is included when you publish the help set. If you edit the contents of an existing help set by adding or removing topics, you may not see your content changes reflected in the help set's table of contents until you clear your browser cache. See your browser documentation for information on how to clear the cache

7. Click OK.
   The Selected Help Update window closes and the content is listed on the Contents tab.

8. Click Publish.
   This generates the help set by packaging the selected topics into a help system you can display in a web browser.

9. Wait a few moments for the publishing process to complete; then select View, Refresh on the menu bar.
   The View Help button becomes active.

10. Click View Help.
    The custom help set appears in your default web browser.

How to Manage Roles Using Menu Trees

Contents

You can manage roles using the menu trees, implementing a custom menu tree, and copying a menu tree.

Menu Trees

Menu trees are the hierarchical listings of nodes (menu tree resources) that are displayed in the navigation pane on the left-hand side of the main web interface window. Menu tree resources define the items users can access from the menu tree. A menu tree resource consists of a name, description, and a URL fragment or HTMPL filename used by the web engine that controls the web page displayed.

A role can have a menu tree, which provides nodes for access to many functional areas of the system. For example, the predefined Administrator role has a menu tree that includes nodes to the System and Role Management administration features, Service Desk administration features, and many others.

For roles that include a menu tree, the menu tree provides access to a specified set of resources that provide access to functional areas of the system.

CA SDM provides predefined menu trees for the following roles:

- Administrator (admin_tree)

- CA CMDB Administrator (cmdb_adm_tree)
- Knowledge Management Administrator (kt_adm_tree)
- Knowledge Manager (kt_mgr_tree)
- Support Automation Administrator (sa_admin_tree)
- Service Desk Administrator (sd_adm_tree)
- System Administrator (sys_adm_tree)
- Tenant Administrator (tn_admin_tree)

You can edit the Name, Record Status, and Description fields of the predefined menu tree records, but you cannot modify them by adding or removing their menu tree resources.

To produce a custom a menu tree, you can create new menu tree record or copy and modify one of the predefined menu trees.

Note: The non-modifiable Internal field on each menu tree record indicates whether the menu tree can be modified. A value of YES in the Internal field indicates a predefined menu tree, which cannot be modified. A value of NO indicates a site-defined menu tree, which can be modified. The Customize Menu button appears only on menu tree detail records with an Internal field value of NO.

When you attach a menu tree to a tab, it becomes available for all roles that have access to that tab.

How to Implement a Custom Menu Tree

For many sites, the predefined menu trees are sufficient. There can be situations, however, when you want to configure a role by implementing a custom menu tree for it.

In most cases, it is easier to start with a copy of a predefined menu tree and then add, remove, or reorganize nodes within the hierarchy. Alternatively, you can create a menu tree and construct an all new hierarchy of nodes.

You can use either of the following methods to make custom menu tree available to a role:

- Replace the menu tree in the web form (Start Page) for the tab that shows the original admin_tree.
- Create a web form and attach the new web form with the new menu tree to a tab.

Follow these steps:

1. Copy one of the predefined menu trees.

Note: Make a note of value you enter in the Code field.

2. Create a web form using the following field values:
   - **Type:** HTMPL
   - **Resource:**

```
$cgi?SID=$SESSION.SID+FID=123+OP=DISPLAY_FORM+HTMPL=admin_main_role.htmpl+KEEP.tree_code=menu_tree_code
```

   Note: Specify the value of the code for the menu tree you created in Step 1 for menu_tree_code. The admin_main_role.htmpl code uses the value of the KEEP. tree_code variable as its menu tree.

3. Create a tab record using the following field values:
   - **Starting Page:** The web form you created in Step 2
   - **Menu Bar:** Administration

   Note: Administration is a generic menu bar used by many roles; it is not role-specific.

4. Assign the tab you created in Step 3 to the role you want to have access to the custom menu tree.
5. Log out of CA SDM and log back in again.
   The Administration tab displays your custom menu tree.

Copy a Menu Tree

You can copy an existing menu tree to use as a starting point for a modified menu tree.

Follow these steps:

1. Select Security and Role Management, Role Management, Menu Trees on the Administration tab.
   The Menu Tree List page appears.
2. Click the Menu Tree to copy.
   The Menu Tree Detail page appears.
3. Click File, Copy.
   The Create New Menu Tree page appears.

4. Complete the following fields:

   - **Menu Tree Name**
     (Required) Specifies the name you assign that identifies this menu tree.

   - **Code**
     (Required) Specifies the code that identifies the menu tree to the system. After the code is defined, it cannot be changed.

   - **Record Status**
     Indicates whether this menu tree is active or inactive.

   - **Description**
     Describes the menu tree. The description can be used to give additional details about the menu tree and the roles that use it.

   Click Save.
   The Menu Tree Detail page for the new menu tree appears.

5. Click Customize Menu.
   A copy of the original menu tree appears.

6. Modify the menu tree as you want.

Create and Format a Menu Tree

You can create and format menu trees, based on one of the default menu trees provided.

Follow these steps:

1. Select Security and Role Management, Role Management, Menu Trees on the Administration tab.

2. Click Create New. The following fields require explanation:

   - **Menu Tree Name**
     (Required) The name you assign that identifies this menu tree.

   - **Code**
     (Required) The code that identifies the menu tree to the system. Once the code is defined, it cannot be changed.

   - **Record Status**
     Indicates whether this menu tree is active or inactive.

3. Click Save.

4. Click Customize Menu.
   A form appears, allowing you to modify the menu tree. At this point, the menu tree contains only a top node with the text you entered as the menu tree name.

5. Right-click the node in the menu tree and select Create New Node.
   The following fields require explanation:

   - **Node Name**
     Enter a name for the node. This is the name that appears in the menu tree.

   - **Description**
     Enter a description for the node. This description can be used to further define the purpose of the node.

   - **Resource**
     Enter the resource name directly in the field, or click the search icon to select the resource from a list. The menu tree resource determines the action to perform when the user selects the node from the menu tree.

6. Repeat steps 4 and 5 as many times as necessary to create the set of nodes you want to appear in the menu tree.

7. Click Save.
   The menu tree definition is saved and the Menu Tree Detail page appears.

Create a Menu Tree Resource

Menu tree resources are the items users can access from the left pane of one of the tabs. A menu tree resource consists of a name, its description, and a URL fragment or HTMPL filename used by the web engine that controls the web page displayed.

You can create your own menu tree resources to configure the user access points available from the left pane of a tab.

Follow these steps:

1. Select Security and Role Management, Role Management, Menu Tree Resources on the Administration tab.

2. Click Create New.

3. Fill in the following fields and click Save:

Name

The name displayed in the menu tree in the left pane of the tab. This is a required field.

Status

Indicate whether the resource is active or inactive. This is a required field.

Description

The description of the resource. The description can be used to further define the purpose of the resource.

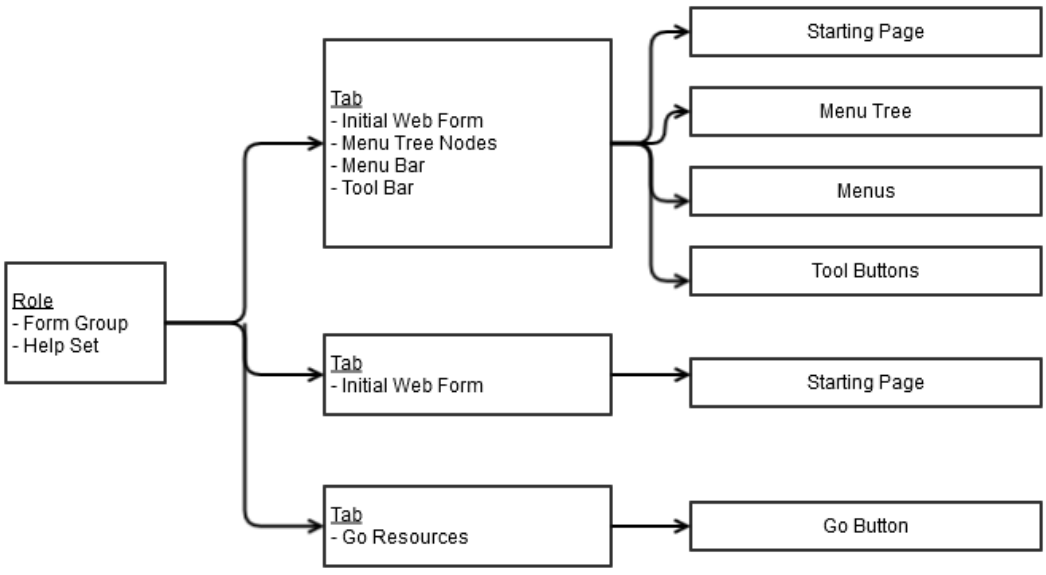
Resource

The action performed when the user selects the resource from the menu tree. This can be the name of the form that is displayed or the search operation that is performed.

How Role-Based Navigation Works

Contents

Each user's view of the web interface is defined by a role. Users with multiple role assignments can switch to multiple web interface views. The following diagram shows how roles interrelate with other objects to produce a role-based presentation of the user interface:



Create a Tab

A tab is a graphical display entity that links to a role in order to present features to the users of that role. When a user logs in to the system, the main window displays the tabs assigned to the user default role.

Tabs define major subdivisions in the web interface main window. Each tab is configured to expose an appropriate set of user interface features to the role or roles that use it.

All roles must have at least one tab. You can associate one or more tabs with a role. Each tab has a sequence number that controls its display order in the main window. If only one tab is associated with a role, the tab starting page is displayed and not the tab.

You can configure tabs to include the following kinds of display features:

- A starting page (default web form) that is displayed when a user selects the tab. The starting page is a required element of all tabs. You can assign only one starting page to each tab.

  Note: You can configure a starting page to display graphical reports from Business Object, which enables users to generate reports at run time. For more information, see CA Business Intelligence Reporting documentation.

- A menu bar, which presents drop-down lists of commands, such as File, View, and Search commands. The menu bar is optional. You can assign only one menu bar to each tab.

- A toolbar, which presents tool buttons for easy access to frequently used menu commands. The toolbar is optional.

CA SDM provides several predefined tabs. You can assign the predefined tabs to a role, modify the predefined tabs, and create custom tabs.

Important! Do not assign more tabs than your browser window can display; doing so causes tabs with higher sequence numbers to extend beyond the window viewable display area and make them inaccessible to the user.

Important! Include only tabs that contain forms that are included in the form group that is assigned to the role you are creating or editing. For example, do not assign the Customer tab or the Employee tab to the Administrator role; doing so causes an error when users attempt to access that tab. The role form group is specified in the Customization Form Group field on the Role Detail page, and is also displayed in the Form Group column on the Role List page. For a list of the web forms in each form group, see Form Groups.

You can create your own tabs to display on the main page. You can then define the tabs that display when users of different roles log into the system.

Follow these steps:

1. Select Security and Role Management, Role Management, Tabs on the Administration tab.
2. Click Create New.
3. Fill in the tab fields (see page) as appropriate and click Save.

Tab Fields

Code

The code that identifies this tab to the system. After you save the tab record, the code cannot be changed.

Record Status

Indicates whether the tab is active or inactive.

Display Name

The name of the tab that is displayed to users.

Starting Page

The initial web page that appears in the main window when a user selects this tab. The starting page and menu bar must belong to the same form group. Defining a tab with a starting page and a menu bar that belongs to different form groups causes an error when users access the tab.

Menu Bar

The menu bar that appears in the main window when a user selects this tab.

Predefined Tabs

The following table shows the predefined tabs that are assigned to each role. The tabs are listed in sequence number order, indicating their left-to-right position in the window.

Note: In many cases, there are multiple versions of tabs with the same display name. For example, the Service Desk tab for the Administrator role provides full access to CA SDM functionality, while the Service Desk tab for the Change Manager role is more focused on change orders.

Role	Tabs
Administrator	Service Desk tab with full menu and scoreboard Knowledge tab Administration tab with full menu tree Reports tab - Administrator Change Calendar tab CA CMDB tab Support Automation tab
Change Manager	Reports tab - Change Manager Service Desk tab - Change Manager Change Calendar tab
Configuration Administrator	CA CMDB tab Administration tab - Configuration Administrator

Role	Tabs
Configuration Analyst	CA CMDB Scoreboard - Configuration Analyst
Configuration Viewer	CA CMDB Scoreboard - Configuration Viewer
Customer	Customer tab
Customer Service Manager	Service Desk tab - Customer Service Manager Knowledge tab Reports tab - Customer Service Manager
Customer Service Representative	Service Desk tab - Customer Service Rep Quick Profile tab Knowledge tab
Employee	Employee tab
Incident Manager	Reports tab - Incident Manager Service Desk tab - Incident Manager Knowledge tab
Knowledge Analyst	Service Desk tab - Knowledge Analyst Knowledge tab Knowledge Management Schedule Knowledge Report Card tab Reports tab - Knowledge Analyst
Knowledge Manager	Service Desk tab - Knowledge Manager Knowledge tab Knowledge Management Schedule Administration tab - Knowledge Manager Knowledge Report Card tab Reports tab - Knowledge Manager
Knowledge Management Administrator	Administration tab - Knowledge Administrator
Level 1 Analyst	Service Desk tab - Level 1 Analyst Quick Profile tab Knowledge tab
Level 2 Analyst	Service Desk tab - Level 2 Analyst Knowledge tab Change Calendar tab
Problem Manager	Reports tab - Problem Manager Service Desk tab - Problem Manager Knowledge tab
Service Desk Administrator	Administration tab - Service Desk Administrator
Service Desk Manager	Reports tab - Service Desk Manager Service Desk tab - Service Desk Manager Knowledge tab Change Calendar tab
Support Automation Administrator	Service Desk tab - Level 1 Analyst Support Automation tab Support Automation Admin Quick Profile tab Knowledge tab
Support Automation Analyst	

Role	Tabs
	Service Desk tab - Level 1 Analyst Support Automation tab Quick Profile tab Knowledge tab
System Administrator	Administration tab - System Administrator
Tenant Administrator	Administration tab - Tenant Administrator
Vendor Analyst	Service Desk tab - Vendor Analyst

Create a Web Form

Web forms define the pages that appear in the CA SDM web interface.

There are four web form types:

- Business Object Report URL
- HTMPL page
- GO resource
- Custom (for example, a URL for a third-party web page)

Administrators can create web forms to be the starting pages for tabs, reports to display on tabs, "go button" resources, or another URL.

Follow these steps:

1. From the Administration tab, navigate to Security and Role Management, Role Management, Web Forms.
   The Web Forms List page displays.

2. Click Create New.
   The Create New Web Form page displays.

3. Complete the following fields:

   - **Web Form Name**
     (Required) Specifies the name that identifies the web form.

   - **Record Status**
     Indicates whether this form is active or inactive.

   - **Code**
     (Required) Specifies the code that identifies the web form to the system. After the code is defined, it cannot be changed.

     Note: This field specifies the web_form_name on the Properties tab for a multiframe form in Web Screen Painter.

- **Type**
  Specifies one of the following types of web form that you are creating:
  - **HTMPL page** -- Displays a web page to use as the starting page for one of the custom tabs you create.
  - **Report** -- Specifies a CA SDM report that displays on any tab.
  - **Go Resource** -- Specifies a "Go Button" resource.
  - **Other** -- Accesses any other external Web page through URL.
- **Description**
  Describes the web form. Use this description to further identify this web form, where it displays, and its purpose.
- **Resource**
  Specifies the code that calls the web form. This code can be command line code or a URL.
  Example: Open a simple htmpl form "menu_tab_dflt.htmpl":

```
$cgi?SID=$SESSION.SID+FID=123+OP=DISPLAY_FORM+HTMPL=menu_tab_dflt.htmpl
```

Click Save.

Form Groups

Form groups define the sets of CA SDM web interface pages that are available to a role. Each role has one form group. Users can display only the web pages that are included in the form group that is assigned to their role.

Each interface type has an associated form group, a set of HTMPL files that define the pages displayed to the users.

CA SDM provides the following predefined form groups:

- Analyst
- Customer
- Employee
- ITIL

You can use the predefined form groups in their default configuration, modify the predefined form groups, and create new form groups using Web Screen Painter. You can view a listing of the HTMPL filenames included in each predefined form group.

Create a Menu Bar

A menu bar is a user interface element that displays a horizontal list of menus in the web interface main window. Each menu contains a drop-down list of options or commands. You can define custom menu bars for any custom roles you might create. Menu bar records specify the HTMPL form that controls the menu items that the menu bar can access.

Note: To define the functionality of the menu bar, you must use the Web Screen Painter application. For information about configuring the functionality of a predefined or custom menu bar, see the *Web Screen Painter Online Help*.

The following table lists the predefined menu bars and identifies the predefined tabs that use them.

Menu Bar	Associated Tabs
Administration	Administration tab - Configuration Administrator Administration tab - Knowledge Administrator Administration tab - Knowledge Manager Administration tab - Service Desk Administrator Administration tab - System Administrator Administration tab - Tenant Administrator Administration tab with full menu tree
CA CMDB	CA CMDB tab with full menu and scoreboard
Change Calendar	Change Calendar tab
Knowledge	Knowledge tab Knowledge Management Schedule
Service Desk	Service Desk tab with full menu and scoreboard
Service Desk-Change Manager	Service Desk tab - Change Manager
Service Desk-Cust Service Mgr	Service Desk tab - Customer Service Manager
Service Desk-Cust Service Rep	Service Desk tab - Customer Service Rep
Service Desk-Incident Manager	Service Desk tab - Incident Manager
Service Desk-Knowledge Analyst	Service Desk tab - Knowledge Analyst
Service Desk-Knowledge Manager	Service Desk tab - Knowledge Manager
Service Desk-Level 1 Analyst	Service Desk tab - Level 1 Analyst
Service Desk-Level 2 Analyst	Service Desk tab - Level 2 Analyst
Service Desk-Problem Manager	Service Desk tab - Problem Manager
Service Desk-Service Desk Mgr	Service Desk tab - Service Desk Manager
Service Desk-Vendor Analyst	Service Desk tab - Vendor Analyst
Support Automation-Analyst	Support Automation tab - Support Automation Analyst

You can create your own menu bars to control the access to system functionality for your user-defined roles.

Follow these steps:

1. From the Administration tab, navigate to Security and Role Management, Role Management, Menu Bars.
2. Click Create New.
3. Fill in the menu bar fields (see page) as appropriate.
4. Click Save.

Menu Bar Fields

Code

The code that identifies this menu bar to the system. Once the code is defined, it cannot be changed. This is a required field.

Record Status

Indicates whether the menu bar is Active or Inactive.

HTMLP Name

The name of the HTMPL form that contains the menu bar definition. The menu bar is actually designed using the Web Screen Painter.

Go Resources

The *Go* button provides an easy means of locating a particular record.

Go resources are a type of web form. If a role has associated Go resources, when a user logs in with that role the Go button appears in the upper-right corner of the main CA SDM window and in all popup windows. The Go button has two associated fields in the user interface:

- A drop-down list for selecting the type of record to search for (for example, Change Order)
- A text box for entering a value to identify a particular record (for example, 135 to locate Change Order 135)

By assigning Go resources to a role, you can specify the kinds of records users in that role can search for. For example, the predefined Administrator role has the following Go resources:

- Change Order
- Document by ID
- Incident
- Issue
- Knowledge
- Problem

- Request
- User by ID
- User by Name
- User by Phone

Toolbars

Toolbars extend the functionality of menu bars by adding the capability to display one or more tool buttons to the right of the menus.

Tool buttons appear as icons on the toolbar. Clicking a tool button gives the user easy access to frequently used menu options or commands.

Note: You can use the Web Screen Painter application to define the functionality of the toolbar. For more information, see Using the Web Screen Painter (WSP) (see page 1898).

Create a Functional Access Area

Functional access areas define the role level access to ticket records and other system components. The usp_functional_access_type table defines the area and the usp_functional_access_level tables describe user access.

Name	Code Name	New
Administration	admin	No
Incident/Problem/Request	call_mgr	No
Change Order	change_mgr	No
Inventory	inventory	No
Issue	issue_mgr	No
Knowledge Document	kd	No
Notification	notify	No
Reference	reference	No
Security	security	No
Announcement	announcement	Yes
Incident/Problem/Request Reference	call_mgr_reference	Yes
Incident/Problem/Request Template	call_mgr_template	Yes
Change Order Template	change_mgr_template	Yes
Change Order Reference	change_reference	Yes
Configuration Item	ci	Yes
Configuration Item Common Readonly	ci_common_ro	Yes

Configuration Item Reference	ci_reference	Yes
Contact	contact	Yes
Group	group	Yes
Issue Template	issue_mgr_template	Yes
Issue Reference	issue_reference	Yes
Location	location	Yes
Multisite Administration	multisite_admin	Yes
Multisite Reference	multisite_reference	Yes
Notification Reference	notification_reference	Yes
Organization	organization	Yes
Prioritization	prioritization	Yes
Service Level	service_level	Yes
Site	site	Yes
Stored Query	stored_queries	Yes
Support Automation	sa	Yes
Survey	survey	Yes
Tenant Admin	tenant_admin	Yes
Timezone	timezone	Yes
Workflow Reference	workflow_reference	Yes
Workshift	workshifts	Yes

When you add a functional access area, the existing roles automatically have Modify access. You can review and change the access levels to grant the appropriate authority.

Follow these steps:

1. On the Administration tab, select Security and Role Management, Functional Access.

2. Click Create New.
   The Create New Functional Access List page appears.

3. Complete the functional access area fields as appropriate. The Code field defines the CA SDM or site-defined object name. Objects can only map to one functional access area. However, one functional access area can manage multiple objects.

4. Click Save.
   The Functional Access Detail page appears.

5. Apply access levels to one (see page 1193) or more (see page 1191) roles.

Apply Access Levels to Many Roles

For a functional access area, you can set the access levels for every role to save time. Instead of using Role Management, you update the functional access area with the appropriate role access levels.

Follow these steps:

1. On the Administration tab, select Security and Role Management, Functional Access.
2. Click the name of the function area.
3. On the Roles Tab, click Edit in List.
4. Review and update each role as appropriate. The following access levels are available:
   - **None**
     Denies the role access to the function object.
   - **View**
     Grants read-only capability to the function object.
   - **Modify**
     Grants read/write access to the function object.
5. Continue selecting roles and choosing access levels.
6. (Optional) Click Change All.
7. Click Save.
   The changes for the roles apply immediately.

Example: Change the Access Levels for the Announcement

This example shows you can role access levels for the Announcement functional access area.

1. On the Administration tab, select Security and Role Management, Functional Access.
   The Functional Access Detail page appears.
2. Click Announcement.
3. On the Roles Tab, click Edit in List.
4. Select Level 2 Analyst.
5. Select View from the Access Level.
   The Access Level for the Level 2 Analyst role highlights with the value of View.
6. Select Configuration Analyst.
7. Select Modify from the Access Level.
   The Access Level for the Configuration Analyst highlights with the value of Modify.
8. Click Save.
   A message confirms the change.
9. Log in as a Level 2 Analyst role.

10. Select View Announcements.
    The Announcements page appears.

11. Click an announcement.
    A message reminds you that as a Level 2 Analyst, you can only view announcements.

12. Set the Role to Configuration Analyst.

13. Select View Announcements.
    The Announcements page appears.

14. Click an announcement.
    The Update Announcement page appears. As a Configuration Analyst, you can modify announcements.

Apply an Access Level to a Role

You can use Role Management to change the way users access the user interface. When you change the access levels for a role, the user interface shows only objects, pages, and menu items based on the access level. For example, if a role can no longer create contacts, the File menu omits New Contacts.

Follow these steps:

1. On the Administration tab, select the Security and Role Management, Role Management, Role List.

2. On the Role List, right-click the role name and select Edit from the short-cut menu.

3. Click Edit in List on the Function Access tab.

4. Click a function name.
   The row highlights.

5. Update the functional access areas with the following access levels as appropriate:

   - **None**
     Denies the role access to the function object.

   - **View**
     Grants read-only capability to the function object.

   - **Modify**
     Grants read/write access to the function object.

6. Click Save.
   A message confirms the change. The role can immediately use the functional access area at the specified access level.

7. Verify the access level, by logging in as the role and checking menus, page options, and buttons.

Example: Grant the Level 2 Analyst Role Modify Access to Tickets

This example shows how the user interface changes when you grant a Level 2 Analyst access to modify tickets.

1. On the Administration tab, select the Security and Role Management, Role Management, Role List.
   The Role List appears.

2. Right-click Level 2 Analyst and select Edit from the short-cut menu.

3. Click Edit in List on the Function Access tab.

4. Select Incident/Problem/Request Reference.

5. Select Modify on the Access Level.
   The access level updates to Modify.

6. Click Save and log out.
   A message confirms the change.

7. Log in as a Level 2 Analyst role.

8. Select Search, Incidents.

9. Click Search and open an incident.
   The Incident Detail page includes an Edit in List button. As a Level 2 Analyst, you can modify the ticket.

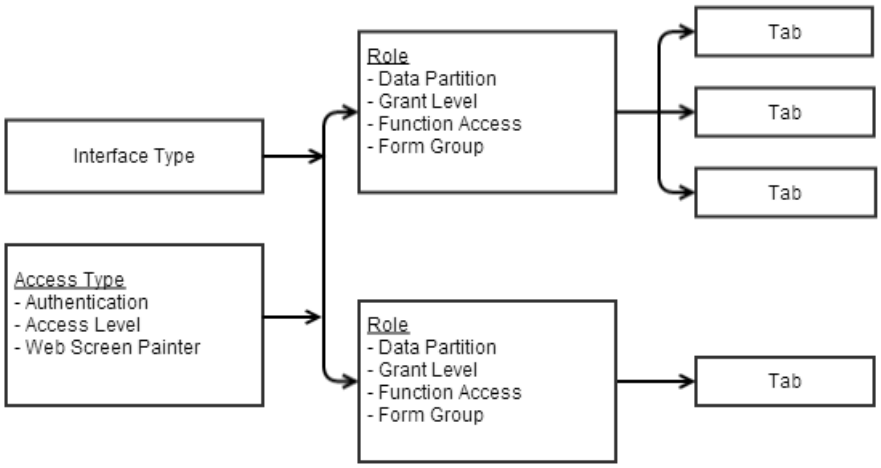
Role-Based Security

This article contains the following topics:

Access types and roles are the primary components you use to control CA SDM security.

The following diagram shows an overview of how roles interrelate with other system objects to provide role-based security.

Note: For more information about other aspects security, see Security (see page 1002).



How Access Types Work

Each access type for a user controls the following aspects of system behavior:

- How CA SDM performs web authentication when the user logs in
- The access level for the user
- Whether the user can modify web forms or the database schema using Web Screen Painter
- Which roles are available to the user

You can associate an access type with a contact by selecting the access type while creating or updating the contact record.

Note: The following table lists the predefined access types, identifies their linked roles, and gives a brief description.

Access Type	Linked Roles	Description
Administration	Administrator (default) Configuration Administrator Employee Level 2 Analyst Service Desk Administrator	Provides the highest level of security access to all key administration roles. Used during implementation and ongoing administration. **Note:** The Administration access type is preconfigured to allow administrators to switch to any of the linked roles. For example, to see a different view of the system, administrators can switch to the Employee role without having to log out and log in again.

Access Type	Linked Roles	Description
	System Administrator Tenant Administrator	
Customer	Customer	Provides highly restricted access to *external* customers who use the self-service view.
Employee	Employee	Provides highly restricted access to *internal* employees who use the self-service view. Used to create new incident and update incident pages.
IT Staff	Configuration Analyst Employee Level 2 Analyst (default) Knowledge Analyst Knowledge Management Administrator Knowledge Manager	Provides analyst-oriented access to users who work within your IT organization but are not actual members of the support team. This access is designed specifically for users who need access to Knowledge Management.
Knowledge Management	Configuration Administrator Configuration Analyst Configuration Viewer Employee Knowledge Analyst Knowledge Management Administrator (default) Knowledge Manager Level 2 Analyst	Provides administrative access tailored to users who administer Knowledge Management features.
Process Management	Change Manager Configuration Analyst Employee Incident Manager (default) Level 2 Analyst	Provides access tailored to users who perform key process management roles.

Access Type	Linked Roles	Description
	Problem Manager Service Desk Manager	
Service Desk Management	Customer Service Manager Configuration Analyst Employee Level 1 Analyst Level 2 Analyst Service Desk Manager (default)	Provides access tailored to users who manage IT support or external customer support functions (typically front-line support supervisors).
Service Desk Staff	Configuration Analyst Configuration Viewer Customer Service Representative Employee Level 1 Analyst (default) Level 2 Analyst	Provides access tailored to users who perform support tasks. Access is focused on those users that perform frontline support.
Support Automation Admin	Support Automation Administrator	Provides access to users that perform Support Automation administration.
Support Automation Analyst	Support Automation Analyst	Provides access to users that provide live assistance to end users.
Vendor Staff	Vendor Analyst	Provides highly restricted access to external vendors, who work only on items directly related to their product (for example, a particular brand of hardware).

Role Records

You can assign roles to an access type, or directly to a user contact record. If a role assignment conflict occurs, the contact role assignments take precedence.

Each role record must be configured with the following components:

- One form group
- One user interface type
- Function access settings
- One or more tabs
- One help set

The following optional components can also contribute to each role definition:

- Menu trees
- Scoreboards
- Menu bars
- Toolbars
- One data partition
- Knowledge Management access
- Support Automation access levels
- Report web forms
- Go resources

Data Partitions

Data partitions are subsets of the CA SDM database that enable you to control access at the record level. You can associate a data partition to a role to control access to tickets and other records accessible through the web interface.

For information about working with data partitions, see How to Set Up the Data Partition (see page 1281).

Configuring User Accounts

Contents

Configure the user accounts to set up contacts, contact types, groups, special handling types, LDAP data authentication, and communication.

Contacts

An important part of establishing a working service desk is defining the users who are going to access it. In CA SDM, users are named *contacts*, and you can perform several tasks to set up and manage them:

- Set up contacts manually.
- The Organize contacts into groups that define areas of responsibility.
- Create contact types to organize your CA SDM contacts into logical groupings.
- Import LDAP user information into a CA SDM contact record.
- Assign a contact to a role to define the accessible system functionality.
- Assign a special handling type, such as Very Important Person (VIP), to a contact.

Contact Definitions

Everyone who uses CA SDM must be defined as a contact. The contact record of a user defines the user information that the system needs as follows:

- **Basic Identification**
  Defines basic identification, such as the name of a user and contact type. The Contact name is used as the primary identifier when selecting a contact or filling in contact information in other contexts.
- **Login**
  Defines login information, such as the user ID and in some cases, a PIN field to use as a password that verifies the user upon login. The user ID is used to identify the user in the contact table for authentication purposes and for determining the access types assigned to the user. Depending on your security configuration, another field such as the contact ID, can be specified as the PIN field. The user can use the PIN as login password.
- **Security**
  Defines the access type that is assigned in their contact record or by a default access type, depending on how you set up the security for your system. In addition, the access type of a user can be assigned based on their membership in an LDAP Directory group.
  The user access type determines all aspects of security, including authentication, web interface they can view, and what product functionality they can access.
  Security management is a feature of the web interface.
- **Service Type**
  Determines the level of service a user receives. A service type defines the level of service a user can receive. The Service Level Agreements (SLAs) are negotiated with CA SDM customers. Service types serve as the mechanism for CA SDM to implement SLAs. As an Administrator, you can use service type to set up SLAs using the web interface.

- **Automatic Assignment**
  Defines automatic assignment information, such as work shift and availability (used for analyst contact types only). You can set up analyst contacts to determine if they are eligible for automatic assignment. The Automatic assignment is valid only for requests, and is defined as part of the request area definition. Automatic Assignment is also linked to the groups to which the analyst belongs.

- **How to Send Users Notification Messages**
  Defines the notification information of a contact for the following:

- - Various email addresses and telephone numbers to be used for notification

  - Method to be used for the notifications with different urgency levels

  - work shifts during which notifications are received
    The notification delay calculation takes the Contact Time Zone into account. If the Contact Time Zone is not set, the server time zone is used, instead. Using the server time zone may result in notifications firing at times, perceived to be outside the Work shift settings.
    Organizational information (such as location, organization, and department) lets you group contacts based on the organization to which they belong. For example, associating a contact with a location links the contact to a physical address and also helps in determining automatic assignment. The organization can be assigned a service type, making it easier to manage SLAs by organization rather than by individual contacts.

- **Groups to which a User Belongs**
  Organizes contacts into groups that represent specific areas of responsibility within your service desk. You can set up and can define contacts using the web interface.

Groups

A group is a collection of contacts that share a common area of responsibility. In CA SDM, groups are implemented using the predefined group contact type, making a group just a special type of contact. A group has the same basic information as a contact, with the important additional feature that groups are one of the keys to automatically assigning requests. You can associate request areas, locations, and a work shift with a group. These attributes are used to determine if and when the contacts in the group can accept the automatic assignment of a request.

Working with Special Handling Types

This article contains the following topics:

You can define special handling types that identify contacts who require special attention. You can use the special handling types that CA Service Desk Manager provides or create your own types. You can view and locate tickets that specify an affected end user who requires special attention. For example, analysts can browse the V.I.P. folder on the Scoreboard to identify tickets that specify a VIP as the affected end user.

The following examples are contacts that special handling types can identify:

- Very Important Persons (VIPs) such as executives
- Customers with support renewal in process
- Customers with disabilities requiring special handling or equipment
- Visitors
- Contacts suspected of misusing or abusing system resources

When one or more special handling types are assigned to a contact, tickets that specify the contact in the Affected End User field show an alert banner, icon, or both. You can use ticket fields and special handling types to track tickets, and distinguish between two related but possibly distinct contact types. For example, a VIP (Affected End User) has an assistant (Requestor) acting on their behalf. When the Affected End User is a contact assigned to a VIP special handling type, an analyst can prioritize tickets more accurately.

How to Configure Special Handling Contacts

To configure special handling contacts, do the following steps:

1. Create special handling types (see page).
2. Associate a contact to any number of special handling types (see page 1201). Similarly, a specia handling type can have many contacts.
   A contact that is associated with one or more Special Handling types is visually distinguished in the Contact Detail form and the Quick Profile browser using a banner at the top of each page. This banner displays the alert icon and alert text for each Special Handling type that is assigned to the contact.
   Additionally, any tickets that identify the contact as the Affected End User are indicated as follows:
   - Alert Icons and Alert text appear in a banner at the top of the ticket detail form.
   - Alert Icons appear in the ticket list.
   - The Scoreboard includes a V.I.P. folder and subfolders for each ticket type. The V.I.P. subfolders include tickets for affected end users who are VIP special handling contacts.

     Note: The V.I.P. Scoreboard folder displays for analyst roles.

Associate a Contact to a Special Handling Type

You can assign a special handling type to a contact to alert analysts about tickets that affect end users with special requirements, such as for a visually impaired person or a contact that poses a security risk.

To associate a contact to a special handling type, perform the following:

Follow these steps:

1. On the Contact Detail page, select the Special Handling tab.
   The Associated Special Handling List tab lists special handling types that are associated with the contact.

2. Click the Update Contact's Special Handlings button.
   The Search filter appears.

3. Search for the special handling type that you want to associate to the contact.
   The Special Handlings Update page appears.

4. Select one or more handling types from the left column and use the move button (>>) to move the types to the right column. Click OK.

   Note: You can remove an association from a contact by using the move button (<<) to move the type from the right column to the left column. You can click the search icon to search for the value you want.

   The contact is associated to a handling type.
   CA SDM displays the following depending on the handling type, when a ticket specifies the contact in the Affected End-User field:

   - An alert banner appears on the Contact Detail for the affected end user on a ticket.
   - Alert text appears as a banner at the top of the ticket detail page and in the Quick Profile.
   - Ticket lists highlight the contact row and show an alert flag.
   - A V.I.P. folder appears in the Scoreboard for analyst roles. The folder contains all tickets that are associated with contacts (Affected End Users) that have a VIP special handling type.

Special Handling Types Options

This article contains the following:

Create a Special Handling Type

You can associate contacts to special handling types. This association lets you easily view and locate contacts that require special attention, for example, to identify tickets in a list that specify Very Important Person (VIP), vision that is impaired, or visitor as affected end users. You can create special handling types and can associate them to contacts.

To create a special handling type, perform the following:

Follow these steps:

1. On the Administration tab, select Service Desk, Application Data, Codes, Special Handling Types.
   The Special Handling List page appears.

2. Click Create New.
   The Create New Special Handling page appears.

3. Complete the fields (see page) as appropriate, and click Save.

4. Click Update Special Handling Members.
   The Contact Search page appears.

5. Complete the search fields as appropriate and click Search.

6. Select one or more contacts from the Contacts column and use the move button (>>) to move the contacts to the Special Handling column. Click OK.

   Note: You can remove a contact from an association by using the move button (<<). Move the contact from the right column to the left column.

   The special handling type is created and it is associated with contacts.

7. Click Close Window.

Edit a Special Handling Type

You can edit special handling types that you can use to associate to contacts. For example, you can add contacts (members) to a special handling type.

To edit special handling types, perform the following:

Follow these steps:

1. On the Administration tab, select Service Desk, Application Data, Codes, Special Handling Types.
   The Special Handling List page appears and lists special handling types.

2. Click a name link.
   The Special Handling Detail page appears.

3. Click Edit.
   The Update Special Handling page appears.

4. Edit the fields (see page) as appropriate.

5. Select the Special Handling tab, and click Update Special Handling Membership.
   The Special Handling Search page appears.

6. Complete the page fields as appropriate, and click Search.
   The Special Handling Update page appears.

7. Use the move controls (>> and <<) to add or remove special handling type associations. Click OK.
   The special handling type is updated.

8. Click Save.
   The special handling type is updated.

Special Handling Types Fields

The following fields require explanation:

- Name
  Specifies the name of the special handling type, for example, VIP, Visually Impaired, Visitor, and so on.

- **Icon**
  Specifies the URL for the icon graphic that displays with the alert banner, for example, icon\visitor_icon.jpg, to display an alert banner. If you do not specify an icon URL, no alert icon appears on the ticket detail page. The format of the URL is http[s]://*server_name*:*server_port* /CAisd/img/icon_file. For example:

  ```
  http://server_name:8080/CAisd/img/glasses.gif
  ```

- **Escalate Urgency**
  Uses the special handling type to escalate the corresponding ticket priority.

- **Auto-Display Notes**
  Indicates whether the contact notes (ca_contact.comments) automatically display in an alert banner following the alert text banner when the affected user of the ticket is associated with the special handling type.

- **Alert Text**
  Specifies the text to display in an alert banner, for example, Visitor. If you do not specify text, no alert text or highlighting appears on the ticket detail page.

- **Description**
  Describes the special handling type, such as Very Important Person.

Add an Icon to a Special Handling Object

You can add an icon to a special handling object to identify the object. The icon file is located in the NX_ROOT/bopfg/www/wwwroot/img folder.

To add an icon to a special handling object, perform the following:

Follow these steps:

1. On the Administration tab, select Service Desk, Application Data, Codes, Special Handling Types.
   The Special Handling List page appears and lists special handling types.

2. Click a name link.
   The Special Handling Detail page appears.

3. Click Edit.
   The Update Special Handling page appears.

4. Specify the URL in the Icon field and click Save. The format of the URL is http[s]://*server_name*:*server_port*/CAisd/img/*icon_file*. For example:

   ```
   http://server_name:8080/CAisd/img/glasses.gif
   ```

   Note: The filename can be case-sensitive depending on the web server used. If the case is incorrect, the icon is not displayed.

   The special handling icon is added.

How to Identify Tickets for Special Handling Contacts

Special handling contacts are contacts that require special attention, for example, security-risk monitoring, a visitor badge, or requiring special equipment. You can identify tickets for which the affected end user is a contact that requires special attention. For example, you can identify tickets in a list that specify Very Important Person (V.I.P.), vision that is impaired, or visitor as affected end users.

To identify tickets for which the affected end user is a special handling contact, perform the following:

- Navigate the Scoreboard to ticket lists.
  Special handling contact rows are highlighted and show an alert flag.

- As an analyst, navigate the Scoreboard to the V.I.P. folder.
  The V.I.P. folder includes subfolders for each ticket type. The subfolders include tickets for affected end users who are VIP special handling contacts.

- Navigate the Scoreboard, open ticket Details, and click Quick Profile for the affected end user on a ticket.
  An alert banner appears on the page to identify contacts with special handling types.

  Note: An alert icon also appears if an alert icon is associated with the special handling type.

- Browse the Administration tab and open Contact Details.
  An alert banner appears on the page to identify contacts with special handling types.
  Note: An alert icon also appears if an alert icon is associated with the special handling type.

List Special Handling Types

You can list special handling types that you can use to associate to contacts.

To list special handling types

1. On the Administration tab, select Service Desk, Application Data, Codes, Special Handling Types.
   The Special Handling List page appears, lists special handling types, and corresponding information (see page).

2. (Optional) Click a name link.
   Details about the special handling type appear.

Contact Types

Contents

Contact types are used to categorize CA SDM users into logical groupings based on how they use the system. For example, some of the many contact types that are predefined by the system are analyst, customer, and group. These predefined contact types meet the needs of most CA SDM implementations; however, if your circumstances require it, you can modify the predefined contact types and create contact types. When you define users as contacts, you can associate a contact type with each one. You can base notification on contact type, which allows you to send a notification message to all contacts of a particular type.

You can select users based on contact type in various contexts. For example, most list and selection windows that display contacts have a search field where you can select a contact type as a search criterion.

Determine Behavior Based on Contact Type

The contact *type* determines which contacts display (and have permission) in different situations. For example, when you manually assign any type of ticket, such as a request or an issue, the field to specify the assignee requires that the person you specify have a contact type of analyst. If you choose to select a contact from a selection list for this field, only contacts with the type of analyst display in the selection list. Entering a contact with a different type displays the analyst search screen only.

Note: An important feature of the contact type is in the implementation of groups of contacts through the predefined group contact type.

How to integrate CA SDM with LDAP

Contents

Configure LDAP Options

You can configure CA SDM to access LDAP directory data.

Follow these steps:

1. Manually install LDAP options using the Web Interface Options Manager.

   Note: The options necessary for basic LDAP integration are identified as required in the Description column in the following table. Options identified as optional are features you can add only if all the required options are installed. The values you specify when installing these options are written to the $NX_ROOT/NX.env file.

2. Restart the CA SDM service.
   The changes take effect.

Manage LDAP Servers Using the LDAP Configuration Utility

You can use the LDAP Server utility to manage multiple LDAP servers. You can perform the following tasks by using the utility:

- Add a new LDAP server.
- Delete an LDAP server that you no longer want to use.

- View LDAP server details.
- Restart LDAP virtual database.

Important! In an advance availability configuration, run the utility on the background server. After you add a new LDAP server, restart the CA SDM services on all the standby servers.

Follow these steps:

1. (Optional) To specify the domain name of the default LDAP server, execute the following command:

   ```
   pdm_options_mgr -c -a pdm_option.inst -s LDAP_DOMAIN -v
   <Default_LDAP_DomainName>
   pdm_options_mgr -c -a pdm_option.inst -s LDAP_DOMAIN -v
   <Default_LDAP_DomainName> -t
   ```

   Configure the default LDAP server domain name in the following cases:

   - CA EEM server is configured with multiple Microsoft Active Directory domains.
   - Default LDAP server and any other LDAP server configured with CA SDM have the same user details.

   After the configuration is complete, the default LDAP users must log in to CA SDM in the format domain_name\userid.

2. Open the windows command and navigate to the location $NX_ROOT/bin.
3. Run the following command:

   ```
   pdm_perl pdm_ldap_config.pl
   ```

4. Based on the task that you want to perform, select the appropriate option.

Option	Default Value	Description
ldap_domain		Required for configuring mulitple LDAP servers. Specifies the domain name of the LDAP server.
default_ldap_tenant		Required for multi-tenancy installation. Specifies the default tenant assignment for contacts imported from LDAP. You must use the tenant UUID when setting the Option Value field. You can get the tenant UUID from a database query. For example, "SELECT * FROM ca_tenant".
ldap_enable	Yes	Required. Enables LDAP integration with CA SDM.
ldap_host		Required. Specifies the LDAP database server host name or IP address.

Option	Default Value	Description
ldap_port	389	Required. Specifies the LDAP server port number.
ldap_dn		Required. Specifies the LDAP server logon distinguishedName. **Example**: CN=Joe, CN=Users, DC=KLAND, DC=AD, DC=com If the LDAP server supports anonymous binds, this value can be empty.
ldap_pwd		Required. Specifies the password for LDAP server logon distinguishedName. If the LDAP server supports anonymous binds, this value can be empty.
ldap_search_base		Required. Specifies the starting point for searches in the LDAP schema tree: (UNIX) You must specify a starting container. For example: CN=Users, DC=KLAND, DC=AD, DC=com (Windows) You do not have to specify a container. You may start at the top of the schema tree. For example: DC=KLAND, DC=AD, DC=com
ldap_filter_prefix	(&(objectClass=user)	Specifies the prefix applied to an automatically generated filter when searching for LDAP users. This variable has been superseded by the ldap_user_object_class option. It is not available in Options Manager, but can be set manually in the NX.env file.
ldap_filter_suffix	)	Specifies the suffix applied to an automatically generated filter when searching for LDAP users. This variable has been superseded by the ldap_user_object_class option. It is not available in Options Manager, but can be set manually in the NX.env file.
ldap_user_object_class	person	Required. Specifies the value of the LDAP objectClass attribute applied to an automatically generated filter when searching for LDAP users.
ldap_enable_group	Yes	Optional. Enables CA SDM access type assignment based on LDAP group membership.
ldap_group_object_class	group	Required only if the ldap_enable_group is installed. Specifies the object name applied to an automatically generated filter when searching for groups.
ldap_group_filter_prefix	(&(objectClass=group)	Specifies the prefix applied to an automatically generated filter when searching for LDAP groups. This variable has been superseded by the ldap_group_object_class option. It is not available in Options Manager, but can be set manually in the NX.env file.
ldap_group_filter_suffix	)	Specifies the suffix applied to an automatically generated filter when searching for LDAP groups. This variable has been superseded by the ldap_group_object_class option. It is not available in Options Manager, but can be set manually in the NX.env file.
ldap_enable_auto	Yes	Optional. Enables auto generation of contact records from LDAP data.
ldap_sync_on_null	Yes	Optional. Overwrites existing CA SDM contact attributes with null data if the corresponding LDAP user attribute contains a null value.
ldap_service_type	Active Directory	Optional. Use this option if the CA SDM operating environment is Windows and the LDAP directory is *not* Active Directory (for example, eTrust or Novell). On UNIX operating environment, "Non AD" functionality is used only if this option is *not* installed. If it is installed, the service type is set to Active Directory.
	No	

Option	Default Value	Description
ldap_enable_tls		Optional. Specifies whether Transport Layer Security (TLS) is enabled during LDAP processing.

Verify LDAP Integration

After you have installed the necessary LDAP options, CA SDM users can import LDAP data on a case-by-case basis, eliminating the need to fill in all the contact attribute fields manually.

To verify that you can search for and import LDAP records

1. Select File, New Contact from LDAP on the Service Desk tab.
   The LDAP Directory Search window appears.

2. Specify filter criteria, and then click Search. For example, you could enter b% in the Last Name field to retrieve a list of the LDAP user entries with last names that begin with the letter B.

   Note: If your LDAP directory contains thousands of entries and you do not filter your search, your request attempts to retrieve *all* of the LDAP user records. This can cause the request to time-out and return zero records.

   Search results matching your filter criteria are displayed.

3. Select an entry.
   The Create New Contact window appears, populated with imported LDAP attribute values.

4. Click Save.
   The contact record is created.

To verify that you can update a contact using LDAP data

Note: Before performing this procedure, for test purposes you may want to use whatever LDAP editing tool you have available to change one or more attribute values in the entry you used for the previous procedure. You can verify that the contact is updated with the latest LDAP data.

1. Select Search, Contacts on the Service Desk tab.
   The Contact Search window appears.

2. Specify filter criteria to search for a contact that has a corresponding LDAP user entry. For example, you could search for the contact you created in the previous procedure.
   Search results matching your filter criteria are displayed.

3. Select the contact you want to update with LDAP data.
   The Contact Detail page appears, populated with the CA SDM contact information.

4. Click Edit.
   The Contact Update page appears.

5. Click Merge LDAP.
   The LDAP Entry List page displays a list of any LDAP user entries that correspond with the selected CA SDM contact.
   To search the LDAP directory for other entries, you can click Show Filter, specify filter criteria, and then click Search.

   Note: If your LDAP directory contains thousands of entries and you do not filter your search, your request attempts to retrieve *all* of the LDAP user records. This may cause the request to time-out and return zero records.

6. Click the LDAP entry of interest.
   The LDAP Detail page displays the attribute values for the selected entry. Verify that you have selected the correct entry for the contact you want to update, then click Close Window.

7. On the LDAP Entry List page, right-click the entry that best matches the contact you want to update, and then select Merge into Contact.
   The Contact Update page reappears, populated with the current LDAP attribute values. If the LDAP data has changed since you created or last updated the contact, the changes are reflected in the contact attribute fields.

   Note: If you have installed the ldap_sync_on_null option, and the LDAP entry contains null values for any attribute fields that correspond to contact attributes that currently contain values, the values in the contact record are overwritten with null values when you save the contact data.

8. Click Save on the Contact Update page.
   The contact is updated with the corresponding LDAP data.

Create a Contact

A contact is a person who uses your system regularly, such as an analyst or customer. After you have created the business structure and groups, you create contacts and map them to their respective location and organization.

You can create contacts using the following ways:

Create a Contact Using Data From LDAP

If your installation is configured to access a Lightweight Directory Access Protocol (LDAP) server such as Microsoft Windows Active Directory and has the necessary options installed, you can create and update contacts using data from the LDAP database. This method makes it easy to synchronize contacts with network user data.

Note: Administrators can configure automated synchronization of contacts with LDAP data.

Follow these steps:

1. Select File, New Contact from LDAP from the menu bar of the Service Desk tab.
   The LDAP Directory Search page appears.

2. (Optional) Complete one or more of the following filter fields to limit the LDAP Entry list to the records of interest:

   - **Last Name**
     Specifies the last name of the user as it appears in the LDAP directory. For example, you could enter b% in the Last Name field to retrieve a list of the LDAP user entries with last names that begin with the letter B.

   - **First Name**
     Specifies the first name of the user as it appears in the LDAP directory.

   - **Middle Name**
     Specifies the middle name of the user as it appears in the LDAP directory.

   - **User ID**
     Specifies the user name for logging in to the system.

3. Click Search.
   The LDAP Entry List page displays the records that match your search criteria.

   Note: To see the information contained in an LDAP record without creating a contact, right-click the record of interest and select View. The LDAP Entry Detail page appears.

   All fields on the LDAP Entry Detail page are self-explanatory except for the following:

   - **User ID**
     Specifies the ID the user enters to log in to the system.

- **Distinguished Name**
  Specifies the fully qualified LDAP login name. For example, CN=Joe, CN=Users, DC=KLAND, DC=AD, DC=com.

4. Click the LDAP entry to create a contact.
   The Create New Contact page appears and is partially populated with LDAP information.

5. Enter additional information (see page) as necessary.

6. Click Save.
   The contact record is saved and the Contact Detail page appears. The following buttons are now available for configuring the contact:

   - **Update Environment** -- Displays the Configuration Item/Asset Search window for the contact or organization, where you can specify search criteria for the assets you want to consider. When you click Search, the Environment Update window is displayed, where you can add and remove assets for this contact or organization.

     Update Groups -- Displays the Group Search window, where you can specify search criteria for the groups you want to consider for this contact. When you click Search, the Groups Update window is displayed, where you can add and remove groups for this contact.

Create a Contact Automatically

You can configure CA SDM to create a contact automatically from a corresponding LDAP user record whenever a new user logs in to CA SDM.

To enable this feature, install all of the required LDAP options plus the ldap_enable_auto option.

The contact record is automatically created as follows:

1. If a user logging in to CA SDM does not yet have a contact record, but the user's login name exists in an LDAP record, the LDAP data is automatically imported and a contact record is created.

2. The automatically created contact record inherits the defaultaccess type security settings.

3. The contact can then be assigned an access type explicitly, or the access type can be assigned based on the user's membership in an LDAP Group.

This process is completely transparent to the user, appearing as any other login session.

Create Contacts Manually

If you do not want to use an active directory such as LDAP for your contacts information, you can create the contacts manually in CA SDM.

Note: If multi-tenancy is enabled, select the appropriate tenant from the drop-down list.

Follow these steps:

1. Select File, New Contact from the menu bar on the Scoreboard.
   The Create New Contact window opens.

2. Complete the contact fields (see page) .

3. Click Save.
   The contact information is saved.

Contact Fields

Tenant

Specifies the tenant that is associated with the contact (for multi-tenancy installations).

Contact ID

Specifies a unique identifier for the contact. If the default user authentication is being used, the value in this field is used as the password when the user logs in.

User ID

Specifies the user name of the contact. The contact uses this value to log in to the system.

Service Type

Specifies the level of support that is received by the contact.

Data Partition

Specifies the data partition for this contact. This value determines the records that this contact can access.

Access Type

Specifies the access type. The access type determines the system functions the contact can access.

Available

Indicates whether the contact is available for ticket assignments.

Confirm Self-Service Save

Indicates whether the contact receives a confirmation when saving a record from the self-service interface.

Analyst's Tenant Group

(Analyst Contact Type Only) Specifies the tenant group that the analyst is responsible for.
To configure the contact, use the following controls available on the tabs.

Notification

Defines the contact information and method for notifying the contact.

- Select the notification method from the drop-down list (Email, Notification, Pager_Email, xMatters/Email, xMatters/Notification, and xMatters/Pager_Email) that you want to use for each message urgency level for this contact.

  Note: CA SDM supports only one notification method at a time. If you are using Email, then you cannot use Notification at the same time. This applies to all out of the box notification methods like Email, Notification, Pager_Email, xMatters/Email, xMatters /Notification, and xMatters/Pager_Email.

  Note: CA SDM Administrators must update the notification method manually in the contact details page if the xMatters and CA SDM integration is disabled. For more information, see Create a Notification Method (see page 834) and Options Manager xMatters (see page 1303).

- Select the workshift that is valid for each notification urgency level.

For example, you may assign a Regular workshift (five-day week, eight-hours a day) to the normal level notification, but a 24 hour workshift to the emergency level notification.

Address

Specifies the location of the contact.

Organizational Info

Specifies the functional or administrative organization, department, cost center, or vendor information of the contact.

Environment

Specifies the environment of the contact, such as equipment, software, and services.

Groups

Assigns a contact to a group (a collection of contacts with a common area of responsibility).

Roles

Assigns the contact to one or more roles.

Service Contracts

Displays any service contracts that have been associated with the contact.

Special Handling

Lists the special handing contacts and lets you search for and associate a contact to a special handling type, such as a visitor or security risk type.

Event Log

Lists events that are associated with the contact, such as self service and knowledge activities.

Activities

Lists the activity log for the contact.

Merge Contacts Using LDAP

You can synchronize existing contacts with the current LDAP data.

Follow these steps:

1. Select Search, Contacts on the Scoreboard.

   The Contact Search page appears.

2. Fill in the filter fields as desired (or leave all filter fields blank to see a listing of all contacts), then click Search.

   The Contact List page appears.

3. Click the contact you want to edit.

   The contact's Detail page appears.

4. Click Edit.

   The contact's Update page appears.

5. Click Merge LDAP.

   The LDAP Entry List page appears. If the contact you are editing has a corresponding LDAP record, it appears on this page.

6. Click the LDAP entry.

   The LDAP Detail page appears.

7. Click Close Window after you have verified that the LDAP Detail page contains the data for the correct user.

8. Right-click the entry on the LDAP Entry List page for the contact you are updating and select Merge Into Contact.

9. Click Save on the contact's Update page.

Assign Access Type Using LDAP Groups

Assign Access Types values to contacts automatically with a Lightweight Directory Access Protocol (LDAP) server.

Note: To enable this feature, install the ldap_enable_group and ldap_group_object_class options.

Follow these steps:

1. Select Security and Role Management, Access Types on the Administrator tab.
2. Select the Access Type you want to associate with an LDAP Group. For example, select Administration.
   If the ldap_enable_group option is installed, the LDAP Access Group field appears on the Web Authentication tab.

   Note: If an LDAP Group is already associated with the selected Access Type, a link to the LDAP Group Detail appears. Click the link for a read-only description of the LDAP Group and a listing of its members.
3. Click Edit on the Access Type Detail page to associate an Access Type with an LDAP Group.
4. Click the LDAP Access Group link.
5. (Optional) Enter filter criteria to limit the search to the LDAP groups of interest.
6. Select the LDAP Group that you want to associate with this Access Type.
7. Click Save.
   Association of the selected LDAP Group with the Access Type is complete.

Attribute Mapping

CA SDM contact record attribute values are synchronized with LDAP user attribute values based on the attribute mapping definitions in the $NX_ROOT/bopcfg/majic/ldap.maj file.

The following excerpt from ldap.maj illustrates mapping. Attribute names in the left column (id) are the CA SDM contact attribute names. The center column (distinguishedName) contains the corresponding LDAP attribute names.

```
    id               distinguishedName              STRING 512;
last_name          sn,pzLastName                    STRING ;
first_name         givenName,pzFirstName            STRING ;
middle_name     initials,pzMiddleName            STRING ;
userid               uid,sAMAccountName,pzUserName     STRING ;
phone_number    telephoneNumber,pzWorkPhoneNumber STRING ;
```

If an SREL (a single relationship or foreign key in another database table) exists on CA SDM, the contact attribute value is synchronized with the corresponding LDAP value. If the SREL does not exist, it is not created automatically during LDAP synchronization processing.

Note: By default, attribute mapping is configured for the Microsoft Active Directory LDAP schema. If necessary, you can change the mapping by using a mod file.

How to Modify Attribute Mapping

You can change the default attribute mapping.

To change the default attribute mapping, do the following steps:

1. Navigate to $NX_ROOT/site/mods/majic and open the mod file.
2. Use MODIFY statements in the mod file as follows.
   - MODIFY statements must always be stated first in the file.
   - Following the MODIFY statements, any additional fields that are not in the ldap.maj file should be stated using the syntax shown in the following example.
   - If you define a field that contains a hyphen character in the attribute name, you must enclose the name in single quotes; otherwise, when you build the mod file, the attribute fails with a syntax error. For example, the following attribute name must be enclosed in single quotes:

     ```
     c_nx_string1 'swsd-secret-question' STRING ;
     ```
3. Save and close the mod file.
4. Restart the CA SDM service.

   Important! The web engine does not start if there is a discrepancy in the syntax or case.

   Your changes take effect.

Example: Use MODIFY Statements

The following example shows how to modify two existing fields and add a new field.

```
//
// Map CA SDM userid attribute to ADAM Userid
//
MODIFY ldap userid cn ;
```

```
MODIFY ldap middle_name middleName ;
OBJECT ldap LDAP {
ATTRIBUTES LDAP_Entry{
contact_num employeeNumber STRING ;
};
} ;
```

How CA SDM Uses LDAP Data to Communicate

Lightweight Directory Access Protocol (LDAP) is a network communications protocol for querying and modifying directory services running over a TCP/IP network. An LDAP directory is a tree structure that contains entries for managing users, groups, computers, printers, and other entities on a network.

CA SDM can be configured to access an LDAP directory, which allows you to use LDAP data in several ways:

- Synchronize contacts with LDAP user records. Synchronization can occur in the following ways:
  - **At login** -- When a user logs in to the product, if an LDAP record exists for that user but a corresponding contact record does not exist, a contact record is automatically created based on the LDAP information.
  - **New Contact** -- When you manually create a contact record, you can select an LDAP record and can merge its attribute values with their corresponding fields in the new contact record.
  - **Batch Update** -- You can run batch jobs to automate the processes of importing and updating contact records with information from the corresponding LDAP records.

    Note: Synchronization with LDAP is a one-way process. The LDAP data can be used to create and update contacts, but the product does not support updates to the LDAP directory.
- Assign CA SDM access types that are based on LDAP group membership.
- Implement an alternative method of performing CA SDM authentication.

The ldap_virtb component provides LDAP integration functionality on the following servers depending on your CA SDM configuration, regardless of operating system type:

- Conventional: Primary or secondary server.
- Advanced Availability: Background or application server.

Note: The $NX_ROOT/bopcfg/majic/ldap.maj file specifies the mapping between LDAP attributes and contact record attributes.

Important! CA SDM requires that LDAP records have an entry in the last name field in order to facilitate search, view, and import the LDAP data.

Important! CA SDM supports *paged searching*, which searches all records in your LDAP directory. Paged searching also enables you to import new contact records or sync existing contact records from any number of LDAP records. These capabilities are limited, however, if you are using Sun Java System Directory Server or Novell eDirectory because these LDAP servers do not support paged searching. In that case, you can only search, import, and sync with the number of LDAP records specified by NX_LDAP_MAX_FETCH. For more information about paged searching, see NX.env File.

Access Type Assignments From LDAP Groups

You can configure CA SDM to assign access type values to contacts automatically, based on LDAP group membership. With automatic access type assignment enabled, if an LDAP user record that was used to create a contact belongs to an LDAP group that is associated with one of the CA SDM access types, then the contact is automatically assigned that access type. Otherwise, the contact inherits the default access type.

To enable automatic access type assignment, you must install the ldap_enable_group and ldap_group_object_class options.

For more information, see Configure LDAP Options (see page 1207).

LDAP Authentication

You can use LDAP to authenticate users logging in to CA SDM. The LDAP authentication is available when the CA EEM authentication component is integrated with CA SDM, which replaces the default validation that is performed by the host operating system. The LDAP authentication is only applicable when CA EEM is configured to use an external LDAP directory and you have selected OS authentication for an user validation type in an access type record.

When a CA EEM feature is activated, login requests are checked with the CA EEM server. A log in request is granted only if the following occurs:

- The specified user ID matches a CA SDM contact record.
- The user ID matches a user profile in CA EEM.
- The user ID and password combination is successfully validated by CA EEM.

Note: For more information about using CA EEM for authentication and to move authentication module to external server, see How to Move the Authentication Module to an External Server (see page 864). Also, see Assign Access Type Using LDAP Groups (see page 1216).

Transport Layer Security

You can configure CA SDM to use Transport Layer Security (TLS) during LDAP processing. TLS, a secure communications protocol, is the successor of Secure Socket Layer (SSL v3) security. You install the ldap_enable_tls option to enable TLS.

Important! If this feature is enabled, all communications between CA SDM and the LDAP server are encrypted. If this feature is *not* enabled, all data communications (including the administrative login and password that is used to access the LDAP server) are sent in clear text.

Note: For information about configuring TLS, refer to your LDAP server and operating system documentation. Manually install the LDAP options using the Web Interface Options Manager. For more information, see Configure LDAP Options (see page 1207).

Create Contacts in Batch Mode Using LDAP Data

This article contains the following topics:

Batch Import Contacts Using LDAP Data

You can run the pdm_ldap_import command-line utility to create CA SDM contacts in batch mode using LDAP data.

Note: In addition to creating contacts, pdm_ldap_import updates existing contacts if they are not synchronized with their corresponding LDAP entries. You can use the pdm_ldap_sync batch process to update existing contacts, but not create ones.

When you import contacts using LDAP data, restart the CA SDM services if you encounter the following error:

pdm_ldap_import: Method got_record in Ldap_Group_Catcher failed (LDAP agent not found).

pdm_ldap_import has the following syntax:

```
pdm_ldap_import -n "domain_name" -l "ldap_where_clause" [-c "contact_where_clause"] [-
u "userid"]
```

- **-n *"domain_name"***
  Specifies the LDAP directory domain name from where you want to import contacts to CA SDM. If you do not specify the domain name, CA SDM retrieves the data using the default LDAP domain name.

- **-l "*ldap_where_clause*"**
  Specifies the userids of LDAP records to be searched. Replacement variables are indicated with the '?' character. For example, for *userid = ?*. The default value is *userid = ?*. In this special case, id is mapped to the contact attribute ldap_dn.
  Note: Use the keywords as defined in the *ldap.maj* file. You can also search by using the memberOf = 'group_dn' syntax.

- **-c "*contact_where_clause*"**
  (Optional) Specifies how to determine whether the contact record already exists. If the contact record does not exist, a new contact record is inserted. If the contact record does exist and is not synchronized with the current LDAP data, the contact record is updated.

- **-u "*userid*"**
  (Optional) Specifies the login name under which the pdm_ldap_import program runs.

Note: You can use wildcards with pdm_ldap_import to specify multiple records.

Examples: Batch Imports Using LDAP Data

This example imports a single LDAP record for userid jsmith11 from the LDAP directory with the domain name example.com:

```
pdm_ldap_import -n "example.com" -l "userid = 'jsmith11'"
```

This example imports all LDAP records with a userid that begins with the letter C from the LDAP directory with the domain name example.com:

```
pdm_ldap_import -n "example.com" -l "userid = 'c%'"
```

This example imports all LDAP User records in the directory from the LDAP directory with the domain name example.com:

```
pdm_ldap_import -n "example.com" -l "userid = '%'"
```

Batch Import Contacts by Date and Time

You can configure the pdm_ldap_import utility to import LDAP records that were created before or after a specified date and time. To enable this functionality, create an ldap.mod file with the following content:

```
OBJECT ldap {
  ATTRIBUTES LDAP_Entry {
```

```
    whenCreated whenCreated STRING ;
  };
};
```

This adds the *whenCreated* attribute to the LDAP object.

The rules for filtering records using the whenCreated attribute are as follows:

- Use only the >= or <= operator.
- Specify *all* characters for the date/time value, including the Z. Place a 0 in any location you do not wish to explicitly state (for example, the time of day).
- Place the date/time specification at the beginning of the filter; do not use leading 0s at the beginning of the string.
- Do not include the leading century. For example, to specify the year 2008, use 08.

Note: Single quotation marks must surround the date/time value.

Example: Using the whenCreated Attribute to Import LDAP Entries

The following example uses the whenCreated attribute to import LDAP entries created after 3/11 /2008.

```
Pdm_ldap_import -l "whenCreated >= '080312000000Z'"
```

Example: Using the whenCreated Attribute to Search for LDAP Records

The following example uses the whenCreated attribute with pdm_ldap_test to search for LDAP records created after 3/11/2008.

```
pdm_ldap_test.exe -f "whenCreated>=080312000000Z" -a whenCreated
Starting ldap_test.exe...
LDAP Directory Type    : active directory
Service Desk Platform    : windows
Search Base    : DC=kirklandsd,DC=ca,DC=com
Search Filter    : (&(objectClass=person)(whenCreated>=080312000000Z))
Administrator Username    : CN=Administrator,CN=Users,DC=kirklandsd,DC=ca,DC=com
Administrator Password    : **********
LDAP Host    : gecko.kirklandsd.ca.com
LDAP Port    : 389
LDAP API Version    : 3
DN: CN=aixmail,CN=Users,DC=kirklandsd,DC=ca,DC=com
        whenCreated(17)(0): 20080312035327.0Z
DN: CN=hpmail,CN=Users,DC=kirklandsd,DC=ca,DC=com
        whenCreated(17)(0): 20080312035425.0Z
DN: CN=sunmail,CN=Users,DC=kirklandsd,DC=ca,DC=com
        whenCreated(17)(0): 20080312035726.0Z
3 Total LDAP records found...
```

Batch Import Summary and Log Data

The pdm_ldap_import command maintains a detailed log of all activity of each run. The ldap_logging.0-n log file is located in the $NX_ROOT/log directory.

The following is an example of the summary data pdm_ldap_import returns at the command line:

```
pdm_ldap_import Starting...
pdm_ldap_import Summary:  Processed(21) Updated(1) No Matches(7) New Contacts(11)
Multiple Matches(0) Empty Filter(2) Errors(0)
pdm_ldap_import Complete...
```

The following table describes the summary data.

Status	Count	Description
Processed	21	The number of CA SDM contacts with corresponding LDAP entries.
Updated	1	The number of contact records that were updated because the corresponding LDAP entry contained different information
No Matches	7	The number of CA SDM contact records with no corresponding LDAP entries.
New Contacts	11	The number of new contact records that were created based on corresponding LDAP entries
Multiple Matches	0	The number of LDAP entries with multiple matching contact records, as defined by the ldap_search_base option
Empty Filter	2	The number of LDAP entries that cannot be used to generate a valid search filter
Errors	0	The number of LDAP entries that encountered an error during processing. For example, LDAP records that do not contain a value in a field required by CA SDM (such as Last Name) are counted as failures and cannot be imported.

Batch Update Contacts Using LDAP Data

You run the pdm_ldap_sync utility to update contact records in batch mode using LDAP data.

Important! This utility overwrites the existing tenant of the LDAP contact defined in CA SDM. If you want to retain the tenant value, you must modify NX.env by adding the NX_RETAIN_TENANT_VALUE variable manually, and set it to "yes". If this variable is set to "no", missing, or not set properly, the utility overwrites the tenant information.

Note: The pdm_ldap_sync utility synchronizes existing contacts with corresponding LDAP entries, but does not create contacts. You can use the pdm_ldap_import batch process to create contacts.

pdm_ldap_sync has the following syntax:

```
pdm_ldap_sync -n "example.com" -l "ldap_where_clause" [-c "contact_where_clause"] [-u "userid"]
```

- **-n *"domain_name"***
  Specifies the LDAP directory domain name from where you want to import contacts to CA SDM. If you do not specify the domain name, CA SDM retrieves the data using the default LDAP domain name.

- **-l "ldap_where_clause"**
  Determines how to search for matching LDAP records. Replacement variables are indicated with the '?' character. For example, for *userid = ?*, the default value is *id = ?*. In this special case, id is mapped to the Contact attribute ldap_dn.

- **-c "contact_where_clause"**
  (Optional) Determines which contacts are used when searching for matching LDAP records.
  Default: "ldap_dn IS NOT NULL"

- **-u "userid"**
  (Optional) Specifies the userid under which pdm_ldap_sync runs.

Note: You can use wildcards with pdm_ldap_sync to specify multiple records.

Examples:

This example establishes a baseline of contact records that have a corresponding LDAP record:

```
pdm_ldap_sync -n "example.com" -l "userid = ?" -c ""
```

This example uses the default parameters to update all contacts that have an LDAP distinguishedName:

```
pdm_ldap_sync -n "example.com"
```

This example updates a single contact:

```
pdm_ldap_sync -n "example.com" -l "userid = ?" -c "userid = 'jsmith11'"
```

Batch Update Summary and Log Data

The pdm_ldap_sync command maintains a detailed log of all activity for every run. The ldap_logging.0-n file is located in the $NX_ROOT/log directory.

The following is an example of the summary data pdm_ldap_sync returns at the command line:

```
pdm_ldap_sync Starting...
pdm_ldap_sync Summary:  Processed(21) Updated(1) No Matches(7) No Changes(11)
Multiple Matches(0) Empty Filter(2) Errors(0)
pdm_ldap_sync Complete...
```

The following table describes the summary data:

Status	Count	Description
Processed	21	The number of CA SDM contacts with corresponding LDAP entries
Updated	1	The number of LDAP entries with information different from their corresponding CA SDM contact record
No Matches	7	The number of CA SDM contact records with no corresponding LDAP entries.
No Changes	11	The number of LDAP entries with information identical to their corresponding CA SDM contact record
Multiple Matches	0	The number of LDAP entries with multiple matching contact records in CA SDM, as defined by the ldap_search_base option
Empty Filter	2	The number of LDAP entries that cannot be used to generate a valid search filter
Errors	0	The number of LDAP entries that encountered an error during processing

Test Connections to LDAP Directories

This article contains the following topics:

Use the pdm_ldap_test command-line utility to test the connection to an LDAP directory, ensure that the search options are correctly configured, and test the TLS configuration.

By default, pdm_ldap_test uses the parameter settings that are entered in the $NX_ROOT/NX.env file when you install, edit, or uninstall LDAP options. To override the defaults, you can specify parameters at the pdm_ldap_test command line.

To see the available parameters for this command, enter the following command:

```
pdm_ldap_test -h
```

Important! On UNIX, the LIBPATH must be set before running several CA SDM utilities. Use *pdm_task* to set the LIBPATH before running a utility. For example, input "pdm_task pdm_clean_attachments ...".

Verify Connection to LDAP Server

To verify the connection to the LDAP server, run pdm_ldap_test without parameters:

```
pdm_ldap_test
```

Successful Connection to LDAP Server

If the connection is successful, you receive output similar to the following:

```
Starting pdm_ldap_test...
LDAP service type=active directory
Service Desk platform=windows
Using search base=DC=mycontroller,DC=xyz,DC=com
Using filter=(&(objectCategory=person))
ldap_init(myserver.mycontroller.xyz.com,389): (Success)
ldap_bind_s(Administrator) (Success)
LDAP API Verion 3
```

View Search Parameters

To verify that the search parameters are correctly configured, run pdm_ldap_test without parameters:

```
pdm_ldap_test
```

Successful Search

When your search is successful, you see output similar to the following:

```
DN: CN=John A. Smith,CN=Users,DC=COMPUTERTEST
       c(2)(0): US
       displayName(14)(0): John A. Smith
       mail(14)(0): account02@mycompany.com
       givenName(4)(0): John
       initials(1)(0): a
       distinguishedName(38)(0): CN=John a.
Smith,CN=Users,DC=COMPUTERTEST
       objectGUID(3)(0): 314738
       pager(12)(0): ###-111-1111
       postalCode(5)(0): 11111
       SAMAccountName(7)(0): account02
       sn(6)(0): Smith
       telephoneNumber(12)(0): ###-342-6265
       userPrincipalName(16)(0): account02@COMPUTERTEST
DN: CN=Mike Johnson,CN=Users,DC=COMPUTERTEST
       displayName(10)(0): Mike Johnson
```

```
       givenName(4)(0): Mike
       distinguishedName(34)(0): CN=Mike
Johnson,CN=Users,DC=COMPUTERTEST
       objectGUID(12)(0): 312328
       SAMAccountName(7)(0): account03
       sn(5)(0): Johnson
       userPrincipalName(16)(0): account03@COMPUTERTEST
```

Determine which Attribute Names have Values

Use the -a "*" parameter and the -f parameter with the pdm_ldap_test command to determine which attributes are defined for LDAP User or Group records. This test is useful for seeing if there are LDAP attributes that you want to map to Contact attributes, and to verify that a particular attribute has a value and should be available when creating or updating Contact records.

The following example shows output from an iPlanet directory:

```
pdm_ldap_test -a "*" -f sn=Account_1000001
2 LDAP records found...
DN: cn=Account_1000001,ou=200K_Plus,o=SmartLabs
   sn(15)(0): Account_1000001
   objectClass(13)(0): inetOrgPerson
   objectClass(20)(1): organizationalPerson
   objectClass(6)(2): Person
   objectClass(18)(3): ndsLoginProperties
   objectClass(3)(4): Top
DN: cn=Account_1000001,ou=2_Plus,o=SmartLabs
   mail(28)(0): ThisIsTheMailingAddressField
   uid(13)(0): Login_1000001
   givenName(17)(0): GivenNameOfPerson
   sn(15)(0): Account_1000001
   objectClass(13)(0): inetOrgPerson
   objectClass(20)(1): organizationalPerson
   objectClass(6)(2): Person
   objectClass(18)(3): ndsLoginProperties
   objectClass(3)(4): Top
```

The following example shows output from Active Directory:

```
Ldap_test  - a "*"  - f (&(sn=Brown)(initials=A))"
1 LDAP records found...
DN: CN=John A. Smith,CN=Users,DC=mycontroller,DC=xyz,DC=com
   objectClass(3)(0): top
   objectClass(6)(1): person
   objectClass(20)(2): organizationalPerson
   objectClass(4)(3): user
   cn(16)(0): John A. Smith
   sn(5)(0): Brown
   givenName(7)(0): John
   initials(1)(0): A
   distinguishedName(55)(0): CN=John A. Smith,CN=Users,DC=mycontroller,DC=xyz,DC=com
   displayName(16)(0): John A. Smith
   memberOf(52)(0): CN=Domain Admins,CN=Users,DC=mycontroller,DC=xyz,DC=com
```

```
   sAMAccountName(7)(0): smijo04
   userPrincipalName(25)(0): smijo04@mydomain.xyz.com
   objectCategory(63)(0): CN=Person,CN=Schema,CN=Configuration,DC=mycontroller,DC=xyz,
DC=com
```

Narrow Your Search

Use the -f parameter with the pdm_ldap_test command to specify a filter to be added to the base filter for narrowing the search criteria. You must use appropriate LDAP syntax and LDAP schema attribute names in your filter. Surround your filter with double quotation marks and use parenthesis to clarify the order of operator precedence.

For example, use the following command to search for all records where sn=Account_10001:

```
pdm_ldap_test  - f "(sn=Account_10001)"
```

The pdm_ldap_test utility supports the following equality operators:

Equality Operator	Description
=	equal to
<=	less than or equal to
>=	greater than or equal to
~=	like

The pdm_ldap_test utility supports the following Boolean operators:

Boolean Operator	Description
&	AND
|	OR
!	NOT

The AND and OR operators affect each set of parenthesis () in the search filter. The NOT only affects the first set of parenthesis. Always place these operators *before* the search filters to be operated on, rather than between them. They can be applied to any number of filters, as shown in the following examples:

```
"(&(sn=Brown)(initials=A)) "
"(|(sn=Brown)(sn=Smith))"
"(!sn=Brown)"
```

Error Messages for Failed Connections to LDAP Directories

This article contains the following topics:

Failed Connection Server Down or Incorrect Name or Port

If the connection fails because the server is down or you specified an incorrect LDAP server name or port, you receive output similar to the following:

```
Starting pdm_ldap_test...
LDAP service type=active directory
Service Desk platform=windows
Using search base=DC=mycontroller,DC=xyz,DC=com
Using filter=(&(objectCategory=person))
ldap_init(junk,389): (Success)
ldap_bind_s(Administrator) (Server Down)
```

Failed Connection Invalid LDAP_DN or LDAP_PWD

If the connection fails because you specified an incorrect LDAP_DN or LDAP_PWD, you receive output similar to the following:

```
Starting pdm_ldap_test...
LDAP service type=active directory
Service Desk platform=windows
Using search base=DC=mycontroller,DC=xyz,DC=com
Using filter=(&(objectCategory=person))
ldap_init(myserver.mycontroller.xyz.com,389): (Success)
ldap_bind_s(junk) (No Such Object or Invalid Credentials)
```

Failed Search Invalid SEARCH_BASE

If the search fails because you have an invalid SEARCH_BASE, you receive output similar to the following:

```
Starting pdm_ldap_test...
LDAP service type=edirectory
Service Desk platform=windows
Using search base=o=SmartLabsx
Using filter=(&(objectClass=InetOrgPerson)
ldap_init(155.35.173.110,15389): (Success)

ldap_bind_s() (Success)
LDAP API Verion 3
ldap_search_st() (No Such Object or Referral)
```

Failed Search SIZELIMIT_EXCEEDED, TIMEOUT

The search can fail with a SIZELIMIT_EXCEEDED or TIMEOUT message if you specify a filter that does not sufficiently narrow the search. Most LDAP Servers limit the size of the result set returned from a search request. If you exceed this limit, you receive a SIZELIMIT_EXCEEDED message. If your search request takes longer than the default timeout of 20 seconds, the LDAP server times out your request and you receive a TIMEOUT error message similar to the following:

```
Starting pdm_ldap_test...
LDAP service type=edirectory
Service Desk platform=windows
```

```
Using search base=o=SmartLabsx
Using filter=(&(objectClass=InetOrgPerson)
ldap_init(155.35.173.110,15389): (Success)
ldap_bind_s() (Success)
LDAP API Verion 3
ldap_search_st() (TIMEOUT or SIZELIMIT_EXCEEDED)
```

Failed Search 0 Records Returned

The search may fail because your default filter is not correct. If pdm_ldap_test returns zero (0) records, always check the Using filter line, which is the base filter generated by the LDAP_FILTER_PREFIX and LDAP_FILTER_SUFFIX, or the LDAP_OBJECT_CLASS options:

```
Starting pdm_ldap_test...
LDAP service type=edirectory
Service Desk platform=windows
Using search base=o=SmartLabs
Using filter=(&(objectClass=InetOrgPerson)
ldap_init(155.35.173.110,15389): (Success)
ldap_bind_s() (Success)
LDAP API Verion 3
ldap_search_st() 0 records
```

Configuration File Modification

When you install the CA SDM web interface, a sample web engine configuration file (*web.cfg*) is installed that you can modify to suit your needs. The *web.cfg* file itself contains helpful comments that you can read by viewing the file. You can open the *web.cfg* file from the appropriate directory:

- (Windows) %NX_ROOT%\bopcfg\www\
- (UNIX) $NX_ROOT/bopcfg/www/

> **Note:** Some additional configuration variables, such as charset, are also available in Options Manager. These are accessible using the Administration tab in the web interface.

AllowInactiveSrelEntry
Specifies whether a record can be saved when it references inactive records in a reference table.

- When this property is omitted or set to zero, inactive reference table entries (such as request status or change category) are not included in drop-down selects, and cannot be specified for lookup or hierarchical search fields.
- When this property is set to 1, the inactive flag is ignored in reference table entries.

Regardless of the setting of this flag, records already containing a reference to an inactive reference table entry can be saved without changing the reference; the flag affects only new field values.

AnnouncementLength
Specifies the maximum number of announcements to display on the opening screen for both customer and analyst interfaces. CA SDM begins the display with the most recent announcement, continuing for the number of announcements specified by this parameter. Users of the analyst interface can view additional announcements by selecting Announcements from the Search menu.
Default: 10, meaning that the ten most recent announcements display.

AnonymousPrio
Specifies valid priorities for tickets created by guest users. Such users can specify only one of the priorities in the AnonymousPrio list for their tickets. Entries in the list of priorities are separated by spaces. Each entry must be either a number between 1 and 5 or the word “none” (without quotes). The default priority for tickets created by guest users should be specified first, and can be repeated in the list.
The values valid for AnonymousPrio correspond to the symbolic names of the priorities as distributed. You can use the java client to modify these symbolic names; however, this does not affect the specification for AnonymousPrio, which must continue to reference priorities by their default names, where 1 corresponds to the highest priority.
Default: None, meaning that all requests created by a guest user have a priority of none.

Autofill
Specifies that the web interface should auto-fill lookup fields when a user keys data into them and presses Tab to exit the field. When a user does this and the Autofill option is selected, the browser asks the server to confirm that the update is correct. This results either in the full name filling in the field (if the user provided a partial name), or a pop-up search window appearing (if the user’s selection was incorrect or ambiguous).
This property is optional. Autofill is enabled by default so if this property ID is omitted or set to Yes, tabbing out of a lookup field automatically searches the database. If this property is set to No, no auto-fill occurs, and lookup fields are not verified until the record is saved.

CAisd
Specifies the path (including a leading slash) to the alias or virtual directory in your HTTP server that contains the files needed by the CA SDM web server. This property typically has a value of /CAisd in both UNIX and Windows installations. For Apache servers, it should be defined in an Alias statement in a configuration file. For IIS, it should match an Alias field in the Directory Properties Window.

CGI
Specifies the name of the CGI executable program supplied with the web interface (without the .exe suffix).
Default: pdmweb

Note: If you rename this program, you must update this property.

CgiReport

Specifies the name of the CGI executable program for web reports supplied with the web interface (without the .exe suffix).
Default: pdm_cgireport

Note: If you rename this program, you must update this property.

ContactAutoDesc

Specifies whether the contact's name should be inserted into the description of new issues and requests created in the customer and employee interfaces. If this property is omitted or specified as 0, no automatic information is added to the description of new issues and requests. If this property is specified as 1, the contact's name is automatically inserted into the description of issues and requests created in the customer and employee interfaces. This property has no effect on the analyst interface.

ContactAutoDescWithIP
Specifies whether the contact's IP address should be inserted into the description of new issues and requests created in the customer and employee interfaces. If this property is omitted or specified as 0, no IP address information is added to the description of new issues and requests. If this property and the ContactAutoDesc property are both specified as 1, the contact's name and IP address are automatically inserted into the description of issues and requests created in the customer and employee interfaces. This property has no effect on the analyst interface. It is ignored unless ContactAutoDesc is 1.

CstPrio
Valid priorities for issues created with the customer web interface. Users of the customer interface can only specify one of the priorities in the CstPrio list for their issues and cannot update the priority of an issue if an analyst has altered it to a value that is not in the list.
Entries in the list of priorities are separated by spaces. Each entry must be either a number between 1 and 5 or the word "none" (without quotes). The default priority for issues created with the customer interface should be specified first (and can be repeated in the list).
Default: none, 3, 4, 5
The values valid for CstPrio correspond to the symbolic names of the priorities as distributed. You can use the java client to modify these symbolic names; however, this does not affect the specification for CstPrio, which must continue to reference priorities by their default names, where 1 corresponds to the highest priority.

DateFormat
Defines the order of elements in dates.
Default: MM/DD/YYYY hh:mm a(am,pm)

Symbol	Description
M	Print 1 or 2 digits of month
MM	Print 2 digits of month
D	Print 1 or 2 digits of date
DD	Print 2 digits of date
YY	Print 2 digits of year
YYYY	Print 4 digits of year
H	Print 1 or 2 digits of hours on 24 hour clock
HH	Print 2 digits of hours on 24 hour clock
H	Print 1 or 2 digits of hours on 12 hour clock

Symbol	Description
hh	Print 2 digits of hours on 12 hour clock
M	Print 1 or 2 digits of minutes
mm	Print 2 digits of minutes
S	Print 1 or 2 digits of seconds
ss	Print 2 digits of seconds
a(am, pm)	Print am and pm as a string

DateFormatNoTime

Specifies the same definition as DateFormat, but without specifying the time portion.

DebugSource
Enables the standard browser right-click menu on CA SDM forms. When this property is not set, you can right-click a form to display a CA SDM menu. You should use caution when setting this property, because some of the options on the standard browser right-click menu can cause execution errors (this is the reason why it is usually disabled). On Internet Explorer, you can display the standard browser right-click menu although the DebugSource property is not set by pressing the Ctrl key when you right-click.

DebugTrace
Causes the web engine to write trace information to the stdlog file.

Important! This property should *not* be set for typical use. It should only be used when requested by CA Support.

EmpPrio
Valid priorities for requests created with the employee web interface. Users of the employee interface can only specify one of the priorities in the EmpPrio list for their requests and cannot update the priority of a request if an analyst has altered it to a value not in the list.
Entries in the list of priorities are separated by spaces. Each entry must be either a number between 1 and 5 or the word “none” (without quotes). The default priority for requests created with the employee interface should be specified first (and can be repeated in the list).
Default: none, 3, 4, 5
The values valid for EmpPrio correspond to the symbolic names of the priorities as distributed. You can use the java client to modify these symbolic names; however, this does not affect the specification for EmpPrio, which must continue to reference priorities by their default names, where 1 corresponds to the highest priority.

ExclLockSeconds
Specifies the maximum number of seconds that a user is given an exclusive lock on a record after clicking Edit. After this period elapses, the web engine releases the lock, allowing other users to update the record. The web engine attempts to retake the lock if a user asks to save after ExclLockSeconds has expired. This attempt succeeds only if no other user has updated the record

while the lock was available. If the attempt to retake the lock fails, the user must re-enter the updates.
Default: 120 (two minutes)
This argument is optional. If omitted, the default value is assumed.

Note: The ExclLockSeconds setting must be shorter than the Timeout setting. ExclLockSeconds is specified in seconds and Timeout is specified in minutes.

FormCacheMax
Specifies the maximum number of forms to be retained in web engine memory for each user. The web engine always retains the last FormCacheMax forms used by each user. Forms beyond this number are eligible to be timed out. Timed out forms cannot be accessed by the Back or Forward buttons on the main page, and can no longer be submitted on a pop-up form.
Default: 10
Timed out forms save memory in the web engine, but they occasionally require users to manually refresh them. You can set FormCacheMax to - 1 to disable the FormTimeout feature.

FormTimeout
Specifies the minimum number of seconds that a form is retained in the web engine before it is eligible for removal from the cache. Users always have at least the number of seconds specified in this parameter to work on a form before submitting it. In addition, the web engine always retains the most recently used FormCacheMax forms for each user.
You can use the StayCacheList property to prevent specified forms from timing out.
Default: 180 (3 minutes)

FormTitle
Specifies a string to be included in the title bar of a web browser displaying a CA SDM web form. The value of FormTitle supplements the title of the specific form displayed.
Default: CA SDM
For example, if the default value is retained, and Microsoft Internet Explorer is used to display the Announcement Detail form, the title bar displays the following:
Announcement Detail -- CA SDM -- Microsoft Internet Explorer
This property is optional. If omitted, the analyst web interface does not use a constant value in the title. The customer and PDA web interfaces revert to the default value.

HitTrackFile
Specifies the full path to a file that receives a log of all web pages used. One line is written to this file each time a user requests a page. The file can grow indefinitely, so be cautious when specifying this property.

Note: Records containing a time stamp, user ID, database record ID, and HTMPL form name are appended to this file. The format of the records may change. You must periodically maintain this file so that it does not get too large.

This property is optional. If omitted, no hit tracking file is written.

HtmplCacheSize
Specifies the size of the HTMPL cache. When this size is exceeded, the least used form is removed from the cache.
Default: 1000.

ListAllMaximum
Specifies the maximum number of records that can be displayed in a list before a request to display the entire list produces a pop-up warning message advising the user that the request adversely impacts performance and is not allowed.
Default: 2500

ListAllWarn
Specifies the maximum number of records that can be displayed in a list before a request to display the entire list produces a pop-up warning message advising the user that the request may adversely impact performance, and asking for confirmation.
Default: 1000

ListBottomMaximum
Specifies the maximum number of records that can be displayed in a list before a request to scroll to the bottom produces a pop-up warning message advising the user that the request adversely impacts performance and is not allowed.
Default: 2500

ListBottomWarn
Specifies the maximum number of records that can be displayed in a list before a request to scroll to the bottom produces a pop-up warning message advising the user that the request may adversely impact performance, and asking for confirmation.
Default: 1000

ListPageLength
Specifies the maximum number of found records to be shown on a list page after performing a search.
Default: 10

LogoutURL
Specifies the complete URL of a web page to be displayed after a user logs out of CA SDM. This property is optional. If it is not specified, logging out returns the login form.

Lr_Refresh
Specifies the log reader refresh interval in seconds. If this property is non-zero, the Notification Log Reader automatically refreshes itself at the specified interval (with a minimum of thirty seconds). This property is optional. If omitted, the log reader refreshes itself every 5 minutes (a default value of 300 seconds). If this property is specified as zero, the log reader does not automatically refresh at all.

MacroPath
Specifies a list of directory paths that the web engine searches to find files requested by the PDM_MACRO tag. You can specify multiple directories separated by spaces. You can include environment variables in the directory names by prefixing them with a dollar sign (for example, $NX_ROOT). For both Windows and UNIX, separate path components with a forward slash (/), not a backslash (\). This property is required. It is typically set as follows:

```
$NX_ROOT/site/mods/macro $NX_ROOT/bopcfg/www/macro
```

MatchesFound
Specifies the text of the message to display under a field when a user's key for a lookup field is ambiguous and the edit form must be redisplayed with a drop-down select list. This property is optional; if omitted, it defaults to Multiple Matches.

MaxRecordsAutoSuggest

Specifies the number of records that autosuggest displays when search as you type or autosuggest displays suggestions below a lookup.
Default: 25

MaxSelectList
Specifies the maximum number of matches to display in the drop-down select list shown when a user' s key for a lookup field is ambiguous and the edit form must be redisplayed. If more than this many matches are found, the message specified for Too Many Matches is displayed.

MinCharsAutoSuggest
Specifies the minimum number of characters to enter in the lookup fields before search as you type or autosuggest displays suggestions.
Default: 3

MouseoverPreviewDelayTime
Specifies the delay time (in milliseconds) between hovering the mouse pointer over a link and the display of the mouseover preview.
If the mouse moves away from the link before the delay time expires, the preview does not appear.
Default: 1000

NoMatchesFound
Specifies the text of the message to display under a field when a user's key for a lookup field is incorrect and the edit form must be redisplayed. This property is optional; if omitted, it defaults to No Matches Found.

PreLogin Timeout
Specifies the maximum number of minutes the web engine keeps a session active before login. The web engine automatically starts a session when a user requests a login form, in anticipation of the user completing the login. If the user does not login within the time period specified, the web engine destroys the session. If the user subsequently logs in, the web engine creates a session that is transparent to the user.
This property has no end-user impact. Its sole purpose is performance -- balancing web engine memory usage versus the overhead of destroying and recreating a session. This property is optional; if omitted, it defaults to one minute.

RedirectingURL
Specifies the URL the WebDirector should use to send requests to this web engine. This property specifies the full URL of the web engine, including http. This property is required if you are using WebDirector. It is ignored if you are not.

SchedExpMaximum

Specifies the limit of the number of schedule events that can be exported at a time.
Default: 1000

Important! The default is the maximum exports that CA SDM can handle at a time. Increasing this default could cause system instability. If you attempt to export more than the value specified in SchedExpMaximum, a message appears refusing your exporting request.

SelListCacheExclude
Specifies the names of the factories (objects) to be excluded from caching for <PDM_SELECT> lists. To improve performance, the web engine usually caches in its own memory of the contents of small tables used in <PDM_SELECT> (drop-down) lists and hierarchical search lists. You may want to suppress caching for a table if you are using data partition constraints to specify that different users should receive different views of the table. In addition, including tables in the value of this property eliminates the need for the web engine to query their record count at startup, slightly improving startup performance. This property is optional. If specified, it should contain one or more object names separated by spaces.

SelListCacheMax
Defines the maximum number of records in a table that can be cached in the web engine. The web engine keeps the entire contents of tables at or below its cache size in its own memory, improving its performance in building <PDM_SELECT> lists using these tables. Specifying a higher value for this property improves performance at the expense of memory usage.
Default: 10
SelListCacheMax is ignored for tables used in hierarchical search lists, such as category on requests, issues, and change orders. The web engine always stores the entire contents of tables used in hierarchical search lists in its own memory. If you have a large number of values in any of these tables, you may want to specify the SelListCachePreload property.

SelListCachePreload

Specifies one or more tables to be loaded into the web engine's select cache at startup time. Tables not specified in this property are loaded the first time they are used. If SelListCacheMax is large, or if you have a large number of records in a hierarchical search list (such as category), you may want to specify the table in SelListCachePreload. This avoids a response time delay the first time a user accesses a form using the table.
The specification for the SelListCachePreload property is a blank-separated list of object names. Each object name can be followed by an optional list of attribute names in parentheses. The attributes specified in the list are loaded into the web engine. If no attributes are specified, only the common name and rel attr value of the object are loaded. This is sufficient for drop-down selects, but may not be sufficient for hierarchical searches. If you modify the hierarchical search forms (hiersel_xx.htmpl, where xx is an object name), be sure that the SelListCachePreload property specifies every attribute used in the form. If you omit an attribute, the cache is reloaded when the form is used.
The SelListCachePreload property is optional. If it is omitted, nothing is loaded into the select cache until a user requests a form using a drop-down select or a hierarchical search.

```
chgcat(description owning_contract) chgstat crs isscat(description owning_contract)
issstat pcat(description cr_flag in_flag pr_flag owning_contract) pri tskstat urg
pcat_cr(description cr_flag in_flag pr_flag owning_contract) pcat_pr(description
cr_flag in_flag pr_flag owning_contract) pcat_in(description cr_flag in_flag pr_flag
owning_contract)
```

StayCacheList

Specifies the names of forms that are never removed from the forms cache, regardless of the length of time they have been displayed. This property ensures that the fixed frames on a frame display remain for the lifetime of a session. It can be used with caution to cause other forms to be permanently cached. The default is as follows:

```
scoreboard.htmpl top_splash.htmpl buttons.htmp hiersel_admin_tree.htmpl
```

SuppressHtmplCache

Specifies that the web engine should reread all files defining the contents of a page each time the page is requested. Parsing an HTMPL file takes a significant amount of web engine processing time, and usually involves reading several physical files (because most pages use PDM_INCLUDE tags). The web engine normally saves parsed files in its own memory so that future requests for the same page can be satisfied immediately. This markedly improves performance, but can be inconvenient for users in the process of developing new or updated pages, as the web engine must be recycled for changes to take effect.
This property is optional and requires no value. If it is specified, the web engine does not cache parsed files, and changes to HTMPL files take effect immediately. Because of its impact on performance, this property should not be specified in a production environment.

SuppressLoginAndLogoutMsg
Specifies that the web engine should not log a message to the CA SDM log file each time a user logs in or logs out of the web interface.
This property is optional. If it is not specified, the web engine logs a message each time a user logs in or logs out.

SuppressMacroCache
Specifies that the web engine should discard all saved macros each time a new page is requested. The web engine normally saves parsed macros in its own memory so that future requests for the macro can be satisfied immediately. This improves performance, but can be inconvenient for users in the process of developing new or updated macros, as the web engine must be recycled for changes to take effect.
This property is optional. If it is specified, the web engine does not cache parsed macros, and changes to macros take effect immediately. Because of its impact on performance, this property should not be specified in a production environment.

Timeout
Specifies the number of minutes that a user's session can be idle before it is automatically terminated, freeing up all server resources.

Note: The Timeout setting must be longer than the ExclLockSeconds setting. ExclLockSeconds is specified in seconds and Timeout is specified in minutes.

TooManyMatches
Specifies the text of the message to display under a field when a user's key for a lookup field is ambiguous and the number of matches for the key exceeds the value of MaxSelectList. This property is optional; if omitted, it defaults to Too Many Matches.

UpdatedAnnouncementsPopup
The interval that browser checks for a new announcement. When a new announcement is found, it automatically shows the announcement in a popup window. The interval value is in minutes. To reduce the impact to the browser performance, it's recommended to set this variable to the value greater than 5 (minutes).

UseDirector
Specifies when the WebDirector is controlling this web engine. The following table defines possible values:

Value	Description
No	The web engine is independent of the WebDirector. This is the default value.
Yes	The WebDirector must initiate all sessions, including the login form. If a user attempts to make a direct connection to the web engine, the web engine asks the WebDirector for a referral.
AfterLogin	The web engine refers a session to the WebDirector after authenticating a user. A web engine configured with UseDirector AfterLogin is responsible solely for authentication, and is thereby a candidate for the use of secure sockets (SSL) for maximum security.
BeforeLogin	The web engine refers a session to the WebDirector before authenticating a user. A web engine configured with UseDirectory BeforeLogin never displays a login page, and never accepts a login password.

This property is optional. If omitted, the web engine does not use the WebDirector.

UseNestedTabs
Specifies whether to display the nested tab control on detail forms.
Default: Enabled

WebDirectorSlumpName
Specifies the name of the WebDirector servicing this web engine. This property is needed only if you are running more than one WebDirector, or if you have configured your WebDirector to use a slump name other than its default of web:director.
This property is optional if you are using WebDirector. It is ignored if you are not.

WillingnessValue
Specifies the willingness of this web engine to accept sessions, based on a scale of 0 to 10. This property is used only if you are using WebDirector. This value is meaningful only in comparison with the willingness of other web engines associated with the same WebDirector. The WebDirector transfers sessions to web engines in proportion to their willingness values. A web engine with a willingness value of twice that of another web engine's, on average, services twice the number of sessions.
A WillingnessValue of zero means that the web engine does not accept any sessions. This value can be useful when UseDirector is AfterLogin.
This property is optional if you are using WebDirector. It is ignored if you are not. If omitted, the web engine sets its willingness to 5.

WorkFrameTimeout
Specifies the maximum number of seconds the web engine waits for a response to an internal server request before concluding the request has failed. The workframe is used for CA SDM web interface features requiring server data other than normal web pages. This includes such features as autofill, loading category properties, and updating scoreboard counts. Workframe requests to the CA SDM

are unlikely to fail. However, workframe requests to other servers (such as integrated products, such as Knowledge Management) may fail if the targeted server is not running, or if a network problem prevents access to it. The WorkFrameTimeout property specifies a length of time before the request is considered to have failed, and the workframe is available for other requests.

Note: WorkFrameTimeout is not checked unless a workframe is needed and all workframes are in use. Therefore, it is quite likely that a remote server is going to have more time than that specified for WorkFrameTimeout to respond. The value of WorkFrameTimeout is a minimum.

This property is optional. If omitted, the web engine uses a 30 second work frame timeout.

Creating the Business Structure

Contents

A business structure is a logical representation of your enterprise in a CA Service Desk environment. This scenario describes how an administrator can create a business structure for an enterprise to manage and track contacts, groups, and assets that are spread across distributed locations. After you create a business structure, you can generate reports to analyze requests by site, organization, or group.

Example

The fictional company Forward, Inc. uses a request processing system for multiple offices that are spread across geographical locations. The company plans to implement CA Service Desk to analyze the number and types of requests that are generated from its various business segments.

To facilitate effective tracking and decision making, the organization must track the following elements:

- Contacts, contact groups, and locations
- Assets at various locations

Creating a business structure allows the management team at Forward, Inc. to perform the following actions:

- Generate reports to analyze requests by site, organization, and group
- Increase overall efficiency by implementing corrective measures for any gaps in the request process

Create a Site

A site is a geographical region where your organization has one or more locations.

For example, North America can be a site, with locations (offices) in New York, California, and Texas.

Note: If multi-tenancy is enabled, select the appropriate tenant from the drop-down list.

Follow these steps:

1. Select File, New Site from the menu bar on the CA Service Desk Scoreboard.
2. Enter the information as appropriate specific to your site.
3. Click Save.
   The site record is created and saved.

Create Locations

A location is a physical place such as an office address. For example, the addresses for New York, California, and Texas offices can be locations under the site North America.

Creating locations helps you manage contacts and resources in that location. After you create a location, you can assign it to a site.

Follow these steps:

1. Select File, New Location from the menu bar on the Scoreboard.
2. Enter the information specific to your location, then configure the location using the following controls on the tabs:
   - **Address**
     Specifies the physical address of the location.
   - **Auto Assignment**
     Automatically assigns the tickets (requests, change orders, and issues) to members in this location.
     - **Update Request Areas**
       Select the request areas that you want to auto-assign to members of the location.
     - **Update Change Categories**
       Select the change categories that you want to assign to members of the location.
     - **Update Issue Categories**
       Select the issue categories that you want to assign to members of the location.

- **Update Groups**
  Select the groups that you want to update for auto assigning tickets.

Important! After updating the request areas and categories, enable the automatic assignment for each request area and category individually.

3. Click Save.
   The location details are saved.

4. (Optional) Repeat steps 1-3 to add more locations.

Create Organizations

An organization refers to an internal department or division or an external company. You can assign organizations to tickets, Configuration Item (CI) classes, and contacts.

For example, you can define CIs for organizations to specify the hardware, software, and services that the organization uses.

Note: If multi-tenancy is enabled, select the appropriate tenant from the drop-down list.

Follow these steps:

1. Select File, New Organization from the menu bar on the Scoreboard.

2. Enter the information specific to your organization, then specify organization details in the following fields:

   - **Address**
     Displays the address of the location to which you associate the organization. The fields are automatically populated when you assign location to the organization.

   - **Environment**
     Displays the Configuration items (for example, equipment, software, and services) that the organization uses. You can associate one or more configuration items with the organization. Associating the CI items to the organization helps administrators to keep track of the resources used by the organizations in various locations.

3. Click Save.
   The organization details are saved.

4. (Optional) Repeat Steps 1-3 to add more organizations.

Set Up an Organization's Environment

An organization's environment consists of the equipment, software, and services they use.

Follow these steps:

1. Select the Environment tab on the Organization Detail page
2. Click Update Environment.

   The Configuration Item Search page appears.
3. Enter the search criteria to display the configuration items of interest and click Search.

   The Organization Environment Update page displays the configuration items that matched the search criteria.
4. From the list on the left, choose the configuration items you want to add to this organization's environment. To choose multiple items, hold down the CTRL key while clicking the left mouse button.
5. When you have selected all the configuration items you want, click the double right-arrow button.

   The selected configuration items move to the Organization Environment list on the right.
6. Click OK.

   The Organization Detail page displays the selected items listed on the Environment tab.

Create Groups

A group is a collection of contacts that represent a specific area of responsibility. Defining groups lets you assign the responsibility for resolving a ticket when that responsibility is shared among several individuals. For example, a Dallas Human Resources group is responsible for dealing with the personnel issues in the Dallas office of your organization. When an employee in that office has a problem, you can assign the problem to the Dallas Human Resources group for resolution.

Note: The public (shared) option creates the object for all tenants.

Note: If multi-tenancy is enabled, select the appropriate tenant from the drop-down list

Follow these steps:

1. Select File, New Group from the menu bar on the Scoreboard.
2. Enter the information specific to this group and your organization by specifying the group details in the following fields:

- **Notification**
  Defines the contact information and method for notifying the group.

- **Address**
  Assigns the group to a location.

- **Organizational Info**
  Specifies the functional or administrative organization, department, cost center, or vendor information.

- **Environment**
  Specifies the environment (for example, equipment, software, and services).

- **Members**
  Adds or removes contacts.

- **Service Contracts**
  Lists service contracts that have been associated with the group.

- **Auto Assignment**
  Lists auto assignments of tickets that are based on the group membership.

- **Remarks and Special Handling**
  Lists remarks and special handling types, such as VIP or security risk types. You can click Update Contact's Special Handling to search for special handling members.

3. Click Save.
   The group record is saved and the group detail page opens. The following buttons are now available for configuring the group:

   - **Update Environment**
     On the Contact Details, Environment tab, click this button to display the Configuration Item Search window for the group. You can specify search criteria for the assets you want to consider on this page. You can create new configuration item and search assets using the Update window of Contacts respectively.

   - **Update Members**
     On the Members, Service Contracts, Auto Assignment, Members tab, this button displays the contacts. You can add and remove contacts for this group.

4. (Optional) Repeat Steps 1-3 to add more groups as needed.

CA SDM User Authentication

This article contains the following topics:

CA SDM provides a user authentication solution that you can modify as part of the access type. The same authentication is used by all CA SDM interfaces and by other CA products.

Authentication is flexible, allowing you to take advantage of external authentication mechanisms, such as Windows, HTTPD user validation or LDAP authentication. You can also select from a variety of internal authentication options, including operating system password, PIN, guest user access, or no access at all.

How CA SDM Authenticates Users

CA SDM authenticates users based on the user ID defined in their contact record. The product also does the following when a user requests access to the system:

1. If an external user ID is available (from HTTPD or Windows validation), CA SDM looks up the contact by login ID. If the contact is found and has an access type that permits external authentication, the user is allowed into the product.

2. If there was no successful external authentication, CA SDM prompts the user for a user ID and password. The product looks up a contact record for the user ID, obtains the access type, and then authenticates the user as specified by the access type.

Many installations find the predefined access types define authentication that is reasonable for that type of user; however, in some cases you may need to modify the authentication information for a predefined access type or define a new access type to handle a different authentication method for some of your users. You should review the authentication settings for the predefined access types to determine if they meet your needs, or if you need to modify them, or define additional types.

External Authentication

CA SDM permits users to access the system without supplying a user ID if all of the following conditions are met:

- External authentication is set for the user.
- The user's externally authenticated user ID is associated with a contact in your contact table.
- The contact record has an access type whose authentication definition permits external authentication.

External authentication does not permit users to access the system in the following cases:

- A user attempts access through a non-secure server.
- A user attempts access but is assigned to an access type that does not allow external authentication.

None of the predefined access types use external authentication. If you want to use external authentication for users, consider modifying the employee, analyst, and administrator access types to set external authentication. Your individual site requirements and different types of users determine whether to allow external authentication. When external authentication is used, the server configuration controls the access to files and directories. When you define authentication for an access type, you can decide the usage as follows:

- Do not use any external authentication that is already implemented, such as the user login on Windows or validation by the HTTPD server.
- Use the authentication that is implemented and allow or deny access based on it.

Note: If external authentication is not allowed, the user is authenticated based on the validation type that you specify.

Following are some examples of external authentication:

- If a user who has administrator access logs into a Windows computer, the user can perform administrative tasks without re-entering any login information.
- If a user who has HTTPD server validation, the user can access the web interface without re-entering any login information. Because the administrator access type specifies the analyst web user type, the appropriate web interface for the analyst is presented automatically.

Validation Types

Validation types authenticate users only under the following circumstances:

- The user access type does not permit external authentication.
- The user access type permits external authentication, but the user has not been validated externally (for example, the user has attempted access through a nonsecure server).

CA SDM provides you with the following validation options:

- **No Access** -- Users of this type have no access unless external authentication is allowed and is valid.
- **Open** -- Users of this type have access, with no additional authentication required.
  - **OS** -- Users of this type enter their operating system password for access. The operating system used for validation is the one running User Validation Host. This option is the default validation type for the administrator, analyst, and employee access types.
  - **PIN** -- Users of this type gain access by entering the correct value for the PIN field in their contact record as their password. You define the PIN field by entering the field attribute name when you select PIN as the validation type. PIN is the default validation type for the customer access type, which uses the value in the customer ID (contact_num) field as the PIN.

Logged In User Counts and Session Counts

The following KPIs count the number of unique licensed users that are logged in to the system (for example, CA SDM Web UI, SOAP Web Services, REST Web Services, and so on), regardless of how many sessions each user has opened:

Note: For a licensed user, ensure that the Licensed? check box is selected from the Access type page of the contact (navigate to Security and Role Management, Access Type on the Administration tab and search for the contact).

- webConcurrentLicenseCt
- webConcurrentSOAPLicenseCt
- webConcurrentRESTLicenseCt
- webConcurrentTotalLicenseCt

The following KPIs count the numbers of unique unlicensed users that are logged in to the system, regardless of how many sessions each user has opened:

- webConcurrentNonLicenseCt
- webConcurrentSOAPNonLicenseCt
- webConcurrentRESTNonLicenseCt
- webConcurrentTotalNonLicenseCt

The following KPIs count the number of unique sessions that started during the interval:

- webSessionCt
- webSOAPSessionCt
- webRESTSessionCt

For more information about the KPI description, see the KPI detail page (navigate to Service Desk, KPIs on the Administration tab and search for the KPI). For more information about how these KPIs count from different session types, see the How KPIs Count from Different Session Types (see page 1010) topic.

How KPIs Count from Different Session Types

There are different session types that are defined in the system. The following table shows how KPIs count these sessions:

Note: All predefined KPIs are installed as Inactive. For a KPI to begin functioning in your system, it must be set to Active. Navigate to Service Desk, KPIs on the Administration tab and search for the inactive KPI. Open the KPI and click Activate.

Important! Multiple versions of a KPI with the same name cannot be active at the same time.

Session Type	Session Type Description	Counted by KPIs
Web Client	Web browser session	webSessionCt webConcurrentLicenseCt webConcurrentNonLicenseCt webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Java Client	Java client session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Web Services	SOAP Web services session	webSOAPSessionCt webConcurrentSOAPLicenseCt webConcurrentSOAPNonLicenseCt
Utility	Server utility session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Portal	Portal session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Knowledge Chat	Knowledge Chat session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Mail Server	Mail Server session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
Custom Application	Custom Application session	webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
PDA Client	PDA Client session	webSessionCt webConcurrentLicenseCt webConcurrentNonLicenseCt webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt
REST Client	REST Web Services Session	webRESTSessionCt webConcurrentRESTLicenseCt webConcurrentRESTNonLicenseCt webConcurrentTotalLicenseCt webConcurrentTotalNonLicenseCt

Example: KPIs calculating user counts

One licensed (that have the Licensed? check box selected) and two unlicensed end users are logged into the web self-service interface and reviewing some announcements.

At the same time five licensed analysts (that have the Licensed? check box selected) are logged into the analyst interface and working on incidents. One of the analysts also logs in to the SOAP Web Services interface.

- The webConcurrentLicenseCt KPI shows a count of six, meaning that six licenses are currently being used, irrespective of the number of interfaces each user is using.
- The webConcurrentNonLicenseCt KPI shows the count of two, which means that two unlicensed users are logged on to the system, irrespective of the number of interfaces each user is using.

- The webSessionCt KPI shows a count of eight, meaning that eight total users are logged in to the CA SDM Web UI.

- The webSOAPSessionCt KPI shows a count of one, meaning that one user is logged in to the SOAP Web Services interface.

(Applicable for advanced availability configuration only) Example: KPIs calculating user counts from different nodes

A licensed analyst logs in to the analyst interface from the background server and works on incidents. The same analyst logs in to the analyst interface from the application server. The webConcurrentLicenseCt KPI shows a count of one, meaning that one license is currently being used, irrespective of the number of nodes or servers the user has logged in from.

Encrypt Session IDs to Address Vulnerability Issues

CA Service Desk Manager (CA SDM) uses the Session ID for authenticating each request from the user. This Session ID is sent back and forth through the web browser. An attacker can auto-generate the Session ID and can gain unauthorized access to CA SDM, if it matches any of active SIDs in CA SDM. An attacker can sniff the CA SDM web URL using man-in-the-middle attack and can replay the URL to gain unauthorized access to CA SDM. Using encrypted Session ID and cookie for authenticating user requests may have some minimal performance impact on CA SDM.

The following attributes are added in Options Manager to support encrypted Session IDs:

- **use_encrypted_sid_and_cookie (optional)**
  Use the encrypted Session ID and cookie to prevent spoofing and Man-in-the-middle attack. By default, this attribute is disabled. If you want to have enhanced CA SDM security, this attribute can be enabled (Yes).

- **force_browser_to_send_cookie_only_in_ssl_connection** (optional)
  Force the browser to send the Session ID (SID) cookie only if there is an SSL connection. This attribute is applicable only if you have enabled the **use_encrypted_sid_and_cookie** to (Yes). By default, this is turned off. If this flag is enabled, CA SDM can only be accessed through an SSL connection.
  For more information, see Options Manager (see page 1303), Security Options.

Retry Mechanism for CA SDM and CA Process Automation Workflow Options

CA Process Automation Workflows can be attached to CA SDM tickets (for example,Change Orders) through CA SDM Events and Macros. The attached events are triggered by CA SDM at the specified retry interval duration. During retry, if the CA Process Automation is unavailable, the attached event is marked as **Unknown** and the process is not executed. CA SDM retry mechanism automatically re-triggers the attached **Unknown** events when CA Process Automation is available.

CA SDM administrators can enable the retry mechanism by installing additional options in the CA Process Automation Workflow Options Manager. For more information, see Options Manager, CA Process Automation Workflow Options (see page 1303).

- **caextwf_retry_count**: Default value is 3 and can be set in the range [1 – 20].
- **caextwf_retry_interval**: Default minimum value is set as 10 minutes in the range [10-999].

This feature can be disabled by uninstalling these options. Restart CA SDM services after installing or uninstalling these options.

How the CA SDM Retry Mechanism Works

Install the Options Manager options (caextwf_retry_count and caextwf_retry_interval) and restart the CA SDM services. The retry mechanism for a failed event checks if the CA Process Automation services are up and running during the specified time interval in the Options Manager value (default value of 10 minutes). If CA Process Automation Manager services are available, the CA SDM retry mechanism checks for any attached events that are in **Unknown** status. CA SDM triggers such events at the specified time.

The retry mechanism checks for **Unknown** status events for a maximum count value which is equal to Options Manager **caextwf_retry_count** value. This event is not re-triggered once it reaches the maximum retry count value.

For more information, see Options Manager, CA Process Automation Manager Workflow Options (see page 1303).

How to Configure the F5 Load Balancer for CA Service Desk Manager

F5 Load balancers help to enhance the reliability, availability, and scalability of CA Service Desk Manager (CA SDM) servers and improves the overall performance. An F5 load balancer monitors the CA SDM Health Servlet by sending requests to servers and applications that can respond in a timely manner.

To configure an F5 load balancer in your envirnonment, complete the following steps:

- Prerequisites for configuring the F5 Load Balancer (see page 1252)
- Create a Custom Health Monitor (see page 1252)
- Create an F5 Pool for the CA Service Desk Manager Application Server (see page 1253)
- Create an F5 Virtual Server or Node for CA Service Desk Manager (see page 1254)
- Verify the F5 Load Balancer Configuration (see page 1256)

Note: For more information on configuration tasks other than the ones discussed in this article, refer to your F5 Load Balancer documentation.

Prerequisites for configuring the F5 Load Balancer

Before you configure an F5 load balancer for CA SDM, complete and keep handy the following information:

- Identify the CA SDM hosts where you need the load balancing capability.
- Credentials to log in to the F5 interface.
- Before you deploy an F5 load balancer, ensure that you have configured the CA SDM Health Servlet on application servers. For more information on how to deploy the health servlet on a CA SDM Application Server, see Deploy the Health Servlet on the Application Server (see page 898).

Configure the following F5 elements so that these elements can function with the CA SDM Application Servers:

1. Create a Custom Health Monitor (see page 1252)
2. Create an F5 Pool for the CA Service Desk Manager Application Server (see page 1253)
3. Create an F5 Virtual Server or Node for CA Service Desk Manager (see page 1254)
4. Verify the F5 Load Balancer Configuration (see page 1256)

Create a Custom Health Monitor

You can create a custom monitor when the values that you have defined for a pre-configured monitor does not meet your requirements, or when a pre-configured monitor is not available for the type of monitor you are creating. You can give a unique name to your monitor, specify the monitor type, and, if a monitor of that type already exists, import settings and values from the existing monitor. You can change the values of any imported settings.

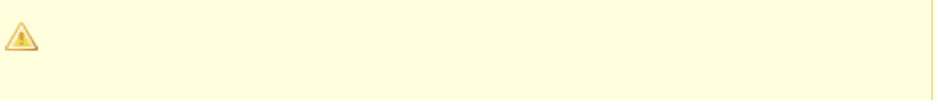
To create a custom health monitor, complete the following steps:

Follow these steps:

1. Navigate to **Local Traffic**, **Monitors**, and Click **Create**. Complete the following field information:
   a. **Name**: Enter the name of the health monitor.
   For example: **SDM_health**

   b. **Type**: Select **HTTP** from the drop-down list.
   You must base each custom monitor on a monitor type. To specify a monitor type, simply choose the one that corresponds to the service you want to check.

   c. **Send String**: Enter **GET /HealthServlet/GetHealth\r\n**.



> **Note:** When you create a new HTTP monitor type, you must include **\r\n** at the end of a non-empty Send String. If you do not include **\r\n** at the end of the Send String, the HTTP monitor fails.

d. **Receive String**: Enter **AA-Server-Status: All OK!**
The above string is displayed when the CA SDM server is healthy. When the server is down, the status displayed is **AA-Server-Status: NOT OK!**

e. **Receive Disable String**: Enter **Quiesce time remaining**.

2. Click **Finished**.
You have successfully created a custom health monitor.
When a user accesses the F5 load balancer URL, CA SDM health check is performed, and the user is routed to a server that is functional and not disabled or temporarily inactive (quiesced).

.

Create an F5 Pool for the CA Service Desk Manager Application Server

Create an F5 pool for the CA SDM server where you want to enable the F5 load balancing capability.

Follow these steps:

1. Select **Main**, **Local Traffic**, and click **Pools.**

> **Note:** The Pool List is empty if you are setting up pools for the first time. The Pool List displays the details for each pool.

2. Click **Create**.

3. Complete the Configuration section on the New Pool page:

a. Select **Basic** from the drop-down list.

b. Enter a name and description for the new pool. .

c. Select an already pre-configured health monitor from the available health monitors list. Select **HTTP** and move it to the active list.

d. If a pre-configured health monitor is not available, create a custom health monitor. For more information on how to create a custom health monitor, see Create a Custom Health Monitor. (see page 1252)

Note: Before you deploy the F5 Load balancer, ensure that you have configured the CA SDM Health Servlet on the application servers to verify the CA SDM application server status. Health Monitors monitor the health of your CA SDM application servers. For more information about CA SDM health servlets, see Deploy the Health Servlet on the CA SDM Application Server (see page 898).

4. Select **Round Robin** from the Load Balancing Method drop-down list. Default option is Round Robin.

5. Select **Disabled** from the Priority Group Activation drop-down list.

6. Add each node or server to the new F5 pool as follows:

    a. Select **Node List** if you are adding a node that is already defined.

    b. If the nodes are not defined, select the **New Node** option to create a node.

    c. Select the CA SDM Application Server IP address (host name) from the **Address** drop-down list that identifies the CA SDM node to add to this F5 pool.
    If the applicant server is no longer valid or no longer in use, select the pool member and click **Disable**.

7. Click **Add**.
The details that you added for this node appear in the New Members list.

8. Click **Finished**.
The new pool is added to the F5 Pool List.

Note: Before quiescing the CA SDM Application Server server for performing a rolling maintenance, ensure that you have deployed the CA SDM application health servlet, or else, remove this server from the F5 Node List. For more information, see Deploy the Health Servlet on the CA SDM Application Server (see page 898).

Create an F5 Virtual Server or Node for CA Service Desk Manager

You can create an F5 Virtual Server for CA SDM application servers to enable the F5 load balancing capability. Complete the following steps to create an F5 Virtual Server:

Follow these steps:

1. Log in to F5. Select **Main**, **Local Traffic**, **Virtual Servers**, and **Virtual Server List**.

2. Click **Create**.

3. Complete the following General Properties on the New Virtual Server page.

a. **Name**: Specifies the name of the virtual server, for example, casdm.

b. **Destination Type**: Specifies Host for a single IP address.
This IP address should be available in the network and must not be assigned to any other device.
For more information, see the F5 Load Balancer documentation.

c. **Destination Address**: Specifies the IP address of the virtual server.

d. **Service Port**: Specifies the associated port for the virtual server.
For example: 80 for HTTP.

e. **State:** Select **Enabled**.
Specifies whether the virtual server is available for load balancing.

4. Complete the Configuration section. Accept all defaults, except for the **HTTP Profile**.

   a. **HTTP Profile**: Select **http**.
   Specifies the HTTP profile for managing HTTP traffic.

   Complete the Resources section:

   a. **iRules**: Specifies the iRules to enable for this virtual server.

   b. **Default Pool**: Specify the CA SDM pool which was created in **step 1** as the default pool.
   The virtual server routes traffic to this pool.

   c. **Default Persistence Profile**: Specifies the persistence profile for this virtual server.
   Select **cookie**.

   d. **Fallback Persistence Profile**: Specifies the persistence profile that this virtual server uses when the default persistence profile cannot be used.
   For example: **source_addr**.

5. Click **Finished**.
   For more information about the F5 Load Balancer persistence profile, see the F5 documentation.

6. Navigate to **Local Traffic**, **Profiles**, **Persistence** to modify the properties of a persistence profile. Select the persistence profile that you want to modify.
   For example, click **source_addr** and change the **Timeout** option to **600** seconds.

   Click **Update**.

   Note: For CA SDM, it is recommended that you set the **Timeout** option to a value of **600**.

7. Click **Finished**.

Verify the F5 Load Balancer Configuration

To verify the F5 load balancer configuration in your environment, complete the following steps:

Follow these steps:

1. Open any web browser, and enter the F5 Virtual Server destination IP address that you created in step 3 (see page 1254) earlier in this article while creating the F5 virtual server. You must be able to view the CA SDM login page.

2. Enter the CA SDM login credentials and click Login.
   Login must be successful.

3. Repeat **step 1** and **2** on all CA SDM application servers and verify that you are routed to these servers by checking the CA SDM logs in the CA SDM install directory.

How to Configure the Mailbox to Handle Inbound Emails

Email lets you communicate with end users, such as employees or customers. The mailbox in CA SDM handles inbound emails from users and provides action according to the email. For example, the user sends an email to CA SDM to create an incident. Mailbox checks the email, creates an incident, and sends a notification back to the user.

CA SDM provides a default mailbox (named Default) that is active and ready for use within your organization. You can modify the default mailbox, create more mailboxes, or both. After creating a mailbox or modifying the Default mailbox, define the mailbox rules. The Mailbox rules let you configure any actions, replies, or both.

Note: The rules that are applicable for one mailbox cannot be associated with another mailbox. To reuse the same rules for a different mailbox, recreate them for the other mailbox. You can also copy the existing mailbox. We recommend that you set the associated mailbox to inactive before configuring a mailbox rule. Else, any messages that are retrieved between your first change and last change are processed with rules that are in effect.

Follow these steps:

1. Log in to the web UI from the following servers, depending on your CA SDM configuration:

   - Conventional: Primary or secondary servers
   - Advanced availability: Application or background servers

2. Choose a Notification Phrase (see page 1257)

3. Define a Mailbox (see page 1261)

Choose a Notification Phrase

The notification phrase is sent to the sender of the email. For example, to confirm that an incident has been created successfully. CA SDM provides predefined notification phrases which are set to inactive by default. You can activate and modify the phrases. You can also create notification phrases to best suit your organization needs.

Choose from the following options:

- Activate a predefined notification phrase (see page 1257).
- Create a notification phrase (see page 1257)

Activate a Predefined Notification Phrase

By default, predefined notification phrases are set to inactive. You activate a notification phrase so that the notifications can use the phrase. Select Notifications, Notification Phrases on the Administration tab and search for the notification phrase. Edit the notification phrase and select Active from the Active drop-down list.

Create a Notification Phrase

You can create notification phrase that contains standardized text and macros. This notification phrase is sent as a response to emails from users.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Notifications, Notification Phrases on the Administration tab.
   The Notification Phrase List page opens.
2. Click Create New.
   The Create New Notification Phrase page opens.
3. Complete the Notification Phrase Fields (see page 1257), as appropriate.
4. Click Save.
   The notification phrase is created.

Notification Phrase Fields

Complete the following fields to edit or create a notification phrase:

- **Symbol**
  Defines a unique identifier for this record.

- **Code**
  Specifies a unique value to use for the notification phrase, in the usp_notification_phrase table. The usp_notification_phrase table lists common phrases that notification message templates can use. For information about the usp_notification_phrase table, see the *Technical Reference Guide*.

- **Phrase**
  Specifies the phrase for the notification. You can specify both plain-text and HTML versions. HTML consolidates most of the whitespace into single spaces, so you must specify line breaks or paragraph breaks with tags.
  For example, the following plain-text phrase is used in the Confidential Notice notification phrase:

```
This e-mail and any files transmitted with it are for the sole use of the intended recipient(s) and contain
information that may be privileged and confidential. Any unauthorized review, use, disclosure or distribution is
prohibited. If you are not the intended recipient of this e-mail, please delete this e-mail and any files transmitted
with it and notify the sender immediately.
```

  The following HTML phrase can be used to ask the user to view the notification list:

```
Click on the following URL to view Notification List:
@{call_req_id.web_url}+HTMPL=cr_lr.htmpl+INSTANCE=@{id}
```

  For more information about phrases, see the Notification Codes and Phrases (see page 1258) topic.

Notification Codes and Phrases

Notification phrases let you add a standardized piece of information or text to a number of different notification messages, without having to enter and maintain the text or formulae separately in each notification template. For example:

Reply to this notification to add additional information to the ticket

Phrases standardize text for use in multiple message templates. For example, you can maintain a common phrase such as a confidential notice in a single record and use it in multiple message templates. Notification phrases are also useful for message replies, such as a Reply Notice, or a web URL link. CA SDM provides phrases and you can create your own phrases. You can set a phrase as active or inactive for use in a message template globally. (Notification phrases are inactive by default.) When a phrase is inactive, the phrase is suppressed in all message templates that use the phrase.

Notification phrases can also be used in the automatic responses to incoming email messages. The processing context for this type of message is different; omit the prefix (change_id., issue_id., call_req_id.) used in certain macros such as ref_num and web_url for phrases that the message uses. As a result, you cannot share notification phrases between notification templates and email automatic responses.

For example, some of the phrases that CA SDM provides are as follows:

Symbol	Code	Phrase
Notify History - Change		

Symbol	Code	Phrase
	notify_history_chg	Click the following URL to view the Notification List: @{change_id.web_url}+HTMPL=chg_lr.htmpl+INSTANCE=@{id}
Notify History - Issue	notify_history_iss	Click the following URL to view the Notification List: @{issue_id.web_url}+HTMPL=iss_lr.htmpl+INSTANCE=@{id}
Notify History - Request/Incident/Problem	notify_history_cr	Click the following URL to view the Notification List: @{call_req_id.web_url}+HTMPL=cr_lr.htmpl+INSTANCE=@{id}

Example: New Phrases

The following phrases are examples of phrases that you can create:

Symbol	Code	Phrase
Notify Confidential	ConfidentialNotice	This email and any files transmitted with it are for the sole use of the intended recipient (s) and contain information that may be privileged and confidential. Any unauthorized review, use, disclosure or distribution is prohibited. If you are not the intended recipient of this email, please delete this email and any files transmitted with it and notify the sender immediately.
Notify Incident Reply	IncidentReply	To add a comment to your Incident, just reply to this email or include the line below (on a line by itself). %incident_id=@{call_req_id.ref_num}
Notify Incident URL	IncidentURL	Click the following URL to view: @{call_req_id.web_url}

Note: Use separate phrases for the plain-text and HTML versions of message templates or email auto-replies. HTML consolidates the whitespaces into single spaces, so line- or paragraph-breaks must be specified with tags. HTML tags included in plain-text versions of messages are displayed rather than processed.

Notification Phrase Syntax

You insert notification phrases in message templates and email reply messages using the following macro syntax:

```
@{notification_phrase[code].phrase}
```

- ***code***
  Specifies the unique Code value, such as ConfidentialNotice, of the Message Phrases (usp_notification_phrase) table.

Note: The usp_notification_phrase table lists common phrases that notification message templates can use.

For example:

```
@{notification_phrase[IncidentURL1].phrase}
@{notification_phrase[RequestReply].phrase}
```

When CA SDM locates the macro, the phrase text from the usp_notification_phrase table replaces the syntax. If no matching code exists (or if it is inactive), an empty string replaces the macro. No errors are written to the standard log (STDLOG), instead a warning message is logged to help you resolve potential problems.

Note: Embedding phrases within other phrases is limited to a maximum depth value that you configure by setting the NX_MAX_EXPAND_DEPTH environment variable (see page 862). This limitation prevents problems which can occur when processing phrases that are accidentally self-referenced (embed themselves) or circular-referenced (when a phrase embeds a phrase into which it is embedded).

Example How Notification Phrases Appear in a Message

This example demonstrates how notification phrases appear in a notification message. The example uses the following codes and phrases:

Code	Phrase
Conf idenc tialNo tice	This e-mail and any files transmitted with it are for the sole use of the intended recipient(s) and contain information that may be privileged and confidential. Any unauthorized review, use, disclosure or distribution is prohibited. If you are not the intended recipient of this e-mail, please delete this e-mail and any files transmitted with it and notify the sender immediately.
IncidentReply	In order to add a comment to your Incident, just reply to this email or include the line below (on a line by itself). %incident_id=@{call_req_id.ref_num}
IncidentURL	Click the following URL to view: @{call_req_id.web_url}

The following message template includes the notification phrases:

```
@{call_req_id.type.sym} @{call_req_id.ref_num} Closed.
Assigned to: @{call_req_id.assignee.combo_name}
Customer: @{call_req_id.customer.combo_name}
Description: @{call_req_id.description}

@{notification_phrase[IncidentURL].phrase}
@{notification_phrase[IncidentReply].phrase}
```

```
@{notification_phrase[ConfidentialNotice].phrase}
```

The phrases appear in a message as follows:

```
Incident 1234 Closed.
Assigned to: Analyst, Joe
Customer: Doe, John
Description: This is a description of my problem

Click on the following URL to view:
http://helpdesk/CAisd/pdmweb.exe?OP=SEARCH+FACTORY=chg+SKIPLIST=1+QBE.EQ.id=400723

In order to add a comment to your Incident, just reply to this email or include the
line below (on a line by itself).
%incident_id=1234

This e-mail and any files transmitted with it are for the sole use of the intended
recipient(s) and contain information that may be privileged and confidential. Any
unauthorized review, use, disclosure or distribution is prohibited. If you are not
the intended recipient of this e-mail, please delete this e-mail and any
files transmitted with it and notify the sender immediately.
```

Define a Mailbox

This topic contains the following information:

CA SDM provides a default mailbox to connect to the mail server. You can configure this default mailbox to change the password, user name, hostname, and so on. You can also create extra mailboxes to suit your organizational needs. Each mailbox can have its own definition, instead of using a single global set of definitions. You can define multiple mailboxes and can use different templates or default values for each mailbox. Multiple definitions allow individual tenants or organization use separate mailboxes with different settings.

Use the Default Mailbox or Create a Mailbox

CA SDM provides an active default mailbox. You can edit the mailbox for incoming mail delivery according to your requirement or create a mailbox that connects to the mail server. Configure the mailbox to set values for host, user, password, and so on.

Follow these steps:

1. Select Email, Mailboxes from the Administration tab.
   The Mailbox List page opens.

2. Click Default from the Name column and click Edit to edit a default mailbox or click Create New to create a mailbox.

3. Complete or update the other fields as appropriate:

   - **Check Interval**
     Specifies the time after which the mail server is polled for new emails.

   - **Active**
     Indicates the mailbox status.

   - **Email Type**
     Specifies the protocol that the mail server uses. CA SDM supports both POP3 and IMAP4. If you select IMAP4, CA SDM polls only the Inbox folder from the mailbox.

   - **Hostname**
     Specifies the hostname of the email server.

   - **Port Override**
     Specifies the port number when the default port number is overridden.

   - **User Name**
     Specifies the user ID on the mail server.

   - **Password**
     Specifies the password on the mail server.

   - **Security Level**
     Specifies the SMTP security level.

   - **Attachment Repository**
     Specifies the repository where the email attachments are stored.

   - **Attach Entire Email**
     Specifies whether to allow entire email as an attachment.

   - **Force Attachment Splitout**
     Specifies whether to split all attachments in the email when an entire email is added as an attachment. The email and its attachments are split into separate files and attached to the tickets. Only applicable when the **Attach Entire Email** option is selected.

- **Allow Anonymous**
  Specifies whether tickets can be created from anonymous mails.

- **Save Unknown Emails**
  Specifies whether to save the emails that the rules defined in the mailbox did not process. These emails are stored in $NX_ROOT/site/mail_unknown.

- **Use Reply-To Address**
  Specifies whether to use the alternate email address for replies.

- **Use TLS**
  Specifies whether to use Transport Layer Security support in emails.

- **CA Certificate Path**
  Specifies the path where the trusted certificate has been deployed.

  Note: For the advanced availability configuration, ensure that you deploy the trusted certificate on the same location for both background and standby servers. CA SDM supports only Base-64 encoded (PEM) format for CA Certificates.

4. Click Create New from the Rules tab to create a mailbox rule.
   The Create New Mailbox Rule page opens.

5. Complete the Mailbox Rule Fields (see page 1263) as appropriate and click **Save**.

6. Select the **Policy** tab to define the mailbox policies to protect your organization against certain types of email abuse. Complete the Mailbox Policy Fields (see page 1273) as appropriate and click **Save**.
   The changes to the default mailbox are saved and applied or a new mailbox is created. The first poll occurs after one second.

Mailbox Rule Fields

Important! We recommend that you set the associated mailbox to Inactive before you configure a mailbox rule. Else, any messages that are retrieved between the first and the last change are processed with rules in effect.

The table (usp_mailbox_rule) maintains the rules that are used to connect to each mail server account (usp_mailbox). CA SDM provides predefined rules which you can use to modify or create mailbox rules.

Complete the following mailbox rule fields, as appropriate:

- **Sequence**
  Specifies the sequence number of the rule. Messages are checked against rules in sequence number order from lowest to highest.

- **Mailbox**
  Specifies the mailbox to which this rule belongs.

- **Active**
  Sets the rule to active or inactive.

- **Filter**
  Specifies what part of the email to search for the filter pattern, for example, Subject contains. For more information, see the Pattern Matching in Mailbox Rules (see page 1267) topic.

- **Filter String**
  Specifies a regular expression string to match with the email content. For example, [\t\r\n]request [\t\r\n]. The placeholder {{object_id}} lets you specify the artifact value for the Text API to use for associating the message with a specific ticket. For more information, see the Filter String Object Identifier Restrictions (see page) and Special Characters in Regular Expressions (see page) topics.

- **Ignore Case**
  Specifies whether to consider letter case when matching patterns.

- **Action**
  Specifies the action to take when the filter criteria matches, for example, Create/Update Object.

- **Action Object**
  Displays the type of ticket object to which message actions apply, for example, Request.

- **Minimum Artifact Type**
  Sets the minimum type of artifact checking that you want to allow:

  - **NONE**
    Specifies no validation of artifacts. This value is the same as not adding the keyword to the input file. Also accepts Text API ticket ID commands.

  - **PROTECTED**
    Validates a ticket against the hash for confirmation. If confirmation fails, the artifact is considered invalid and the email fails filtering where filtering is looking for an artifact ({{object_id}}).

  - **SECURE**
    Validates the ticket number from an encrypted data block. If the value is not a valid encrypted ticket number, the artifact is considered invalid and the email fails filtering where filtering is looking for an artifact ({{object_id}}).

Note: Types that are more secure than what is set are allowed. In other words, if you set the minimum type to **PROTECTED**, then both **PROTECTED** and **SECURE** are allowed, but **NONE** is not. Also, if **PROTECTED** or **SECURE** are selected, Text API ticket ID commands are not accepted. For more information about the artifacts, see the Artifacts Use Considerations (see page) topic.

- **Reply**
  Specifies a notification method to send an automatic response. For example, Email. If you do not set this option, no response is returned. The response indicates success or failure of the actions performed for the message, and is separate from any notifications. If you are using multiple mailboxes, we recommend you to use the notification method to configure email replies (see page 1278).

- **Reply Subject**
  Specifies a subject line for the reply, for example, Service Desk Response.

- **Write to stdlog**
  Write email text to the standard log (stdlog) if the filter matches.

- **Log Entry Prefix**
  Specifies a prefix to add when writing email text to the standard log entries. Use this option to enable matching log entries to rules.

- **Add Subject Line**
  Adds the subject line from the original message to the message body before processing. You can append, prepend, or not add a subject line. The subject line is attached to either the ticket Description or a Log Comment, depending on the actions for the message.

- **Text API Defaults**
  Specifies additional default commands for the Text API when the filter matches. Combines with the contents of the [EMAIL_DEFAULTS] section of the text_api.cfg file. The TextAPI Defaults field includes TextAPI keyword commands that are applied to a ticket when it is created from an email that matches a mailbox rule. The commands are not applied when the message affects an existing ticket.
  To specify TextAPI Defaults commands, place each command on a separate line in the TextAPI Defaults field. Format the commands as follows:

```
OBJECT.FIELD=value
```

  Note: Do not include a leading percentage symbol (%), which is required only for corresponding commands that are embedded in the body of the email.

  For example, format the commands as follows:

```
REQUEST.PRIORITY=3

PROBLEM.CATEGORY=Facilities

INCIDENT.GROUP=Plumbing
```

- **Text API Ignore Incoming**
  Specifies additional Ignore Details for the Text API when the filter matches. Combines with the contents of the [EMAIL_IGNORE_INCOMING] section of the text_api.cfg file.

The TextAPI Ignore Incoming field lists TextAPI keyword commands that are not permitted to be used in the text of the incoming email message. Any commands that are listed in this field are ignored when they are found in an incoming email message.
To specify TextAPI Ignore Incoming commands, do the following steps:

1. Place each command on a separate line in the TextAPI Ignore Incoming field.
2. Format the commands as follows:

```
OBJECT.FIELD
```

> **Note:** Do not include a leading percentage symbol (%), which is required only for the corresponding commands that are embedded in the body of the email.

For example, format the commands as follows:

```
CHANGE.ASSIGNEE

PROBLEM.GROUP

REQUEST.EFFORT
```

3. Define all commands used in either field in the [KEYWORDS] section of the text_api.cfg file. This file is located in the “site” subdirectory of the CA SDM installation directory.

- **Details**
  Specifies information about the rule.

- **Success Text**
  Specifies the plain-text contents of a reply message when the message is processed successfully. For example:

```
Thank you for submitting an update to your request. A support technician will contact you within the next 24 hours.
```

  You can also enter a notification phrase, if already created. For example, you can use a notification phrase for email auto-replies.

```
Thank you for submitting your request.

@{notification_phrase[notification phrase code].phrase}
```

- **Success HTML**
  Specifies HTML contents of a reply message when the message processes successfully. The following options let you edit and preview HTML text:

  - **Edit Success HTML**
    Opens the HTML Editor which you can use to format the HTML.

  - **Quick View**
    Previews the HTML.

- **HTML Source**
  Shows the HTML source.

You can also use a notification phrase, for example,

```
Thank you for submitting your request.</p>

@{notification_phrase[notification phrase code].phrase}</p>
```

- **Failure Text**
  Specifies the plain-text contents of a reply message when the message does not process successfully. You can also enter a notification phrase, if already created. For example, you can use the following text:

```
Thank you for submitting your request.

@{notification_phrase[notification phrase code].phrase}
```

- **Failure HTML**
  Specifies HTML contents of a reply message when the message does not process successfully.

Mailbox Rule Actions

Mailbox rules let you perform any of the following email actions:

Ignore Email -- Does not process the email and does not reply.
This action is useful for system-level messages such as Out of Office or Mail Delivery errors.

Ignore Email and Reply -- Does not process the email, and replies to the sender. Response emails use the reply success messages and the reply failure messages are ignored.

Update Object -- Uses the filter string to determine the object identifier (for example, %Incident: {{object_id}}% in the email), and sends an update request to the Text API. If the object identifier is not found, the Text API does nothing.
This action typically handles email replies where the object identifier is embedded in the email. If no object identifier is present, the failure response message is typically sent.

Create/Update Object -- Uses the filter string to determine the object identifier (for example, % Incident:{{object_id}}% in the email), and sends an update request to the Text API. If the object identifier is found, the Text API updates a ticket. If the object identifier is not found, the Text API creates a ticket.
This action is the standard behavior of the mail daemon (Mail Eater) in which the email does or does not contain Text API keywords.

Pattern Matching in Mailbox Rules

The Mailbox rules use regular expressions for pattern matching. Consider the following whitespace characters that apply to regular expressions in mailbox rules:

- **\t**
  Used for representing a horizontal tab

- **\r**
  Used for representing a carriage return character

- **\n**
  Used for representing a line feed or new line character

The characters that represent line breaks in text can vary with the operating system, mail server, and mail client. For example:

- UNIX uses a \n.
- Microsoft uses \r\n
- Macintosh uses \r
- MacOS X uses \n

CA SDM mail processing elements exchange substitute line break characters to identify text elements like message and attached parameters. Use a line or paragraph break for building filters to match \r or\n. Line breaks between two keywords identify a sequence of one or more \r and \n characters.

Line wrapping can result in unexpected line breaks. Line breaks appear in the middle of the text. A space can change to a carriage return or line feed or both. The carriage return or line feed or both can be inserted after a space. Include spaces in the middle of a filter string through the Regular Expression Block:

[\t\n]+(open-bracket, space, backslash, t, backslash, r, backslash, n close-bracket, plus sign).

Example: Use [\t\r\n] to Match the exact keyword:

The sample example shows how to match the exact keyword "request" and ignore other possible similar keywords:

```
requester
requesting
requested
orequestra
```

To match the exact keyword ''request'', enter the keyword request by one or more white space characters as:

```
[ \t\r\n]request[ \t\r\n]
```

The Mail Eater performs a keyword-based search for ''request and ignores other possible keywords like 'requester', requesting.

Filter String Object Identifier Restrictions

Filter strings determine the object identifier (for example, %Incident:{{object_id}}%) in an email. Text that surrounds an object identifier ({{object_id}}) must be unambiguous in both content and length. The text must clearly define the beginning and end of the ticket ID artifact value between the text.

The following restrictions apply to how the Mail Eater interprets the *start* of the ticket ID artifact value:

1. The {{object_id}} placeholder must not be the first element in the filter string. At least, one character is required. Generally, a distinctive keyword or a sequence of letters, numbers, and symbols must precede the object ID keyword.

2. The character immediately preceding the {{object_id}} placeholder must not be a repeatable or optional character having a plus sign (+), an asterisk (*), or a question mark (?). Whitespace characters (space, tab, carriage return, line feed) must not be part of a ticket ID artifact value.

3. The character immediately preceding the {{object_id}} placeholder must not be a repeatable or optional bracketed-set of characters.

The following restrictions apply to how the Mail Eater interprets the *length* of the ticket ID artifact value:

- The {{object_id}} placeholder must not be the last element in the Filter String. One or more characters must follow the {{object_id}} placeholder.
- The character immediately following the {{object_id}} placeholder must not be a repeatable or optional character with a plus sign (+), an asterisk (*), or a question mark (?). Whitespace characters (space, tab, carriage return, line feed) must not be part of a ticket ID artifact value.
- The first character after the {{object_id}} placeholder must not be a character.
- Avoid the following characters immediately before and after the {{object_id}} placeholder:
  - All upper or lower-case letters
  - Numerals
  - The plus sign (+)
  - The slash (/)
  - The comma (,)
  - The period (.), as it can represent any character in this list except for a line break.

  Any of these characters can exist within the ticket ID artifact value. If a bracketed set (several characters between brackets) precedes or follows the {{object_id}} placeholder, the bracketed set must not contain any of these listed characters.

Special Characters in Regular Expressions

Pattern matching for the filters in mailbox rules follows the rules for ASCII Regular Expressions with C-style special characters.

Important! We recommend that you are familiar with Regex syntax to use special characters in regular expressions.

For example, consider the following special characters for Regex patterns that apply to regular expressions in mailbox rules:

- **\t**
  The mailbox filter string \t specifies a horizontal tab. This string matches the beginning and end of text (and tabs), and is specific to MailEater.

- **\r**
  This string specifies a carriage return (return to the beginning of the current line).
  Note: Do not use \r for searching message subjects or sender addresses.

- **\n**
  This string specifies a newline (combination of line feed and carriage return).

  Note: Do not use \n for searching message subjects or sender addresses.

\t, \r, and \n are the special characters that occur most often in regular expressions for mailbox rules.

Example: \t, \r, and \n Use

```
[ \t]request[ \t]
```

The filter string performs a keyword search for 'request'. The brackets match any one character from the set, including the space, so [\t] matches a space or a tab.

```
[\r\n]+critical[ \t\r\n]
```

The filter string performs a keyword search for 'critical'. This string searches at the start of a line, the start of the message, or the entire line. The brackets match any one character from the set. The + (plus sign) matches one or more of the previous, so [\r\n]+ matches one or more carriage returns and newlines.

Sample Text for Notification Phrases in a Mailbox Rule

This example shows sample text that you can use to include notification phrases in a mailbox rule. Define separate versions of a notification phrase for plain text and for HTML when the phrase contains any line breaks or other formatting.

Use the following text in Success Text, Success HTML, or both fields on the Update Mailbox Rule page, Reply Success tab:

Success Text

```
Thank you for submitting your request.
@{notification_phrase[IncidentURL1].phrase}
```

Success HTML

```
Thank you for submitting your request.</p>
```

```
@{notification_phrase[IncidentURL1H].phrase}</p>
```

Artifacts Use Considerations

An email *artifact* refers to something that arises from the mail process, for example, an email address that is included in a forwarded email. The Text API uses artifacts that contain a ticket ID (such as a reference number) for reply support. When the ticket ID is found, an existing Text API keyword (such as %INCIDENT_ID) is set and added to the input for the Text API. The Mail Eater identifies that a reply is associated with a particular ticket by finding the artifact in the message.

The Mailbox rules let you specify the artifact and the value that the Text API uses. For example, you can define a rule for incidents as Incident:{{object_id}}%. When a rule finds Incident:1234, the Text API uses %INCIDENT_ID=1234 (1234 is the ref_num for the Incident). Because the artifact must be unique in an email and easy to find, you can make the artifact more distinctive such as %Incident: {{object_id}}%. A percentage sign (%), whitespace, or some other character that cannot appear in an artifact value must follow {{object_id}}. Uppercase and lowercase letters, numbers, forward slashes, commas, and plus symbols are potentially part of a value. The secure artifacts are Base64-encoded after encryption. If you do not use the Secure artifacts, the characters that follow the artifact must not be contained in the ticket ID suffix, if any, which has been configured for that type of ticket.

When using the filter string of the mailbox rules to identify the ticket ID Artifact, the keyword {{object_id}} represents the position in the filter string where the ticket ID artifact is expected. This keyword is case-sensitive, even if the mailbox rule is not.

Example: Email Artifact Use

The following example shows an ARTIFACT format for use in a mailbox rule for a change request ticket.

Usage: %REQUEST=@{call_req_id.ref_num}%

Example: %REQUEST=1234%

When you construct the filter string of the mailbox rule, consider the following conditions:

- A clear boundary must exist between the ticket ID artifact and the keywords which precede and follow it. We strongly recommended that you include whitespace text in this boundary text.
- Do not end the portion of the filter string that precedes the {{object_id}} keyword in a repeatable or optional pattern that can match the beginning of the ticket ID Artifact, and do not end a pattern whose length is ambiguous. For example, the filter string must not contain the request (er|ed|ing)?{{object_id}}, because this construction causes an ambiguity whether a trailing er, ed, or ing is the end of the leading text or part of the prefix of an unprotected ticket ID.
- The portion of the filter string that follows the {{object_id}} keyword must not begin in a repeatable or optional pattern that may match the end of the ticket ID artifact, must not begin with a pattern whose length is ambiguous, and must contain at least one element of whitespace. For example:
  - The filter string must not contain {{object_id}}[A-Z]?, because the [A-Z]? may match the last character of the ticket ID artifact.

- The filter string must not end with {{object_id}}Item, because it is possible for Item to appear in the ticket ID artifact, either as the suffix of a ticket ID in a plain-text or protected artifact, or as characters within a secure artifact.

- {{object_id}} Item is acceptable, because the space cannot be part of a ticket ID artifact, and is not part of a protected or plain ticket ID artifact. However, {{object_id}}[\t\r\n]+Item (open-bracket, space, backslash, t, backslash, r, backslash, n, close-bracket, plus sign, +Item) is better, because the [\t\r\n]+ compensates for the mail program inserting a line break after the {{object_id}}.

- When you construct the filter strings for different mailbox rules, avoid using a filter string that completely includes another mailbox rule filter string, or in which the portion before or after a {{object_id}} keyword completely includes that portion of another mailbox rule filter string. Depending on the order in which these filters are checked, a message match intended for one filter can match with another, with a portion of the ticket ID artifact matching the additional text that distinguishes between the two filter strings.

Example: How to Create a Mailbox Rule That Matches Every Inbound Message

You can create a mailbox rule that matches every inbound message that another mailbox rule does not filter.

To create this type of rule, set the filter as Subject Contains and the filter string as a period and an asterisk (".*").

A period matches any character except the line break.

An asterisk matches zero or more occurrences of the symbol immediately before it.

As a result, this combination matches zero or more characters that are not line breaks.

Example: A "Catch-All" Mailbox Rule

This example demonstrates how you can use a ".*" combination to match every inbound message:

```
Filter = "Subject contains"
Filter String = ".*"
```

Example: How to Use the Mailbox Rules TextAPI Defaults and TextAPI Ignore Incoming Settings

The TextAPI Defaults and TextAPI Ignore Incoming fields let you specify default values for incoming mailbox rules, and specify TextAPI commands that should not be accepted in incoming emails. These fields work with the default values that are set in the [EMAIL_DEFAULTS] section and with the forbidden-commands list in the [EMAIL_IGNORE_INCOMING] section of the text_api.cfg file. When a conflict occurs between the definition in a mailbox rule and the definition in the text_api.cfg file, the value set in the mailbox rule applies.

The TextAPI Defaults field includes TextAPI keyword commands that are applied to a ticket when it is created from an email that matches a mailbox rule. The commands are not applied when the message affects an existing ticket.

Follow these steps:

1. Place each command on a separate line in the TextAPI Defaults field.
2. Format the commands as follows:

   ```
   OBJECT.FIELD=value
   ```

   > **Note:** Do not include a leading percentage symbol (%), used only for corresponding comma embedded in the body of the email.

   For example, format the commands as follows:

   ```
   REQUEST.PRIORITY=3
   PROBLEM.CATEGORY=Facilities
   INCIDENT.GROUP=Plumbing
   ```

The TextAPI Ignore Incoming field lists TextAPI keyword commands that are not permitted to be used in the text of the incoming email message. Any commands that are listed in this field are ignored when they are found in an incoming email message.

To specify TextAPI Ignore Incoming commands, follow these steps:

1. Place each command on a separate line in the TextAPI Ignore Incoming field.
2. Format the commands as follows:

   ```
   OBJECT.FIELD
   ```

   > **Note:** Do not include a leading percentage symbol (%), used only for the corresponding commands embedded in the body of the email.

   For example, format the commands as follows:

   ```
   CHANGE.ASSIGNEE
   PROBLEM.GROUP
   REQUEST.EFFORT
   ```

3. Define all commands used in either field in the [KEYWORDS] section of the text_api.cfg file. This file is located in the “site” subdirectory of the CA SDM installation directory.

Mailbox Policy Fields

Email Address/Hour
Specifies the maximum number of emails per email address per hour. You can specify the following values:

- -1 -- No limit (default)

- 0 -- No emails allowed.
- 1 – Maximum number of emails allowed.

Log Violation
Logs the violation to the standard log. You can specify the following values:

- Do not log
- First violation only (default)
- All violations

Note: The First violation only option keeps a list of email addresses associated with messages that violate mailbox policies and uses the list for the log to avoid duplicate log entries. The list is cleared when the Mail Eater daemon is restarted. However, if you change the setting from First violation only to one of the other options and back, the list of email addresses which were logged under this setting is not cleared. If a mailbox logs numerous violations while using this setting, we recommend that you restart the Mail Eater daemon periodically to clear the list, or use the Do not log option.

Inclusion List
Specifies email addresses or domains that are allowed to process emails -- only emails matching the list are allowed. You can specify multiple addresses or domains by delimiting them with a comma, semicolon, space character, or line break. An entry of an asterisk ('*') by itself is the "World Domain," and matches all domains that are not in the Exclusion List.

Exclusion List

Specifies email addresses or domains that are not allowed to process emails. You can specify multiple addresses or domains by delimiting them with a comma, semicolon, space, or line break.

Note: Addresses in the Exclusion List override any values in the Inclusion List. Addresses in the Inclusion List override domains in the Exclusion List, and can provide specific exemptions for specific senders in an otherwise-banned domain. Domains in the Exclusion List override the World Domain in the Inclusion List. The World Domain is not valid in the Exclusion List.

Multiple Mailboxes

CA SDM can process and manage multiple mailboxes. Each mailbox can have its own definition, instead of using a single global set of definitions. You can define multiple mailboxes and use different templates or default values for each mailbox. Multiple definitions let individual tenants use separate mailboxes, or let an individual tenant or organization use different mailboxes, and have different behaviors for each mailbox. You can set up multiple mailboxes by using the Administration interface. Each mailbox uses the following tables:

- usp_mailbox -- Defines the mailbox.
- usp_mailbox_rule -- Specifies a set of rules for each mailbox.
  Because mailbox rules supply Text API defaults, you can establish email interfaces with other software and parameters (such as category, assignee, and so on) that are configured specifically for the interface.

Note: IMAP servers support multiple mailboxes for a single account, but alternate mailboxes are not supported; only the default inbox is supported.

How Multiple Mailboxes Use Rules

The Mail Eater (pdm_maileater_nxd) component on the primary server uses mailbox connections and rules to read and process messages from one or more accounts on one or more mail servers. The Mail Eater processes mailboxes serially (only one mailbox is processed at a time), and processes rules in sequence number order.

Multiple mailboxes use rules as follows:

1. Upon primary server startup, the Mail Eater reads the following tables:
   - **usp_mailbox**
     Represents a connection to a mail server.
   - **usp_mailbox_rules**
     Represents the rules that apply to the connection (usp_mailbox).
   - **Contact_Method**
     Represents the Contact Methods used for automatic replies.
   - **Document_Repository**
     Represents the Document Repositories for storing attachments.

   The Mail Eater automatically detects changes to the objects in any of these tables, including the addition of additional objects. If a change is made to usp_mailbox or usp_mailbox_rule, the polling interval for the affected mailbox is rescheduled to one second after the change is applied.
2. At the interval defined by each mailbox, the Mail Eater retrieves each email in the inbox for the associated account, and processes the email as:
   a. Checks the email address for policy violations. When the Mail Eater finds a violation, processing stops, and the standard log is affected according to the mailbox definition.
   b. Compares the email to each rule (mailbox_rule) that belongs to that mailbox.

c. If a matching rule is found, the Mail Eater submits the message to the Text API for posting, and replies to the user as appropriate based on the specified action for the rule.
For reply emails, the filter string identifies the object and uses the Text API for processing. After processing is complete, the response goes either to the Reply to or the From address.

d. When a matching rule is located, no other rules are checked, and the Mail Eater processes the next email in the inbox.

e. If no matching rule is found, the message is discarded.

3. After the Mail Eater processes all emails for an inbox, the processed and discarded messages are purged from the mail server, and the next processing interval is scheduled.

How to Configure the Email Replies

This article contains the following topics:

The email notifications that you use in mailboxes are specific to the replies that are sent to a contact in response to their emails. For example, you can configure email so that when a contact clicks a reply link in an email notification, the reply email is directed to a mailbox.

Note: This setup differs from the regular email notifications.

Follow these steps:

1. Open the CA SDM Web UI (see page).
2. Verify that you have configured the mailbox for inbound email (see page 1256).
3. Configure the mail server (see page 1277).
4. (Optional) Specify a notification email address in the contact definition.

Note: Select Security and Role Management, Contacts on the Administration tab and select the contact to edit.

5. Modify the email notification method (see page 1278).

Open CA SDM Web UI

Log in to the web UI from the following servers, depending on your CA SDM configuration:

- Conventional: Primary or secondary servers
- Advanced availability: Application or background servers

Configure the Mail Server

Notifications for an event (automatic and manual notify) are sent using a single mail server definition.

Follow these steps:

1. Select Options Manager, Email from the Administration tab.
   The Option List page opens.
2. Click the email option (see page 1277) that you want to install.
   The Options Detail page opens.
3. Click Edit, complete the fields as appropriate, and click Install.
   The mail server is configured to send notifications (outbound mail).
4. Repeat the procedure until all relevant Option List options are configured.

Email Options

The email interface sends email notifications and lets users create tickets from an email.

Option	Description
mail_from_address	Specifies the mail notification From: address. The address is in the format Displayname<user@company.com (http://company.com/)>.
mail_login_password	Specifies the SMTP server login password.
mail_login_userid	Specifies the SMTP server login userid.
mail_max_threads	Specifies the maximum number of concurrent SMTP connections that can attempt to communicate with the server.
mail_reply_to_address	Defines the reply to address for email notifications. This option is useful if emails are sent from one user account, but you want replies sent to another email address. The default value is the same as the from address.
	Defines the domain name of the SMTP server. You can clear the domain name by setting the value to NONE.

Option	Description
mail_smtp_domain_name	
mail_smtp_hosts	Specifies a space-separated list of SMTP server host names for email notifications.
mail_smtp_host_port	Specifies an SMTP port to override the default SMTP port.
mail_smtp_security_level	Specifies the SMTP security level. Valid settings are: 0=no security, 1=basic authentication, 2=NTLM, 3=MD5 and 4=LOGIN. If you set this option to 1, set the mail_login_password and mail_login_userid options. Most SMTP servers do not require authentication.
mail_smtp_use_tls	Specifies the Transport Layer Security (TLS) usage in the email. The valid settings are Yes= Use TLS, No=Do not use TLS.
mail_ca_cert_path	Specifies the path where the trusted certificate has been deployed. **Note**: For the advanced availability configuration, you must deploy the trusted certificate on the same location in all the CA SDM servers. CA SDM supports only Base-64 encoded (PEM) format for CA Certificates.
mail_show_to_cc_list	Shows all the recipients of the email notification. For manual email notification, both “To” and “Cc” list recipients are displayed and for automatic email notification, only “To” list recipients are displayed. By default, this option is installed. **Note:** Pager email notification method does not support the listing of all recipients in To or CC list.

Modify the Email Notification Method

Modify the email notification method to configure the email replies.

Follow these steps:

1. Select Notifications, Notification Methods, Email on the Administration tab and click Edit.
2. On the Email Update Notification Method page, select the Supports SMTP checkbox to enable SMTP.
3. Enter pdm_mail [- F from_email_address] [- T reply_to_email_address] as the Notification Method.

- **from_email_address**
  Specifies the address that is used as the From address of the message. This address overrides the sender address in the outbound mail server configuration.

- **reply_to_email_address**
  Specifies the address to which replies are sent. This address overrides the reply-to address in the outbound mail server configuration.
  When a reply-to address is set in the outbound mail server configuration and no reply-to address is specified in the Notification Method, the reply-to address in the outbound mail server configuration is used with that Notification Method.

Note: If the keyword "$(REPLY_FROM)" is specified as either address, that address is constructed from the username and mail server hostname for the mailbox. This keyword is only valid when a mailbox rule uses the Notification Method; Notification Methods that use it must not be used for any other purpose. For example, user name=dev, server name=mail32.ca.com, $(REPLY_FROM) =dev@mail32.ca.com. Only use this keyword if your mail server is configured to accept the mail server name as equivalent to the email domain name. Use this keyword with caution: If the hostname is not fully domain-extended in the mailbox configuration (for example, mailserver1 instead of mailserver1.customer7.com), it is not extended automatically by the field interpreter.

Note: The from_email_address and reply_to_email_address are the addresses that appear in the From and Reply-To headers of the message when the user reads it. If the addresses are identical, you can specify only the from_address.

4. Click Save.
   The email notification method is modified. When the contact replies to the email notification, the reply is addressed by default to the specified mailbox.

Alternate Sender Address Identification

You can use a -m parameter in the subject of the message so that CA SDM identifies the sender of the message using a different email address from the one that originally sent it. The -m keyword, followed by a space and by the email address that CA SDM recognizes, must be the last elements of the subject line. Consider the following information when you use the -m parameter in the subject:

- Both the actual From address and the alternate address that is specified with -m are verified in the Inclusion and Exclusion lists.

- The email address that is specified as the alternate address must contain only the address, and not the accompanying display name.

- If more than one word follows the -m parameter in the subject line, the alternate address is not recognized.

Mailbox Polling

If an error occurs on the outgoing mail server, email notifications are not sent and queue in the %NX_ROOT%\site\mail_queue directory. When the mail server becomes active again, after an interval it processes and sends email. You can change the interval to recycle the email that was queued when the mail server was busy.

Notification email messages that the outgoing mail server fails to send are resubmitted until you do one of the following:

- Stop the Mail Daemon (pdm_mail_nxd) that handles outbound email notifications.
- Manually delete the messages from the %NX_ROOT%\site\mail_queue directory.

Set the Email Retry Interval Variable

You can define the time interval (in seconds) to retry failed attempts to send outgoing email to the mail server.

Note: CA SDM does not retry sending messages that the outgoing mail server accepts, but cannot be delivered. For these messages, the outgoing mail server retry capabilities and policies, if any, are in effect.

Retries are on a per-message basis. If the mail server is unavailable for a period, each message is retried when its own timer expires, rather than all the messages being sent at once. However, if you restart the outgoing mail daemon, all unsent messages attempt to be sent at that time, and if they all fail to be sent, their retry timers are all reset at the same time.

The setting (NX_EMAIL_RETRY_INTERVAL) in the NX.env file controls the retry interval. You can change the default retry interval setting on one or more servers.

Follow these steps:

1. Log in to the following server, depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server.
2. Navigate to the $NX_ROOT directory
3. Use a text editor such as WordPad to open the NX.env file.
4. Modify the value of to the NX_EMAIL_RETRY_INTERVAL interval you want as follows:

   ```
   NX_EMAIL_RETRY_INTERVAL=number_of_seconds
   ```

   - **NX_EMAIL_RETRY_INTERVAL**
     Defines the time interval (in seconds) to retry failed email attempts.

- ***number_of_seconds***
  Specifies the number of seconds for each email retry interval. The default time is 600 seconds (10 minutes). The minimum value that you can use is 20 seconds. If you set a value that is less than the minimum of 20 seconds or more than 2000000 seconds, the default value of 10 minutes is used.

5. Save and close the file.

6. Restart the CA SDM servers (see page 913).
   The change takes effect.

How to Set Up the Data Partition

Data partitions can be assigned to individual contacts, but the preferred method is to assign data partitions based on access type. After associating data partitions with different access types, you can associate a contact to a particular access type, and define its data partition. The access type has a specific option to override the contact data partition.

To associate a data partition to an access type, you set up data partitions that are meaningful to your site and then select one of the data partitions when you define or modify an access type.

Important! Other CA SDM security settings can take precedence over data partition.

The data partition is a subset of CA SDM database that controls a user access to tickets and other data records based on their content.

For example, you can restrict a user view of the database to only those configuration items that are assigned to the user organization. You can also restrict a user to update only assigned tickets and allow read-only access to other configuration items.

A data partition consists of a set of constraints. The data partition constraints identify the table that is being controlled by the data partition and the constraint type. The constraint typesspecify what the user can do, such as create, delete, update, view, and so forth, within the data partition. After you assign a data partition to an access type, which you in turn assign to a user contact record, the constraints and constraint types are what control the user access to the records in the CA SDM database table.

You can also view constraints independent of the data partition using them. For example, you want to view all constraints for a specific table, regardless of the data partition.

Follow these steps:

1. Verify the prerequisites (see page)
2. Create a data partition (see page 1293)
3. Create an access type (see page 1285)

4. Configure Knowledge Management Data Partition Constraints for Role-Based Permissions (see page 1284)

Verify the Prerequisites

Before you set up the data partition, verify the following prerequisites:

- Data Security Structure and Policy (see page 1282)
- Data Partitions Setup (see page 1282)
- Constraint Specifications (see page 1283)

Data Security Structure and Policy

Planning data security involves enforcing restrictions to access the specific portion of the database. These restrictions can be enforced on individual contacts either through roles or access types:

- **Roles**
  Defines the functionality that users in the role are allowed to access. You can assign one or more roles to an individual contact record, or to an access type to define the functional access for all of the access types who are associated with contacts.

- **Access Type**
  Defines how contacts are authenticated when they log in to the web interface. For example, an access type decides whether the contacts can modify web forms or the database schema using Web Screen Painter and which roles are available for the contacts.

As a service desk administrator, you can modify the predefined access types and also create new ones. You can enforce the restriction to the individual users or a group of users through Roles.

Identify the following:

- The objects and the type of restrictions you want to enforce on these objects.
- The Users or Roles on whom the Data Partition are applied. Data Partitions can be applied to contacts directly, but the preferred method is to assign data partitions based on the role and assign this role to all the contacts directly or through the access type.

Data Partitions Setup Specifications

You can define an unlimited number of data partitions. Each data partition consists of a set of constraints and validations on each database table that is restricted by the data partition. For each table in a data partition, you can specify independent authorizations to view, update, create, or delete records using criteria that are specified in a format similar to an SQL WHERE clause. You can base the restriction on any attribute in the record being accessed, combined with any data in the user contact record. This allows considerable flexibility when defining data partitions. For example, using the Vendor field in the Contact table allows data partition restrictions to be placed on vendors that are permitted to access CA SDM directly.

For performance reasons, CA SDM does not allow a data partition constraint to contain a Cartesian join. A Cartesian join results from a constraint containing an “OR” that does fully restrict all joined tables on both sides of the OR. To ensure that your data partition constraint does not produce a Cartesian product join, enter the following command:

- **Windows**

```
bop_cmd -f $NX_ROOT\bopcfg\interp\bop_diag.frg "check_queries()"
```

- **UNIX**

```
bop_cmd -f $NX_ROOT/bopcfg/interp/bop_diag.frg "check_queries()"
```

Important! Any data partitions that are flagged by this program must be updated appropriately.

Constraint Specifications

You specify constraints and validation tests in Majic using the object definition metalanguage.

Constraints that are defined in Majic closely resemble an SQL WHERE clause, with the following exceptions:

- Attribute names in the constraint are object attribute names, not the database attribute name from the schema.
- You can refer to the value of an attribute in the contact record for the logged-in user with a name of the following form, where *att_name* is the Majic name of the desired attribute:

  ```
  @root.att_name
  ```

  For example, specifying @root.location refers to the location ID of the current contact.
  You specify joins with a specification of the following form, where the *foreign-key* is the Majic name of the SREL attribute in the table for which you are writing the data partition constraint, and *attribute-in-referenced-table* is the Majic name of the attribute in the table being joined:

  ```
  foreign-key.attribute-in-referenced-table
  ```

  For example, to refer to the maintenance vendor of the asset that is associated with an incident report, specify the following:

  ```
  resource.vendor_repair
  ```

  This specification is recursive. For example, you could refer to the name of the vendor with the following name:

  ```
  resource.vendor_repair.name
  ```

The following table contains examples of valid constraints to use for the Change_Request table, used to store change order information:

Constraint Type	Code and Description
View	assignee.organization = @root.organization Specifies the user can only view change orders where the assignee's organization is the same as the user's organization.
Pre-Update	requestor = @root.id Specifies the user can only update the change orders where he is the caller or requester.

However, you cannot write a constraint that uses joins on both sides of the expression, as shown in the following example:

```
assignee.org = requestor.org
```

Configure Knowledge Management Data Partition Constraints for Role-Based Permissions

Knowledge Management data partitions are enabled to let you use group and role permissions by default in CA SDM. If you are upgrading from a previous release, the migration tool updates your data partition constraints.

If you used custom data partition constraints to manage knowledge permissions in a previous release, update the constraints manually for the O_INDEXES and SKELETONS tables. You can view the default data partition constraints and apply the changes, as appropriate to your environment.

Follow these steps:

1. Select Security and Role Management, Data Partitions, Data Partition Constraints on the Administration tab.
   The Data Partition Constraints List page opens.

2. Click Show Filter and search use the following search criteria:

   - **Service Desk Analyst** in the Data Partition search.
   - **O_INDEXES** in the Table search.

3. Edit the View constraint type by modifying the Constraint tab to replace "READ_PGROUP in @root.pgroups" as follows:

   ```
   READ_PGROUP in @root.pgroups OR
   READ_PGROUP.[pgroup]contained_roles.role IN @root.id
   ```

4. Save the constraint.

5. Edit the Delete and Pre-Update constraint types by modifying the Constraint tab to replace "WRITE_PGROUP in @root.pgroups"as follows:

```
WRITE_PGROUP in @root.pgroups OR WRITE_PGROUP.[pgroup]contained_roles.role IN
@root.role
```

6. Save the constraints.

7. Repeat the steps to update the View, Delete, and Pre-Update constraints in the SKELETONS table in your data partition.
   The data partition constraints are updated.

Create an Access Type

Access types define how contacts are authenticated when they log in to the web interface, whether the contacts can modify web forms or the database schema using Web Screen Painter, and which roles are available for the contacts.

You can modify the predefined access types and create new ones.

The access types define all aspects of security. Several predefined access types are included, and you can modify them or can define new ones. Each access type for a user controls the following aspects of system behavior:

- How CA SDM performs the web authentication when the user logs in.
- The access level for the user.
- Whether the user can modify web forms or the database schema using Web Screen Painter.
- What are the roles available to the user.

Follow these steps:

1. Select Security and Role Management, Access Types on the Administration tab.
   The Access Type List page opens.
   Default: 15

2. Click Create New and complete the access type fields (see page), as appropriate, on the Create New Access Type page.

3. Use the tabs to complete the following tasks:

   - Configure Web Authentication for an Access Type (see page)
   - Assign Web Screen Painter Permissions to an Access Type (see page)
   - Assign Roles to an Access Type (see page)

4. Click Save.
   The access type is created.

Access Type Fields

The following fields appear on the Create Access Type, Access Type Detail, and Update Access Type pages.

- **Symbol**
  Specifies a unique identifier for the access type.
- **Default?**
  Indicates whether this access type is the default that is associated with contacts.
- **Record Status**
  Specifies whether this access type is Active or Inactive.
- **Description**
  Describes the access type. Use this field to help identify the characteristics of the access type.
- **Receive Internal Notification**
  Determines whether the contacts associated with the access type receive internal notification of activities that are related to tickets.
- **Access Level**
  Determines which access types a user can grant to another user. A user can assign an access type to the contact record of another user only if the access level of the access type they are attempting to assign is ranked the same as or lower than the grant level for their own access type. The levels are ranked as follows:
  - Admin (highest)
  - Analyst
  - Cust/Emp
  - None (lowest)
- **Licensed?**
  Determines whether this contact is a licensed access type. Contacts assigned to unlicensed access types can only view or update their own personal data.

Note: KPIs count the concurrent usages of the users from the system (for example, CA SDM Web UI, SOAP Web Services, REST Web Services, and so on). For example, the webConcurrentLicenseCt KPI counts the maximum number of unique users (with the "Licensed?" option selected) logged in to the CA SDM Web UI during the interval.The following fields appear on the Create Access Type, Access Type Detail, and Update Access Type pages.

Configure Web Authentication for an Access Type

You can configure the web authentication and validation type to specify how roles assigned to this access type are authenticated when users attempt to access the CA products. Complete the following fields in the **Web Authentication** tab.

- **Allow External Authentication**
  Select this check box if you want to allow contacts to be authenticated externally, for example by the HTTPD server or the operating system. If you select this option, users with this access type are validated by the appropriate external method as configured during installation. Checks ensure that no external validation has taken place (for example, that the user has not attempted access through a non-secure server) and that the user is defined as a valid contact in the system using the login ID. Then, it uses the access type to determine the correct interface to use.

- **Validation Type**
  Defines how users are authenticated when an external authorization is either not permitted or fails (for example, if the user is attempting access through a non-secure server). The available options are:

  - **No Access**
    Denies access to CA products unless external authentication is allowed and is valid.

  - **Open**
    Access to the CA products are always allowed, with no additional authentication required.

  - **OS**
    Access to the CA products are allowed through operating system user name and password.

  - **PIN / PIN Number**
    Users of this type can access only if they enter the correct value for the PIN field in their contact record. If you select the PIN option, you can choose which field in the contact record stores the PIN by entering the field attribute name in the PIN Field edit box.

  - **CA EEM**
    Access to the CA products are allowed through CA EEM. This option is available only if CA SDM is integrated with EEM.

Assign Web Screen Painter Permissions to an Access Type

The Web Screen Painter (WSP) utility allows CA SDM users to build and publish web forms and schemas. The Web Screen Painter tab also controls the database access for Web Screen Painter preview sessions. For the details about WSP, see Using the Web Screen Painter (WSP) (see page 1898).

Select the permissions that you want to allow for an access type in the Web Screen Painter tab.

- **Modify Forms**
  Allows the users to do the changes to existing forms without doing the changes available to all users.

- **Modify Schema**
  Allows the users to do the changes to an existing schema without doing the changes available to all users.

- **Publish Forms**
  Allows the users to make their modified forms available to all users.

- **Publish Schema**
  Allows the users to make their modified schema available to all users.

- **Preview Session Can Update Database**
  Allows the users to do the changes to the database during a preview session. By default, database changes are not allowed during a preview session.

Assign Roles to an Access Type

Assign the roles to an access type to limit contacts access to functional areas for assigned roles.

Follow these steps:

1. Select the following roles for this access type:

   - **Reporting Role**
     Defines the reporting access for this type.

   - **REST Web Service API Role**
     Defines the access to the REST web services for this type.

   - **SOAP Web Service API Role**
     Defines the access to the SOAP web services for this type.

   - **Command Line Utility Role**
     Defines the access to the command-line utilities for this type.

2. Click Update Roles.
   The Role Search page opens.

3. Enter any search criteria that you want to limit the list to the roles of interest, and then click Search.
   The Roles Assigned - Update page opens, listing the roles that matched the search criteria.

4. Select the roles that you want to assign. To select multiple items, hold down the CTRL key while clicking the left mouse button.

5. Click the double right-directional arrows, after you have selected all the roles that you want.
   The selected roles move to the Roles Assigned list on the right.

6. Click OK.
   The Access Type Detail page opens, with the assigned roles listed on the Roles tab.

7. Click Save.
   The Access Type Detail page opens, with a confirmation message that your changes have been saved.

8. Select the role that you want to be the default for this access type upon login. Click Set Default Role.
   Your selection for the default role is saved.

- **Symbol**
  Specifies a unique identifier for the access type.

- **Default?**
  Indicates whether this access type is the default that is associated with contacts.

- **Record Status**
  Specifies whether this access type is Active or Inactive.

- **Description**
  Describes the access type. Use this field to help identify the characteristics of the access type.

- **Receive Internal Notification**
  Determines whether the contacts associated with the access type receive internal notification of activities that are related to tickets.

- **Access Level**
  Determines which access types a user can grant to another user. A user can assign an access type to the contact record of another user only if the access level of the access type they are attempting to assign is ranked the same as or lower than the grant level for their own access type. The levels are ranked as follows:

  - Admin (highest)
  - Analyst
  - Cust/Emp
  - None (lowest)

- **Licensed?**
  Determines whether this contact is a licensed access type. Contacts assigned to unlicensed access types can only view or update their own personal data.

  Note: KPIs count the concurrent usages of the users from the system (for example, CA SDM Web UI, SOAP Web Services, REST Web Services, and so on). For example, the webConcurrentLicenseCt KPI counts the maximum number of unique users (with the "Licensed?" option selected) logged in to the CA SDM Web UI during the interval.

Data Partitions

Contents

Data partitions are subsets of the database with restricted access to data records. Restrict access by defining a set of constraints for each data partition. Assign these data partitions to access types. The data partition assignment determines the records that the contact can access.

Create a Data Partition Constraint

Data partition constraints restrict the database record access for users that are assigned to the data partition.

Follow these steps:

1. Select Security and Role Management, Data Partitions, Data Partition Constraints on the Administration tab.
   The Data Partition Constraints List page opens.

2. Click Create New.
   The Create New Data Partition Constraint page opens.

3. Complete the data partition constraint fields (see page), as appropriate.

4. Complete the information in the tabs, as appropriate:

   - **Constraint**
     Specifies the criteria that controls the records in the table and can be viewed, created, updated, or deleted by a user that is assigned to the data partition. For example, you can specify that users can only update issues that are assigned to them. When a user in the data partition requests a record that does not match the condition then the record is read-only.
     Limit: 4000 bytes

   - **SQL Translation**
     Displays the constraint definition in SQL format. The condition that you entered on the Constraint tab is validated, and the underlying SQL WHERE clause is built. This translation is displayed on the SQL Translation tab for the verification.

5. Click Save.
   The constraint is saved and added to the data partition.

Example: Create a Data Partition Constraint for CAB Assignments

You can create a data partition constraint that lets users update only change orders that are assigned to a CAB to which the logged in user belongs.

To create a data partition constraint for CAB change order user assignments, assign the following constraint values for a Change_Request controlled table in a data partition:

- Constraint type: Pre-Update

- Constraint specification: cab.[group]group_list.member IN (@root.id (http://root.id))

The logged in user can only update change orders that are assigned to a CAB to which the user belongs.

Constraint Definition

Specify the condition in Majic format (the metalanguage used to define CA SDM objects).

If the Constraint Type is View, the condition can include joins to other tables and references in the form @root.att_name to Majic attributes in the contact record for the logged-in user. Otherwise, it cannot include joins to other tables, but it can include references in the form @root.att_name to Majic attributes in the contact record for the logged-in user.

If the Constraint Type is Defaults, you may specify one or more assignment statements, separated by semicolons, which specify values to be assigned to empty fields in a new record at the time the record is stored. The syntax of each assignment statement is:

```
att_name=value
```

where att_name is the name of a Majic attribute from the record, and value can be an integer, a string enclosed in quotes, or a reference in the form @root.att_name to a Majic attribute in the contact record for the logged-in user. The way CA SDM uses default values depends on the table they affect.

For tables updated by CA SDM, such as Issues, default values are placed into the record at the time it is displayed, and are shown on the initial display of a new record. A default value can be assigned to a reference field (a Majic SREL) by coding it in the form of a persistent ID (a table name followed by a colon and an integer ID). For example, you might set a default value for category by including the following in the Defaults specification:

```
category='PCAT:12345'
```

where 'PCAT' is the target of the SREL, as shown in the Majic file, and 12345 is the ID number of the desired category. You can list persistent IDs for a table with a command of the form:

```
bop_odump domsrvr pcat "" sym
```

Data Partition Constraints Fields

Complete the following fields to add or modify the data partition constraint fields:

- **Data Partition Name**
  Specifies the name of the data partition for which the constraint being defined.

- **Table Name**
  Specifies the database table that is controlled by the constraint.

- **Constraint Type**
  The type of constraint being defined. There are six constraint types for each table in a data partition.

  - **Create**

  Specifies the criteria that must be met before creating a record. When a user in the data partition attempts to create a record that does not match the create test condition, CA SDM displays the error message that is associated with the constraint and does not save the record.

  - **Defaults**

Specifies one or more assignment statements, separated by semicolons, defining values to be assigned to empty fields in a new record at the time the record is stored. The syntax of each assignment statement is, where *att_name* is the name of a Majic attribute from the record, and *value* can be an integer, a string that is enclosed in quotes, or a reference in the form @root.*att_name* to a Majic attribute in the contact record for the current user:

```
att_name=value
```

For tables updated for tickets, default values are placed into the record at the time it is displayed and are shown on the initial display of a new record. You can assign a default value to a reference field (a Majic SREL) by coding it in the form of a persistent ID. A persistent ID is an object name followed by a colon and an integer ID. For example, you can set a default value for category by including the following in the defaults specification, where PCAT is the target of the SREL (as shown in the Majic file) and 12345 is the ID number of the desired category:

```
category='PCAT:12345'
```

You can list persistent IDs for an object using a command of the form:

```
bop_odump domsrvr pcat "" sym
```

- **Delete**

Specifies the criteria that must be met to delete a record. When a user in the data partition attempts to delete a record that does not match the delete condition, CA SDM displays the error message that is associated with the constraint and does not delete the record.

- **Pre-Update**

Specifies the records in the controlled table that a user can update in the data partition. When a user in the data partition requests a record that does not match the pre-update condition, CA SDM makes the record read-only and displays the error message that is defined with the constraint.

- **Update**

Specifies the criteria that must be met when a record is saved. When a user in the data partition attempts to save a record that does not match the update condition, CA SDM displays the error message that is associated with the constraint and does not save the record.

- **View**

Specifies the records in the controlled table that a user can view in the data partition. This constraint is automatically applied to all lists selected by a user in this data partition, in addition to any selection criteria explicitly specified by the user.
View can include joins to other tables and references in the form @root.*att_name* to Majic attributes in the contact record for the current or logged-in user. The valid examples are:

```
requestor.organization = @root.organization
```

```
requestor.organization.name = 'MIS'
```

```
assignee = @root.id

assignee.organization = @root.organization
```

Note: The Create, Delete, Pre-Update, and Update constraint types now support joins to other tables. They can also include references in the form @root.attribute to attributes in the contact record for the current user.

- **Record Status**
  Indicates whether the constraint is active or inactive.

- **Error Message**
  Specifies the message returned to the user, if the constraint criteria is not met. For example, "You can only update issues assigned to you" or, "You can only create issues for your organization" or, "You can update your contact record but cannot change the data partition."

Create a Data Partition

A data partition is a subset of a CA SDM database. Data partition controls a user access to tickets and other data records based on their content.

Follow these steps:

1. Select Security and Role Management, Data Partitions, Data Partitions List on the Administration tab.
2. Click Create New.
3. Complete the fields as appropriate:
   - **Data Partition**
     A unique identifier for the data partition.
   - **Record Status**
     Record status whether the partition is active or inactive.
4. Click Save.
5. Click New Constraint and attach constraint definitions to the partition.
6. Click Save.
   The data partition is saved with the data partition constraint.

How to Configure Notifications

This article contains the following topics:

With CA Service Desk Manager, you can automatically notify key personnel about ticket activities (researching, escalating) and events (opening a ticket, for example). You can also notify key personnel about Knowledge Report Card (KRC) and Support Automation Assistance Sessions. When a significant activity or event occurs, CA Service Desk Manager creates a notification message that does the following:

- Identifies the ticket activity or the notification event
- References the ticket
- Includes other optional information
- Can identify potential contacts

You can view a notification message for a ticket because of a system action. A system action includes opening, closing, or modifying a ticket through its history information.

Setting up automatic notifications involves the following tasks:

- Defining activity notifications that determine the types of activities that generate notifications.
- Defining object contact notifications that determine the object contacts that can be used to send notifications in an activity notification.
- Identifying the methods used to send messages.

How to Create Object Contact Notifications

Object contact notifications let you notify the recipients based on the current value of a field on the ticket. Instead of identifying a person to notify, as in a notification method, you identify an object. For example, you can identify the To field to ensure that notification goes to the person currently identified in the To field, even if the value has changed since the ticket was defined.

Follow these steps:

1. Select Notifications, Object Contact Notifications on the Administration tab.
   The Object Contact Notification List page opens.

2. Click Create New.
   The Create New Object Contact Notification page opens.

3. Complete the following fields:

   - **Symbol**
     Defines a unique identifier for the object contact notification.

   - **Status**
     Specifies if the object contact notification is active or inactive.

   - **Object Type**
     Displays the name of the object to which the attribute applies.

   - **Object Attribute Name**
     Provides the name of the object contact notification (in the Symbol field) in Majic, which is internal CA code. The attribute name depends on the Object Type selection:

     - If the Object Type is Issue or Workflow Task, the attribute name is assignee, requester, or group; these are the attribute names in the chg objects and they map to fields in the Change_Request tables.

     - If the Object Type is an Issue Activity log, the attribute name must start with the attribute name in the activity log object that links it to a specific instantiation of the chg object. The attribute name could be change_id.group.

   - **Description**
     Describes the object contact notification.

4. Click Save.
   The new object contact notification is displayed in the Object Contact Notification List.

Manual Notification Recipients List

You can set up a default set of Available Recipients that the Manual Notification composition page presents for requests, incidents, and problems. Available Recipients streamline the manual notify process for analysts because you can set up a list of contact objects (for example, Affected End User) or individual contact names for easy use as recipients of manual notifications.

Adding an Object Contact Recipient adds the individual contact names that the Object Contact represents to the Recipients list (consolidating any duplicate entries). The same contact can be referenced multiple times for different Contact Objects such as Assignee and Affected End User. Some entries, such as the Stakeholders List contact object, can add multiple entries to the Recipients list.

Contacts and Contact Objects remain in the Available Recipients list after you add them to the list. This behavior lets you remove recipients without affecting the initial Available Recipients list.

Example: How the Available Recipients List Works

The following examples demonstrate how default recipients streamline the manual activity notification process.

Object Contact Recipients includes the following entries:

- UserA belongs to the "Assignee" and "Affected End User" Contact Objects.

- Stakeholders List includes multiple contact names. For example, UserB and UserC.

You do the following actions:

- Add both Contact Objects that refer UserA to the Recipients list.
  Only one UserA entry is listed in the Recipients list.

- Accidentally remove UserA from the Recipients list.
  You do not have to refer to the ticket to get the UserA name and search to add it back. You can quickly add UserA to the Recipients list because UserA is listed in the Available Recipients list.

- Accidentally remove one contact name, such as UserC, from the Recipients List which came from the Stakeholders List.
  You can add the Stakeholders List from Object Contact Recipients to add the contact name again. Because duplicate entries are consolidated, other Contacts in the Stakeholders List who were not deleted from the Recipients List are not affected.

Previous Assignee Notifications

You can define Previous Assignee or Group values for an activity notification that detects changes to key fields when a ticket is saved. Previous values let you notify a previous assignee when a ticket is transferred, or notify both the current and previous groups when the priority of a ticket is escalated.

The Previous value fields of a ticket are local fields that exist only in memory and not in the database. The fields are populated during the save operation of the ticket only when respective attributes are changed and cleared at the completion of the notification processing. A previous value field is associated with a particular activity type through an activity association.

You can define Previous values that detect changes to the following key fields of a ticket:

Field	Requests, Incidents, Problems	Change Orders	Issues
Status	Yes	Yes	Yes
Active	Yes	Yes	Yes
Assignee	Yes	Yes	Yes
Request Area/Category	Yes	Yes	Yes
Group	Yes	Yes	Yes
Impact	Yes	Yes	Yes
Priority	Yes	Yes	Yes
Urgency	Yes	No	No
Severity	Yes	No	No

There are several contacts that you can specify for each object type (request, incident, problem, change order, or issue), which notify the current and previous contacts when an activity occurs.

- **Assignee** -- Person assigned to handle the ticket.

- **Assignee Previous** -- Person previously assigned to handle the ticket.

- **Group** -- Group assigned to handle the ticket.

- **Group Previous** -- Group previously assigned to handle the ticket.

After the notification rule is saved, the Assignee Previous and Group Previous fields display on the Object Contact Notifications List page.

Example: Configure Current and Previous Values for Key Fields

The following usage example describes how an administrator configures current and previous values for key fields to help ensure that the previous support representative is notified when a request is transferred away from them.

1. **Situation --** A support representative is frustrated because a ticket was transferred away from them and they were never notified.

2. **Task --** The administrator adds the Assignee and Assignee Previous object contacts to the notification rule for the Transfer activity notification. They attach a message template and specify the current and previous assignees to notify on the request form.

3. **Action --** When the request is saved, the Assignee and Assignee Previous fields of the request are populated. When the activity occurs (ticket is transferred), the condition for the rule is evaluated.

4. **Result --** If the condition is met, a notification message that describes the ticket activity is sent to the current assignee and the previous assignee.

Notify Contacts When a Ticket is Transferred Example

You can notify both the current and previous contacts when a CA SDM ticket is transferred.

Example: Notify both the current and previous contacts when a ticket is transferred

1. On the Administration tab, browse to Notifications, Activity Notifications.
   The Activity Notifications List page appears.

2. Select the Transfer activity notification.
   The Transfer Activity Notification Detail page appears.

3. In the Object Type field, select Requests/Incidents/Problems.

4. On the Notification Rules tab, under Symbol, select the Default Transfer Notification Rule.
   The Default Transfer Notification Rule page appears.

5. On the Object Contacts tab, click Update Object Contacts.

6. Click Search.
   The Notification Rule Update Recipients page appears.

7. From the Object Contacts list, select Assignee and Assignee Previous from the list on the left, and click the contact selection button (>>).
   The selected item is added to the list on the right.

Note: Use the CTRL or SHIFT keys plus the left mouse button to select multiple object contacts.

8. Click OK.

9. Save the notification rule.
   The Object Contacts list displays the selected object contact.

10. On the Default Transfer Notification Rule page, click Message Template. Select a template and ensure that the Auto Notification option is enabled.

11. Create a request, specify an Assignee, and click Save.

12. On the Request Detail page, select Activities, and Transfer from the File menu.

13. Specify a new Assignee, and click Save.
    The notification is sent to the current and previous assignees when the transfer activity occurs.

Configuration Item Notifications

A configuration item (CI) notification lets you define an activity notification that is associated with a specific CI that is associated with a specific CA SDM ticket. This feature lets you track information about the users, organizations, and vendors of a CI.

You can specify the CI object contacts on the Notification Rules Update Recipients page, such as CI Maint Org, CI Primary Contact, and so on.

Notify the Primary Contact of a Configuration Item for an Issue Example

You can define an activity notification for a primary contact that are sent for a specific CI for a specific CA SDM ticket.

Example: Notify the primary contact of a configuration item for an issue

1. On the Administration tab, browse to Notifications, Activity Notifications.
   The Activity Notification List page appears.

2. Select the Initial Activity Notification from the list.
   The Initial Activity Notification Detail page appears.

3. Select the object type you want to use.

4. On the Notification Rules tab, select the Default Notification Rule link.
   The Default Notification Rule page appears.

5. Select the Default Message Template link and ensure that the Auto Notification option is enabled.

6. Select the Object Contacts tab, and click Update Object Contacts.
   The Object Contact Notification Search page appears.

7. Click Search. A list of object contacts appears.

8. Select CI's Primary Contact from the list on the left, and click the contact selection button (>>).
   The selected item is added to the list on the right.
   You can use the CTRL or SHIFT keys plus the left mouse button to select multiple object contacts. You can add one object for a request and multiple objects for a change order or issue.
   The object contact is in the list on the right.

9. Click OK.

10. Save the notification rule.
    The Object Contacts list displays the selected object contact.

11. Complete the following tasks:

    - On the Service Desk tab, create or update an existing CI.
    - Add the primary contact listed on the Object Contacts tab. The selected object contact appears on the Configuration Items Detail page.
    - Add the CI to the Issue.

When an activity event occurs, the rule is implemented and the condition is evaluated. If the criteria for the condition is met, a notification message that describes the ticket activity is sent to all contacts of the CI associated with this notification rule.

Notification Log Reader

The Notification Log Reader displays the notifications received for the logged-in user by date, urgency, and status. With the Notification Log Reader, you can do the following:

- Change the sort order and set menu options to have the Notification Log Reader appear automatically when new messages are received.
- Double-click a notification message to request that CA SDM display the detail page for the ticket associated with the notification.
- Monitor notification messages by entering specific selection criteria to query the database for analysis or for selection of notification messages based on data entered in the fields. For example, you can list only those notification messages that have not been cleared by changing the Message Status field to Not Cleared.
- Clear notification messages to keep your list of notifications to a manageable size. Cleared notifications are not displayed when you first access the Notification Log Reader, although you can display them, if needed.

Set Notification Log Reader Options

You can set options for the Notification Log Reader to define how you are notified when new messages are received for an issue.

Follow these steps:

1. On the ServiceDesk tab, browse to View, Log Reader.
   The Notification Log Reader page appears.

2. Use the check box to the left of each notification to set the following options. You can select items to perform operations such as Clear Selected or Delete Selected.

   - **Header**
     Displays the header of the message, which usually contains the number of the ticket and the activity type.

   - **Start Date**
     Displays the date and time the notification was sent to your Log Reader window.

   - **Status**
     Displays the status of the notification.

   - **Urgency**
     Defines the level of urgency for the notification (low, normal, high, or emergency), which indicates the relative importance of different activities. Urgency levels are predefined; however, the system administrator is responsible for setting up other aspects of notification, such as notification methods and activity associations. The system administrator also defines the method of notification used for contacts and groups for each urgency level.

   - **Message Text**
     The full message text for the notification.

   The Log Reader displays any changes.

3. Click Close.
   The Notification Log Reader page closes and the options are set.

Personalized Responses

You can create personalized responses and attach them to requests, issues, and change order records when adding activities to the record. For example, you can append a personalized response on the Status Change or Log Comment windows available from the Activities menu.

Create a Personalized Response

You can create a personalized response to append to requests, issues, and change order records.

Follow these steps:

1. From the Administration tab, navigate to Service Desk, Personal Responses.
   The Personal Response list page displays.

2. Click Create New.
   The Create New Personalized Response page displays.

3. Complete the fields on the page:

- **Response Owner**
  Specifies the contact who owns the response. If this field is left blank, the response is available to all analysts.

- **Response**
  Specifies the text delivered to all those who receive this response. This field can be up to 1000 characters long.
  You can use variables in this field, for example:

```
Ticket ref_num: @{call_req_id.ref_num}

Assignee: @{call_req_id.assignee.combo_name}

Customer: @{call_req_id.customer.combo_name}

Description: @{call_req_id.description}
```

4. Select the type of records for which you want this response available. Click Save.
   A personalized response is created.

Personalized Response Variable Substitution

Variables can be embedded in the text of a Personal Response. These variables allow information to be substituted from the corresponding Request, Change Order, Issue, Problem or Incident. The syntax of the variables is the same as is used elsewhere in the CA SDM product, such as in the Activity Notification Message Templates and the Manual Notify Activity Message Text. The information can only be substituted from the corresponding Request, Change Order, Issue, Problem or Incident. Activity Notification Message Templates and the Manual Notify Activity Message Text allow information from the Activity Log Record to be included as well.

Check boxes for each object type (Requests, Change Orders, Issues, Incidents, and Problems) allow Responses to be filtered during selection. If the object type is not checked, the Response is not available for that object. For example, if only the Request box is checked, the Response is only presented in Activities for a Request.

A single Response can be used for all object types (Requests, Change Orders, Issues, Problems or Incidents). Because each object has different attributes, information that does not apply to the object is not substituted (for example, attempting to substitute the Request Number in a Response for an Issue).

A Response text example and the variable substitutions that occur for each object type follows:

```
This is Request # '@{call_req_id.ref_num}'
This is Change Order #' '@{change_id.chg_ref_num}'
This is Issue # '@{issue_id.ref_num}'
```

For a *Request*, the following substitution occurs:

```
This is Request # 'cr_demo:11'
This is Change Order # "
This is Issue # "
```

For a *Change Order*, the following substitution occurs:

```
This is Request # "
This is Change Order # 'chg_demo:3'
This is Issue # "
```

For an *Issue*, the following substitution occurs:

```
This is Request # "
This is Change Order # "
This is Issue # 'iss_demo:6'
```

By using the "Display this Response for" check boxes, you can create different versions of a Response with the appropriate substitution variables for the corresponding object (Requests, Change Orders, Issues, Problems or Incidents).

The format of the substitution variables for the different objects is as follows.

Object	Variable Format
Request / Incident / Problem	@{call_req_id.attr}
Change Order	@{change_id.attr}
Issue	@{issue_id.attr}

The substitution occurs when the Response is copied to the User Description field. The Response is copied after it is selected from the Personalized Response drop-down list and the drop-down list loses focus.

Internal Logs

You can define whether a particular access type is qualified to view internal logs. If allowed to view internal logs, contacts see a check box labeled Internal on each of the Log Activity windows, which they can select to mark the activity as internal. When activities are marked as internal, only contacts with an access type that is qualified to view internal logs sees the activity or is notified of it.

Administering CA Service Desk Manager

The Administrator role has full access to all product functionality. This role is used typically when implementing the product to help ensure that all users and roles are set up correctly. The Administrator role can also be used for a product environment that has a single person who performs all administration tasks.

Options Manager

Contents

The Options Manager lets you modify the functionality of your system. You can easily install and uninstall specific modified options.

Note: In advanced availability configuration, you can install or uninstall an option only from the background server. You can view the options and the descriptions from the application server.

The Options Manager pages list the applications that can be modified, the options that apply to those applications, and the values that are associated with the options, if any. They also provide descriptions of each option and indicate the status of each option (installed or uninstalled).

You can install these customization options when you install the rest of the product, or you can install any or all the options later. (Some options are automatically installed when you install the application that uses them.) You can also change the values of installed options at any time.

Important! Depending on your role, you may not have access to all the options.

Important! Installing or uninstalling an option requires you to restart the CA SDM servers. For advanced availability configuration, not all options require you to restart all the servers. Ensure that you read the Server Restart List (https://wiki.ca.com/pages/viewpage.action?pageId=103913584#id-.Install/UninstallOptionsManagerOptionsv14.1-ServerRestartList) before restarting any server.

Archive and Purge Options

Option	Description
busy_agent_threshold	Controls the threshold for processing the archive and purge background requests. For efficiency, requests in the background process queue should be processed during low system utilization ("non-busy" times). The Option Value field allows you to specify the number of the busy agents in a percentage. For example, if the Option Value is set to 70, the system starts processing requests in the background process queue when the percentage of busy agents is lower than 70 percent of the total agents in the system. The Option Value field sets the NX_BUSY_AGENT_THRESHOLD variable, which is located in the NX.env file.
default_schedule	The Option Value specifies the default schedule (workshift entry) used by the archive and purge rules. If the Option Value is set to an invalid workshift entry name or empty string, the rule does not execute the rule with the schedule value. The Option Value field sets the NX_DEFAULT_SCHEDULE variable, which is located in the NX.env file.
rule_history_length	The Option Value specifies the maximum number of rule history records saved in the database. The Option Value field is retrieved by archive and purge process at the startup. The default value for this variable is 50, which means 50 of the most recent rule history records are saved. The Option Value field sets the NX_RULE_HISTORY_LENGTH variable, which is located in the NX.env file.

Asset Information Service Options

Option	Description
allow_exceed	An asset/item contains an Inventory Count field. The number of parents an asset/item can have cannot exceed the inventory count. Installing this option allows the number of parents to exceed the inventory count.
allow_unrestricted_asset_upd	If installed, users can fully modify assets/configuration items owned by CA Asset Portfolio Management. If this option is not installed (the default), only a limited number of fields of the asset/item record can be updated.

Audit Log Options

These options control the logging of activities on the data partitions, change orders/issues, and requests. If these options are installed, an audit log entry is created for each field update and insert operation. The operation to be monitored is determined using the following options:

Option	Description
audit_ins	Monitors insertion.
audit_upd	Monitors field updates.

CA CMDB Options

Option	Description
allow_updates_to_inactive_ci	Specifies whether to permit inactive CIs to be updated. Default is NO (new installation) or YES (product upgrade). To uninstall this option, click Edit, Deinstall, Refresh. Then stop and restart the CA SDM server.
allow_updates_to_superseded_ci	Specifies whether to permit superseded CIs to be updated. Default is NO. To uninstall this option, click Edit, Deinstall, Refresh. Then stop and restart the CA SDM server.
ci_filter	Specifies whether to search for CIs in the CI List page. Default is YES. If the option is not installed, the CI search filter has no initial value. To uninstall this option, click Edit, Deinstall, Refresh. Then stop and restart the CA SDM server.
ci_hierarchy_levels	Specifies the number for levels (depth) to search for dependent services for CIs. Valid values are integers 0 (zero) through 9 (nine).
cmdb_model_class_inconsistency	Specifies to prevent, warn, or allow a CI class from being inconsistent with the class that a user specified in the optional CI model. ▪ **Prevent** Stops the CI save from occurring and displays an error message. ▪ **Allow** Allows the class and the class of the model to remain inconsistent. **Note:** Use this option for compatibility with earlier releases of the product, such as CA SDM r12.6. ▪ **Warn** Updates the standard log (stdlog) with a warning and lets the save occur. For example, use this option if you want to transition from Allow to Prevent. **Default:** Prevent

Option	Description
cmdb_versioning_maxrows	Specifies the maximum number of audit log and Change Order history entries that displays in the Versioning tab. **Default:** 400
critical_service_relationship	Specifies a relationship type to identify dependent services for CIs. You can specify multiple relationships separated by a comma. For example, supports, is managed by.

CA Process Automation Workflow Options

Option	Description
caextwf_eem_hostname	Specifies the name of the CA EEM server. For example, *http://<workflow_hostname>* identifies the authentication host. You install caextwf_eem_hostname only if you configured CA Process Automation to use CA EEM as an authentication server. CA SDM uses this value to transform a user name and password into a CA EEM token. Then, the user name and password do not pass in plain text over HTTP. **Note:** If the CA Process Automation installation is not using CA EEM, do not place a value in the caextwf_eem_hostname option, and do not install the caextwf_eem_hostname. Placing a false value or installing caextwf_eem_hostname when it is not necessary causes the integration to fail.
caextwf_endpoint	Specifies the URL that points to the CA Process Automation web services by including the CA Process Automation host name, port, and the mandatory /itpam/soap path. For example, *http://<workflow_hostname>:<workflow_tomcat_port>/itpam/soap* identifies the endpoint. If your implementation uses CA EEM, installing the caextwf_eem_hostname option is required for the integration between CA Process Automation and CA SDM to operate properly.
caextwf_log_categories	Specifies a comma separated list of CA Process Automation process instance log category names to appear on the CA SDM Request, Change Order, and Issue Workflow Tasks tab. For example, *Operator,Response,MyOwnCategory* supplies three log categories. You install caextwf_log_categories based on business decisions from the CA SDM and CA Process Automation process design personnel. This option adjusts the default data that appears on the Workflow Tasks tab for requests, change orders, and issues. When you install the caextwf_log_categories option, all CA Process Automation process instance log messages from the Process category and the categories that you specify appear on the Workflow Tasks tab. When you do not install caextwf_log_categories, only the CA Process Automation process instance log messages from the Process category appear on the Workflow Tasks tab. **Note:** For information about the CA Process Automation predefined log message categories, and defining custom message categories, see the CA Process Automation reference documentation.

Option	Description
caextwf_processdisplay_url	Specifies how to launch a graphical snapshot of a CA Process Automation process instance by supplying the host name and the mandatory /itpam/Web.jsp?page=runtimeeditor&ROID= path. For example, *http://<workflow_hostname>:<workflow_tomcat_port>/itpam/Web.jsp?page=runtimeeditor&ROID=* launches a snapshot of a process instance. On the Workflow Tasks tab of a request, change order or issue, the user selects View Process to see the snapshot. Installing the caextwf_processdisplay_url option is required for the integration between CA Process Automation and CA SDM to operate appropriately.
caextwf_retry_count	Specifies the number of times the CA PAM attached Workflow Events can be re-triggered to retry the Unknown status events. Default retry count value is 3 and range [1-20].
caextwf_retry_interval	Specifies the retry interval duration in minutes to re-trigger each unknown CA PAM Workflow events.Default retry interval duration is 10 and range [10-999].
caextwf_worklist_url	Specifies the process instance path by supplying the host name and the mandatory /itpam?page=tasklist path. For example, *http://<workflow_hostname>:<workflow_tomcat_port>/itpam?page=tasklist* enables CA SDM users to see a list of CA Process Automation process instances that require attention. The list appears in CA Process Automation when the CA SDM user selects a link associated with any listed task in the request, change order, or issue Workflow Tasks tab. Installing the caextwf_worklist_url option is required for the integration between CA Process Automation and CA SDM to operate properly.
caextwf_ws_password	Specifies the administrative password associated with the CA Process Automation user name from the caextwf_ws_user option. CA SDM uses the user name and password to access the CA Process Automation web service functions to perform integration activities such as selecting start request forms, process definition information, and process instance information. Installing the caextwf_ws_password option is required for the integration between CA Process Automation and CA SDM. The password and user name that you specify requires the appropriate access to CA Process Automation. However, it is not necessary for CA SDM to use the user name and password for authentication.
caextwf_ws_user	Specifies the CA Process Automation administrative user name associated with the CA Process Automation user name from the caextwf_ws_password option. CA SDM uses the user name and password to access the CA Process Automation web service functions to perform integration activities. Integration activities include selecting start request forms, selecting process definition information, selecting process instance information, or launching process instances. **Note:** Installing the caextwf_ws_user option is required for the integration between CA Process Automation and CA SDM to operate. The user name and password that you specify requires the appropriate access to CA Process Automation. However, it is not necessary for CA SDM to use the user name and password for authentication.

CA Service Catalog Options

To enable the self-service integration, install the following options:

Option	Description
casc_aty_sync	Specifies the type of activity logs to be synchronized from CA SDM to CA Service Catalog. If this field is left blank, Log Comment activity logs are synchronized. To synchronize other activity log types, (such as, Escalate, Update Status) enter the respective log type codes, separated by comma.
casc_endpoint	Specifies the CA Service Catalog Web Services URL. **Format:** http://<CA_Service_ Catalog_hostname>:<CA_Service_Catalog_portnum>/usm /services
casc_session_timeout	(Optional) Specifies the time in minutes for which the CA Service Catalog web services session will be cached. **Range:** 20 to 60 mins.
casc_user	Specifies the CA Service Catalog administrator username that is responsible for making the web service calls to CA Service Catalog. This user must exist in CA EEM against which CA SDM is configured.
casc_user_password	Specifies the password of the CA Service Catalog user as entered in the casc_user option.
casc_ws_retry	(Optional) Specifies the number of retries to synchronize a CA SDM ticket update (activity logs/ attachments/status) with CA Service Catalog, if there is a failure. Enter -1 to try indefinitely, until the synchronization succeeds. As a system administrator you can define the time interval after which you want the failed ticket update to be retried again. Run the following command to define the time interval:pdm_options_mgr -c -a pdm_option.inst -a option.inst -s NX_CASC_RETRY_INTERVAL -v [time interval in minutes] By default this time interval is set to 15 minutes. If you do not set any value or provide a non-numeric value to this variable, the failed update is retried according to the default time interval (15 mins.). **Range:** -1 to 50
casc_integrated	Enables the self-service integration.

Call Service Desk Options

Option	Description
call_service_desk_default_phone_number	Install this option and specify the value as a phone number for the mobile users to call the Service Desk using this specified number from their mobile.

Option	Description
call_service_desk_mobile_enable	(Installed by default) Enables the mobile users to call the Service Desk number from their mobile. The Service Desk number can be specified using the **call_service_desk_default_phone_number** or **call_service_desk_tenant_phone_number_field** (in case of multi-tenancy) option.
call_service_desk_tenant_phone_number_field	(Applicable if multi-tenancy is enabled) Install this option and set the value as phone_number or alt_phone, as specified in the tenant detail page. This option enables the tenant mobile users to call Service Desk using this specified number from their mobile.

Note: For more information, CA SDM Mobile application users can see the Mobility Wiki (https://wiki.ca.com/display/CASM/.Call+Service+Desk+from+your+Mobile+Device+v14.1) documentation

Change Order Mgr Options

Option	Description
asset_only_one_chg	Restricts Assets from being attached to more than one active change order.
Category_Defaults	Automatically fills certain fields on a change order detail page when the user selects a category. A category can have a default type, assignee, group, and organization/business. When this option is activated, the corresponding fields on the change order detail page are populated with category defaults if they have not been manually filled by the user. If the values are entered by the user, the default rule does not apply.
chg_allow_sla_downgrade	Alters the behavior of the chg_sla option by allowing the system to automatically downgrade a change order's Service Type. The chg_sla option selects the best Service Type from among several change order attributes, but cannot replace the change order's current Service Type with one of lesser rank. If this option is installed, the Service Types for all affected attributes are evaluated whenever one of the attributes changes. The change order's Service Type is set to highest ranked Type found, even if the new Service Type is lesser in rank to the change order's current Service Type. The Service Type with the smallest Rank value is considered the best service. If all the Service Types considered are equal in Rank (including Service Types with empty Rank values), the Service Type created first in the database is selected. The chg_sla option must be installed for this option to function correctly.
Auto Events	Automatically attaches events to newly created change orders. This attachment is specified using the following options: ▪ **chg_auto_events** -- Installs or uninstalls the option itself. ▪ **chg_auto_events_name** -- Specifies the format of a name for the attached events. ▪ **chg_auto_events_count** -- Specifies the number of events attached.

Option	Description
	Event names to be attached are constructed by joining the chg_auto_events_name to a number ranging from 1 to chg_auto_events_count. For example: ▪ chg_auto_events_name is "Auto Event" ▪ chg_auto_events_count is "3" With these settings, installing the chg_auto_events option would cause the following events to be attached to all new change orders: ▪ Auto Event 1 ▪ Auto Event 2 ▪ Auto Event 3 To complete the implementation of this option, you must define an event with these names. For more information, see create an event from How to Configure SLAs (see page 1099) topic.
chg_calendar_start_day_of_week	Specifies the start day of the week in the Change Calender. **Default:** Friday
chg_sla	Installs the rule for defaulting the Service Type field of a change order. The rule is as follows: ▪ The best service among the priority, requester, affected contact, and category is applied to the change order. ▪ The service type with the smallest rank value is considered the best service. If all the service types considered are equal in rank (including service types with empty rank values), the service type created first in the database is selected. ⚠ **Note:** This option is only available if the Classic SLA Processing Option is installed.
conflict_added	Generates Activity Log entries when conflicts are added.
conflict_updated	Generates Activity Log entries when conflicts are updated.
force_closure_code	Modifies the closure code value of children to be identical to the parent. The following values are valid: ▪ **Empty** - (Default) Forces the closure code value of the parent to the children when the child does not have a value for the closure code. It does not overwrite an existing closure code. ▪ **All** - Forces the closure code value of the parent to all children even if they already have a closure code value.
impact_explorer_exclude_hier	Used when building a list of child CIs for a CI in the Impact Explorer tree. If this option is installed and set to Yes, child CIs that are related through the CMDB Relationships tab of a CI Detail page are *not* displayed in the Impact Explorer tree or in the CI Descendants List.

Option	Description
	Note: Child CIs that are related through CA CMDB are displayed.
require_change_assignee	Prohibits change orders with no value in the Assignee field from being saved.
require_change_group	Prohibits change orders with no value in the Group field from being saved.
require_closure_code	Requires a closure code value prior to closing or resolving a change order.

Change-Issue Options

- **edit_completed_tasks**
  When this option is installed with a value of Yes, you are allowed to set both the "Allow Task Update" and the "Task Completed" flags on a Change Order or Issue Task Status detail. However, if you set both the "Allow Task Update" and the "Task Completed" flags, you can only update the Workflow Task Description. The default behavior is to not allow setting of both the "Allow Task Update" and the "Task Completed" flags on a Task Status detail.

Email Options

The email interface sends email notifications and lets users create tickets from an email.

Option	Description
mail_from_address	Specifies the mail notification From: address. The address is in the format Displayname<user@company.com (http://company.com)>.
mail_login_password	Specifies the SMTP server login password.
mail_login_userid	Specifies the SMTP server login userid.
mail_max_threads	Specifies the maximum number of concurrent SMTP connections that can attempt to communicate with the server.
mail_reply_to_address	Defines the reply to address for email notifications. This option is useful if emails are sent from one user account, but you want replies sent to another email address. The default value is the same as the from address.
	Defines the domain name of the SMTP server. You can clear the domain name by setting the value to NONE.

Option	Description
mail_smtp_domain_name	
mail_smtp_hosts	Specifies a space-separated list of SMTP server host names for email notifications.
mail_smtp_host_port	Specifies an SMTP port to override the default SMTP port.
mail_smtp_security_level	Specifies the SMTP security level. Valid settings are: 0=no security, 1=basic authentication, 2=NTLM, 3=MD5 and 4=LOGIN. If you set this option to 1, set the mail_login_password and mail_login_userid options. Most SMTP servers do not require authentication.
mail_smtp_use_tls	Specifies the Transport Layer Security (TLS) usage in the email. The valid settings are Yes= Use TLS, No=Do not use TLS.
mail_ca_cert_path	Specifies the path where the trusted certificate has been deployed. **Note**: For the advanced availability configuration, you must deploy the trusted certificate on the same location in all the CA SDM servers. CA SDM supports only Base-64 encoded (PEM) format for CA Certificates.
mail_show_to_cc_list	Shows all the recipients of the email notification. For manual email notification, both “To” and “Cc” list recipients are displayed and for automatic email notification, only “To” list recipients are displayed. By default, this option is installed. **Note:** Pager email notification method does not support the listing of all recipients in To or CC list.

General Options

Option	Description
add_utf8_byte_order_mark	Causes the default data to include an encoding signature (UTF-8 Byte Order Mark). Editors that support UTF-8 use this signature to display and maintain UTF-8 encoding.
catalog_server	Specifies the CA Service Catalog server location (for example: http[s]://*servername*:8090). If a load balancer is in use, verify that this option specifies the load balancer.
default_superuser_id	Specifies the default superuser ID for CA SDM, such as ServiceDesk.

Option	Description
Status_Policy_Violations	Specifies how strictly the system enforces **Status** policies. This option only applies to automated system processes, such as integrations and macros. The end user is unaffected by this option. Valid option values are: ▪ **Warn** -- Allows the status policy violation to proceed, but a warning message is written to the log. ▪ **Allow** -- Allows the status policy violation to proceed, but *no* warning message is written to the log. ▪ **Reject** -- Rejects the status policy violation and an error message appears.
singleton_notify_list	CA SDM sends the singleton daemon failure notification when it fails to restart a failed singleton daemon. This option controls the list of email recipients that will be notified when a singleton daemon fails to restart on the CA SDM server. Some fields in this page are self-explanatory. Following are the fields that need explanation: **Action Status** Indicates the installation status of the option. ▪ **Option Value** Specifies a list of comma-separated email addresses for sending the singleton daemon failure email. ▪ **Action Status Message** Specifies the message text to be included in the singleton daemon failure email.

Issue Mgr Options

Option	Description
iss_allow_sla_downgrade	Alters the behavior of the Iss SLA Option by allowing the system to automatically downgrade an issue's Service Type. The Iss SLA Option selects the best Service Type from among several issue attributes, but cannot replace the issue's current Service Type with a type of lesser rank. If this option is installed, the Service Types for all affected attributes are evaluated whenever one of the attributes changes. The issue's Service Type is set to the highest ranked type found, even if the new Service Type is lesser in rank than the issue's current Service Type. The Service Type with the smallest Rank value is considered the best service. If all the Service Types considered are equal in Rank (including Service Types with empty Rank values), the Service Type created first in the database is selected. The Iss SLA Option must be installed for this option to function correctly.
iss_assignee_set	Sets the assignee for issues to that of the logged in user, if the user is an analyst. If the option is installed, when an analyst creates a new issue, it is automatically assigned to that analyst.
Issue Auto Events	▪ Automatically attach events to newly created issues. This is specified using three options: ▪ **iss_auto_events** -- Installs or uninstalls the option itself. ▪ **iss_auto_events_count** -- Specifies the number of events attached. ▪ **iss_auto_events_name** -- Specifies the format of a name for the attached events. Event names to be attached are constructed by joining the iss_auto_events_name to a number ranging from 1 to iss_auto_events_count. For example:

Option	Description
	▪ iss_auto_events_name is "Auto Event" ▪ iss_auto_events_count is "3" With these settings, installing the iss_auto_events option would cause the following events to be attached to all new issues: ▪ Auto Event 1 ▪ Auto Event 2 ▪ Auto Event 3 To complete the implementation of this option, you must define events with these names.
Iss_Category_Defaults	Determines what happens when the category field is specified on an issue detail page. A category can have a default assignee, group, and organization/business. When this option is activated, the corresponding fields on the issue detail page are populated with the category defaults, if they have not been manually entered by the user. If these values are filled by the user, the defaulting rule does not apply. Make sure that the default assignee is actually a member of the default group.
iss_sla	Installs the rule for defaulting the Service Type field of an issue. The rule is as follows: The best service among the priority, requester, affected contact, and category is applied to the issue. The service type with the smallest rank value is considered the best service. If all the service types considered are equal in rank (including service types with empty rank values), the service type created first in the database is selected. **Note:** This option is only available if the Classic SLA Processing Option is installed.
require_issue_assignee	Prohibits issues with no value in the Assignee field from being saved.
require_issue_group	Prohibits issues with no value in the Group field from being saved.

Knowledge Options

This option controls the Knowledge functionality:

Option	Description
analyst_preferred_ticket	Sets the link for opening a ticket from a Knowledge Document for the analyst user interface. The analyst has a default setting of Incident, and the available options are Incident, Request, IncidentandRequest, and Issue.
kt_disallow_forums	If this option is set to Yes, the Forum feature is disallowed (inactive), which means you cannot create or update forums or view any menu items.

Option	Description
kt_report_card_issue_status	Allow issue statistics to be calculated and displayed in the Reuse section of the Knowledge Report Card. The validity of the where clause is not checked. **Example:** status='CL'
kt_report_card_request_status	Allow request statistics to be calculated and displayed in the Reuse section of the Knowledge Report Card. The validity of the where clause is not checked. **Example:** status='CL'

KPI Options

These options control the operation of the KPI daemon:

Option	Description
kpi_ticket_data_table	Enables the KPI daemon to collect data whenever CA SDM tickets are opened, closed, or certain fields are modified. Ticket data is written into the usp_kpi_ticket_data database table, and is available for generating web-based reports.
concurrent_lic_refresh_interval	Specifies the concurrent refresh time interval (in seconds) for all the concurrent KPIs (for example, webConcurrentLicenseCt KPI). If this option is installed, all the concurrent KPIs calculate the count only after the specified interval. If you do not install this option, refresh interval time is defaulted to 3600 seconds for all the concurrent KPIs.**Range:** 600 to 7200 seconds.

Note: Enabling this feature may result in degraded CA SDM performance.

LDAP Options

You can set the domain name for LDAP Servers that was configured through Options Manager, by adding the domain name in the NX.env file variable and executing the following commands:

```
pdm_options_mgr -c -a pdm_option.inst -s NX_LDAP_DOMAIN -v <DEFAULT_LDAP_SERV
pdm_options_mgr -c -a pdm_option.inst -s NX_LDAP_DOMAIN -v <DEFAULT_LDAP_SERV
```

Note: Restart the services and login to CA SDM with domain\username credentials.

The following LDAP options are available for installation from Options Manager on the CA SDM Administration tab.

Note: The options identified as required must be installed together to enable integration with an LDAP directory. The options identified as optional are features you can add only if the required options are installed.

Option	Description
default_ldap_tenant (required)	Specifies the default tenant for contacts imported from an LDAP directory into an installation that is configured for a multi-tenancy environment. The option value must set to the UUID for that tenant. You can get the tenant UUID from a database query. For example, "SELECT * FROM ca_tenant". **Important!** This option is only required if multi-tenancy is enabled. Before you run the pdm_buildtenant utility, and if you want to retain the tenant value, you *must* modify NX.env by adding the NX_RETAIN_TENANT_VALUE variable manually, and set it to "yes". If this variable is set to "no", missing, or not set properly, the utility overwrites the tenant information.
ldap_dn	Specifies the LDAP distinguishedName for logging in to the LDAP server. **Example**: CN=Joe, CN=Users, DC=KLAND, DC=AD, DC=com Depending on your site's network configuration, the userid *may* be used instead of a distinguishedName. **Note:** If the LDAP server supports anonymous binds, this value can be empty. For example, if the LDAP directory is the CA EEM identity store, this option is not required because CA EEM allows anonymous access.
ldap_enable	Specifies whether LDAP integration is enabled. The default value is Yes. In addition to this option, you install all other LDAP options indicated as required.
ldap_enable_auto (optional)	Specifies whether automatic creation of contacts from LDAP information is enabled. The default value is Yes. If you install this option, a contact is automatically created from LDAP information whenever a new user logs in.
ldap_enable_groups (optional)	Specifies whether CA SDM assigns a contact's Access Type based on LDAP Group membership. The default value is Yes. To use this feature, you associate CA SDM Access Types with LDAP Groups. **Note:** This option is only applicable for Microsoft Active Directory.
ldap_enable_tls (optional)	Specifies whether Transport Layer Security (TLS) is enabled during LDAP processing. The default option value is Yes.
	Specifies the value of the LDAP objectClass attribute. The default value is *group*.

Option	Description
ldap_group_object_class	This value is always included in the where clause of the automatically generated filters used to search for LDAP groups.
ldap_host	Specifies the LDAP server hostname or IP address. **Note:** If the LDAP directory is the CA EEM identity store, use the hostname of the machine where Ingres is installed.
ldap_port	Specifies the LDAP server port number. **Note:** If the LDAP directory is the CA EEM identity store, use 1684 for the port number.
ldap_pwd	Specifies the password for the ldap_dn for logging in to the LDAP server. **Note:** If the LDAP server supports anonymous binds, this value can be empty. For example, if the LDAP directory is the CA EEM identity store, this option is not required because CA EEM allows for anonymous access.
ldap_search_base (required)	**Note:** If you want to search contacts for a default LDAP server, keep the domain name field in the LDAP Directory Search page as blank or provide the exact LDAP domain name configured in CA SDM to retrieve the contacts in the specified LDAP directory. Specifies the starting point for searches in the LDAP schema tree: ▪ **UNIX** -- You *must* specify a starting container, such as: CN=Users, DC=KLAND, DC=AD, DC=com ▪ **Windows** -- You do not have to specify a container and may start at the top of the schema tree, such as: DC=KLAND, DC=AD, DC=com **Note:** If the LDAP directory is the CA EEM identity store, then use: cn=Users, cn=Entities,cn=iTechPoz This is only applicable when CA EEM is configured to use the MDB rather than an external directory.

Option	Description
ldap_service_type (optional)	Install this option to establish the LDAP service type. If the LDAP type is Active Directory, specify the string “Active Directory”. If the LDAP type is not Active Directory, specify any other string, for example, “eTrust” or “Novell”.
ldap_sync_on_null (optional)	Specifies whether existing contact attribute values are overwritten with null data if the corresponding LDAP user attribute contains a null value. The default value is Yes.
ldap_user_object_class (required)	Sets the value of the LDAP objectClass attribute. The default value is *person*. This value is always included in the where clause of the automatically generated filters used to search for LDAP users. **Note**: If the LDAP directory is the CA EEM identity store, use pozObject. For many non-AD LDAP stores, the correct setting is inetOrgPerson.
num_ldap_agents	Specifies the number of LDAP agents. Install this option only if you have multiple LDAP agents. The default value is 2.

Multi-Tenancy Options

Option	Description
max_tenant_depth	Specifies a limit to the depth of the tenant hierarchy. Default is four (4) levels of tenants.
multi_tenancy	Controls the multi-tenancy features. Multi-tenancy allows organizations or groups to share a single installation. The following values are available: ▪ **off** -- Multi-tenancy is not in use. ▪ **setup** -- Multi-tenancy is not in use, however, administrators can view and edit the tenant-related objects and attributes on the UI. ▪ **on** -- Multi-tenancy is fully operational. You can also add enforcement level options after the "on" setting, as follows: ▪ **warn** -- Untenanted objects can be created or updated, but an error message are written to the log. ▪ **allow** -- Untenanted objects can be created or updated, but a warning message is written to stdlog. **Note:** Setting an enforcement level is useful during migration. It allows SLA and attached event updates to legacy untenanted data.

Notifications Options

Option	Description
add_know_list	Adds the "in-the-know" notify list to all future notifications regarding a change order, issue, or request. When this option is installed, the contacts listed in the notify list are added to all future notifications.
log_all_notify	Logs all notifications, regardless of the method used. Logging a notification creates a notification log object that records the recipient, date/time, method of notification, and the notification text. The administrator uses the **Notification History** list to view and maintain notification log objects. The notification history can also be viewed from an individual ticket. If this option is not installed, the contact receives only the notification specified in the Contact record. No record is kept of the notification attempt.
notification_allow_temp_address	Allows manual notifications to be sent to manually entered SMTP email addresses, rather than to registered contacts only.
web_cgi_url	Allows the recipient of a notification email to click a URL and view the object they were notified about. This option is also used in survey notifications. To define a URL for a user to reach the CA SDM, a reference to the web interface is needed. The reference value is the web interface URL that is used to access the CA SDM web component. The URL has the following syntax. `http://hostname/CAisd/pdmweb.exe` ▪ **hostname** Specifies the location of your web server. (Recommended) For Advanced Availability configuration, it is strongly recommended that this option points to one of the application servers and not the background or standby server. It can also point to a Web Director or a third-party load balancer. ⚠ **Note**: Change the value of this option to point to: ▪ The load balancer if you have more than one application servers. ▪ The application server, if you have only one application server.

Request Mgr Options

Option	Description
Area_Defaults	Determines what happens when the Request Area field is specified on a Request Detail page. A Request Area can have a default assignee and group. When this option is activated, the Request Detail assignee and group are populated with the Request Area defaults.
Assignee_set	Sets the assignee for requests to that of the logged in user, when the user is an analyst. If the option is installed, when an analyst creates a request, it is assigned automatically to that analyst.

Option	Description
autoasg_ci_assign_lowest_agt	Enables the CI-based auto-assignment to assign an analyst from group. The analyst must have active Status as Active and Available as Yes. The tickets assigned to all of the analysts that meet this criteria are counted but the first one encountered with the least number of tickets assigned to them is assigned to the ticket. You have to install this option to use it. After installing, this option restart the CA SDM servers.
autoasg_override	Controls how Auto Assignment handles a Request that is created with an Assignee, Group, or both. Configure your system by setting this option to one of the following values: ▪ Uses the existing Assignee, Group, or both. Auto Assignment processing does not occur if the Assignee, Group, or both was set during the creation of the Request. ▪ Ignores the existing Assignee, Group, or both. Auto Assignment processing occurs and attempts to find an Assignee, Group, or both. The Assignee, Group, or both can be set in various ways: ▪ Manually by the Analyst ▪ Area Defaults and the Assignee set options ▪ Request Templates ▪ Uninstalling this option causes it to operate in its default mode, which is 0.
Auto Events	▪ Automatically attach events to newly created requests. This is specified using three options: ▪ **auto_events --** Installs or uninstalls the option itself. ▪ **auto_events_count --** Specifies the number of events attached. ▪ **auto_events_name --** Specifies the format of a name for the attached events. Event names to be attached are constructed by joining the auto_events_name to a number ranging from 1 to auto_events_count. For example: ▪ auto_events_name is "Auto Event" ▪ auto_events_count is "3" With these settings, installing the auto_events option causes the following events to be attached to all new requests: ▪ Auto Event 1 ▪ Auto Event 2 ▪ Auto Event 3 To complete the implementation of this option, define an event with these names. For more information, see create an event from How to Configure SLAs (see page 1099) topic.
clear_scratch_pad	Clears the Scratch Pad text is after creating a request. The default behavior is to apply the Scratch Pad text to all new requests.
cr_allow_sla_downgrade	Alters the behavior of the CR SLA Option by allowing the system to downgrade a request Service Type automatically. The CR SLA Option selects the best Service Type from among several request attributes, but never replace the request current Service Type with a type of lesser rank. If this option is installed, the Service Types for all affected attributes are evaluated whenever one of the attributes changes. The request Service Type is set to the highest ranked type found, even if the new Service Type is lesser in rank than the request current Service Type.

Option	Description
	The Service Type with the smallest Rank value is considered the best service. If all the Service Types considered are equal in Rank (including Service Types with empty Rank values), the Service Type created first in the database is selected. The CR SLA Option must be installed for this option to function correctly.
cr_sla	Selects the best Service Type from among several request attributes, and never replace the request current Service Type with a type of lesser rank. The Service Type with the smallest Rank value is considered the best service. If all the Service Types considered are equal in Rank (including Service Types with empty Rank values), the Service Type created first in the database is selected.
efficiency_tracking	Specifies Efficiency Tracking, which lets analysts use options to track incidents. This option displays the Show Efficiency Tracking tab on the Incident Detail page.
employee_intf_incident_support	Displays the Incident, Request, or both ticket types for users logged in under the Employee interface type. You can select one of the following Option Values: ▪ Incident only ▪ Request only ▪ Incident and Request **Note:** The employee_intf_incident_support option is installed during CA SDM installation and cannot be uninstalled.
force_resolution_code	Specifies how the Resolution Code field value is handled for requests and incidents when an analyst closes a request or an incident. When this option is installed, select one of the following values: **Empty** -- The resolution code value of the parent is forced to the children only when the child does not have a value for the resolution code field. The option does not overwrite an existing resolution code value. This is the default value. **All** -- The resolution code value of the parent is forced to all children even if they already have a value for the resolution code field. The option overwrites the current value with the value of the parent. ▪ If this option is not installed, the resolution code values of all children remain unchanged. ▪ If the option is installed, the resolution code value of the parent is propagated to its children.
force_resolution_method	Specifies how the Resolution Method field value is handled for requests and incidents when an analyst closes a request or an incident. When this option is installed, select one of the following values: **Empty** -- The resolution method value of the parent is forced to the children only when the child does not have a value for the resolution method field. The option does not overwrite an existing resolution method value. This is the default value.

Option	Description
	All -- The resolution method value of the parent is forced to all children even if they already have a value for the resolution method field. The option overwrites the current value with the value of the parent. ▪ If this option is not installed, the resolution method values of all children remain unchanged. ▪ If the option is installed, the resolution method value of the parent is propagated to its children.
guest_intf_incident_support	Displays the Incident, Request, or both ticket types for users logged in under the Guest interface type. You can select one of the following Option Values: ▪ Incident only ▪ Request only ▪ Incident and Request ⚠ **Note:** The guest_intf_incident_support option is installed during CA SDM installation and cannot be uninstalled.
monitor_joins	Specifies whether to monitor joined tables for updates to dynamic lists. Updates to another table can affect the contents of a list. This effect often occurs when you use data partition view constraints containing a join. For example, a view constraint on change orders/issues where: `assignee.organization = @root.organization` results in a join from the Change_Request table to the Contact table in all change order, issue, or both lists. Keeping a change order or issue list containing this constraint up-to-date requires monitoring updates to the Contact table, and refreshing the list whenever a contact changes its organization/business. The result can be that a large number of lists updating simultaneously after an update to a joined table, with a possible performance degradation while the update is occurring. The monitor joins option allows the list updating (and the monitoring of the joined table) to be suppressed at sites where the up-to-date accuracy of such lists is less important than the performance degradation.
Netres_pty	Escalates a request based on the associated asset. If you specify an asset with a Priority greater than the Priority on the request, the request Priority is set to match the asset. An escalation activity is not created. This option does not override a Priority that you manually specified on the Request Detail page during the same editing session.
require_incident_assignee	Prohibits incidents with no value in the Assignee field from being saved.
	Prohibits incidents with no value in the Group field from being saved.

Option	Description
require_incident_group	
require_problem_assignee	Prohibits problems with no value in the Assignee field from being saved.
require_problem_group	Prohibits problems with no value in the Group field from being saved.
require_request_assignee	Prohibits requests with no value in the Assignee field from being saved.
require_request_group	Prohibits requests with no value in the Group field from being saved.
urgency_on_employee	Specifies whether to show the Urgency field on Self Service incidents or requests. When the urgency_on_employee option is not installed, the Priority field appears on Self Service incidents or requests. When urgency_on employee option is installed, the Urgency field appears instead of the Priority field. The range of Urgency values are based on *web.cfg* settings.
use_incident_priority	Specifies whether to calculate the Incident Priority field on the Incident Detail page. When the administrator uses Web Screen Painter to add the Incident Priority field, the Incident Priority field appears on the Incident Detail page. When the use_incident_priority option is not installed, the Incident Priority value calculated is zero. When the use_incident_priority option is installed the Incident Priority calculates as the sum of the Urgency and Impact values.

Request-Change Options

Option	Description
edit_inactive	Prevents editing change orders, issues, or requests unless their status is Active. Default behavior is to allow editing of inactive tickets.
set_sla_evt_open_date	Uses the open date/time value of a change order, issue, or request as the start date /time of attached events. The attached events are triggered as soon as the ticket is saved.

Request-Change-Issue Options

Option	Description
	Allows or prevents the Activity Log fields from being edited. The only exception to this option's setting is the Internal field. This is always editable.

Option	Description
activity_log_security	**Note:** The activity_log_security option is installed during installation and cannot be uninstalled.
Any_Contact	Some CA SDM objects restrict field values for Contacts based on Contact Type. This type of restriction is typically found on fields labeled, "Assignee" and only allow Contacts with a Contact Type Analyst. This option removes the contact type restrictions across the entire CA SDM application, allowing any type of contact to be used as an assignee.
classic_sla_processing	Enables the "classic" model of service types and SLA's. This model uses the Rank value for Service Types to determine the correct Type for a ticket. Only one Service Type can be applied to a ticket. **Note:** The Chg SLA Option, CR SLA Option, and Iss SLA Option are available if the Classic SLA Processing Option is installed.
delete_null_properties	Determines what happens to the properties when the Change Category, Issue Category, Request Area, Incident Area or Problem Area change and you install the keep_tasks option. A saved ticket with a specified category can have a number of properties and tasks. If this option is not installed, the following occurs: ▪ All existing properties are preserved. ▪ Any new properties, if any, from the new category are added. If this option is installed, the following occurs: ▪ All existing properties that contain non-empty values are preserved. ▪ All existing properties that contain empty values are deleted. ▪ New properties from the new category, if any, that do not have the same label value as any of the existing kept properties are added. When new properties are added to a ticket with existing properties, the system automatically adjusts (increases) the sequence numbers of the new properties to ensure they do not conflict with existing properties. The new properties always have greater sequence numbers than the existing ones.
filter_template_search	Filter the initial template search with end user's Organization.
force_rootcause	Specifies how the Root Cause field is handled for requests, change orders, and issues. ▪ If this option is not installed, the root cause field values of all children are left unchanged. ▪ If the option is installed, the root cause value of the parent are propagated to its children. When this option is installed, choose one of the following values: ▪ **Empty** -- The root cause value of the parent are forced onto the children only when the child does not have a value for the root cause field. It does not overwrite an existing root cause value. This is the default.

Option	Description
	▪ **All** -- The root cause value of the parent is forced onto all children even if they already have a value for the root cause field. It overwrites the current value with the value of the parent.
init_list_search	Performs a search when opening the Request, Change Order, and Issue List pages to display the logged-in user's list of tickets. If this option is not installed, these list pages are blank on opening until the user performs a search.
keep_tasks	Specifies what happens if you move a ticket to a different category or area: ▪ If keep_tasks is *not* installed, all existing properties on the ticket are removed. Any properties or tasks associated with the new category or area are added. Tasks with a status of Wait are removed. Tasks with any other status are retained. ▪ If keep_tasks *is* installed, all existing properties and tasks on the ticket are retained. Any properties or tasks associated with the new category or area are added. **Note**: When new properties or tasks are added to a ticket with existing properties or tasks, the sequence numbers are automatically adjusted to prevent conflict. New properties and tasks are always assigned greater sequence numbers than the existing ones.
leave_children_open	Keeps child incidents, requests, problems, changes, or issues, open when the parent is closed.
lex_lang	Allows you to select the language to be used for spell checking. Default is US-English. This option sets the NX_LEX_LANG variable located in the NX.env configuration file.
sla_workshift_override	Use this option to default the workshift for Service Type Events. ▪ When this option is not installed, events for a Service Type always uses the workshift specified each event's template. ▪ Installing this option defaults the workshift for Service Type Events to the workshift specified on the Service Type. The default occurs only when the event does not specify its own workshift. If an event template specifies a workshift, it is always used. **Tip:** Set the event's workshift to the supplied '24 hour' workshift if you want the event to always start, regardless of any Service Type workshift.

Search Engine Options

The following options control Knowledge Management search performance:

Option	Description
ebr_max_qps	Specifies the maximum number of queries per second (QPS) that is logged in the .stdlog file. The default is 2 QPS. QPS below this number is logged in trace mode.

Option	Description
ebr_qps_timeout	Specifies the time interval (the number of seconds) by which QPS are measured. Default is 300 seconds.

The following options control search engine integration:

Option	Description
ebr_search_engine_baseport	Specifies the port selected when the search engine was installed. Default is 13000.
ebr_search_engine_host	Specifies the host name or IP address where the search engine is installed.
ebr_version	Defines the search engine you want Knowledge Management to use for searches. The KM Search Engine specifies the engine that is installed and configured with CA SDM. **Note:** The document is not indexed when the Search Engine and all the text fields contain noise words.

Security Options

Option	Description
bopauth_host	(Applicable only for advanced availability configuration) Specifies the server name where bopauth_nxd is running. bopauth_nxd authenticates users accessing CA SDM through different interfaces. Select default if bopauth_nxd has to run in background server. This option cannot be uninstalled.
ldap_virtdb_host	(Applicable only for advanced availability configuration) Specifies the server name where ldap_virtdb is running. Select default if ldap_virtdb has to run in background server. This option cannot be uninstalled.
eiam_hostname	Specifies the hostname of the server where EEM is running. Required for EEM user name and password or artifact authentication.
force_browser_to_send_cookie_only_in_ssl_connection	(optional) Force the browser to send the Session ID (SID) cookie only if there is an SSL connection. This attribute is applicable only if you have enabled the **use_encrypted_sid_and_cookie** to (Yes). By default, this is turned off. If this flag is enabled, CA SDM can only be accessed through an SSL connection.
force_unique_userid	Prevents using duplicate active system login names. **Important!** We recommend that you keep the force_unique_userid option enabled at all times. If this option is uninstalled, and there are multiple contact records with the same login id, you may experience problems with data partitions, multi-tenancy, security, and other functionality.
	Specifies the Guest user login ID. Default is Anonymous. Must be a valid user ID.

Option	Description
guest_user_name	
ignore_security_case	If installed, the user ID is not case sensitive.

Portal_Safe_List	Stores a list of machine names and port numbers where Portal is installed. The machine name and the port are entered as follows
	
	`machine-name:8080`
	
	For multiple Portal installations, separate the machine name/port number with a comma. For example:
	
	`machine-name1:8080,machine-name2:8081,machine-name3:8080`

url_etrust_password_reset	The URL for the eTrust Admin web interface. This enables the password reset link on the web interface. For example: `http[s]://hostname/EAOWebi/EAOLogin`
use_eiam_artifact	Allows EEM artifact to be used when users log in to CA SDM / Knowledge Management using URL.
use_eiam_authentication	Allows use of EEM authentication when users log in to CA SDM / Knowledge Management and the access type authentication is set to OS.
use_encrypted_sid_and_cookie	(optional) Use encrypted Session ID (SID) and cookie to prevent SID spoofing and Man-in-the-middle attack. By default, this attribute is disabled. If you want to have enhanced CA SDM security, this attribute can be enabled (Yes). Enabling this attribute can have some performance impact on the CA SDM Application.

Support Automation Options

Option	Description
sa_domsrvr	Specifies that the Support Automation main server communicates with the specified Support Automation domsrvr. If this variable is not installed, the Support Automation main server communicates with the default primary CA SDM Domsrvr named "domsrvr".
sa_primary_domsrvr	Specifies whether to start the Support Automation primary domsrvr. This variable is used to determine if a dedicated object server is already configured. If this option is not installed, the domsrvr:sa runs on one of the secondary CA SDM servers and you are required to startup for domsrvr:sa.
supportautomation_url	Specifies the URL of the Support Automation web application, which CA SDM uses to communicate with the Support Automation main server. The host name and port number should correspond with the values set during configuration. We recommend that you configure the supportautomation_url with a host name because you may encounter problems when you configure the supportautomation_url with an IP address, if you use an IP address which has an existing host name mapping, the HTTP request processing resolves to this host name.

Option	Description
	Note: The administrator installs this option after you configure the Support Automation main server on a primary or secondary CA SDM server to enable Support Automation usage in CA SDM. Do not install this option if Support Automation is not configured.

Time-to-Violation Options

These options control the process that monitors the service level agreements on all open tickets and tasks, and records the time the Service Type enters violation:

Option	Description
ttv_enabled	Runs the Time to Violation daemon, which monitors the SLAs for all open tickets and tasks. This process does not set the SLA violation, but records the date the ticket or task is violated in its current state. This projection is updated when the ticket or task is updated. This option must be installed in order for the other Time to Violation options to function correctly. **Important!** This option requires that the classic_sla_processing option *not* be installed.
ttv_evaluation_delay	Sets the delay between a request to the time-to-violation (TTV) daemon and when it actually evaluates a ticket. Whenever a ticket is updated, a request is sent to the TTV daemon to update the time-to-violation projections. Because tickets are often updated several times in quick succession, a delay in evaluation helps prevent needless evaluations and improves performance. **Important!** This option is dependent on the ttv_enabled option, which must also be installed. **Note:** This value may never be set below 60 seconds.
ttv_highlight	Highlights a ticket in a list if the ticket has a Time to Violation value set to start by a certain time. The default highlight color is a pale yellow. The ticket number is highlighted only if one of its Time to Violation values is less than the date /time specified by the Timespan, "TTV_THRESHOLD". By default, this Timespan is set to show tickets with Time to Violation values less than midnight of the current day, for example, "today". You may modify this Timespan to any value. This option only affects ticket list forms on the web interface client. It applies to lists of Requests, Issues, Change Orders, Incidents, Problems and Tasks. It's an option because the Time to Violation value is stored in a database table separate from the ticket, and requires an extra database fetch *for each row displayed*. Given this extra DBMS activity, installing this option may increase the load on your database so that performance may be affected.

Option	Description
	Important! This option is dependent on the ttv_enabled option, which must also be installed.

Ver Ctl Options

The ver_ctl option controls the actions that are taken by the Version Control Manager when a version discrepancy is detected. The Version Control Manager detects discrepancies by comparing version files across all CA SDM servers (client and servers). Depending upon the CA SDM configuration, the following client and servers are used:

- Conventional:
  - Client: Secondary server
  - Server: Primary server
- Advanced availability:
  - Client: Application and Standby servers
  - Server: Background server

Only components that are listed in the version files are controlled. When you restart the servers and if a discrepancy is detected, the client connects to the server to send a list of its controlled components. The server compares the list to its own master list. The affected components on the client are upgraded or terminated, depending on the ver_ctl option.

ver_ctl
Installing this option activates the Version Control Manager. Valid option values are:

- **Fail** -- A version discrepancy terminates the secondary server's connection to the primary server. The secondary server is prevented from connecting to the primary server until it is manually updated.
- **Notify** -- Default value. On Windows, a version discrepancy results in a message window asking if you want the secondary server to continue or quit. On UNIX, a version discrepancy is logged, but the secondary server always completes initialization.
- **Upgrade** -- When a version discrepancy is detected, an upgrade of the affected components is attempted on the secondary server. If the upgrade is successful, the secondary server connection continues; otherwise, the secondary server connection terminates.
- **Disable** -- Version discrepancies are ignored. All secondary servers are allowed to connect to the primary server.

Web Options

These options control the CA SDM web interface operation:

Option	Description
auto_suggest_status	Displays matching records for the text entered in lookup fields within the Analyst interface. **Note**: For this option to work correctly, the Using Screen Reader user preference must be disabled. To specify user preferences, select View, Preferences on the menu bar. **Default:** On
copy_inactive	Copies the inactive attributes of an object (such as the previous assignee) from the original record to the new record. **Note:** By default, this option is uninstalled so that links to inactive objects are not copied. If you install this option, or if you migrated from CA SDM r12.5, links to inactive objects are copied.
charset	Defines the default HTTP character set for the web interface. You cannot uninstall this option. The value of this option is set in the charset parameter of the HTTP content-type header and it matches the character encoding of the operating environment when CA SDM is configured. Under normal circumstances, this option does not need updating after initial configuration. **Important:** Restarting the CA SDM server is *not* required.
export_max_fetch_rows	Determines the maximum number of rows that users can export for a list. **Default:** 5000
max_files_to_upload_simultaneously	Defines the maximum number of files that you can simultaneously upload during the same operation. **Valid Range:** Greater than or equal to 0. Zero means unlimited. **Default:** 10
max_records_auto_suggest	Specifies the number of suggestions to display in matching results. For example, increase the number of suggestions if analysts in your environment request 50 suggestions. **Default:** 25
min_chars_auto_suggest	Specifies the minimum number of characters that a user enters in a lookup field before the field starts displaying matching results. For example, increase the number of characters if your environment contains many users that share the first three characters in their user names. T **Default:** 3

Option	Description
mouseover_preview_delay_time	Specifies the delay time, in milliseconds, between hovering the mouse cursor over an object link and the display of the mouseover preview. The preview is not generated if the mouse is moved away from the link before the delay time expires. Enter a value from 100 to 5000 in the Option Value field. **Default:** 1000
pdmweb_cache_disable	All regular files from bopcfg/www are cached. If this option is installed, the PDMWEB servlet does not cache the files, which means all files are retrieved from the directory each time one is needed.
pdmweb_cache_site mods	The PDMWEB Servlet, by default, does not cache files from the $NX_ROOT/site/mods folder. If this option is installed, files are cached from the sitemods folder.
prompt_for_knowledge	Enables a dialog that prompts users to search the knowledge base before creating issues from the customer web interface and requests from the employee web interface.
scoreboard_entry_limit	Limit for adding new scoreboard nodes and folders. When the system reaches the limit, existing folders and nodes continue to display information. However, the user must delete unused folders or nodes before creating new ones.
suppress_web_hier_search	Suppresses the hierarchical search used on the web for request, incident, and problem areas, category, and root cause. This option is useful for tables that are not organized hierarchically, or when one or more of the hierarchical levels contains a great many records. When hierarchical search is suppressed for a table, search requests on the table are processed as lookups. The value of this option is list of object names of the tables for which hierarchical search is suppressed. If more than one table name is specified, values are separated by spaces. Valid values are: ▪ **chgcat** - Change order category ▪ **isscat** - Issue category ▪ **pcat_cr** - Request area ▪ **pcat_in** - Incident area ▪ **pcat_pr** - Problem area ▪ **rc** - Request root cause **Important!** To avoid errors when using autocomplete, we recommend that you use this option instead of modifying the dtlHier macro to dtlLookup in the HTMPL file.
use_nested_tabs	Displays nested tabs within the current form. The analyst can expand each tab to view key details. If you want to revert to the notebook styles used in CA SDM r12.5, you can disable the nested tabs control. For example, analysts in your environment prefer to click a tab that shows only the content of that tab.

Option	Description
web_auto_update	Requests the automatic update of scoreboard counts for analyst web users. When this option is installed, each web analyst session requests updated scoreboard counts at the interval specified in the option. The value of this option is the number of seconds between updates, with a minimum value of 60 seconds (one minute). Web scoreboard updating occurs in the background. The analyst end user can see periodic activity on the main page. In addition, updated count values are highlighted on the scoreboard. The highlighting remains until the user either clicks on the scoreboard link to display the associated list, or presses the Update Counts button. Activating this option affects the overall load of the system as follows: ▪ Each web user can send additional requests to the server at the frequency specified in the option. ▪ The web engine receives messages from the object engine each time a database update causes the count associated with a query to change. When the web auto update option is not installed, the web engine requests counts from the object engine only when a web user explicitly requests an update.
web_wildcard_search	Installing this option enables a wildcard search for all text fields when using Search Filters. To perform a wildcard search, you add the "%" symbol after a text string. For example, entering the string "option%" retrieves all records that begin with the word "option". Installing this option eliminates the need for the "%" symbol and conducts wildcard searches by default. **Note:** Installing this option enables functionality equivalent to using the "%" symbol only at the *end* of the search string, not at the beginning. For example, with this option installed, searching the Options Manager option list for the string "ldap" finds all options with names beginning with "ldap" but does not find the "default_ldap_tenant" option.
wsp_domsrvr	Specifies the name of an object engine dedicated to the Web Screen Painter (WSP). The WSP webengine, designated by the companion option wsp_webengine, is the only client process allowed to connect to the object engine identified by wsp_domsrvr. You must install both the wsp_domsrvr option and wsp_webengine option in order to enable the WSP schema modification test feature. The value of this option must be a string beginning with the characters "domsrvr:". It is recommended that you use domsrvr:wsp as the name of the WSP object engine. Installing this option automatically runs the WSP object engine on the primary server.
wsp_webengine	Specifies the slump name of the webengine used by Web Screen Painter users. All WSP users connect to this webengine, and use it for preview sessions. All files saved by WSP users are stored in the site/mods directory on the server running this webengine, which must be the CA SDM primary server. Because WSP saves information on the server running its webengine, all WSP users must connect to the same webengine. If the wsp_wengine option is not installed, WSP users connect to the default webengine: web:local, sharing it with other users. The value of this option must be a string beginning with the characters: "web:". We recommend you use web:wsp as the name of the WSP webengine.

Web Report Options

These options control the CA Business Intelligence reporting integration with the BusinessObjects server:

Option	Description
bo_server_auth	Specify which type of authentication you want to use for reporting. You can specify the following types of authentication: ▪ **secEnterprise**. (Default) Specify Enterprise Authentication as your authentication type if you prefer to create distinct accounts and groups in BusinessObjects for use with CA Business Intelligence, or if a user hierarchy has not been set up on an LDAP server or a Windows AD server. ⚠ **Note**: If you choose the secEnterprise option, you need to add your CA SDM report users to the BusinessObjects Central Management Console (CMC). The CMC allows you to control users' access to Business Intelligence Launch Pad and other BusinessObjects applications. In the CMC, you must enter the same user names and passwords configured in CA SDM. ▪ **secLDAP**. Specify LDAP Authentication as your authentication type if you have already set up an LDAP directory server and want to use your LDAP user accounts and groups in BusinessObjects for use with CA Business Intelligence. ▪ When you map LDAP accounts to BusinessObjects, users can access CA Business Intelligence with their LDAP user name and password. This eliminates the need to recreate individual user and group accounts within BusinessObjects. ▪ **secWinAD**. Specify Windows AD Authentication as your authentication type if you are working in a Windows 2000 environment and want to use your existing AD user accounts and groups in BusinessObjects for use with CA Business Intelligence. ▪ **secExternal**. Specify External Authentication as your authentication type if you integrate the BusinessObjects authentication solution with a third-party authentication solution (for example, using JCIFS with Tomcat). This authentication type requires setting up Trusted Authentication in BuisnessObjects to allow users to log on without providing their passwords. ⚠ **Note:** During the Trusted Authentication configuration, you must set the user name retrieval method to REMOTE_USER in the BusinessObjects web.xml file. ⚠ **Note:** For information about alternative security options, see the *CA Business Intelligence (see page 3180)*.

Option	Description
bo_server_cms	Specify the name of the Central Management Server (CMS) that is responsible for maintaining a database of information about your BusinessObjects that you use with CA Business Intelligence. For the bo_hostname, use the hostname of the machine where CA Business Intelligence is installed. The default bo_cms_port is 6400.
bo_server_location	Specify bo_hostname by using the hostname of the machine where CA Business Intelligence is installed. CA SDM uses this URL to put together report URLs for requesting reports from the BusinessObjects server. The CMS location is specified by hostname and port. **Important!** The default bo_application_server_port is 8080 (for example, this can be the Tomcat port). If you install CA SDM and CA Business Intelligence on the same server, you must specify a different port. Use the port specified when starting Business Intelligence Launch Pad. For example, http://hostname:8180/businessobjects/enterprise115/desktoplaunch/businessintelligencelaunchpad/logon/logon.do displays that 8180 is the value to use for bo_tomcat_port.

Web Service Options

Option	Description
rest_webservice_access_duration	Specifies the number of hours that the REST Web Service Access Key remains active before expiration. The Access Key timeout is not based on inactivity time, but it is based on duration time since the Access Key creation. After the Access Key meets the specified duration, the Access Key ends regardless of whether it is being used. Optionally, the REST client can also provide the Access Key duration time for the specific Access Key during the Access Key request. To provide the duration value, set it directly on the expiration_date attribute of the rest_access resource, as part of the POST request payload. **Valid Range:** 1-8760 hours **Defaut:** 168
rest_webservice_disable_basic_auth	Disables Basic Authentication in REST Web Services. **Default:** No
rest_webservice_list_max_length	Specifies the maximum number of rows that a REST Web Service query returns. **Default:** 500
rest_webservice_list_page_length	Specifies the default number of rows that a REST Web Service query returns per page. **Valid Range:** 1-500 **Default:** 25

Option	Description
rest_webservice_resources_to_expose	Specifies the list of Majic factories (resources) that CA SDM exposes through REST Web Services. This option overrides the default behavior. By default, CA SDM exposes all factories through REST Web Services. If you do not enter values in this option, the default behavior exposes any Majic factory that does not have the REST_OPERATIONS property set to NONE. By default, no Majic fatory has this property set to NONE. Use the REST_OPERATIONS property to set the specific HTTP CRUD (CREATE, READ, UPDATE, DELETE) methods for CA SDM to expose on a given Majic factory. **Default:** rest_access **Example:** rest_access, cnt, grp, cr, crs, pri, alg, urg, imp, pcat, org
hmac_algorithm	Specifies the algorithm that you use to compute the signature for Custom/Secret Key Auhentication in REST Web Services. **Default:** HmacSHA1
string_to_sign_fields	Specifies the fields that you use to compute the signature for Custom/Secret Key Authentication in REST Web Services, in addition to the default REQUEST_METHOD, REQUEST_URI, and QUERY_STRING fields. **Default:** blank
webservice_domsvr	Specifies the name of the object engine that SOAP web services use. If not installed, SOAP web services use "domsvr". The value of the option must be a string beginning with the characters "domsvr:"
webservice_session_timeout	Sets the timeout value (in minutes) for SOAP Web Service sessions. When the time between successive web method calls is greater than the value specified, the session ID is marked expired. The session is then no longer valid. To prevent sessions from expiring due to activity, set the value for this option to 0. Other methods, such as logoff routines, can still invalid sessions.

xMatters

xMatters is used for mass notifications and Alerts. When a CA SDM ticket (incident, request, or problem) is created or updated, the integration mechanism sends the notification along with ticket information to the xMatters agent. The notification works only with CA SDM CR objects (incident, request, or problem). The CA SDM notification feature sends notifications to users based on the rules set for notification. CA SDM sends the Notify Log Reader information automatically along with ticket information to the configured xMatters agent.

CA SDM administrators can enable or disable integration with xMatters through the Options Manager options. You must install these options as these options are not installed out of the box. Restart CA SDM services after installing or uninstalling these options. On successful installation of xMatters options, a new daemon the pdm_xmatters_sync is started and can be monitored through the task manager process list. This daemon is a singleton process and runs on the primary or background server.

The pdm_xmatters_sync daemon gathers notification records with status **Pending** or **Error** based on the **xmatters_retry_count** option value. It also maintains a list of newly created notification records. After the existing record list is run, the pdm_xmatters_sync runs the newly created record list. This is an ongoing process. In case of failure, when the xMatters agent is not available, the records wait for the time specified in the Options Manager **xmatters_retry_interval** option and re-triggers the pdm_xmatters_sync daemon till all records attain a status of either **Success** or **Abort**.

The pdm_xmatters_sync daemon runs the records in the same order in which they are created. Records having **xMatters-Pending** or **xMatters-Error** status are processed first and then, the newly created records are processed.

Based upon the set notification rules, the notification history page will have information along with the status.

Rule	Information
xMatters – Error	Return error code status to CA SDM. Indicates that this notification message was sent to xMatters agent but was not received by xMatters agent. This can happen due to xMatters agent not running or other issues with the agent. Notifications having this status will retry based on the Options Manager *xmatters_retry_count* and *xmatters_retry_interval*.
xMatters – Abort	Return error code status to CA SDM. Indicates that CA SDM triggered the number of iterations mentioned in the Options Manager *xmatters_retry_count* and *xmatters_retry_interval* options, but the xMatters agent did not receive this message.
xMatters – Success	This status indicates that xMatters agent received this notification message successfully and returned the success status code. These records can be shown from xMatters system web interface.

Install the following xMatter Options Manager Options. These options control the CA SDM and xMatters integration provides a reliable and stable mechanism to integrate notifications.

Option	Description
xmatters_cr_attr	The valid CR majic attribute name. Specify the request attributes for xMatters notification. This can include custom attributes.
xmatters_retry_count	The default and minimum value is set as 3 in the range [1-20]. This value indicates the number of times the retry option can be triggered for failed transactions or notifications.
xmatters_retry_interval	The default and minimum value is set as 15 minutes in the range of [15-999]. This value indicates the time gap between each retry and specifies the retry interval duration in minutes for each failed xMatters notification.
xmatters_URL	Valid xMatters server agent and port number. Specifies the xMatters integration URL link. **Example URL:** http://<xmattersagentname>:<port>/http /caservicedesk15_caservicedesk15

For more information, see Create a Notification Method (see page 834) and Create Contacts Manually. (see page 1213) To complete the implementation of this option, you must define an event with these names. For more information, see create an event from How to Configure SLAs (see page 1099) topic.

Install/Uninstall Options Manager Options

Contents

You can install Options when installing CA SDM or can install them later. Some Options are automatically installed when you install the application that uses them.

Install an Option

You install an option from CA SDM. If you are using advanced availability configuration, you can install an option only from the background server. From the application or standby server, you can view the option details after it is installed.

Follow these steps:

1. Log in to the following server, depending upon your CA SDM configuration:
   - Conventional: Primary or secondary server
   - Advanced Availability: Background server
2. On the Administration Tab, browse to Options Manager.
   The Option Search page opens.
3. Search for the option you want to install.
   The Option Detail window opens.
4. Click Edit.
   The Update Option window opens.
5. Click Install.
   The Option Detail window displays a refresh message.
6. Click Refresh.
   The Option Detail window displays the Action Status of the option as "Installed."
7. Click Close Window.
8. Depending on your CA SDM configuration,

Important! Changes in some options do not require you to restart all the servers. Ensure that you read the Server Restart List (see page 1341) before restarting any server.

- Restart the CA SDM servers in conventional configuration (see page).
- Restart the CA SDM servers in advanced availability configuration (see page 866).

The Option List displays the updated status of the option when you restart the servers.

You can also install options from the command line using the following script:

```
$NX_ROOT/bin/pdm_options_mgr -c -b -a pdm_option.inst
```

Uninstall an Option

You can edit an option to uninstall it. If you are using advanced availability configuration, you can edit an option only from the background server. From the application or standby server, you can view the option details.

Follow these steps:

1. Log in to the following server, depending upon your CA SDM configuration:
   - Conventional: Primary or secondary server
   - Advanced Availability: Background server
2. On the Administration Tab, browse to Options Manager.
   The Option Search page opens.
3. Search for the option you want to uninstall.
   The Option Detail window opens.
4. Click Edit.
   The Update Option window opens.
5. Click Deinstall.
   The Option Detail window displays a refresh message.
6. Click Refresh.
   The Option Detail window displays the Action Status of the option as "Not Installed."
7. Click Close Window.
8. Depending on your CA SDM configuration,

   Important! Changes in some options do not require you to restart all the servers. Ensure that you read the Server Restart List (see page 1341) before restarting any server.

   - Restart the CA SDM servers in conventional configuration (see page).
   - Restart the CA SDM servers in advanced availability configuration (see page 866).

The Option List displays the updated status of the option when you restart the servers.

You can also uninstall options from the command line using the following script:

```
$NX_ROOT/bin/pdm_options_mgr -c -b -a pdm_option.deinst
```

Restart the CA SDM Servers in Conventional Configuration

For the conventional configuration, you restart the servers in the following order:

Note: To restart a server click Start, Settings, Control Panel, Administrative Tools, Services. Right-click the CA SDM Server and select Start.

1. Restart the secondary server.
2. Restart the primary server.

Restart the CA SDM Servers in Advanced Availability Configuration

For the advanced availability configuration, we recommend that you restart the CA SDM servers in the following order:

Note: To restart a server click Start, Settings, Control Panel, Administrative Tools, Services. Right-click the CA SDM Server and select Start.

1. Restart all Standby Servers.
2. Promote the Standby Server as the New Background Server (see page 867).
3. Start the Old Background Server.
   When you start the background server, it becomes a standby server.
4. Choose the Less Active Application Server (see page 868).
5. Restart the Less Active Application Server.
6. Stop the Other Application Server (see page 868).
7. Start the Application Server.
8. Perform the steps 6 and 7 for the other application servers.

Promote the Standby Server as the New Background Server

Before you stop the background server, promote the standby server (that you have upgraded) as the new background server. If Support Automation is installed with CA SDM, notify the active Support Automation users about the background server shutdown.

Follow these steps:

1. Execute the following command on the background server to notify all active users using Support Automation to save their work:

   ```
   sa_server_notifier [-h] | [-q seconds] | [-c]
   ```

   - **-h**
     Displays the help page.

   - **-q seconds**
     This option notifies a local server (background) to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. This option cannot be used for a standby server or application server.

   - **-c**
     This option cancels a previously sent quiesce request.

   A pop-up message is displayed to all the active users using Support Automation. This message notifies the users about the server shutdown and the time that is left for the shutdown. The users must save their work and logout within that scheduled time.

2. Execute the following command on the standby server that you wish to promote as the new background server:

   ```
   pdm_server_control  -b
   ```

   - **-b**
     Notifies a local standby server to become the background server. The standby server must already be running. If the server is not running, it is started but no failover is performed; to start a failover, run the command again.

   The background server shuts down automatically and the standby server is promoted as the new background server. This change does not affect the end-user sessions. The in-progress updates (if any) are stored and delayed, until the new background server comes online.

Choose the Less Active Application Server

You choose an application server with the least user activity. Run the following command on each application server to choose the one with no or minimal active sessions.

```
pdm_webstat
```

Note: This command does not capture the SOAP or REST Web Service sessions.

Stop the Other Application Server

You inform all the active users on an application server to move to the less active application server before you stop it. Ensure that you have restarted the less active application server before moving all the users to it.

Follow these steps:

1. (Recommended) Inform all active Support Automation analysts on the application server which you want to stop, to create a ticket in CA SDM with their session information. This process ensures that the session information is not lost. For example, the Support Automation analyst is in a session with a customer to resolve a hardware issue. In such a case, the Support Automation analyst can create an issue in CA SDM with the session information before the application server shuts down.

2. Send a notification (for example, an email notification) to all the active users on the application server to move to the less active application server that you just restarted. This notification can include the details of the updated application server.

3. Execute the following command on the application server:

   ```
   pdm_server_control [-h] -q interval -s server_name
   ```

   - **-h**
     Displays the help page.

   - **-q interval -s server_name**
     Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

   A pop-up message is displayed to all the active users on the application server to notify them about the server shutdown and the time left for the shutdown. The users must save their work and logout within that time. The application server stops after the specified time. The users log on to the other application server to resume their work. The Support Automation analyst can refer to the ticket and resume their work.
   The application server is stopped successfully.

Server Restart List

Depending upon the CA SDM configuration, restart the following servers:

- Conventional: Primary server

- Advanced Availability: Application, Background, and standby servers. The following options do not require you to restart all the servers:

Options Type	Options	Action

Change Order	Category_Defaults, chg_auto_events, chg_sla	Restart all servers *quickly* to maintain functionality consistency. Change in these options contains Majic and/ or Spel changes
Email	mail_from_address, mail_login_password , mail_login_userid, mail_max_threads, mail_reply_to_address, mail_smtp_domain_name, mail_smtp_hosts, mail_smtp_host_port, mail_smtp_security_level	Restart all standby servers and then the current background server.
Issue Mgr	iss_auto_events, Iss_Category_Defaults, iss_sla	Restart all servers *quickly* to maintain functionality consistency. Change in these options contains Majic and/ or Spel changes.
LDAP	ldap_dn, ldap_enable_tls, ldap_group_object_class, ldap_host, ldap_port, ldap_pwd, ldap_search_base, ldap_service_type, ldap_user_object_class, num_ldap_agents	Restart all standby servers and then the current background server.
Request Mgr	Area_Defaults, auto_events, cr_sla, Netres_pty	Restart all servers *quickly* to maintain functionality consistency. Change in these options contains Majic and/ or Spel changes.
Request-Change-Issue	Any_Contact	Restart all servers *quickly* to maintain functionality consistency. Change in these options contains Majic and/ or Spel changes.
Search Engine	ebr_cr_where_clause, ebr_index_queue_timeout, ebr_iss_where_clause, ebr_max_qps, ebr_qps_timeout, ebr_search_engine_	Restart all standby servers and then the current background server.

	baseport, ebr_search_engine_host, ebr_version	
Security	force_unique_userid	Restart all servers *quickly* to maintain functionality consistency. Change in these options contains Majic and/ or Spel changes.
Support Automation	sa_domsrvr, sa_primary_domsrvr	Restart all standby servers and then the current background server.
Time-to-Violation	ttv_evaluation_delay	Restart all standby servers and then the current background server.
Web	export_max_fetch_rows	No action required. Changes to this option takes effect when the user exports the list.
Web	web_wildcard_search	Restart all standby servers and then the current background server.
Web Service	hmac_algorithm, rest_webservice_access_duration, rest_webservice_disable_basic_auth, rest_webservice_list_max_length, rest_webservice_list_page_length, rest_webservice_resources_to_expose, string_to_sign_fields	Restart all application servers where RESTful Web Services are configured.

Multi-Tenancy

This section contains the following articles:

Multi-tenancy enables multiple independent tenants (and their users) to share a single implementation of CA SDM. All Tenant users interact with each other in defined ways as per assigned roles and tenant hierarchies. Typically, each tenant views the CA SDM implementation as per the assigned access right. Tenants cannot update or view data that are related to other tenant unless specified.

Multi-tenancy allows tenants to share hardware and application support resources and reduce cost.

Service Provider

This article contains the following topic:

The service provider is the primary tenant (owner) in a CA SDM multi-tenancy installation. The first tenant added to a CA SDM installation is always the service provider tenant. The service provider tenant cannot have a parent tenant.

CA SDM associates the privileged user (typically ServiceDesk on Windows, or srvcdesk on Linux/UNIX) with the service provider tenant.

Only the service provider tenant can perform any of the following CA SDM tasks:

- Set the CA SDM options
- Set the Knowledge Management options
- Set the Support Automation options
- Create the tables or columns
- Create, edit, or delete the tenants
- Allow the tenants to have subtenants
- Update the public data

Note: An administrator can grant tenant users access to data other than their own. The Non-Service Provider tenant analysts have access to only their tenant and sub-tenants. For example, a role definition can set separate read and write access to certain tenant groups for users within that role.

Important: When a tenant is created and set as the service provider, the service provider check box and record status fields are read-only.

Service Provider Administration

The service provider can permit tenants to administer their own settings. The Tenant administrators have access to a subset of administration tasks that is the same for all tenants. The default Tenant Administrator role defines the administration functions that are available to tenant administrators. To designate a user as a tenant administrator, select the Tenant Administrator for that user role.

How Multi-Tenancy Works

This article contains the following topics:

After enabling CA SDM multi-tenancy, you can grant contacts access to all tenants (public), a single tenant, or a tenant group (user-defined or product-maintained). A contacts role controls access and specifies the read-write access independently. As the tenant access is role-dependent and a contact can modify roles during a session, contact tenant access is also subject to change.

Most of the CA SDM objects when multi-tenancy is installed include a tenant attribute to specify owner of the object. Objects fall into three groups, depending on their tenant attribute and how it is used:

Untenanted

Defines objects without a tenant attribute. All data in these objects is public.

Examples: Priority and urgency.

Tenant Required

Defines objects with a tenant attribute that cannot be null (enforced by CA SDM, not the DBMS). All data in these objects is associated with individual tenants; there is no public data.

Examples: Ticket tables (Request, Issue, and Change Order).

Tenant Optional

Defines objects with a tenant attribute that can be null. Some of the data in these objects is public, and some is associated with specific tenants. Each tenant's view of the object is a merged view of the public data and their tenant-specific data.

Examples: Category and location.

When a user queries the database, CA SDM restricts the results to objects belonging to tenants. The user is authorized to access these tenants. This restriction applies in addition to any data partition restrictions that are in effect.

If a user creates an object with update access to multiple tenants, the user must specify the tenant explicitly.

Note: Few SREL references (such as the assignee of an incident) are permitted to reference objects that belong to tenants in their containing object's tenant hierarchy. Such references are designated as SERVICE_PROVIDER_ELIGIBLE in the CA SDM object schema (the Majic). The SERVICE_PROVIDER_ELIGIBLE flag makes a difference only if the service provider tenant is not in the tenant hierarchy; if the service provider tenant is in the hierarchy, tenant validation rules permit service provider references.

Note: If CA SDM limits a user from updating tenant data, an error message can announce a data partition limitation. If you receive this error message, either data partition or multi-tenancy restrictions are in effect.

The Multi-Tenancy Option

You activate multi-tenancy by installing one of the following multi-tenancy options:

- **Off** -- Multi-tenancy is not in use. Multi-tenancy features are not available, and objects do not have a tenant attribute. This option is the default setting at a new CA SDM installation.
- **Setup** -- Multi-tenancy features are in effect for administrators, so that tenant-related objects and attributes are visible and editable. However, CA SDM does not enforce tenancy restrictions, and non-administrator users see no changes. This setting allows an administrator to prepare for multi-tenancy by performing such tasks as defining tenants or assigning objects to tenants without impacting normal use of CA SDM.
- **On** -- Multi-tenancy is fully operational. All users see the UI changes appropriate to them, and CA SDM enforces tenancy restrictions.

Tenant Information

You create and update tenants when you install multi-tenancy (in either setup or full enforcement mode). Information that is maintained for a tenant is similar to the data maintained for Organization, except for the following two attributes:

- **Logo**
  Provides a URL to an image file with the logo of the tenant. The logo is shown both on the Tenant Detail page itself, and as a substitute for the CA logo on web forms that are displayed by a tenant user or showing an object that is associated with the tenant.
- **Service Provider**
  Indicates whether the tenant is the service provider. The service provider tenant is always the first tenant added. When the administrator adds the first tenant:
  - The first tenant becomes the service provider. This designation cannot be changed.
  - The privileged user (usually ServiceDesk) and all system contacts (such as System_AHD_Generated) are set to belong to the new service provider tenant.

Note: The system user "Administrator" is added in Windows only and is not assigned a tenant. The privileged user must assign a tenant to Administrator manually.

Tenant Access

The role of a CA SDM user governs both access authorization and the user interface. The set of roles available to users depends on their access type. Multi-tenancy lets you control the tenant or tenant group that a user can access within the role.

The Role Detail page provides Tenant Access and Tenant Write Access drop-down lists on its Authorization tab. Tenant Access is view-only, and Tenant Write Access also allows create and update.

You can assign the following associations to roles:

- **Same As Tenant Access (Tenant Write Access Only)**
  Sets Tenant Write Access to be the same as the Tenant Access setting. Default for Tenant Write Access and only valid for Tenant Write Access.

- **All Tenants**
  Removes tenant restrictions. CA SDM allows a user in a role with this access to view any object in the database (read access) or create and update (write access) any tenanted object in the database. When users with All Tenant access create an object, CA SDM requires that they select the tenant of the new object.

- **Single Tenant**
  Sets a role's tenant access to a named tenant. When this option is selected, a second field appears on the web UI that allows selection of a specific tenant. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects that are associated with the named tenant. This selection is valid for either Tenant Access or Tenant Write Access.

- **Tenant Group**
  Sets a role's tenant access to a user-defined or system-maintained tenant group. When the Tenant Group option is selected, a second field appears on the web UI that allows selection of a specific tenant group. CA SDM restricts a user with the role to view (read access) or create and update (write access) only those objects that are associated with one of the tenants in the group. When a user with tenant group access creates an object, CA SDM requires that they select the tenant for the new object. This selection is valid for either Tenant Access or Tenant Write Access.

- **Contact's Tenant**
  Sets a role's tenant access to the tenant of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects that are associated with their own tenant. This selection is valid for either Tenant Access or Tenant Write Access.

- **Contact's Tenant Group (Analyst Only)**
  Sets an analyst's role access to the tenant group that the analyst works with, as specified on the analyst's contact record. If the user with the role is not an analyst, this selection has the same effect as Contact's Tenant. It is valid for either Tenant Access or Tenant Write Access.

- **Contact's Subtenant Group**
  Sets a role's tenant access to the Subtenant group of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects that are associated with their own Subtenant group. This selection is valid for either Tenant Access or Tenant Write Access.

- **Contact's Supertenant Group**
  Sets a role's tenant access to the Supertenant group of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects that are associated with their own Supertenant group. This selection is valid for either Tenant Access or Tenant Write Access.

- **Contact's Related Tenant Group**
  Sets a role's tenant access to the Related Tenants Group of the contact using it. CA SDM restricts a user in a role with this access to view (read access) or create and update (write access) only those objects that are associated with their own Related Tenants Group. This selection is valid for either Tenant Access or Tenant Write Access.

All users can view public data, regardless of their current role's access rights. The Update Public check box controls whether a service provider user in the role has the authorization to create or update public data. The Tenant users (users belonging to a tenant other than the service provider) cannot update public data, regardless of their role.

Edit Tenant Access for a Role

The role of a CA SDM user governs both access authorization and the user interface. The set of roles available to users depends on their access type. Multi-tenancy lets you control the tenant or tenant group that a user can access within the role.

The Role Detail page provides Tenant Access and Tenant Write Access drop-down lists on its Authorization tab. Tenant Access is view-only, and Tenant Write Access also allows create and update.

You can assign or edit tenant access for a role.

Follow these steps

1. Navigate to Security and Role Management, Role Management, Role List.

2. Click a role and click Edit.

3. Select options for Tenant Access and Tenant Write Access.
   Note: Exercise caution if you select different options for these settings.

4. Click Save.
   The updated tenant access options are saved for the role.

Tenant Terms of Usage

An end user is presented with a terms of usage statement while logging in the CA SDM application. The terms of usage statement is regarding proper usage, terms and conditions of using the product by the end user. The user must agree to the terms before logging to CA SDM. Entries are written to the standard log and in the user event log after the attempted session login.

You can perform the following terms of usage actions:

- Create, update, and delete a terms of usage statement.
- Associate a terms of usage statement with a tenant.

  Note: You must enable multi-tenancy and configure one or more tenants before associating a terms of usage statement with a tenant.

- Force the end user to accept the statement every time they log in.
- Let the end user ignore the initial statement by presenting a blank terms of usage statement.

For more information about creating terms of usage statement, see Setting Up Terms of Usage (see page 1000).

How to Configure Terms of Usage

The terms of usage statement presents the end user with an initial page statement when they log in to CA SDM. The statement reminds the user about the proper use of the product. The user must agree to the terms before they can continue to log in to CA SDM. If the end user selects Accept, CA SDM proceeds with the login and displays the main form. If the user selects Reject, CA SDM returns to the login. Entries are written to the standard log and in the user event log after the attempted session login.

Typically, you configure the contact tenant terms of usage statement. If the contact tenant is configured with an inactive terms of usage statement, the terms of usage is not configured, or if <empty> is selected in the Terms of Usage drop-down list, CA SDM displays the terms of usage statement for the tenants parent, grandparent, and so on. If no terms of usage statement is found at any level, CA SDM proceeds with the login. If you configure a tenant with a blank terms of usage statement, CA SDM proceeds with the login and displays the main form.

You can configure terms of usage as follows:

1. Enable multi-tenancy (see page 974).
2. Configure one or more tenants (see page 974).
3. Define a terms of usage statement (see page 1001).
4. Update a tenant to use the specific terms of usage statement (see page 1001).

User Interface Impact

This article contains the following topics:

Installing the multi-tenancy feature changes the user interface, depending on the authorization and tenant access that is associated with the user role. The changes affect both tenant users and service provider users.

Tenant Users

If the role of a user is restricted to a single tenant and the user is not an administrator, substitute a custom tenant logo for the default CA Technologies logo on all pages. Substitution depends on whether a logo is defined on the Tenant Detail page for the tenant.

For non-administrator tenant users, the user interface menu items or buttons allowing update or edit are suppressed for public objects. The tenant users are not authorized to update the public object.

Tenant Administrators

List pages for these objects automatically include a Public column specifying whether the list row is public data. In addition, the first element in the search filter is a Public Data drop-down list containing the following selections:

- Include (default)
- Exclude
- Only

A tenant administrator with access to multiple tenants sees a Tenant column on list pages for any tenanted object. This column takes the place of the Public column in lists of tenant optional tables.

Users with View access to a Tenant Group

A user role allows view access to multiple tenants.

- **Untenanted objects**
  Untenanted objects contain only public data. The service provider user is allowed to create or update an untenanted object only if their role has Update Public authorization. If not, the UI suppresses menu items or buttons allowing update or edit, such as the Edit button itself, or the Create New button on a list page. Tenant users cannot update public objects, and these users never see an Edit or Create New button on a list page for an untenanted object.

- **Tenant-required objects**
  Tenant-required objects contain only data associated with a particular tenant. List forms for these objects automatically include a Tenant column after the last link column. In addition, the search filter contains a tenant selector allowing the user to restrict a list to a single tenant.

- **Tenant-optional objects**
  Tenant-optional objects contain both public and tenant-specific data. List forms for these objects automatically include a Tenant column (a blank tenant indicates a public object). In addition, the search filter contains both a tenant selector and a Public Data drop-down list (the same one seen by tenant administrators).

Note: If tenant required tables incorrectly contains untenanted data in a multi-tenancy system, a public data drop-down list appears in tenant required tables. The following message: “AHD05358 is displayed. There were untenanted active xxx objects at Service Desk startup.”

Users with Update Access to Multiple Tenants

If a user role allows access to multiple tenants, or a service provider user role has Update Public authorization (typical for an analyst that works for a service provider), detail pages change as follows:

- **Untenanted objects**
  Untenanted objects contain only public data. There are no changes to their detail pages for a service provider user with Update Public authorization. If the user is in a role without Update Public authorization, or does not belong to the service provider, read-only pages for untenanted objects are with no Edit button.

- **Existing Tenant-required objects**
  Tenant-required objects contain only data that are associated with a particular tenant. Detail pages for existing tenant-required object show the object tenant as part of the standard page header.

- **Tenant-optional objects**
  Tenant-optional objects contain both public and tenant-specific data. The detail page for these objects depends on whether the user belongs to the service provider and is in a role with Update Public authorization:

  - If a service provider user role has Update Public authorization, the detail page is the same as that for tenant-required objects.

  - If the user role does not have Update Public authorization, or the user does not belong to the service provider, detail pages for public objects do not have an Edit button. Other detail pages are the same as those for tenant-required objects.

Support Automation Impact

The impact of multi-tenancy on your support environment depends on tenant and role restrictions that are placed on end users and analysts. The Service Provider manages read/write permissions for both public and tenant-specific data. For example, an analyst can handle assistance sessions from the public queue and a tenant-specific queue, but the analyst can only use Live Assistance tools that are enabled for each tenant.

For end users with Support Automation access, do not configure the end user to have write access to a tenant that is not a sub-tenant of the owning tenant of the end user, unless the foreign key (FK) group is altered to include the owning tenant. If the end user selects a login tenant, or is invited

through a ticket in a tenant that does not meet this criterion, they receive an error when they try to access the Support Automation end-user client. This restriction does not apply if the owning tenant of the end user is the service provider tenant.

For analysts with Support Automation access, do not configure the analyst to have write access to a tenant that is not a sub-tenant of the owning tenant of the analyst, unless the foreign key (FK) group is altered to include the owning tenant. If the analyst attempts to handle an end user, or invite an end user from a ticket, in a tenant that does not meet this criteria, the analyst sees an error.

Analysts and end users without read access to their tenant cannot launch the Support Automation client. For analysts, a warning message appears in CA SDM in this case, such as from the main Support Automation tab.

You can use the following roles to manage Support Automation users:

- **Support Automation Analyst**
  SA Analyst provides end-user support using Live Assistance. The Service Provider determines the appropriate tenant access and can enable Live Assistance tools and can read/write access to automated tasks.

  Important! If a non-Service Provider analyst has write access to a parent, sibling, or unrelated tenant, function access must be updated for that tenant. Analysts without read access to their tenant cannot launch the Support Automation analyst client, and a warning message appears in CA SDM, such as from the main Support Automation tab or a ticket.

- **Support Automation Administrator**
  Configures the Support Automation environment for analysts and end users. The Service Provider determines your tenant access and lets you view a tenant drop-down list on List and Detail forms. These forms let you select specific tenants or public data when searching, creating, and modifying Support Automation data in a multi-tenancy environment.
  Note: Objects such as queues, privacy levels, and chat presets are tenant optional.

Knowledge Management Impact

This article contains the following topics:

The impact of multi-tenancy on your knowledge environment depends on the tenant restrictions that are placed on users:

- **Tenant Users**
  Substitutes the logo of the tenant for the default, if the role is restricted to a single tenant.

- **Tenant Administrators**
  This option enables administrators to view both public and tenant-specific data. List pages for these objects automatically include a Public column specifying whether or not the list row is public.
  When searching for knowledge, the filter contains a Public Data drop-down list with selections of Include (default), Exclude, and Only.

Note: Objects such as approval process templates, categories, documents, files and forums are tenant optional.

Knowledge Categories and Documents

Knowledge Documents and Knowledge Categories are both tenant optional. Consider the following information for tenant optional and public objects:

- Public Knowledge Documents can only be added under public Knowledge Categories.
- Public Knowledge Categories can only be added under public categories.
- Tenant categories can be added under public categories and under tenant categories.
- Only tenant documents can be added under tenant categories.
- Public and tenanted documents can be added under public categories.

Note: The Cut/Copy/Paste category functionality is allowed only if the source and destination have the same tenant, or if the destination is public.

Repositories are defined as tenant optional, so the administrator can create different repositories for different tenants.

Embedded images are allowed only when the document and image are set to the same tenant. Attachment Folders, Attachments and Attachments to document links are also defined as tenant optional.

FAQ Rating

When viewing the FAQ rating for tenant users, consider the following information about public documents:

- Public documents are viewed by a larger audience than tenant users.
  The FAQ rating of public documents is higher than a tenant-specific document.

- Each tenant has different needs, so usage patterns are different between tenants.

The Top Solutions on the CA SDM home page displays the top five public documents, as well as a tenant's top five documents.

You can configure the Top Solutions by navigating to Knowledge, Solution Survey, FAQ Settings on the Administration tab.

Knowledge Report Card

The Knowledge Report Card allows analysts and administrators to view various metrics such as document creation, publication, hits, and votes. This report is for a predetermined time period, per analyst, category, and organization.

When using the Knowledge Report Card to provide information for a role having single tenant access, the data is limited by the tenant criteria.

Create a Remote Reference

You can configure remote references to execute external programs from the CA SDM application. CA SDM lets you create a remote reference to an external program.

Follow these steps

1. Select Service Desk, Application Data, Remote References on the Administration tab.
   The Remote References List page appears.

2. Click Create New.
   The Create New Remote Reference page appears.

3. Fill in the remote reference fields (see page) as appropriate.

4. Click Save.
   The remote reference definition is saved and the Remote Reference Detail page appears.

Remote Reference Fields

You can use the fields on the Remote Reference pages to define, search, and edit Remote Reference definitions.

Note: All search fields that allow text entry support use of the % wildcard character.

The following fields require explanation:

- **Function Access**
  Specifies the functional area where the remote reference belongs. For example, if the reference pertains to administrative functions, select Admin. If the reference pertains to notifications, select Notify.

- **Architecture Type**
  Specifies the appropriate operating environment for the remote reference (Windows or UNIX).

- **NT Server, UNIX Server, or UNIX Client Exec Command**
  Specifies the character string that executes the remote reference on a Windows server or a UNIX operating environment.

You can click the More icon to display the Additional Search Arguments field. This field is intended only for expert users who understand SQL and Majic. You can enter a SQL WHERE clause in this field to specify an additional search argument.

Audit Log List

The Audit Log List displays information regarding changes to the issue, change order, requests, and data partition tables. The audit log captures the user ID and an associated day/date/time stamp. The log also records the before and after values of the operation performed (update or insert). You can search the Audit Log List, and can use the results for report generation.

The Audit Log is automatically installed. Enable it by installing the Audit Log options with the Options Manager:

- audit_ins
- audit_upd (see Audit Log Options)

Define Form Groups

Form groups define the sets of pages in the web interface that are available to a role. Each role can have one form group. Users can display only the web pages that are included in the form group that is assigned to their role.

You can create a form group to specify which forms are visible to the members of a group.

Follow these steps

1. From the Administration tab, navigate to Service Desk, Form Groups.
   The Form Group List page appears.

2. Click Create New.
   The Create New Form Group page appears.

3. Fill in the following fields:

- **Symbol** -- A unique identifier for the form group.
- **Record Status** -- Indicates whether the form group is active or inactive.
- **Description** -- Provides a detailed description of the form group. Identifies the forms that are contained in the group or the roles that would use this form group.

SOAP Web Services Policy

This section contains the following articles:

Create a SOAP Web Services Error Type

CA SDM SOAP Web Services provide a defined set of default error types, which are created for*every* policy. The default types that are designated as *internal* error types, can be deactivated but cannot be deleted. Use the Web Services Access Policy Detail page to see the default error types when a policy is created.

CA SDM provides the following default error types:

The following information describes each internal error type:

- **ACCESS_ERROR**
  Indicates that the system failed to connect to or find a resource, such as a file or website.
- **EXCEPTION_FATAL**
  Indicates that the application is shutting down unexpectedly.
- **EXCEPTION_RUNTIME**
  Indicates that the application code encountered an exception.
- **LOGIN_ERROR**
  Indicates that the operator failed to gain access to the application.

You can create SOAP Web Services error types.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps

1. Select SOAP Web Services Policy, SOAP Error Types on the Administration tab.
   The SOAP Web Services Error Type List page appears.

2. Click Create New.
   The SOAP Create New Web Services Error Type page appears.

3. Fill in the SOAP Web Services Error Type fields (see page) as appropriate.

4. Select the Duplicate Handling tab to define the actions to take if the system detects an identical ticket that exists in the system. Select one of the following options:

   - Create the ticket and ignore duplicates. This option is the default action.
   - Do not create a ticket; add an activity log to the existing duplicate.
   - Do not create a ticket; add an entry to the CA SDM standard log.
   - Create a ticket and attach it as a child to the duplicate.

   A ticket is considered a duplicate when all following statements are true:

   - At least one ticket of the same type (request, issue, change order) and is ACTIVE.
   - The existing ticket was created using the web service.
   - The existing ticket was created with the same Policy and Error Type as the potential new ticket.
   - The create date of the existing ticket is within a specified threshold (for example, it was opened less than two days ago). This threshold is specified in the Maximum time interval for searching for duplicates field. Use the format of: HH:MM:SS.

5. Select the Return Data tab to specify data that indicates an action to take or a message displayed to the user.

6. Click Save.
   The SOAP Web Services error type is created.
   The error type definition is saved and the SOAP Web Services Error Type Detail page appears.

SOAP Web Services Error Type Fields

The following fields require explanation:

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

- **Code**
  Specifies the unique code that identifies the error type to the system. This field is required.

- **Owning Policy**
  Specifies the web services access policy that owns this error type.

- **Default**
  Indicates that this type is the default error type for the policy. Only one active default error type is allowed. If this option is selected while creating an error type, the default setting of the current default error type is removed.

- **Internal**
  Indicates whether this type is a default error type.

- **Ticket Template Type**
  Specifies the type of ticket that is created when this error is reported.

- **Ticket Template Name**
  Identifies the template to use to create a ticket when this error is reported.

> **Note:** The owning policy contact is the end user of the ticket.

Create a SOAP Web Services Policy

To minimize web services ticket flooding, and to maintain the stability of the server, CA SDM SOAP Web Services uses an Access Control and Management system. Handles excessive service activities by trusted user applications resulting from programming errors or exceptions. This system also works as a barrier and controls access to CA SDM SOAP Web Services from malicious attackers.

> **Note**: CA SDM provides a default access policy that has a code of DEFAULT. The default access policy contains no access restrictions and is only applied to sessions authenticated through username and password.

You can create SOAP web services policies to control access from SOAP web services applications.

> **Note:** If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps

1. Select Administration tab, SOAP Web Services Policy, SOAP Policies.
2. Click Create New.
3. Fill in the fields as appropriate.
4. Select the Access Control tab to define the number of operations permitted per hour for each web services category.

5. Enter a number in each operation counter field to represent the number of operations that are permitted per hour.

   Note: The default value of -1 in any operation counter indicates that no restrictions apply to the corresponding operation. A value of 0 (zero) indicates that the corresponding operation is not allowed.

6. Select the Error Types tab to review the error types in effect for the web services policy.

7. To add an error type, click Add an Error Type.

8. Click Save.
   The policy definition is saved and the SOAP Web Services Policy Detail page appears.

SOAP Web Services Policy Fields

The following fields require explanation:

- **Code**
  Specifies the unique code that identifies the access policy to the system. This field is required.

- **Proxy Contact**
  Specifies the contact to use for all web service operations and security. You can enter a contact name directly into this field, or click the search icon to select the contact name.

- **Default**
  Indicates that this policy is the default policy. Only one active default policy is allowed. If you select this option when creating an access policy, the default setting of the current default policy is removed.

- **Has Key**
  Indicates whether a public key as been associated with this policy. This field is updated when a public key is associated with a policy using the pdm_pki utility and cannot be changed.

- **Allow Impersonate**
  Allows the policyholder to invoke the impersonate() web services method and create a web services session. Additional access authentication is not performed when creating the session. However, only when the grant_level of the new user access type is less than or equal to the access_level of the proxy user access type, can this method be successfully called.

  If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Manage Service Type and Service Type Events

This article contains the following topics:

Service types identify the levels of support service provided to or contracted by your service desk customers.

Create a Service Type

You can also use service types to categorize customers.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps

1. Select Service Desk, Service Types on the Administration tab.
   The Service Type List page appears.
2. Click Create New.
   The Create New Service Type page appears.
3. Fill in the service type fields (see page 1360) as appropriate.
4. (Optional) Use service type tabs (see page) to add events to the service type.
5. Click Save.
   The service type definition is saved and the Service Type Detail page appears.

Service Type Fields

The following fields require explanation:

- **Symbol**
  A unique identifier for this service type. Use the symbol to identify the service type. For example, to set up a service type that requires a response within an eight hour time period, assign the symbol 08_hr_resolution.
- **Ranking**
  Service types can be associated with various objects, such as contacts, organizations, categories, and priority codes. If different service types are associated with a ticket, the one that is used depends on the value in this field. The one with the lowest number has the highest priority. For

example, if an issue is opened and the Affected End-User contact has a 12-hour resolution service type, which is ranked as 2, while the priority code has a four-hour resolution service type and is ranked as 1. The service type for the issue is four hour resolution.
Enter a value of one or greater; values of 0 or negative numbers are not allowed.

- **Workshift**
  Specifies the dates, days, and hours when the service type is in effect. Usually coincides with your service desk is operating time period (for example, 24 Hours, Regular, or Non-Business Hours).
  The following rules apply to a workshift:

  - If you apply a workshift to a service type, stop and restart the service for the workshift to take effect immediately.
  - If a workshift for a service type has been specified, but one has not been specified for an event, the service type workshift is in effect.
  - If a workshift for an event has been specified, but one has not been specified for a service type, the service type workshift is ignored.
  - If a workshift for event and for service type have been specified, the service type workshift is ignored.

- **Timezone**
  The time zone for the service type. You can enter the time zone directly in this field, or click the search icon to select the time zone from a list.
  This time zone is used for triggering events in the system if the Use End-User Time Zone option is not selected.

- **Use End User's Timezone**
  Select this option if you want to use the timezone that is defined for the affected end user on a ticket for triggering events in the system.

- **Violation Cost**
  The cost that is incurred if the service type time limit is violated.

If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Service Type Tabs

The following tabs are available on the Create Service Type, the Service Type Detail, and the Update Service Type pages:

Requests

- **Requests**
  Allows you to add service type events to request tickets. The event object type must be Request.

- **Request Tasks**
  Allows you to add service type events to Request, Incident, and Problem workflow tasks. The event object type must be Request/ Incident/ Problem Workflow Task.

- **Request Targets**
  Allows you to link a Service Type to a Service Target Template for managing Request, Incident, and Problem tickets.

Change Orders

- **Change Orders**
  Allows you to add service type events to change order tickets.

- **Change Order Tasks**
  Allows you to add service type events to change order workflow tasks. The event object type must be Issue Workflow Task (not Workflow Task).

- **Change Order Targets**
  Allows you to link a Service Type to a Service Target Template for managing Change Orders.

Issues

- **Issues**
  Allows you to add service type events to issue tickets.

- **Issue Tasks**
  Allows you to add service type events to issue workflow tasks. The event object type must be Issue Workflow Task (not Workflow Task).

- **Issue Targets**
  Allows you to link a Service Type to a Service Target Template for managing Issues.

Attach a Service Type Event

Service types determine the level of support that is given for a ticket. You can associate service type events with tickets. An event that is associated with a service type is attached to records defined with that service type.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Select the desired ticket from the list that appears.

4. Choose the Service Type tab, and click Attach Service Type Event.
   The Attach Service Type Event page appears.

5. Click Service Type Event.
   The Event Search page appears.

6. Complete one or more of the search fields, and click Search.
   The Event List displays the events that match your search criteria.

7. Select the desired event.
   The Attach Service Type Event page appears.

8. Click OK.
   The Delay Time field appears. The delay time indicates the interval of time after which the event occurs.

9. Specify the delay time as hh:mm:ss (hours, minutes, seconds).
   For example, if the event is attached to the incident at 2:20, and the Delay Time is 01:00:00 (one hour), the event occurs at 3:20.

10. Click OK.
    The ticket detail page appears with the event listed on the Service Type tab.

Create Service Type Event

You can create service type events for requests, change orders, change order tasks, issues, and issue tasks.

Follow these steps

1. From the Service Type Detail page, select the appropriate tab (Requests, Change Orders, Change Order Tasks, Issues, or Issue Tasks).
   The Event List for the ticket type appears.

2. Click Add Service Type Event.
   The Create New Service Type Event page appears.

3. Fill in the fields on this page, including:

   - **Event**
     The name of the event to which this service type event is attached. An event is a procedure that is automatically followed after a certain amount of time has elapsed. Events consist of checking for conditions and performing actions that are based on the results of those conditions. Attach events to tickets to make it easier to monitor and take measures to close these tickets.
     For example, an event may send a message if a priority 1 issue is not resolved in an hour. The event begins when an hour has elapsed. First, the system checks for the condition, which is "open issues with the priority of 1." If the condition is true, the system performs an action, which is sending the message.

   - **Delay Time**
     The interval of time after which the event occurs. Specify the delay time as hh:mm:ss (http://hhmmss/), For example, if an event is attached to an issue at 2:20, and the Delay Time is 01:00:00 (one hour), the event occurs at 3:20.

4. Click Save.
   The tab definition is saved and the Tab Detail page appears.

Delay or Resume a Service Type Event

You can delay and resume service type events.

Follow these steps:

1. Select the desired ticket from the list page on the Service Desk tab.
   The ticket detail page appears.

2. Select the Service Type tab.
   A list of any service type events that have been added to the ticket appears.

3. Click Delay or Resume.
   The Reason page appears.

4. Enter the reason, and click OK.
   The ticket detail page displays the Status of the event.

Create a Service Target Template

A service target is the estimated time frame for completing and resolving a ticket. To minimize Service Level Agreement (SLA) violations, create service target templates for analyzing each stage of ticket resolution. *A* service target template *is* a set of service targets with conditions for managing and prioritizing tickets. Each template identifies a condition, deadline, and relative cost for failing to complete the service target on time.

You can apply service target templates to requests, incidents, problems, change orders, and issues. When you link the service target template to a service type for a ticket, the service target automatically attaches only to new tickets.

On new tickets with service targets, analysts can use the Remaining Time and Violation Cost fields to prioritize ticket resolution. During ticket creation, a service type assigns one or more service targets to track each stage of the ticket resolution. Each time the ticket opens or changes, the active service target evaluates the condition. If the condition is met, the ticket and activity log show the actual completion time.

Note: If you are also using priority calculation, fields such as Priority automatically update and can affect the way service targets attach to tickets. After you configure a service target template, test your service targets on the intended ticket type.

You can create a service target template to measure service targets for requests, incidents, problems, issues, or change orders. After you create the template, you can link it to a service type.

Note: If multi-tenancy is installed, specify the tenant in the Tenant field.

Follow these steps:

1. Select **Service Desk**, **Service Target Templates** on the **Administration** tab.
2. Click **Create New**.
3. Select a ticket type from the **Object Type** field, and click **Continue**.
4. Complete the following fields as appropriate:
   - **Name**
     Defines a descriptive identifier for the service target.
   - **Object Type**
     Identifies the ticket type for this service target.
   - **Target Duration**
     Specifies the maximum amount of time for service target completion in the hh:mm:ss (http://hhmmss) format.
   - **Workshift**
     Specifies the workshift which contains a range of working hours that are used in time calculations for a service target, for example, M-F 08:00-17:00.
   - **Cost**
     Defines information such as the estimated cost associated with missing the service target.
   - **Record Status**
     Indicates whether this target is active or inactive.
   - **Condition**
     Specifies the name of the condition macro or site-defined condition. Evaluates the ticket data and determines whether the service target is met.
   - **Required Outcome**
     Specifies a True or False value that indicates whether the service target is complete.
   - **Allow Set Actual**
     Specifies whether to allow users to set the date and time for a service target.
   - **Allow Reset Actual**
     Specifies whether to allow users to reset the date and time for a service target.
5. Click **Save**.
   The service target template is created.

Create Log Interval Configuration

Interval Logging allows you to collect resource usage data from the CA SDM servers. The collected interval log is used to analyze and troubleshoot any performance or memory-related issues in the CA SDM servers. You can also share the collected data with CA Support Online to help identify and resolve CA SDM server problems.

Note: For Windows, install and add the pslist.exe tool to the windows OS %PATH% environment variable on each of the CA SDM servers.

To collect the usage data on the CA SDM servers, add the servers to the Interval Log Configuration list. Select the type of data you want to collect from each server, and change the logging options for the servers.

For example, if you select only the CPU usage option for a particular server, the utility collects the server CPU usage data.

Follow these steps:

1. Select **System**, **Interval Logging** from the **Administration** tab.
2. Click **Create New** to add an interval logging configuration.
3. Complete the fields as appropriate for the configuration.
   - **Server Name**
     Specifies the server for which you want to collect the log data. Use the Search icon to view the list of servers you can add for the interval logging.
   - **Recurrence Interval**
     Specifies the time interval during which the log data is collected for the server in hh:mm:ss (http://hhmmss/) format. For example, if the recurrence interval is set to 3 minutes, the log data is collected for every 3 minutes.
     - **Default: 3 minutes**
     - **Minimum: 2 minutes**
   - **Enabled**
     Indicates whether logging is enabled or disabled for the server. If enabled, log data is generated for the server.
   - **Record Status**
     Indicates whether the interval logging configuration is active or inactive.
   - **Scheduled Start Date**
     Specifies the start date and time for collecting the log data. If you do not enter a start date, interval logging starts immediately till the configuration is active, enabled, or scheduled end date.
   - **Scheduled End Date**
     Specifies the end date and time for collecting the log data. If you do not enter an end date, interval logging continues to run till the configuration is active and enabled.
4. Select the appropriate interval log you want to collect from the server. For example, select CPU Usage if you want to collect the log for CPU usage data.

- **CPU Usage**
  Collect the CPU usage statistics for the server by executing the pslist - x on Windows, or "ps" on Unix.

- **Memory Usage**
  Collects the memory usage data for the server by executing the pslist - m on Windows, or "ps" on Unix.

- **Network Status**
  Collects the information of all active connections and network statistics by executing the netstat /b or /a.

- **Task List**
  Collects the application and services information for all the tasks running on the server.

- **Web Session Counts**
  Collects the CA SDM sessions and user statistics for the web engine processes by executing the pdm_webstat command.

- **Server Status**
  Collect the information about all CA SDM daemons or processes on the server by executing the pdm_status command.

- **DB Report**
  Collects the information of database record types by executing the db_report command.

- **Virtual DB Info**
  Collects the information that is related to queued database requests by executing the pdm_vdbinfo command.

- **List Server Connections**
  Collects the information on active connections for the server by executing the pdm_listconn command.

- **List Slump Processes**
  Collects the information about slump connections and processes by executing the slstat command.

Note: Depending on the selected server type, the interval logging options are enabled or disabled for the server.

5. Click **Save**.
   The server is configured for interval logging.

6. (Optional) Repeat Steps 1-5 to create more interval log configurations.

How to Manage Contact Groups

This article contains the following topics:

A group is a collection of contacts that represent a specific area of responsibility within your service desk. Groups let you assign responsibility for resolving a ticket.

For example, you can have a Dallas Human Resources group responsible for dealing with personnel issues in the Dallas office. You can assign employee issues and request redressal from the Dallas Human Resources group.

You can associate request areas, locations, and a work shift with a group. You can also determine how contacts within a group can accept the automatic assignment of a request.

Create a Group

A group is a collection of contacts that represent a specific area of responsibility.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Select Security and Role Management, Groups on the Administration tab.
2. Click Create New.
3. Complete the fields as appropriate for the group.
4. (Optional) Use the controls available on the tabs at the bottom of this page to configure the group.
5. Click Save.
   The group record is saved and the Group Detail page appears. The following buttons are now available for configuring the group:

-

- **Update Environment** -- The Configuration Item/Asset Search window for the group to specify search criteria for assets. Click Search and on the Environment Update window add and remove assets for this group.

- **Update Members** -- The Contact Search window to specify search criteria for the contacts for a group. Click Search and on th eContacts Update window to add and remove contacts for this group.

Set Up Group Notification Parameters

You can define the contact information and the method you want to use to notify a group.

Follow these steps:

1. On the Group Detail page, select the Notification tab.

2. Enter the appropriate contact information, such as Telephone Number, Fax Number, Email Address, etc.

3. Select the notification method you want to use for each message urgency level for this group (low, normal, high, and emergency).
   For example, you may want to notify this group using the Email method for normal level activities, but you may want to use the Pager_Email notification method for emergency level activities.

4. Select the workshift that is valid for each notification urgency level.
   For example, you may assign a Regular workshift (five-day week, eight-hours a day) to the normal level notification, but a 24 hour workshift to the emergency level notification.

5. Click Save to save the notification parameters.

Assign a Group to a Location

Locations precisely identify a specific physical place, such as the address of a particular company, or an office address. You can assign contacts, groups, and configuration items to a specific location.

Follow these steps:

1. On the Group Detail page, select the Address tab.

2. Enter the location where you want to assign the group, or click the search icon to select the location.
   The address information for the location is automatically filled in on the Address tab.

3. Click Save to assign the group to the selected location.

Assign a Group to an Organization

Organizations describe internal departments and divisions or external companies that can be assigned to tickets, CI classes, groups, and contacts.

Follow these steps:

1. On the Group Detail page, select the Organizational Info tab.
2. Enter the field values as follows:
   - **Functional Organization** -- The organization for which the group works.
   - **Department** -- The department where the group works.
   - **Administrative Organization** -- The organization to which the group reports for accounting purposes.
   - **Cost Center** -- The code to which this group's expenses are charged.
   - **Vendor** -- The name of the vendor associated with this group.
   - **Supervisor** -- The name of the person to which this group reports.

   Note: You can enter the values directly in the fields or click the search icon to search for the desired field value.
3. Click Save to save the organizational information to the group detail record.

Set Up a Group Environment

A group's environment consists of the equipment, software, and services they use.

Follow these steps:

1. On the Group Detail page, select the Environment tab.
2. Click Update Environment.
3. Enter the search criteria to display the desired configuration items and click Search. For more information, see Search Configuration Items.
4. From the list on the left, choose the configuration items you want to add to this group's environment. To choose multiple items, hold down the CTRL key while clicking the left mouse button.
5. When you have selected all the configuration items you want, click the double right-arrow button.
   The selected configuration items move to the Group Environment list on the right.
6. Click OK.
   The Group Detail page displays with the selected items listed on the Environment tab.

Group Remarks

You can enter notes regarding a group on the Remarks tab. These notes can be anything related to the group's role, or any other pertinent information that needs to be saved to the group detail record.

Follow these steps:

1. On the Group Detail page, select the Remarks tab.
2. Type the remarks in the Contact Notes field.
3. Click Save to save the remarks to the group detail record.

Assign Members to a Group

A group is a collection of contacts that represent a specific area of responsibility. Adding members (contacts) to your group lets you assign responsibility for resolving a ticket to several individuals who share this responsibility.

Follow these steps:

1. On the Group Detail page, select the Members tab.
2. Click Update Members.
3. Enter the search criteria to display the desired contacts and click Search. For more information, see Search Contacts.
4. From the list on the left, choose the contacts you want to assign to this group. To choose multiple items, hold down the CTRL key while clicking the left mouse button.
5. When you have selected all the contacts you want, click double right-arrow button.
   The selected contacts move to the Members list on the right.
6. Click OK.
   The Group Detail page displays, with the selected contacts listed on the Members tab.

Group Auto Assignments

The Auto Assignment tab lets you establish a relationship between change category, issues categories, and locations. You can automatically assign tickets (requests, change orders, and issues) using the request areas or category to eligible group members.

Important! The system administrator must enable automatic assignment for each request area and category individually. Listing them on the Group Auto Assignment tab does not enable this function.

Follow these steps:

1. On the Group Detail page, click Edit and select the Auto Assignment tab.
2. Click one of the following buttons:
   - Update Request Areas to select request areas for auto assignment.
   - Update Change Categories to select change categories for auto assignment.
   - Update Issue Categories to select issue categories for auto assignment.
   - Update Locations to select locations for auto assignment.

   The Search page for the selected item displays.
3. Enter the search criteria to display the items you want, and click Search.
   The Update page displays, listing the items that matched the search criteria.
4. From the list on the left, choose the desired items. To choose multiple items, hold down the CTRL key while clicking the left mouse button.
5. When you have selected all the items you want, click double right-arrow button.
   The selected items move to the Assigned list on the right.
6. Click OK.
   The Group Detail page displays, with the selected items listed on the Auto Assignment tab.

CA SDM Environment Promotion

CA Service Desk Manager Environment Promotion lets you promote configuration, customization, and object data changes between the source and target systems with minimal manual intervention. As an administrator, you can promote any configuration, customization, or object data changes between the development, test, pre-production, and production systems. For example, you can promote modified forms, added tables, columns, spel, majic files, object data to the production system. Based on the type of change (Configuration/Customization or Object Data), the environment promotion is initiated either through Command Line Interface or CA SDM User Interface.

How CA SDM Environment Promotion Works

CA SDM Environment Promotion works in the following two-phased manner:

1. Promotion of the configuration and customization of files.
   For more information, see SDMP Configuration and Customization . (see page 1374)
2. Promotion of the object data.
   For more information, see Database Promotion . (see page 1383)

All modifications made to the files, .htmpl, .mods, .spl, .maj, and so on, are directly stored in the *NX_ROOT/site/mods* folder. These files are copied from the *NX_ROOT/site/mods* folder and creates an export package. Any modification made to add tables and columns using the Web Screen Painter are stored in the database. These modifications are captured in the form of .dat files as part of the export package.

Prerequisites

Verify the following prerequisites before performing any environment promotion processes:

- To promote changes from the source to target system, ensure that the CA SDM 14.1.02 patch is applied on the CA SDM 14.1 or CA SDM 14.1.01 version.
- Close all the SDM-related files.
- Ensure that the CA SDM services are running before you perform Export or Import.
- When the environments are tenanted, both source and target systems must have the same tenants. The environment promotion does not create any tenants.
- To execute the export or import process, the user must have the operating system administrator privileges to create files and folders.
- The user must have access to Web Screen Painter to successfully execute the import process.
- The user must have read and write access to the *$NX_ROOT* *site* folder.
- Do not change the name of the exported zip file. If the exported zip file name is changed, the import process fails.
- For configuration and customization, the export or import process must be executed on the same type of servers, database, and operating systems.
  For example:
  - If an export is performed on a primary server, import of the package is allowed only on the primary server.
  - If an export is performed on a background server, import of the package is allowed only on the background server.
  - If an export is performed on a secondary server or application server, the import of the package is allowed only on the secondary server or application server.
    For more information about additional scenarios, see Approaches in Typical Environment Promotion Scenarios (see page 1374)
- Administrators are required to copy the .htmpl files to the secondary servers or application servers manually or modify the version control file to propagate the .htmpl files on the secondary servers or application servers.
- Ensure that the Apache Tomcat service is running before you perform database export.

- On Non-windows system, ensure that you enable X-Windows or an equivalent session to launch the browser for Web Screen Painter login.

- On Non-windows system, set the CA SDM bin path and CA SDM LIB path environment variables before executing the export or import process.

  For example:

```
For AIX:
export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
export LIBPATH=/opt/CA/ServiceDeskManager/lib:$LIBPATH

For Solaris and Linux:
export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
export LD_LIBRARY_PATH=/opt/CA/ServiceDeskManager/lib:$LD_LIBRARY_PATH
```

Tip: Performing environment promotion affects the CA SDM application performance and also restarts the services. We recommend that you perform the CA SDM Environment Promotion operations during off peak hours.

Approaches in Typical Environment Promotion Scenarios

Scenario 1: To perform environment promotion when the number of servers vary in the test and production systems.

On the source system, there is one primary server and one secondary server. Whereas, on the target system, there is one primary server and multiple secondary servers.

The environment promotion is successful when the configuration on all the servers is the same.

CA SDM Configuration and Customization

To promote your configuration and customization changes from the source to the target systems, perform the following tasks:

1. Verify the promotion prerequisites (see page 1372)
2. Export the configuration and customization (see page 1375)
3. Import the configuration and customization (see page 1376)

You can use the following SDMP command to execute the export, dryrun, or import processes:

```
sdmp -a <export/dryrun/import> -p <package name> -version
```

-a denotes actions such as export, dryrun, or import.

-p denotes the package name. This parameter is mandatory for dryrun and import processes.

-version displays the version details of CA SDM, Java, OS, Tomcat, and Database type.

-h denotes Help.

The history file *SDMP_HISTORY.HIS* located at *NX_ROOT*, captures the details of the operations performed when promoting configuration and configuration changes.

This section contains the following topics:

- Export (see page 1375)
- Import (see page 1376)
- How to Customize the SDMP CSV File (see page 1378)
- How CA SDM Environment Promotion Utility Works in Advanced Availability and Conventional Mode (see page 1380)

Export

CA SDM Environment Promotion lets you export the configuration and customization changes from the source system. These configuration and customization changes are captured on the source system, which you can import on the target system using the CA SDM Environment Promotion import process. The export process can be run on the primary, secondary, background, and application servers.

Warning: Do not initiate multiple export processes on your system.

Before initiating the export process, perform the following tasks:

- Set the **export_import_path, disk_space, timeout** property values in the SDMP Config properties file. For more information, see SDMP Config Properties File. (see page 1382)
- On Non-Windows, define the following environment variables:
  - Solaris and Linux: define the PATH and LD_LIBRARY_PATH environment variables.
  - AIX: define the PATH and LIBPATH environment variables.
    For example:

```
For Solaris and Linux:
export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
export LD_LIBRARY_PATH=/opt/CA/ServiceDeskManager/lib:$LD_LIBRARY_PATH

For AIX:
export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
export LIBPATH=/opt/CA/ServiceDeskManager/lib:$LIBPATH
```

Export Configuration and Customization Changes

To export the configuration and customization changes, execute the following export command:

```
Windows: sdmp -a export
Non-windows: sdmp.sh -a export
```

After initiating the ***sdmp -a export*** command, the export process validates the CA SDM release version and captures information about Java version, Tomcat Version, host name, OS name and version, CA SDM locale, database type, and server type. Files are copied as per the entries made in the *sdmp_files.csv* file. For more information, see How to make changes to SDMP Files . (see page 1378)

Warning: After export, do not rename the exported package name.

After successful completion of the export process, package and summary report files are generated. To view these files, navigate to *<export_import_path>/Promotion/Export* as specified in the SDMP Config Properties file. If the *export_import_path* property is empty, navigate to *NX_ROOT/Promotion /Export* to view the exported package and summary report. For more information, see SDMP Config Properties File. (see page 1382)

- Package

  `sdmp_export_yymmdd_hhmmss.zip`

  For example: **sdmp_export_151008_122725.zip**

- Summary Report

  `sdmp_export_summary_yymmdd_hhmmss`

  For example: **sdmp_export_summary_151008_122725.txt**

Note: You can skip the customization and promote only the configuration changes by setting *skip.validation.wsp* as *true*. For more information, see SDMP Config Properties File. (see page 1382)

If you encounter any errors or failures during the export process, verify the *sdmp.log* file in the *NX_Root/log* folder.

Import

For the import process, CA SDM 14.1 or CA SDM 14.1.01 versions must have similar installation configuration on both the source and target systems.

Before you initiate the import process, verify the following:

- Verify Prerequisites (see page 1372)
- Manually copy the exported package from the source system to the target system and place this package under the *NX_ROOT/Promotion/Import* folder. However, if you have set *export_import_path* in the SDMP config properties file, create *the Promotion/Import* folder under *export_import_path* and place the exported package.

Warning! Do not rename the exported zip file.

- Ensure that you have set the timeout value in the SDMP config properties file as per your environment. For more information, see SDMP Config Properties File . (see page 1382)
- On Non-windows system, set PATH and LD_LIBRARAY_PATH environment variables.
  For example:

```
For AIX:
export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
export LIBPATH=/opt/CA/ServiceDeskManager/lib:$LIBPATH
For Solaris and Linux:
export PATH=/opt/CA/ServiceDeskManager/bin:$PATH
export LD_LIBRARY_PATH=/opt/CA/ServiceDeskManager/lib:$LD_LIBRARY_PATH
```

- (Optional) Set the **export_import_path**, **disk_space**, **timeout** property values in the SDMP Config properties file. For more information, see SDMP Config Properties File (see page 1382).
- The user must have access to Web Screen Painter to successfully execute the import process.

How to Execute the Import Process

The CA SDM Environment Promotion performs *pdm_configure* as a part of the import process.

Warning: Do not initiate multiple import processes to avoid the target system resulting in an inconsistent state.

Tip: We recommend that you execute the dryrun process before executing the import process.

Follow these steps:

1. Execute the dryrun command:

   ```
   Windows: sdmp -a dryrun -p <exported package>
   Non-windows: sdmp.sh -a dryrun -p <exported package>
   ```

   The dryrun process reports failures, if any.

   For example: **sdmp -a dryrun -p sdmp_import_151008_122725**

   The process generates a dryrun summary report that is located in the *<export_import_path> /Promotion/Dryrun* folder. The summary report contains the number of files that needs to be imported, number of records to be loaded, and failure messages related to read and write access and validation failures (Text fixes, CA SDM version, locale, Java version, server type, and database Type.)

Note: When you encounter a patch level mismatch error, you can choose to fix or ignore the error, and proceed with the import.

2. Create a backup of *NX_ROOT* folder before you proceed with the import.

Note: If the import fails, restore the application files from the location where you saved the backup.

3. Execute the Import command and follow the on-screen instructions.

```
Windows: sdmp -a import -p <exported package>Non-windows: sdmp.sh -a import -p
<exported package>
```

For example: **sdmp -a import -p sdmp_import_151008_122725.zip**
The import process performs the following tasks on the target system:

- Validates that the CA SDM version, text fixes, locale, Java version, Tomcat version, server type, and database type of the target and source systems are similar.
- Generates a summary report, which contains the number of files and records imported, in the *<export_import_path>/Promotion/Import* folder.

4. After completing the import process, verify that the changes are reflected on the target system.

Note: To verify errors or failures encountered during the import process, check the *sdmp.log* file in the *NX_Root/log* folder.

5. If any failures are encountered during import, rerun the import process using the same package.

   The import process restarts from the point of failure.

How to Customize the SDMP CSV File

The import process uses the *SDMP_FILES.CSV* file as the input file, which manages the files for promotion. This article explains how to customize the *SDMP_FILES.CSV* file.

Important: The .exe and .dll files must not be considered for promotion.

Navigate to *NX_ROOT/site/cfg* directory, edit the *SDMP_FILES.CSV* file, and create entries in a sequential order as listed below:

- **path**: Specifies the relative path from NX_ROOT.
- **file**: Specifies the file name or wildcard characters (for example: ***.***,*.xml, eiam*.config).
- **extension**: Specifies the file extension.
- **group**: Specifies the logical group of files for exporting:
  - Onetime - Files that are rarely modified and require administrator intervention to compare the differences and merge manually on the target system. These files are not replaced on the target system.
  - Copy - Copies a specific file.
  - Environment - Files specific to the environment.
  - Recursive - Applicable for folders and sub folders recursively.
  - Reports - Files related to reports.
- **parser:** Controls file processing.
  - Copy: Copies a specific file.
  - Onetime: Files grouped as onetime require administrator intervention to compare the differences and merge manually on the target system. These files are not replaced on the target system. These files are available at *export_import_path/Promotion/Import/<import package>/<exported package>*. Check the respective folder. For more information, see SDMP Config Properties File (see page 1382) .
    If the *export_import_path* property value is empty, navigate to the *NX_ROOT/Promotion /Export* folder to view the exported package and summary report.
  - Recursive: Performs a recursive copy of files and folders.
- **OS**: Specifies the operating system.
  - Both: Applicable for Windows and Non-Windows.
  - Win: Applicable for Windows.
  - Non-Win: Applicable for Non-Windows.

For example:

Path	File	Extension	Group	Parser	OS
/site/mods/interp/	*.*		Recursive	recursive	Both
/pdmconf/	NX.env.tpl	tpl	Copy	copy	Win

Path	File	Extension	Group	Parser	OS
/pdmconf/	NX.env.tpl	tpl	Copy	copy	Non-Win
/fig/cfg/	*.fmt	fmt	Reports	copy	Both
/pdmconf/	eiam*.config	properties	onetime	onetime	Both

How CA SDM Environment Promotion Utility Works in Advanced Availability and Conventional Mode

Before initiating the export process, complete the following tasks:

- Verify Prerequisites (see page 1372).
- Set the **export_import_path, disk_space** and **timeout** property values in the SDMP Config properties file. For more information, see SDMP Config Properties File. (see page 1382)
- For Configuration and customization promotion, the export or import process must be executed on the same type of servers.
  For example:
  - If an export is performed on a primary server, import of the package is allowed only on the primary server.
  - If an export is performed on a background server, import of the package is allowed only on the background server.
  - If an export is performed on a secondary server or application server, the import of the package is allowed only on the secondary server or application server.

Note: CA SDM Environment Promotion is not supported on CA SDM Standby servers.

Environment Promotion For Advanced Availability (Background Server)

CA SDM administrators must copy the .htmpl files to the application servers manually or modify the version control file to sync the .htmpl files on the application servers.

Follow these steps:

1. Export the package.
   For more information about how to export the package, see Export. (see page 1375)
2. Log in to the CA SDM target system.
3. Copy the exported zip (*sdmp_export_<timestamp>.zip*) to the *export_import_path/Promotion /Import* folder.
   If the *export_import_path* is empty, copy the exported zip to *NX_ROOT/Promotion/Import* folder.
4. Run the dryrun command.

```
Windows: sdmp -a dryrun -p <exported_zip>
Non-windows: sdmp.sh -a dryrun -p <exported_zip>
```

5. After successful dryrun, run the import command and follow the on-screen instructions.

   ```
   Windows: sdmp -a import -p <exported_zip>
   Non-windows: sdmp.sh -a import -p <exported_zip>
   ```

   The administrator performs the failover manually when the instructions for performing failover are displayed on the Command Line interface.

6. Log in to the Standby server and run the failover command:

   ```
   pdm_server_control -b
   ```

7. After failover is complete, use the new standby server (old background server). Press **Y** to continue the import process.

8. After successful import, perform failover again on the new standby server to make it as the background server. Run the following command:

   ```
   pdm_server_control -b
   ```

Note: If you want to export or import from one application server to another, see Export (see page 1375) and Import. (see page 1376)

Environment Promotion for Conventional Setup

CA SDM Environment Promotion does not support propagation of files (.htmpl) from the primary server to the secondary server. Either copy the files manually or use version control to propagate the files (.htmpl) to the secondary servers.

Follow these steps:

1. Export the package.
   For more information about how to export the package, see Export. (see page 1375)

2. Log in to the CA SDM target system.

3. Copy the exported zip (*sdmp_export_<timestamp>.zip*) to the *export_import_path/Promotion /Import* folder.
   If the *export_import_path* is empty, copy the exported zip to *NX_ROOT/Promotion/Import* folder.

4. Run the dryrun command.

   ```
   Windows: sdmp -a dryrun -p <exported_zip>
   Non-windows: sdmp.sh -a dryrun -p <exported_zip>
   ```

5. After successful dryrun, run the import command.

   ```
   Windows: sdmp -a import -p <exported_zip>
   Non-windows: sdmp.sh -a import -p <exported_zip>
   ```

Note: To export or import from one secondary server to another, see Export (see page 1375) and Import. (see page 1376)

SDMP Config Properties File

Edit the *sdmp_config.properties* file to control the behavior of the export or import process. By default, the file is installed at *NX_ROOT/site/cfg/sdmp_config.properties*.

The SDMP configuration file contains the following properties:

export_import_path

This property defines the environment promotion root folder. Set to local path, mapped drive path, or authenticated network shared path, only in the supported formats.

For example: *C:\\data\\work* or *C:/data/work*

\\\\sharedpath\\work or //sharedpath/work

If you do not specify a value, the *NX_ROOT* path is used.

disk_space:

This property is applicable for configuration and customization promotion. Ensure that you have enough disk space available on the system to execute the export or import process.

Default: 10 MB

Specify the value in MB.

timeout

CA SDM Environment Promotion uses the CA SDM pdm command utilities. If any command line utility does not respond in the specified time out period, the utility exits.

Default: 600 seconds

Specify the value in seconds.

db_data_disk_space

This property is applicable for object data promotion. Ensure that you have enough disk space available on the system to execute the export or import process.

Default: 10 MB

Specify the value in MB.

skip.validation.tomcat

Indicates if the validation or comparison of source and target Tomcat versions is skipped. If the value is set to True, validation is skipped.

Default: False

skip.validation.java

Indicates if the validation or comparison of source and target Java versions is skipped. If the value is set to True, validation is skipped.

Default: False

skip.validation.wsp

Indicates if the customization changes (WSP) on the source system is skipped. If the value is set to True, customization is skipped.

Default: False

Object Data Promotion

Perform the Export process from Command Line interface or navigate to **Administration**, **System**, **Data Export** page on the CA SDM User Interface to promote customized data from the source to the target system.

- Verify the prerequisites before initiating object data promotion (see page 1372)
- Export Object Data from the CA SDM User Interface (see page 1383)
- Export Object Data from the Command Line Interface (see page 1385)

You can manage the export and the import processes by configuring the property files.

- Import Object Data (see page 1386)
- Property Files for Object Data Promotion (see page 1388)

Note: If CA SDM is tenanted, data from a source tenanted system is promoted to a target tenanted system. CA SDM Environment Promotion does not support creation of tenants.

Export Object Data from the CA SDM User Interface

This article explains the export process when you promote object data from the CA SDM user interface.

Before initiating the export process, perform the following tasks:

- Verify the Prerequisites (see page 1372).

- Set the **export_import_path** and **db_disk_space** values in the SDMP configuration properties file. For more information, see SDMP Config Properties File . (see page 1382)
- When promoting the *risk_level* and *prptpl* objects, update the following property files located in the *NX_ROOT**pdmconf*\ folder, on the source and target systems:
  - Edit the *dbpromote.uniqkey* file and update the following properties:
    - risk_level.uniquekey=enum
    - prptpl.uniquekey=object_type, object_attrname, object_attrval, sequence
  - Edit the *DBImport.properties* file and update the following property:
    - resolve.prptpl.attributes=object_attrval

Follow these steps:

1. Log in to CA SDM user interface with privileged user access.
2. Navigate to **Administration**, **System**, **Data Export**.
3. Specify the **Start Date**, **End Date**, **Last Modified by**, **Active** fields based on your requirement.
   - **S tart Date**: Specifies the earliest modified date of the object data.
   - **End Date**: Specifies the last modified date of the object data
4. Click **Search** to view the list of objects that match the filters.
5. Select the objects that you need to promote from the **Object List** page.
6. Click **Data Export** and enter appropriate description.

   Note: Special characters such as ; : { } / * \ (# + % & ' " are not allowed in the description.

7. (Optional) Click **Data Export/Import History** in the left navigation pane to verify that no other job is in progress before you submit your job.
8. Click **Submit** on the description pop-up.
9. Click **Data Export/Import History** to verify the status and location of the data export package. One of the following status messages may be displayed as per the status of the data export package:

- **In Progress**: Indicates that the data export process is running.
- **Complete**: Indicates that the data export process for the selected objects is complete.

- **Abort:** Indicates that the in progress operation was cancelled using the **Abort** button.

You can view the exported package in the <*export_import_path*>*/Promotion/Export/DB* location on the CA SDM server.
If any errors or failures are encountered during the export process, check the *stdlog* file and the *dbpromote.log* file in the *NX_Root/log* folder.

Export Object Data from the Command Line

Apart from the CA SDM user interface, you can also export the object data from the command line.

Before initiating the export process, perform the following tasks:

- Verify the Prerequisites (see page 1372).
- Set the **export_import_path** and **db_disk_space** values in the SDMP configuration properties file. For more information, see SDMP Config Properties File . (see page 1382)
- When promoting the *risk_level* and *prptpl* objects, update the following property files located in the *NX_ROOT**pdmconf*\ folder, on the source and target systems:
  - Edit the *dbpromote.uniqkey* file and update the following properties:
    - risk_level.uniquekey=enum
    - prptpl.uniquekey=object_type, object_attrname, object_attrval, sequence
  - Edit the *DBImport.properties* file and update the following property:
    - resolve.prptpl.attributes=object_attrval

Execute any of the following commands to promote the object data changes from the source system to the target system:

```
db_promote export -d <description> -w <whereclause> -i <inputfile>
db_promote export -d <description> -w <whereclause> -f <factoryname>
```

The command line options are described as follows:

-d

(Optional) Specifies the description about the package that is exported.

-w

(Optional) Specifies the *Where* clause to filter objects for export.

Important! We recommended that you use the *Where* clause to optimize the search results.

-f

Specifies the factory name of the object.

-i

Specifies the input text file, which lists the object factory names in each row.

-h

(Optional) Denotes help for a command.

```
For Example:db_promote export -d "Export categories" -w "last_mod_dt > {unix
timestamp}" -i "C:/objectlist.txt"
db_promote export -d "Export categories" -w "last_mod_dt > {unix timestamp}" -f
"pcat"
```

After successful completion, the export process generates a zip file in the *<export_import_path> /Promotion/Export/DB* folder. If the *export_import_path* property is empty, navigate to the *NX_ROOT /Promotion/Export/DB* folder to view the exported package and summary report. The report file contains the number of objects that are exported. The exported package and the corresponding report file are shown in the following format:

```
sdmp_db_data_export_yymmdd_hhmmss.zip
```

```
sdmp_db_data_export_report_yymmdd_hhmmss.txt
```

For Example:

```
sdmp_db_data_export_151009_140940.zip
```

```
sdmp_db_data_export_report_151009_140940.txt
```

Import Object Data

You can import a data object using the Command Line interface.

Follow these steps:

1. Log in to the CA SDM target system as an administrator.
2. Create a back up of the existing database.

   Note: If the import fails, restore the database from the backup location.

3. Manually copy the exported zip file, *sdmp_db_data_export_yymmdd_hhmmss.zip,* from the source system to target system.

4. Execute the following command to validate the object schema (number of xml files, table names, and column names) in the target system and follow the on-screen instructions.

   ```
   db_promote import -v -p <path_to_the_zip_file>
   ```

   For example: *db_promote import -v -p c:/temp/sdmp_db_data_export_151008_102754.zip*

5. The command line options are described as follows:

   -p

   Specifies the import package name.

   -u

   (Optional) Performs the import using the specified user name.

   -h

   (Optional) Denotes the help for a command.

   -v

   (Optional) Validates the schema.

6. Execute the following command to import the object data:

   ```
   db_promote import -p Path_to_the_zip_file
   db_promote import -p Path_to_the_zip_file -u <sdm contact userid>
   ```

   For example: *db_promote import -p c:/temp/sdmp_db_data_export_151008_102754.zip*

7. Verify the import status by accessing Administration, System, Data Export/Import History in the CA SDM User Interface and refer the following report files generated at the *NX_ROOT/log* location:

   - **dbimport.dryrun.report.<timestamp>**: The DryRun report validates all the object schema. Schema related issues, if any, are listed here.
   - **dbpromote.log**: This file contains logs for the export/import operation.
   - **Failure_Report_<package ID>_<timestamp>**: This file contains object data failures that were encountered during import.
   - **Imported_Object_Report_<package ID>_<timestamp>**: This file contains the successfully imported object data related information.
   - **<export_import_path>/Promotion/Import/DB/Import_report_<package name>_<timestamp>**: This file contains the consolidated import summary.

Note: The **DBImport.properties** file is available *in the NX_ROOT/pdmconf/* location, which contains all configurable variables for object data import utility (db_promote). Configure this file to customize as per your environment requirements. This property file includes the following:

- **temp.work.area**
  Specifies where import will extract the exported package. If it is empty or undefined, it will use the system temp folder provided by jvm.
  For example, temp.work.area=c:\\mywork\\temp

- **domsrvr.default=domsrvr**
  Specifies the default dom server used for the data i mport process. Update the value if there are multiple dom servers.
  For example: domsrvr.default=domsrvr:02

Behavior of Abort in Import

We recommend that you do not abort the import process. The following scenarios explain the impact of Abort during the Import process.

Scenario 1: When the user closes the Command Line interface or presses the Ctrl+C key during the import process.

The status gets updated as *Aborted* in the database. In this scenario, the data import is partial, which may cause the CA SDM application to be in an inconsistent state.

Scenario 2: When the user clicks the **Abort** button on the **Administration**, **System**, **Data Export /Import History** page during the import process.

The status gets updated as *Aborted* in the database. The process keeps running on the server until the process is complete.

Important! Using the Abort button from the UI updates **only** the status as Aborted in the database and allows you to execute another process. Typically, you need to abort an import process from the user interface when it terminates abruptly.

Property Files for Object Data Promotion

This sections lists the properties files that you can manage to control the behavior of object data promotion tasks:

- Database Promote Unique Key File (see page 1389)
- Export Configuration File (see page 1389)
- Promotable Objects File (see page 1389)

Database Promote Unique Key File

The **dbpromote.uniqkey** property file that contains the secondary key in the form of key value pair for each factory is available in the *NX_ROOT/pdmconf/* location. By default, *common_name* is assumed to be the secondary key. If the *common_name* of any factory has duplicate entries, specify the attribute that works as a secondary key or combination of attributes to form a unique key in order to identify the record. This file can be customized based on requirements. Ensure that the same file exists on the source system and target system after customization.

Specify the unique key in the following format:

```
<factory name1>.uniqKey=<attribute1>
<factory name2>.uniqKey=<attribute1>,<attribute2>,<attribute3>
```

Export Configuration File

The *export.cfg* configuration file is available in the *NX_ROOT/pdmconf/* folder. You can define the following values for the object data export process:

- **MAXDEPTH:** Sets the maximum depth level for export. As this is a recursive export, it limits the export till the MAXDEPTH level, and the dependent data after the MAXDEPTH level is not exported.
  For example: If the value set to 4, data is exported till 0-3 levels.
  Default: 10

- **EXCLUDE**: Contains a list of excluded objects (factory) specified in each row. Data for the excluded objects is not exported. However, when an excluded object is referred to as a dependent object, its value is exported. Importing the objects on the target system does not load the data for the excluded objects. If the excluded object exists on the target system a link is established between the objects.

Promotable Objects File

This article lists the out-of-the-box objects that CA SDM supports for object data promotion.

S. No.	Object Name	User Interface Label	User Interface Navigation Path
1	arcpur_rule	Archive and Purge Rules	Administration tab, Archive and Purge
2	grc	CI Classes	Administration tab, CA CMDB
3	nrf	CI Families	Administration tab, CA CMDB
4	mfrmod	CI Models	Administration tab, CA CMDB
5	ci_rel_type	CI Relationship Types	Administration tab, CA CMDB
6	rss	CI Service Status	Administration tab, CA CMDB
7	ci_managed_attribute	Manage Attributes	Administration tab, CA CMDB ,Configuration Control

108	sdsc	Service Type	Administration tab, Service Desk

CA SDM Environment Promotion Limitations

The following limitations apply to CA SDM Environment Promotion:

1. Delete operation is not supported.
   For example, removing a role from an access type on the source system does not get promoted to the target system.

2. Selective customization promotion is not supported.
   For example, a user who has created multiple schema changes in the development system cannot promote selective changes to the target system.

3. Objects in the exclude list that are defined in the *NX_ROOT/pdmconf/export.cfg* file get linked to the promoted object only if those records are available in the target system.
   For example, OOTB cnt object is in the exclude list and you try exporting a pcat object with area *as testarea* having an assignee as *testuser*. After importing the pcat object to the target system, if the user (*testuser)* exists on the target system, the *testarea* record is linked to the *testuser* as an assignee. If the user (*testuser*) does not exist on the target system, the assignee field for this record is empty.

4. CA SDM administrators cannot promote a soft link on a Non-Windows system.

5. When you press **CTRL+C** on the console where the promotion operation is running, a confirmation message appears **(Y/N)** to terminate the job. The promotion operation is terminated irrespective of the selection.

6. When exporting or importing large amount of data, you may observe the following scenarios:

   a. If you encounter the error *Exception in thread "main" java.lang.OutOfMemoryError: Java heap space* during import, do the following tasks:

      - **Update the JVM:**

        - Navigate to the *NX_ROOT*/bin/ folder and open the *db_promote.bat* file in edit mode.

        - Add the memory heap size parameter to the data import manager jar file: % NX_JRE_INSTALL_DIR%/bin/java" -cp %JAVA_CP% com.ca.ServicePlus.dataimport.DataImportManager -a %*
          For example: Add the heap size as 1024MB to the data import manager jar file: %NX_JRE_INSTALL_DIR%/bin/java" **-Xmx1024M** -cp %JAVA_CP% com.ca.ServicePlus.dataimport.DataImportManager -a %*

          

          Note: For a 32-bit operating system, you can define the maximum heap size as 4 GB only.

      - **Reduce the export package size in the following ways:**

        - Select a smaller filter range from the User Interface.
          For example, search filter is set to 30 days, reduce the date range to 15 days and export again.

        - Decrease the value of the MAXDEPTH property in the *NX_ROOT/pdmconf/export.cfg* file.
          The objects that are exported are restricted to the defined maximum level. Manually export the dependent objects that are beyond the maximum depth level.

b. When large amount of MDB data is selected for promotion, export or import may take several hours to complete. Before you initiate export or import, perform MDB level setting. For more information about the MDB level setting, see How to Move the CA MDB Data from the Source to the Target Systems (see page 747).

Configuring CA Service Catalog

This section contains the following articles:

Manage Business Units and Tenant Administration

This article contains the following topics:

Understand Business Units and Catalog Access

Administrators create and maintain business units (tenants) as the organizational structure that controls access to data. Business units can be:

- A service provider (the highest level or *root* business unit).
- An external client company, if the service provider provides services to external customers.
- An internal corporate department or group within a department.

A business unit administrator can:

- Access the catalog that the business unit publishes.
- Subscribe accounts to services.
- Perform other administrative duties for the business unit and its child business units.

The following rules apply when you create your business unit structure:

- Business units can have child business units.
- Users can have roles in more than one business unit.

- Business units can have one or more accounts.
- Each account can have many users.
- Each user can have many accounts.
- Each user who has an account can be billed to that account.
- When you request a service, the parent business unit of your business unit defines the catalog that you see.
- When you subscribe an account to a service, the parent business unit defines the catalog that you access.

By default, users and accounts can request or subscribe to items *only* in the catalog of their parent business unit.

Example

Review the following example of a four-level hierarchy of business units, in a default configuration:

Service Provider (SP) is the top-level business unit.

- A is a child business unit of SP.
- B is a child business unit of A.
- C is a child business unit B.

In linear form, you can express the relationship as follows: SP-->A-->B-->C

- "A" Users and accounts can request or subscribe to items in the SP catalog *only*.
- "B" Users and accounts can request or subscribe to items in the A catalog *only*.
- "C" Users and accounts can request or subscribe to items in the B catalog *only*.

To change the default behavior, use the following configuration settings:

- The System configuration settings **Use Service Provider Configuration Only** and **Use Service Provider Catalog Only.**
- The Catalog configuration setting that is named **Pass Through Catalog.**

Note: For more information about how to modify configuration settings, see the System Configuration (see page 1461) and Catalog Configuration (see page 1449) section.

Decide Between Common And Stand-Alone Tenant Administration

Administrators decide between *common* or *stand-alone* tenant administration, as follows:

- In *common* tenant administration, you create and maintain a single tenant structure for CA Service Catalog and CA Service Desk Manager. Both parent and child tenants are created in CA Service Desk Manager *only*. You can edit common (shared) attributes (see page 1405) of tenants in CA Service Desk Manager *only*. CA Service Catalog "inherits" the tenants, their structure, and their common attributes from the CA Service Desk Manager. These features appear as read-only in CA Service Catalog. In CA Service Catalog, you can still edit the CA Service Catalog-specific attributes (see page 1405).

- In stand-alone tenant administration, you create and maintain tenants in CA Service Catalog only. The parent and child tenants apply only to CA Service Catalog. Tenant administration functions and tenant attributes are not shared between CA Service Catalog and any other product. If CA Service Desk Manager is installed, you create and maintain its tenant structures separately from CA Service Catalog. Stand-alone tenant administration is the default.

- Common tenant administration ensures efficiency and consistency in your tenant structures for applicable products providing a single point of administration. You can administer tenants once rather than multiple times in CA Service Catalog and CA Service Desk Manager. You can leverage a common data model and thus save costs for multiple service providers and other large organizations.

- Stand-alone administration provides flexibility for tenant structures across products. Thus, to use separate tenant structures for CA Service Catalog and CA Service Desk Manager, use stand-alone administration. For example,

  - You have installed CA Service Catalog *without* CA Service Desk Manager.

  - You have installed CA Service Catalog with CA Service Desk Manager. *However*, you want to administer the business units for CA Service Catalog separately from these other products.

- If you have already implemented separate tenant structures in both products, you perform synchronization activities to enable common tenant administration.

- Continue using your chosen option for the long term, preferably throughout the life cycles of the applicable products. Perform synchronization activities whenever you change from stand-alone tenant administration to common tenant administration.

- As a best practice for efficiency and consistency across applicable products, use common tenant administration.

Note: Common tenant administration has no effect on how you manage users and accounts.

Important! Do *not* move a CA Service Catalog tenant if it has a subscription or a request for an associated account. When such subscriptions exist, moving a tenant impacts its business rules and can cause problems in request management.

Configure Common Tenant Administration

This article contains the following topics:

Common tenant administration (also named multi-tenant administration) lets administrators use a single administration tool to simultaneously create and maintain business units (tenants) for multiple products, including CA Service Catalog and CA Service Desk Manager. To configure CA Service Catalog to use common tenant administration, follow this process:

Important! This topic applies *only* if your organization has CA Service Desk Manager installed.

1. Meet the prerequisites: Verify that CA Service Catalog and CA Service Desk Manager are installed and share the same MDB.
2. Configure the tenancy settings (see page 1399) in CA Service Desk Manager.

   Important! CA Service Catalog requires a tenant of type Service Provider in CA Service Desk Manager, as a prerequisite for completing this process.
3. Create the common tenant mapping file (see page 1399).
4. Prepare to run the common tenant merge utility.
   This utility uses the information in the common tenant mapping file to create a shared tenant structure between CA Service Catalog and CA Service Desk Manager.
5. Run the common tenant merge utility (see page 1400).
6. Set the configuration variables for common tenant administration (see page 1401).
7. (Optional)Implement a common terms of use agreement (see page 1403) for common tenants.

8. Note the effects of common multi-tenancy on business unit functions (see page 1405).

Configure the Tenancy Settings in CA Service Desk Manager

Configure the tenancy settings in CA Service Desk Manager to support the integration with CA Service Catalog.

Follow these steps:

1. Log in to CA Service Desk Manager as ServiceDesk(administrator).
2. Click Administration, Option Manager, Multi Tenancy.
3. Verify that the multi-tenancy option is on.
4. Verify that the multi-tenancy depth is 10.
5. Click Administration, Security and Role Management, Tenants.
6. Click Create New to create a tenant, if no tenant of type Service Provider exists. Enter a meaningful name for the new tenant.
7. Verify that Service Provider Checked is on and Subtenants Allowed is on.

You have configured the tenancy settings in CA Service Desk Manager to support the integration with CA Service Catalog.

Create the Common Tenant Mapping File

When you configure common tenant administration (see page 1398), a required task is creating the common tenant mapping file. Map tenants between CA Service Catalog and CA Service Desk Manager, so that both products use the same tenant structure.

Follow these steps:

1. Review the tenant structures in CA Service Catalog and CA Service Desk Manager. Plan the merged structure that you want to use.
2. Stop the CA Service Catalog services on the computer where MDB is installed.
3. Open the CA Service Catalog command prompt by clicking Start, Programs, CA, Service Delivery, Service Delivery Command Prompt.
4. At the CA Service Catalog command prompt, enter the following ant command:

   ```
   ant generate-merge-config
   ```

   The common tenant merge utility runs and creates the tenant mapping file, which is named merge-tenants.conf. The utility:

   - Creates the initial mapping entry, which maps the Service Provider business units for each product to each other. This entry is the only *required* entry. The CA Service Catalog entry is named ca_tenant, and the CA Service Desk Manager entry is named usm_tenant_ext.

- Lists the names and database IDs of all CA Service Catalog tenants
- Lists the names and database IDs of all CA Service Desk Manager tenants

You use these names and database IDs to create the mapping entries.

5. Open the merge-tenants.conf file that is located in USM_HOME, using a text editor. After the Service Provider mapping entry, add a new line for each new mapping entry that you create. Specify each entry using the following format, using the Service Provider entry as a model:

   ```
   <usdk> business unit ID=<bcsc> business unit ID
   ```

   For example:
   0x60B4EAC8B85E41DH97E647CF84A93CFA=87958EK983987D42AB2A4PAEF808C129

   Important! Mapping a parent tenant maps the parent *only*, *not* the children! Therefore, for automatic mapping, eit*her* map parents and children individually *or* omit the mapping of the parent.

6. Follow the rules for creating entries in the common tenant mapping file (see page 1401).

7. Review the sample common tenant mapping file (see page 1402) and verify the contents of your mapping file.

8. Restart the CA Service Catalog services that you stopped at the beginning of this procedure.

You have created the common tenant mapping file. You are ready to run the utility.

Run the Common Tenant Merge Utility

Follow these steps:

1. Open the CA Service Catalog command prompt on the computer where the MDB is installed. Click Start, Programs, CA, Service Delivery, Service Delivery Command Prompt.

2. Enter the following command:

   ```
   ant merge-tenants
   ```

   The utility prompts you for the name (**Default:** merge-tenant.conf) and location (**Default:** USM_HOME) of the common tenant mapping. The utility also prompts you for the password for any administrator with the Service Provider role in CA Service Catalog. An example is the default user named spadmin. If running the utility creates tenants in CA Service Desk Manager, you enter this password.

3. The utility summarizes the changes to be made in the tenant table in the MDB for each product. The utility also creates any missing tenants in those tables.

4. Restart the CA Service Catalog services that you stopped at the beginning of this procedure.

5. Start CA Service Catalog and CA Service Desk Manager. Verify that the tenant structure and common attributes (see page 1405) of tenants are the same in both products.

You have run the common tenant merge utility.

Important! If the same name is used for two or more tenants being created in CA Service Desk Manager the utility aborts. In such cases, check the tenant structure of each product. Rename any duplicate tenant names and ensure that they are unique. Run the utility again.

Set Configuration Variables

When you configure common tenant administration (see page 1398), setting the related configuration variables is a required task.

Follow these steps:

1. Log in to CA Service Catalog as a user with the Service Delivery Administrator role.
2. Click Administration, Configuration, System Information.
3. Verify that the value of the option *Common Tenant Data Synchronized* is Yes. This value is read-only. "No" indicates that a discrepancy exists between the tenant structures of CA Service Desk Manager and CA Service Catalog. Verify the accuracy of the common tenant mapping file and run the common tenant merge utility again.
4. Set the value of the option *Common Multi-tenant Administration Enabled* to Yes.
   When this setting is Yes, common multi-tenant administration is enabled for CA Service Catalog, through CA Service Desk Manager.

You have set the configuration variables for common tenant administration.

Rules for Mapping File Entries

When you configure common tenant administration (see page 1398), a required task is creating the common tenant mapping file (see page 1399). Follow these rules when creating entries in this file:

Important! Violations of any of these rules cause the common tenant merge utility to abort.

- Do not map business units that are at different levels in CA Service Desk Manager and CA Service Catalog.
- Do not map the same business unit more than once. If you have several business units, print the merge-tenants.conf file and mark each business unit after you map it and save the file.

- Map a child only after mapping all its parents. Map the parents from the tenant level directly above the child through the level directly under the Service Provider business unit.
- Verify that tenant names are unique across all products. For example, if you have a tenant AAA in CA Service Desk Manager and CA Service Catalog, rename at least one of them to a unique name.
- Verify that the values in CA Service Desk Manager for common attributes meet your requirements for CA Service Catalog. This requirement is for every tenant and sub-tenant that you map. Doing so is important because for common attributes, the CA Service Desk Manager values overwrite the CA Service Catalog values.
- Do *not* map that tenant or any of its sub-tenants explicitly in the merge-tenants.conf file, to add a complete tenant structure from one product to the other automatically. Instead, run the common tenant merge utility and confirm that you want to add any tenants that are not mapped in the merge-tenants.conf file. The utility then adds the complete structures of any unmapped tenants to each product automatically.

Sample Common Tenant Mapping File

Review the following sample common tenant mapping file and construct your own file:

```
...
# CA Service Catalog Tenants (id, name)
# ca.222.com   ca.222.com
# 00234A51DC4A4F70A03D3BDE5526278C   BB
# 9F6309A0CB654781B08080AD78C2280F   CC
# 9CF5655B4B8D4833A0C6E74EB56128C5   AA
#
# CA Service Desk Manager Tenants (id, name)
# 0xB3484A535A3D994B9FBCD28D3845F292   ca.111.com
# 0xBB83719AA93DFC48B909D7D72CF8B0CB   A
# 0xD9DC8FF2EB84CC43988FE71F4B489D3D   E
# 0x67958EA983987D42AB2A4BAEF808C029   D
#
# Service Provider tenants must map to each other. This mapping is mandatory.
0xB3484A535A3D994B9FBCD28D3845F292=ca.222.com
#
# Map A to AA
0xBB83719AA93DFC48B909D7D72CF8B0CB=9CF5655B4B8D4833A0C6E74EB56128C5
...
```

In this example, the following tenants exist:

- CA Service Desk Manager tenants: ca.111.com, A, D, and E.
- CA Service Catalog tenants: ca.222.com, AA, BB, and CC.

Service Provider tenants must map to each other. Hence, you merge the CA Service Desk Manager Service Provider tenant (ca.222.com) and the CA Service Catalog Service Provider tenant (ca.111.com).

Otherwise, you add a mapping entry only when you want to merge two tenants together. For example, in the sample file, you merge CA Service Desk Manager tenant A and CA Service Catalog tenant AA.

When you merge tenants, the CA Service Desk Manager tenant only overwrites common attributes in the CA Service Catalog tenant. The CA Service Catalog-specific attributes remain intact. After you run the common tenant merge utility with this sample file, the tenant ca.222.com in CA Service Catalog is renamed ca.111.com. Similarly, tenant AA in CA Service Catalog is renamed A. The tenants inherit the other common attributes (see page 1405) of the CA Service Desk Manager tenant with which it was merged.

If you are simply adding tenants from one product to the other, do not map them in the common tenant mapping file. For this reason, the sample file does not map any other tenants. Thus, the following changes occur when you run the common tenant merge utility with this sample file:

- CA Service Catalog tenants BB and CC are added to CA Service Desk Manager.
- CA Service Desk Manager tenants E and D are added to CA Service Catalog.

(Optional) Implement Common Terms of Use Agreement

You can optionally implement a common terms of use agreement for CA Service Catalog and CA Service Desk Manager. Doing so helps enforce a consistent login policy for all common tenants in both products. CA Service Desk Manager administrators create and maintain this agreement in CA Service Desk Manager. CA Service Catalog administrators configure CA Service Catalog to adopt this agreement.

Note: Verify that the CA Service Desk Manager setting meets the needs of your organization. For more information about configuring terms of use agreement in CA Service Desk Manager, see the CA Service Desk Manager documentation.

1. Select Administration, Configuration, System Information in CA Service Catalog.
2. Specify Yes for the setting *Terms of Usage Prompt Enabled*. If you specify No, then users attempting to log in to CA Service Catalog are *not* prompted to accept the terms of use agreement.
3. Review the effect of the CA Service Desk Manager setting on users logging in to CA Service Catalog. The effect depends on the terms of use agreement that is configured for the common tenant in CA Service Desk Manager.

- If the common tenant has an active, defined (not empty) terms of use agreement, prompt the user to accept it at every login.
- If the common tenant has no terms of use agreement that is defined, or if the agreement is inactive, review the parent hierarchy of the tenant. Then perform the following steps:

- If the nearest parent has active but empty terms of use agreement that is defined, then do not prompt the user with any terms of use agreement. Otherwise, prompt the user to accept the terms of use agreement of the nearest parent tenant that has an active terms of use agreement defined.

- If no parent tenant has an active, specified terms of use, do not prompt the user with any terms of use.

- If the common tenant has an active terms of use agreement defined but is configured to suppress it, then do *not* prompt the user to accept it.

- If users attempting to log in to CA Service Catalog receive the prompt to accept the terms of use agreement but do not accept it, they cannot access CA Service Catalog.

Manage Common Tenants

When common tenant administration is enabled, all tenants exist in both CA Service Catalog and CA Service Desk Manager. Administrators can manage these tenants using CA Service Desk Manager, but not CA Service Catalog. Here, *managing* means adding or deleting tenants, or editing their common attributes. In CA Service Catalog, you can *view* tenants and all their attributes. But you can edit only the CA Service Catalog-specific attributes.

Follow these steps:

1. In CA Service Catalog, view the business units by clicking Administration, Business Unit, and:

   - Verify that any new business units that you created in CA Service Desk Manager are visible in CA Service Catalog.

   - Verify that any inactive business units in CA Service Desk Manager are not visible in CA Service Catalog.

   - Verify that you cannot add or delete business units or edit their primary attributes in CA Service Catalog.

   - Note the effects of common multi-tenancy on business unit functions (see page 1405).

2. In CA Service Desk Manager, perform the following actions:

   - Create one or more new tenants, as needed.

   - Make inactive any tenants that you no longer want to use, if applicable.

   - Edit the common attributes such as description, contact, location, inactive.

   - Optionally, implement a common terms of use agreement (see page 1403).

   - Verify the CA Service Desk Manager and CA Service Catalog tenant and business unit settings that follow. Update these settings, if necessary. These settings enable the tenant mapping between the products.

To begin some of these tasks, select Administration, Security and Role Management, Tenants, Start. For more information about how to perform these tasks, see the CA Service Desk Manager documentation.

Tenant Setting for CA Service Desk Manager	CA Service Catalog Business Unit Setting
Service Provider selected (on)	Service Provider (SP), meaning root or highest level business unit
Subtenants Allowed selected (on)	Contains Sub Units: True, meaning Super Tenant. A super tenant is a tenant with at least one subtenant.
Subtenants Allowed not selected (off)	Contains Sub Units: False, meaning Tenant, also named leaf (end-of-tree) tenant. A subtenant is a tenant with at least one parent tenant.
Inactive Tenant	inactive, formerly deleted tenant
Parent Tenant is Empty	SP is the parent tenant

Effects of Common Tenant Administration

After you have completed configuring common tenant administration (see page 1398), the following results occur in CA Service Catalog:

- A new configuration item appears on the Administration, Configuration page. The name of this item is *Common Multi-Tenant Administration*. Its default setting is No. When you set this option to Yes, the following changes occur:
  - The *common attributes* of the tenant become read-only from CA Service Catalog. You can edit these common fields in CA Service Desk Manager *only*:
    - The Business Unit Name and Description in the General Information section
    - All fields in the Primary Contact Information section
    - All fields in the Location Information section
  - You can edit the *CA Service Catalog-specific attributes* in CA Service Catalog. These attributes include the following fields:
    - Federal Tax Payer ID, State Tax Payer ID, Tax Region
    - Timezone, Currency Name, Date Format, Time Format
    - Decimal Symbol, Opened Date, Email, Web Site
  - The options to add, delete, edit, cut, and paste tenants are disabled.
  - A message appears on the Administration, Business Units page explaining why these functions are disabled.
- If you implement a common terms of use agreement (see page 1403), then the terms of use settings in CA Service Desk Manager govern the attempts of users to log in to CA Service Catalog.

Configure Stand-Alone Business Units

Stand-alone administration means that you use CA Service Catalog alone to manage business units, as follows:

1. Select **Administration**, **Business Units**.
2. Expand the business unit tree and find the business unit that you want.
3. (If applicable) Click the Add icon to add a child business unit. Complete the fields on the **Add a New Business Unit page**, and click OK.

Add a New Business Unit Page

The following fields require explanation:

- **Business Unit Login ID**
  Specifies the value that you use to log in to a business unit (except the service provider business unit). You also use this value when running IXUtil import and export commands. This value must be unique.

- **Business Unit Name**
  Specifies the name of the business unit.
  This field defaults to the same name as the Business Unit Login ID. The Business Unit Name appears throughout the user interface and in all reports and invoices.

- **Business Unit ID**
  Identifies an automatically generated, read-only value, whether you are using common or stand-alone tenant administration (see page 1397).
  After you create the business unit, CA Service Catalog automatically fills in this field. The only exception is the service provider business unit. You specify its business unit ID during the Catalog Component installation and cannot change this ID afterwards.
  If necessary, use the Business Unit ID field for reference. For example, you change your method of tenant administration from stand-alone to common (see page 1397). In that case, you use the business unit ID when you create a common tenant mapping file (see page 1399). You also use the business unit ID with IXUtil and web services.

- **Opened Date**
  Specifies the date when the business unit becomes part of your organizational structure, in local time.

- **Currency Name, Date Format, Time Format, Decimal Symbol**
  Specify the currency name, date and time formats, and decimal symbol that must appear on the user interface. These specifications appear, for example, when users create and manage requests. They also appear when administrators create and maintain services, users, and so forth.

- **Contains Sub Units**
  Specifies whether this business unit can have sub business units (child business units).

  Note: You *cannot* change this setting after you have created the business unit.

- **Create Dashboard Library Namespace**
  Specifies whether to create a folder for the business unit in the Dashboard Library. Doing so helps organize the contents of the library.

- **Single Account Mode**
  Specifies whether the business unit can contain *only one* account.
  If you select this option, specify the name of the single account.

  Note: You *cannot* change this setting after you have created the business unit.

  Create Document Namespace
  Specifies whether to create a folder for the business unit in the Documents folder. Doing so helps organize the contents of the folder.

- **Primary Contact Information**
  Specifies the user ID of the primary contact for the business unit.

- **Theme**
  Specifies the settings for several look-and-feel elements, including images and icons (*except for* logos), menus, and tabs. When applicable, these elements include colors, font name and point size, highlighting, and related specifications. You customize these look-and-feel elements by editing the Cascading Style Sheet (CSS) files for the theme.
  The look-and-feel of the UI matches the theme of the business unit that you are logged in to. If a business unit does not have its own theme, it uses the theme of its closest parent business unit. You can use the same theme for all business units. Alternatively, you can optionally create and use different themes for different business units. If you update a theme for a specific business unit, the change affects the users of that business unit. The change also affects any child business units that do not have their own theme specified. For more information about customizing themes, see the Modify the Branding (see page 2020) section.

- **Logo**
  For each business unit, you can optionally specify a *business unit* logo. This logo replaces the *global* logo in the heading on product pages and request emails of the business unit. You can use a business unit logo to support the brand or other messaging uniquely for a business unit. You can update the logos for every business unit or only for specific business units. For example, you can decide to customize logos only for super tenants directly under the root business unit.

  Important! If you have enabled multi-tenancy with CA Service Desk Manager, CA Service Catalog uses the logo that CA Service Desk Manager specifies. If no CA Service Desk Manager logo applies, then each business unit uses the CA Service Catalog global logo.

  If the child business unit has its own logo, users who log in to it see the child logo. Else, users who log in to it see the global logo. Users with access to multiple business units can see different header logos when they log in to each business unit.

- **Location Information**
  Specifies the location of the business unit.

Manage Users and Assign Roles

This article contains the following topics:

Basic Information About Users

A user in CA Service Catalog typically represents a person who uses the product. A person must have a user ID to log in and use CA Service Catalog. Each user requires a role (see page 1414) and the user must belong to a business unit.

User Data in the MDB

The MDB stores user-related information for multiple CA products. For example, CA Service Catalog and other CA products share users and contacts. Therefore, use caution when managing users.

Some data in the MDB is product-specific and is not shared between products. For example, CA Service Catalog does not share role information. The MDB contains several users that CA Service Catalog does *not* use but that *other CA products* use. Examples are System_ADH_generated, System_AM_User, Systemt_Anonymous, System_Argis_User, System_MA_User, System_NSM_generated, System_SD_User, and UAPM Administrator.

The MDB stores user IDs and all other user data *except* passwords.

User Data in CA EEM

The user ID of each CA Service Catalog user maps to a matching user in CA EEM.

When a user logs in to CA Service Catalog, it passes the user ID to CA EEM for authentication. If CA EEM does *not* use an external directory, CA EEM authenticates the user ID. If CA EEM uses an external directory, the external directory authenticates the user ID.

If CA EEM uses an external directory, the Catalog system fetches important user details from the external directory. Examples include the first name, last name, email address, and organizational hierarchy. This fetching helps create the user quickly and efficiently.

CA EEM also controls access for each role to CA Service Catalog components.

External Directories

If you use an external directory to maintain CA Service Catalog users, perform the following tasks:

- Configure CA EEM to use an external directory.
- Synchronize the MDB users with the external directory users.

These tasks help verify that all CA EEM users have matching CA Service Catalog users.

Single Sign-On

If your organization uses a Windows domain, you can configure CA Service Catalog to use Single Sign-On. For more information, see the section Configure Single Sign-On Using Windows NTLM authentication (see page 1429).

User Groups

You or other administrators can organize CA Service Catalog users into the following types of user groups:

- Global and Application user groups in CA EEM

An application group that CA Service Catalog uses is the Super User.

Note: For information about creating these groups and assigning users to them, see your CA EEM documentation.

- User-defined groups in CA EEM

You create user-defined groups, in either your external directory (if applicable) or CA EEM. You can apply the same action to all users in the user-defined group, instead of modifying the users individually. Once you create a user-defined group in CA EEM or your external directory, it is available in CA Service Catalog.

User group memberships appear as *read-only* data in user profiles.

Note: For information about creating user-defined groups, see the Manage Users with CA EEM (see page 1418) section.

Authorization Level

You can specify an authorization level for each business unit in which the user has a role. The system approval process is the only approval process that uses the authorization level. By default, the following levels are available with the text and numeric values shown:

- Level 0 (0)
- Level 10 (10)
- Level 20 (20)
- Level 30 (30)
- Level 40 (40)
- Level 50 (50)

In the system approval process, each *user* has an authorization level and each *service* has an approval level. The Catalog system automatically approves requests from users whose authorization level matches or exceeds the approval level of the service. Otherwise, the system follows a managerial hierarchy. The request proceeds to request managers until it reaches one whose authorization level matches or exceeds the approval level of the service.

Example:

If a service has an approval level of 40, then a user requesting the service requires *one* of the following criteria:

- The user must have an authorization level of 40.
- The user must obtain approval from a request manager who has an authorization level of 40.

Note: The Requested For user can have different roles - and therefore different authorization levels - in multiple business units. The Catalog system uses the authorization level of that user in the business unit to which the requested *service* belongs.

Administrators create users to let them access CA Service Catalog. Administrators assign a role to each user to specify the access rights of the user.

Follow this process to manage users and roles:

- Step 1 - Manage Users (see page 1410)
- Step 2 - Assign Roles (see page 1413)

Step 1 - Manage Users

This article contains the following topics:

To define the user in CA EEM, use one of the following methods:

- If CA EEM uses an external directory:
  The administrator of the external directory must define the user in the external directory. For more information, see the documentation for the external directory. An example of an external directory is Microsoft Active Directory.
- If CA EEM uses its own repository:
  CA EEM automatically creates a new Global user in the USM/users folder when you add a new CA Service Catalog user. The Create EEM User action on the User Create event rule sets this behavior. Optionally perform one of the following tasks:
  - Disable the action that creates the CA EEM user automatically.
  - Set the format of automatically created passwords (see page 1411).

Administrators create and maintain users to let them access CA Service Catalog. As an administrator, you typically add a user when a new employee starts working in your organization.

Follow these steps

1. Select **Administration**, **Users** from the main menu.
2. Click **Add**.
3. Enter the data for the new user on the Add a New User page (see page 1412), and click OK.

You typically edit a user when an existing employee changes roles or titles or transfers to a new department. You can only edit users who have a role in the business units within the scope of your role.

Important! Do *not* change the user ID of a user. Do *not* reuse deleted user IDs, because all deleted users are maintained as *inactive* in the user database.

Review the Effects of Deleting a User (see page 1413) before you delete a user.

Set the Format of Automatically Created Passwords

You can configure CA EEM to use its own repository. By default, the password is the same as the user ID. You can optionally change the format of the passwords that CA EEM creates automatically.

Follow these steps:

1. Select Administration, Tools, Events.
2. Disable the Create EEM User rule. Create a rule to use in its place, for the User Create event.
3. Disable the associated rule action that is named Create New EEM User or Modify EEM User. Create an action to use in its place.
4. Open your replacement action and locate the Java class field, which appears similar to the following text.

   ```
   com.ca.usm.ruleEngine.action.CreateEiamUserAction,passwordTemplate=valu
   ```

   The passwordTemplate parameter specifies the text to be used as the initial password. The password is set to the user ID that is created when the passwordTemplate parameter is empty.
5. Set this parameter to a specific text value or to an available event variable.

   For example, to set the password to the user ID followed by the letter *a*, specify the following text:

   ```
   com.ca.usm.ruleEngine.action.CreateEiamUserAction,passwordTemplate=$use
   ```

Add a New User Page

You complete several fields when you add a new user in your organization. The following fields require explanation:

> **Note:** If CA EEM is configured to use an external directory, data is auto-populated from the external directory data, if applicable.

- **User ID**
  Specifies the ID by which CA Service Catalog identifies the user.
  The User ID value must be unique.

- **Manager**
  Specifies the manager for the user being creating.
  For system approval process, the manager must approve requests that the user submits. For other approval process, the manager can be a required approver, depending on how you configure the approval process.

- **Request Auto-Delegation: Delegate**
  Specifies the user to whom your requests pending action are delegated automatically when you auto-delegate your own requests pending action. Administrators can also auto-delegate the requests pending action of other users.
  When you clear this field in your own user profile, your requests pending action stop being auto-delegated. The requests remain in your queue. When you clear this field in the profile of another user, the requests pending action of that user stop being auto-delegated. The requests remain in the queue of that user.
  Clearing this field *does not affect* requests pending actions that were already delegated to previously assigned delegates. Therefore, after clearing this field, instruct the former delegates to handle requests pending action promptly. Alternatively, as an administrator, you can also handle them yourself or transfer them to other users.

- **Delegate Use of Catalog: Delegates**
  Specifies the users to whom you delegate the use of your catalog. These users can create and submit requests from your catalog on your behalf. In addition, administrators can delegate the catalog of one user to another user.
  This field is valid only if you or another administrator has enabled delegation of catalogs for your business unit.
  When you clear this field in your user profile, your catalog is no longer delegated. Your former delegates can no longer create and submit requests on your behalf from your catalog. When you clear this field of another user, the catalog of that user is no longer delegated. The former delegates of that user can no longer create and submit requests on behalf of that user from the catalog of that user.

- **User Location**
  Specifies the location details for the user.

  > **Note:** All CA products using the same MDB share the location. Therefore, use caution when modifying the location.

- **Select Business Unit**
  Specifies the business unit (see page 1395) of the new user.
  The default is the business unit that you are currently logged in to.
  Only a Service Delivery Administrator or Super Business Unit administrator can change the business unit of the new user. Otherwise, you *can* create the user but *cannot* change the business unit of the user.
  Users can belong to multiple business units. However, a user can have only one role and one authorization level in each business unit.

- **Select Role**
  Specifies the role (see page 1414) for the new user in the current business unit.
  By default, new users receive the default role for all users (see page 1417). Administrators can optionally assign a different role.
  Select an available role and click the *Add Row* icon to add the role for the user.

- **(Optional) Select Authorization Level**
  Specifies the authorization level (see page 1409) of the new user. This setting applies *only* if you use system approval as the approval process.

Effects of Deleting a User

Deleting a user affects its account, including its subscriptions and requests, as follows:

- **Account**
  The account remains open when you delete the user, because future transactions can exist for an account. As an administrator, you can optionally close the account or leave it open.

- **Subscriptions**
  The status of subscriptions for the deleted user change to the default cancellation status (Pending Cancellation or Cancel).

- **Requests**
  The status of requested service options for the deleted user change as follows:

Original Status	New Status
Not Submitted	None: Request is deleted
Submitted. An Approval status, Fulfillment Status, Pending Resource Assignment or Resource Assigned	Cancelled
Completed	Default Cancellation Status (Pending Cancellation or Cancel) if Accounting Component is installed Cancelled if Accounting Component is not installed
Pending Cancellation or Cancelled	Same as Original Status

Step 2 - Assign Roles

This article contains the following topics:

Relationship Between Users, Roles, and Login

Users, roles, and login have the following relationship:

- A user typically belongs to one business unit, but can optionally belong to multiple business units. A user can have only one role in a business unit.
- A user can optionally have different roles in different business units.
  Example: User A can have a catalog user role in the Finance business unit. The same user can have a catalog administrator role in the IT business unit.
- If the user does not specify a business unit at login, CA Service Catalog logs the user in to the default business unit defined for the user. The user has the role that is assigned to the user in that business unit.
- If an integrating product created the user, then the user is *not* assigned to a role or business unit. Instead, after the user logs in, the user receives the default role for all users (see page 1417). Examples of integrating products include CA Service Desk Manager, CA APM, and CA Business Service Insight.

Roles and Default Access Rights

Users can have one role in each business unit in which they are defined. Users can have different roles in different business units.

- Service Delivery administrators can change some default access rights for the *entire* Catalog system as follows:
  Log in to the root (highest level) business unit, select Administration, Configuration, and change the Access Control configuration settings.
- Service Delivery administrators and business unit administrators can change several default access rights for *specific business units* as follows:
  Log in to the business unit, select Catalog, Configuration, and change the Access Control configuration settings.
- All users can also delegate the use of their catalogs to other users to create requests on their behalf.
- The Catalog system creates only one user at installation time. This user, named *spadmin*, has the Service Delivery Administrator role.

Request-related functionality is available when CA Service Catalog is installed. Subscription and invoice-related functionality is available when Accounting Component is installed.

- **Catalog User**
  Is the user role for requesting services *without* subscriptions. These users can manage their own requests, such as approve, reject, fulfill, and other actions to handle requests pending action.

Most users in the organization use this role *only*.
This role is predefined as the default role for new users. However, administrators can optionally change the default role for new users from the catalog user to another role.
This role is most suitable when you are *not* using subscriptions or billing in your implementation.

- **End User**
  Is the end user for all functions available through the catalog. This user includes all the same access rights as the catalog user. The end user can subscribe to services and view invoices. This role can also view and add news messages, documents, and reports.

- **Request Manager**
  Is the administrator role for managing requests, such as viewing and handling all requests in the business unit and applicable subbusiness units. Request managers handle both their own requests pending action and the requests pending action of other users. Request managers can search *all* requests in the Catalog system. But catalog users can search *only* their own requests.

- **Services Manager**
  Creates, defines, and manages services (not requests) for a specific tenant or business unit. This user also has administrative access to configure reports, dashboards, documents, and message alerts.
  This role is most suitable when you want a user to create and maintain services. This user cannot request or subscribe to services.
  This user can also handle requests pending actions, for example, by approving and rejecting requests.

- **Catalog Administrator**
  Creates, defines, and manages services for a specific tenant or business unit.
  This user also has the same access rights as the request manager role.
  This user can request services but cannot subscribe to them.

- **Super Business Unit Administrator**
  Is the "root" user in a specific super tenant (super business unit). A super business unit is a business unit that contains one or more child business units. This administrator has *almost* complete access to the super business unit and all its sub business units. For example, anywhere in the super business unit, this administrator can create business units, create new users, and assign roles.

- **Service Delivery Administrator**
  Is the "root" (highest level) user in the Service Provider (highest level) business unit. This user has complete system access to all business units. For example, this user can specify default settings that apply to all users by logging in to the root business and accessing the Administration, Configuration, User Default tab. This role is available only for the Service Provider business unit, the default business unit that is created during installation.
  Only this administrator has access to data mediation, system configuration, events, rules, and actions.
  By default, at installation time, the Catalog system creates a user ID named *spadmin* with this role.

- **Default Role Specification**
  Service Delivery administrators can specify a default role for all users (see page 1417).

Tasks that Each Role Can Perform

The roles provide default access rights to various functions. Administrators use configuration settings to add default access rights to a role or remove default access rights from a role.

The following table lists the tasks that each role can perform. The letter **X** indicates that the role *can* perform the task. The dash (**-**) indicates that the user *cannot* perform the task.

	Roles							
Tasks	**Cat U sr**	**Req Mgr**	**Cat Adm**	**End Usr**	**Add m**	**Svc Mgr**	**SB Adm**	**SD Adm**
Shopping								
By default, all users have all shopping functions, except as noted in Roles and Default Access Rights. However, administrators can configure the access rights of each role to create proxy requests, edit requests, and so forth. All users can also delegate the use of their catalogs to create requests on their behalf.	X	X	X	X	X	-	X	X

Roles Key

Code	Role
Adm	Administrator
Cat Adm	Catalog Administrator
Cat Usr	Catalog User (none)
End Usr	end user
Req Mgr	request manager
Svc Mgr	service manager
SB Adm	Super Business Unit administrator
SD Adm	Service Delivery administrator

Tasks that Each Role Can Perform for Other Users

The following table displays the roles that can perform authorized tasks for themselves and for other accounts and users.

	Roles							
Can Perform Tasks for Themselves and	**Cat Usr**	**Req Mgr**	**Cat Adm**	**End Usr**	**Adm**	**Svc Mgr**	**SBU Adm**	**SD Adm**
Other accounts and users with roles in their business unit	-	X	X	-	X	X	X	X
Other accounts and users with roles in their business unit *and* any of its child business units.	-	X	X	-	-	X	X	X
Other accounts and users with roles in *all* business units, including *all* child business units	-	-	-	-	-	X	-	X

Default Role for All Users

The default role for all users applies to every user in the entire Catalog system. This default role applies to *all* users in *all* business units, including all child business units.

Only the Service Delivery administrators can set this default role. To set the role, the administrator logs in to the *root* business unit and selects Administration, Configuration, User Default Role.

The Catalog system automatically assigns this default role to every new user. However, administrators can optionally specify a different role for a user when they add or edit the user.

Manage Users with CA EEM

CA Service Catalog uses CA EEM to authenticate and authorize users. You can configure CA EEM to use an external directory, such as Microsoft Active Directory, for authentication of users.

Use the CA EEM user interface of CA Service Catalog to manage CA EEM users and groups. Start CA EEM from the Users option of the Administration Quick Start dashboard.

Integrating with embedded CA EEM and optionally with an external directory is the only required integration for CA Service Catalog. You use CA EEM and optionally an external directory to manage the CA Service Catalog user database.

After you have installed CA Service Catalog, its required components (including embedded CA EEM), and your external directory (if used), perform the following actions:

1. Import Users into the Database (see page 1418)
2. (Optional) Create User-Defined Groups (see page 1427)
3. (Optional) Update the host name of the CA EEM computer or the application names it uses. Perform this step periodically after CA Service Catalog has been installed and is running.
4. (Optional) Add High Availability and Failover Support as follows:
    a. Verify that you have installed CA EEM on at least two computers in your CA Service Catalog implementation.
    b. Set up high availability and failover support for CA EEM.

Note: For more information, see Configuring Failover (https://wiki.ca.com/display/CAEEM/Failover+Configuration).

    c. Run the setup utility and configure CA EEM.

Note: If you have installed other CA products that use CA EEM, see the documentation for each of those products for information about setting up failover support for CA EEM.

Step 1 - Import Users into the Database

After you install CA Service Catalog, the user database contains no data. To populate the database with user information, configure and run the LDAP utility. Running the utility populates your CA Service Catalog database with the users that you specify from your LDAP server. Run the utility at regular intervals to synchronize updates in the user database from the LDAP server to the CA Service Catalog database. You can optionally use a scheduler to synchronize.

Follow these steps:

Step 1a - Perform Transition Tasks

These tasks apply if you were previously using the CA EEM synchronization utility (syncuputil) to import and synchronize users in the CA Service Catalog user database. Examples include implementations that obtained the LDAP Importer utility by upgrading CA Service Catalog or applying a patch.

These tasks help you transition efficiently from the CA EEM synchronization utility to the LDAP Importer utility.

- Stop using the CA EEM synchronization utility and its properties file (syncuputil.properties).
- Remove scheduled tasks for that utility.
- Run the LDAP Importer utility.

These tasks do *not* apply to first-time installations of CA Service Catalog.

Step 1b - Configure CA EEM to Use an External Directory

Configuring CA EEM to use an external directory is a prerequisite for using the LDAP Importer utility.

Follow these steps:

1. Verify that the external directory contains at least one user ID that matches the user ID of a Service Delivery Administrator in CA Service Catalog:

   a. Log in to CA Service Catalog as the spadmin user and create at least one user ID with the Service Delivery Administrator role.
   This user ID must match a user name in the external directory.

   b. If CA EEM is configured for multiple active directories, create a user ID as Domain Name\userid in CA Service Catalog. Verify that the domain name is part of the principal name of the CA EEM user ID in the CA EEM active directory.

2. Configure the User Store in CA EEM to reference all applicable Active Directory sources.

Note: For more information, see your CA EEM documentation.

3. (For single sign-on) Verify that the domain name for Active Directory matches the domain name of the single sign-on user.
4. Select Manage Identities, Users, and validate that the users returned from a search are from the external directory. If your user base is large, limit the list of users returned.
5. Restart the CA Service Catalog service.
6. Log in to CA Service Catalog as the Service Delivery Administrator whose user name matches a user name in the external directory.

You have configured CA EEM to use an external directory.

Step 1c - (Optional) Determine the Number and Purpose of Configuration Files

If you are using multiple domains, you can use multiple configuration files. In that case, determine the number of configuration files and the purpose of each one. For example, large organizations can use several LDAP servers, one for each business unit, region, or domain. A managed service provider can use one group of LDAP servers for their internal organization and another group for their client organizations.

In such cases, as an administrator, you can use a unique configuration file for each server. You can configure the name and settings of each file to match its purpose. For example, consider a Managed Service Provider (MSP) with three internal LDAP servers and many LDAP servers for their clients. The MSP can decide to copy and customize the default file (LDAPImporter_server1.properties) as follows:

- Internal configuration files
  - LDAPImporter_Internal_Asia.properties
  - LDAPImporter_Internal_Europe.properties
  - LDAPImporter_Internal_NorthAmerica.properties
- Configuration files for clients that are retail companies in Asia.
  - LDAPImporter_Client_Azerbaijan_Retail.properties
  - LDAPImporter_Client_India_Retail.properties
  - LDAPImporter_Client_Singapore_Retail.properties

Note: Clustering alone does *not* require extra configuration files. If CA Service Catalog is clustered, verify that the properties file is available from the computers from which you run the utility.

Step 1d - Create the LDAP User

The LDAP Importer utility requires an LDAP user to connect to the LDAP server and import the LDAP users into the CA Service Catalog database. You specify the login credentials of the LDAP user in the configuration file properties (see page) for the utility.

Note: For more information about how to create LDAP users, see your LDAP documentation.

Step 1e - Create the CA Service Catalog User

To import users from the LDAP server to CA Service Catalog, the LDAP Importer requires a CA Service Catalog user. You create a CA Service Catalog user for this purpose and specify its login credentials in the configuration file properties (see page) for the utility.

Note: If an existing user meets the following specifications, you can use that user.

Follow these steps:

1. Log in to the *root* business unit.

   Important! Creating this user in the root business unit is required for the proper role assignment and access rights.

2. Select Administration, Users from the main menu.
3. Click Add.
4. Enter the data for the new user, as follows:

   - **User Name**
     Specify the same user name, including case, as the LDAP user that you use to connect to the LDAP server.
     If your catalog works with multiple LDAP servers, include the domain name, for example, MyDomain\MyUser.
   - **Role**
     Service Delivery Administrator.

The user is added.

Step 1f - Specify the Configuration File Properties

Replace the default properties in the file with your custom values. See the comments in the file for assistance.

The default configuration file is named LDAPImporter_server1.properties. This file resides in the USM_HOME folder. Copy and modify it to create all the custom configuration files that you require for your organization.

Important! The configuration file includes placeholder values that you *must* customize before running the utility.

Format

Properties in the configuration file follow this format: *name*=*value*. For example, LDAP. LastSynchronizationDate=2013-12-13.

Names *must not* contain spaces. If a name contains one or more spaces, replace each space with an underscore (_).

Values *can* contain spaces and you do not need to replace spaces with underscores.

You do not need to enclose spaces or underscores in quotation marks.

LDAP Properties

- **LDAP.Base.Provider.Url=*value***
  Specifies the URL of the LDAP server. If the LDAP server is *not* using SSL, use this format: LDAP.Base.Provider.Url= ldap://LDAP-server-name:389
  If the LDAP server *is using* SSL, use this format: LDAP.Base.Provider.Url=ldaps://*LDAP-server-name* :636
  If the LDAP server or CA Service Catalog uses SSL, complete the SSL parameters.

- **LDAP.User.DN=*value* and LDAP.User.Domain=*domain-name***
  Specify the name of the LDAP user that you created earlier (see page) for accessing the LDAP database.
  The domain name is required if CA EEM is configured to use multiple domains.
  If you are using multiple LDAP servers, the domain name must match the domain name for the LDAP server in CA EEM.

- **Catalog.User=*domain-name**username***
  Specifies the name of the CA Service Catalog user that you created earlier (see page) for importing the users from the LDAP server into the CA Service Catalog database.
  The domain name is required if CA EEM is configured to use multiple domains.

- **LDAP.User.Password=*password* and Catalog.User.Password=*password***
  Specify the encrypted passwords for each user in the appropriate parameter.
  To generate each encrypted password, enter the following command at the CA Service Catalog command prompt:

```
USM_HOME/SCRIPTS ENCRYPTER.BAT password
```

Copy each encrypted value from the command line and paste it to the appropriate entry in the configuration file.

- **InsertOrUpdateUsersAfterLastSyncDateOnly=True|False**
  We recommend that you specify True. *S*pecify True if you plan to run the utility regularly with a scheduling tool. This setting helps run the synchronization process in optimized mode.
  Alternatively, specify False if you do *not* plan to run the utility regularly with a scheduling tool.

- **LDAP.LastSynchronizationDate=*yyyy-mm-dd***
  This parameter is required if you specify True for the previous parameter, InsertOrUpdateUsersAfterLastSyncDateOnly.
  We recommend that you specify this parameter when you run the file for the first time. Afterwards, this parameter is updated automatically whenever you run the utility with a scheduling tool.
  Specifying this parameter provides more efficient processing. If you use this parameter, the utility imports *only* users that were added or updated since the last time the utility ran. The utility processes deleted users according to your specifications for the next parameter, DeactivateMDBUsersUponLDAPUserDeletion.

Catalog Properties

- **DeactivateMDBUsersUponLDAPUserDeletion=True|False**
  Specifies how to process CA Service Catalog users that were deleted from the LDAP database:

  - **True**
    (Recommended) *D*eactivates these users in the CA Service Catalog database. The user IDs are no longer available in the CA Service Catalog UI.

  - **False**
    Keeps these deleted users active in the CA Service Catalog database and UI.

  In either case, these deleted users cannot log in to CA Service Catalog, because they cannot be authenticated in the LDAP database.
  This setting does not apply the *first* time that you run the utility.

- CatalogUser.Country.*xx*=*country*

  - ***xx***
    Specifies the two-letter country code from the LDAP server.

  - ***country***
    Specifies the country name from the MDB.
    To obtain country names from the MDB, query the ca_country table.

    Note: If the LDAP server does not specify the country code, then the country name is set to NULL in the MDB.

  Examples:

- CatalogUser.Country.IN=India
- CatalogUser.Country.US=United States

- **CatalogUser.*country*.*city*=*location***
  Specifies a custom location name.

  - ***country***
    Specifies the country name from the MDB, as explained in the previous entry.

  - ***city***
    Specifies the city name from the LDAP server.

    Note: If the LDAP server does not specify the city, then the city is set to NULL in the MDB. If the LDAP server does specify the city, but the city is not mapped in this parameter, then the city is set to NULL in the MDB.

  - ***location***
    Specifies any custom location name relevant to your organization, for example, the name of a branch or unit in the *city*.
    If the location does not exist in the MDB, it is created.

    Note: As a best practice, specify a location name that is known to other administrators in your organization. This location and all other user attributes appear when you view user attributes in the CA Service Catalog UI.

  Examples:

  - CatalogUser.United_States.Islandia=UnitedStates1
  - CatalogUser.United_States.New_York=UnitedStates2

- **CatalogUser.DefaultBusinessUnit=*business-unit***
  Specifies the CA Service Catalog business unit to which users are assigned when they are imported for the first time.
  Once the users are imported for the first time, their business unit assignment is the same. Only when you use the CA Service Catalog UI to change the business unit, does this value also change. This restriction applies even if you change the value of this parameter and import the users again. This restriction helps maintain the ability of users to log in to CA Service Catalog.

- **CatalogUser.DefaultRole=*role***
  Specifies the CA Service Catalog role that users are assigned when they are imported for the first time.
  Once the users are imported for the first time, their role assignment is the same. Only when you use the CA Service Catalog UI to change the role assignment, does this value also change. This restriction applies even if you change the value of this parameter and import the users again. This restriction helps maintain the ability of users to log in to CA Service Catalog.
  The following table lists the valid role names for the CatalogUser.DefaultRole parameter, according to the type of business unit.

Role	Root BU	*Node BU	**Leaf BU
spadministrator (Service Delivery Administrator)	x		
servicemanager (Service Manager)	x		
catadministrator (Catalog Administrator)	x	x	
stadministrator (Super Business Unit Administrator)		x	
administrator (Administrator)	x	x	x
requestmanager (Request Manager)	x	x	x
catalogenduser (Catalog User)	x	x	x
enduser (End User)	x	x	x

*A Node BU is a child business unit that contains one or more of its own child business units.

**A Leaf BU is a child business unit that contains no child business units of its own.

- **SSL.KeyStoreLocation=*value***
  Specifies the complete path name of the keystore file that contains the SSL Server certificates of CA Service Catalog and the LDAP server. This parameter is required if CA Service Catalog or the LDAP server use SSL. If the LDAP server uses SSL, configure the LDAP.Base.Provider.Url parameter to use SSL.
  Delimit folder names with double backslashes (\\). The standard path name follows:

```
C:\\Program_Files\\CA\\Service_Catalog\\ssl.keystore
```

Important! Verify that you have imported the complete chain of Certification Authority (CA) certificates for CA Service Catalog and the LDAP server into the Java keystore.

- **SSL.KeyStorePassword=*value***
  Specifies the encrypted password for the CA Service Catalog keystore file.
  To generate the encrypted password, enter the following command at the CA Service Catalog command prompt:

```
USM_HOME/SCRIPTS ENCRYPTER.BAT password
```

Copy the encrypted value from the command line and paste it to this entry.

Step 19 - Run the Utility

Run the LDAP Importer utility regularly to import users from the LDAP server into the CA Service Catalog database. As a CA Service Catalog administrator, determine how often you must run this utility. For example, large organizations or organizations with frequent personnel changes want to run the utility daily. However, other organizations with fewer personnel changes want to run the utility weekly or every two weeks.

The file name of the utility is LDAPImporter.bat. The file resides in the USM_HOME\scripts folder.

You can optionally use *any* of the following methods to run the utility regularly:

- Run the utility manually from the command line of any CA Service Catalog computer.
- Run the utility as a batch job at scheduled times. Use the CA Service Catalog Scheduler or any standard scheduler, such as Windows Scheduler.
  To access the CA Service Catalog Scheduler, click Administration, Tools, Scheduler. Use the following specifications when you complete the fields:
  For Action Type, select Execute Command Line.
  For Cmd Line, enter the path names of the utility and the configuration file or files. The Cmd Line field accepts a limited number of characters. If necessary, specify relative path names (from USM_HOME\view\bin) or specify folder names only, as shown in the following examples:

```
..\..\scripts\LDAPImporter.bat ..\..\scheduler.properties

..\..\scripts\LDAPImporter.bat C:\LDAPFolder\
```

Note: For more information about the CA Service Catalog Scheduler, see the Manage the Scheduler (see page 3068) section. For more information about the Windows Scheduler, see your Windows documentation.

To run the LDAP Importer utility, enter the following command at the command prompt or in a scheduling tool:

```
LDAPImporter.bat properties-files
```

The utility processes all levels of nested groups of users. The utility imports each user and the users *above* it in organizational hierarchy, up to the top, even if the manager is not part of that group.

The utility does *not* import the users *below* the user in organizational hierarchy. For example, the utility does not import the direct reports of the user.

Logging

The log file for the utility is named LDAPImporter.log. This file resides in the USM_HOME\logs\LDAPImporter folder.

The level of logging for the utility is specified in the LDAPImporter.log4j.xml file. This file resides in the USM_HOME\scripts folder.

Examples

Examples of Running Configuration Files:

In this example, you run multiple configuration files in the USM_HOME folder:

```
LDAPImporter.bat USM_HOME\LDAPImporter_server1.properties
USM_HOME\LDAPImporter_server2.properties USM_HOME\LDAPImporter_server3.properties
```

In this example, you store all LDAP server properties in the MyFolder folder. Each LDAP server properties file name within this folder must use this format: ldapimporter_*name*.properties.

```
LDAPImporter.bat USM_HOME\MyFolder
```

Examples of Specifying Configuration File Properties

In this example, you populate the root business unit (ca.com) with users whose location is New York and who have direct reports. Assign the Service Delivery Administrator role to these users.

```
LDAP.ImportType=User
LDAP.MicrosoftAD.User.Filter = (&(objectClass=user)(!(objectClass=computer)))
LDAP.User.Filter= (&(l=New York)(directReports=*))
CatalogUser.DefaultBusinessUnit=ca.com
CatalogUser.DefaultRole= spadministrator
```

In this example, you populate the business unit that is named Europe with users who belong to the group named All Managers Europe. Assign the Super Business Unit Administrator role to these users.

```
LDAP.ImportType=Group
LDAP.Group.Name = All Managers Europe
CatalogUser.DefaultBusinessUnit=Europe
CatalogUser.DefaultRole= stadministrator
```

Step 1h - Verify the Import

Verify that the database has been populated correctly by logging in to CA Service Catalog as a user-defined in the database. A successful login indicates that the database was populated correctly.

Step 2 - (Optional) Create User-Defined Groups

Create user-defined groups in CA EEM to apply the same action to many CA Service Catalog users at once. Once you create the UDG in CA EEM, it is available in CA Service Catalog. You can then administer the UDG much like you would administer an individual user.

When you set the permissions for the UDG, those settings are applied to all individual users in the group. For example, you want to assign read-write access to a service to a group and read-only access to the service to another group. Use UDGs, to group users according to their function and purpose.

As an administrator, you can optionally assign users to one or more UDGs. The product does not require that users belong to any UDG. User who belongs to multiple UDGs have access to all resources authorized by their UDG memberships. If any UDG membership provides a user with access to a resource, then the user is granted access to that resource, regardless of whether other UDGs also grant access to the resource.

You can create and maintain user-defined groups (UDGs) in either CA EEM or your external directory (if applicable). You cannot create and maintain UDGs in CA Service Catalog directly.

Follow these steps:

Note: If the following steps do not match your version of CA EEM, see your CA EEM documentation for more information about assigning users to user groups in CA EEM.

1. Log in to the Service Delivery application of CA EEM. Do *not* log in to the global application of CA EEM.
2. Click Manage Identities, Groups.
3. Click Show Application Groups and click Go, in the Search Groups box on the left side of the screen.
4. Locate the Application Groups folder, in that tree; this folder contains the CA Service Catalog user groups, including the UDGs.
5. Find and click the "people" icon.
6. Enter the name and description for the new group in the fields provided.
7. Click Save to save your changes.

An important administrative task of user-defined groups (UDGs) is assigning rights to the following CA Service Catalog objects:

- Reports, including the data, data view, and layout objects
- Services, service options, and service option groups, including rights to edit, request, and subscribe to these elements.
- Documents
- Dashboards

An administrator can set permissions to a specific object (such as a service) according to the role of a user. The administrator can also set permissions to that object according to UDG.

For example, open a service in CA Service Catalog. Click Permissions, and search for a UDG or all users with a specific role. Next, you can assign rights to the service for the users and groups that are returned in the search results.

Note: When you search for UDGs, CA Service Catalog searches its own portions of CA EEM.

If a user has *either* a role or a group membership for which a permission has been set, the user is granted that permission. If a user has *both* a role and a group membership for which a permission has been set, the user is granted that permission.

You can optionally view the profile of an individual user who is a member of the UDG. While this step is not practical for verification on a large scale, it is helpful for spot checks.

You can assign rights to user-defined groups. By doing so, you ensure that all members of the group are assigned the same rights in a single operation.

Follow these steps:

1. Open the Set Permissions dialog for the Catalog object (such as a service) and click Groups.
2. Click Search EEM Groups.
3. Search for the group.
4. Click the group name in the search results.
   The dialog displays a new EEM Group list below the search results. The new list includes the group name that you clicked. The adjacent columns show the rights of the group to the object.
5. Select or unselect the options in the columns to grant or remove rights for the group to the object.

You have assigned right to the user-defined groups.

Enable External Authentication of Users

This article contains the following topics:

By default, CA Service Catalog uses CA EEM to authenticate users. You can configure CA Service Catalog to authenticate users with external applications such as CA SiteMinder, IBM Tivoli, and others. The process consists of the following tasks:

1. Install and implement the external authentication application, according to its documentation.
2. Review the following examples and understand how these applications typically send user authentication to CA Service Catalog. If applicable, adjust your settings to match these examples.
   - CA SiteMinder sends user identity information (authenticated user) with sm-user artifact name in the request header.
   - IBM Tivoli sends user identity information with iv_user artifact name in the request header.
   - Microsoft Internet Information Server (IIS) sends user identity information with request when configured for Windows NTLM.
   - Apache sends user identity information with request when configured for Windows NTLM.
3. Test the configuration on both CA Service Catalog and the external authentication application.
4. Verify that CA Service Catalog successfully receives and processes the authenticated users that the external authentication application passes. If necessary, adjust the parameters on both systems as needed.
5. Optionally configure Single Sign-On for the authentication method that you are using:

- Windows NTLM authentication (see page 1430)
- External authentication (see page 1432)

Configure Single Sign-on Using Windows NTLM Authentication

When you use Windows NTLM authentication, you can perform this procedure to enable Single Sign-On for CA Service Catalog. Users log in to the Windows domain, they can access CA Service Catalog without logging in to it.

Follow these steps:

1. Verify that you are *not* planning to use clustering. If you are using clustering, instead of performing this procedure, you set up NTLM authentication for each cluster.
2. Verify that your environment meets the following requirements:
   - You are using Windows domain authentication.
   - CA Service Catalog and CA EEM are installed in the same Windows domain.
   - You have configured CA EEM to use Active Directory.
     You are running a version of HTTP *higher* than 1.0.
   - If you are using Windows Server, perform one of the following tasks to use single sign-on using NTLM:
     - Use HTTP instead of HTTPS.
     - Uninstall the Internet Explorer Enhanced Security Configuration Windows Component.
   - If both of the following conditions exist, you cannot use single sign-on using NTLM with HTTPS:
     - The client computer operating system is Windows Server.
     - The Internet Explorer Enhanced Security Configuration Windows Component is installed.
3. Perform the following actions:
   a. Click **Administration**, **Configuration**, **Single Sign On Authentication**.
   b. Locate the **Single Sign On Type** and click the Modify icon.
   c. Select the option **NTLM (NT LAN Manager)** and click **Update Configuration**.
      The dialog closes, and you return to the Single Sign On Authentication page.
4. Verify that all affected users can use single sign-on to access CA Service Catalog on this computer.

You have configured NTLM Authentication.

Implement Single Sign-on for One Group of Users and Manual Login for Another Group

In this use case, you want to enable single Sign-on for one group of users. For example, internal users (Group 1) You also want to force manual login for another group of users. For example, external users such as contractors, vendors, and customers (Group 2).

Follow these steps:

1. Verify that you have two CA Service Catalog computers using the same instances of the MDB and CA EEM. This procedure calls the CA Service Catalog computers *Server 1* and *Server 2*.

2. Verify the following requirements:

   - Group 1 users log in to Server 1 *only*.
   - Group 2 users log in to Server 2 *only*.
   - If necessary, notify users in each group of this requirement.

3. On Server 2, edit the USM_HOME\webapps\usm\WEB-INF\web.xml file. Comment the following lines:

```
<!--
    <filter>
      <filter-name>NtlmAuthFilter</filter-name>
      <filter-class>com.ca.usm.httpfilter.NtlmAuthenticationFilter</filter-
class>
      <init-param>
        <param-name>debug</param-name>
        <param-value>false</param-value>
      </init-param>
    </filter>
-->
 <!--
   <filter-mapping> <filter-name>NtlmAuthFilter</filter-name> <url-pattern>*.
rpc</url-pattern> </filter-mapping>
    <filter-mapping> <filter-name>NtlmAuthFilter</filter-name> <url-pattern>/wpf
/*</url-pattern> </filter-mapping>
    <filter-mapping> <filter-name>NtlmAuthFilter</filter-name> <url-pattern>
/uslm/*</url-pattern> </filter-mapping>
    <filter-mapping> <filter-name>NtlmAuthFilter</filter-name> <url-pattern>
/assure/*</url-pattern> </filter-mapping>
    <filter-mapping> <filter-name>NtlmAuthFilter</filter-name> <url-pattern>
/documents/*</url-pattern> </filter-mapping>
    <filter-mapping> <filter-name>NtlmAuthFilter</filter-name> <url-pattern>
/FileStore/*</url-pattern> </filter-mapping>
-->
```

   Commenting these lines deactivates SSO functionality from this CA Service Catalog computer.

4. Restart CA Service Catalog.

Configure Single Sign-on Using External Authentication

When you use external authentication, you can perform this procedure to enable Single Sign-On for CA Service Catalog. Users who are set up in your external authentication system can access CA Service Catalog without logging in to it.

Follow these steps:

1. Verify that CA Service Catalog and CA EEM are installed in the same Windows domain.
2. Log in to CA Service Catalog running on this computer.
3. Perform the following actions:
    a. Click **Administration**, **Configuration**, **Single Sign On Authentication**.
    b. Locate the property **Single Sign On Type** and click the Modify icon.
    c. Select the option **Artifact Based Single Sign On** and click **Update Configuration**. The dialog closes, and you return to the Single Sign On Authentication page.
4. Verify that all affected users can use single sign-on to access CA Service Catalog on this computer.

You have configured external authentication other than Windows NTLM.

Configure CA Service Catalog to Use Secure Socket Layer

You can optionally configure CA Service Catalog to use Secure Socket Layer (SSL). SSL establishes an encrypted link between a server and a client. For example, a web server and a browser; or a mail server and a mail client. This link helps ensure that all data passed between the server and client remain private and integral. When you configure a product to use SSL, you change its communication method from HTTP to HTTPS.

Follow these steps:

1. Create a keystore file (see page 1433).
2. Use a single keystore for all integrated products. This approach is recommended.
   If you have multiple keystores for different products and cannot use a single keystore for all of them, you can merge keystore files (see page 1433).
3. Configure CA Service Catalog.
4. If you are integrating CA Service Catalog with CA Process Automation, perform the following steps:
    a. Configure CA Process Automation to use Secure Socket Layer. For more information, see your CA Process Automation documentation.

b. Configure CA Process Automation to communicate with CA Service Catalog using Secure Socket Layer (see page 1436)

5. If you are integrating CA Service Catalog with CA Business Intelligence, perform the following steps:

   a. Configure CA Business Intelligence to use Secure Socket Layer. For more information, see your CA Business Intelligence documentation.

   b. Configure CA Business Intelligence to communicate with CA Service Catalog using Secure Socket Layer. (see page)

6. (Optional) Add self-signed certificates to the keystore (see page 1438)

Step 1 - Create a Keystore File

A keystore file is required to enable SSL. Create a keystore file if you do not have one already for another CA product that integrates with CA Service Catalog. You can use a keystore file for a single product or for multiple products. If you must create individual keystores for each product, you can optionally merge your keystore files (see page 1433).

Follow these steps:

1. Open a command window on the Catalog Component server.

2. Enter the following command:

   ```
   keytool -genkey -alias alias_name -keyalg RSA -keystore "USM_HOME\.keys
   ```

   alias_name
   Specifies the logical name for the certificate that you are using for CA Service Catalog and possibly for other products. Record this alias name for reference.

3. Enter the password at the “Enter keystore password” prompt. To make configuring Tomcat easier, you can use “changeit” as the password.

4. Record your password for reference.

5. Enter your password at the prompt.

You have created the keystore file.

Step 2 - (Optional) Merge Keystore Files

A keystore file is required to enable SSL. If you are using SSL for two or more products and have two or more keystore files, use a single keystore for all integrated products. However, if you have multiple keystores for different products and cannot use a single keystore for them all, you can merge the contents of the individual keystore files.

Follow these steps:

1. Copy all keystore files to the USM_HOME folder. For example, any keystore files for CA Process Automation, CA CMDB, or other products that integrate with CA Service Catalog.

2. Find and record all required keystore files, keystore aliases, and keystore passwords for the products of interest. For example, for CA Process Automation, you can retrieve the c2okeystore password from KEYSTOREID property of the OasisConfig.properties file.

3. Restart Catalog Component.

4. Enter the keytool command to merge the keystore of the first product, using the following command as a model:

   ```
   keytool -importkeystore -srckeystore "product1_keystore" -destkeystore
   "USM_HOME\.keystore" -srcalias product1_alias -destalias alias_name-srckeypass
   "product1_password" -destkeypass "changeit"
   ```

   - **"*product1_keystore*"**
     Specifies the name of keystore file (including the complete path name) for the product you are merging.

   - ***product1_alias***
     Specifies the keystore alias for the product you are merging.

   - ***product1_password***
     Specifies the keystore password for the product you are merging.

   - ***alias_name***
     Specifies the *alias_name* that you specified when you created a keystore file for CA Service Catalog.

   The following command merges the contents of the CA Process Automation keystore (c2okeystore) into the CA Service Catalog keystore:

   ```
   keytool -importkeystore -srckeystore "%ITPAM_HOME%\server\c2o\.
   config\c2okeystore" -destkeystore "USM_HOME\.keystore" -srcalias c2o-j -
   destalias tomcat -srckeypass "475ba811-62cd-4ec8-b757-cd7710de3fa8" -
   destkeypass "changeit"
   ```

   The following command merges the contents of the CA CMDB keystore (.cmdb_keystore) into the CA Service Catalog keystore:

   ```
   keytool -importkeystore -srckeystore ".cmbd_keystore" -destkeystore
   "USM_HOME\.keystore" -srcalias cmdb -destalias tomcat
   -srckeypass "changeit" -destkeypass "changeit"
   ```

5. Respond No when you are prompted to overwrite the source alias.

6. Repeat the previous two steps for each product whose keystores you are merging.

7. Verify if all the certificates that you want are in one keystore, using the following command:

   ```
   keytool -list -keystore "USM_HOME\.keystore"
   ```

   This command lists the contents of the merged keystore.

You have merged keystore files.

Step 3 - Configure CA Service Catalog to Use Secure Socket Layer

Configure CA Service Catalog to use Secure Socket Layer (SSL).

Follow these steps:

1. Edit the server.xml file to support SSL (see page 1435).
   The file is updated to help support SSL for CA Service Catalog.
2. Open the USM_HOME\view\conf\viewService.conf file, using a text editor.
3. Update the following line with the path name and file name of the keystore file:

   ```
   wrapper.java.additional.number=-Djavax.net.ssl.trustStore="USM_HOME/.key
   ```
4. Update the following line with the password of the keystore file:

   ```
   wrapper.java.additional.number=-Djavax.net.ssl.trustPass=changeit
   ```
5. Save and close the viewService.conf file.
6. Select Administration, Configuration, Server Information on the CA Service Catalog GUI.
7. Complete the fields in this section as follows:
   For Host Name, specify the name of the host where CA Service Catalog is installed.
   For Port Number, specify the port where HTTPS is configured.
   For Enable HTTPS, specify Yes. Restart CA Service Catalog.
8. Log in to CA Service Catalog using the following URL:
   https://hostname:port/usm/wpf
9. You see a trusted certificate prompt, which indicates that you are using HTTPS.
10. Optionally, disable HTTP access by commenting the section for the HTTP connector, as shown in the following example:

```
<!--
<Connector port="8080" enableLookups="false" redirectPort="8443"
tomcatAuthentication="false"
      maxThreads="400" minSpareThreads="25" maxSpareThreads="100" debug="0"
connectionTimeout="15000"
      disableUploadTimeout="true" compression="on" compressionMinSize="2048"
      compressableMimeType="text/html,text/plain,text/xml,text/css,text/javascript,
image/png,image/gif,image/jpeg,application/json"
      useBodyEncodingForURI="false" URIEncoding="UTF-8" />
-->
```

You have configured CA Service Catalog to use SSL.

Edit the Server.xml File to Support SSL

As part of configuring CA Service Catalog to use Secure Socket Layer (SSL), edit the server.xml file to support SSL.

Follow these steps:

1. Open the USM_HOME\view\conf\server.xml file.

2. Search for the following section. Enable the commented section by removing "<!--" and "-->" from the first and last lines, as shown in the following example:

```
 <!--
    <Connector port="8443" enableLookups="false" tomcatAuthentication="false"
maxHttpHeaderSize="8192"
      maxThreads="400" minSpareThreads="25" maxSpareThreads="100" debug="0"
connectionTimeout="15000"
      disableUploadTimeout="true" compression="on" compressionMinSize="2048"
      compressableMimeType="text/html,text/plain,text/xml,text/css,text
/javascript,image/png,image/gif,image/jpeg,application/json"
      scheme="https" secure="true" clientAuth="false" sslProtocol="TLS"
SSLEnabled="true"
      keystoreFile="__USMHOME__\.keystore" keyAlias="alias_name" keystorePass="
changeit"/>
    -->
```

   - ***alias name***
     Specifies the logical name for the certificate that you are using for CA Service Catalog and possibly for other products.

3. Update the default port (8444) to another secure socket layer port, if necessary.

4. Verify whether either or both of the following conditions exist:

   - You are using an existing keystore.
   - You have changed either the CA Service Catalog installation path or generated keystore name.

5. Perform the following actions, if either or both of the conditions in the previous step exist:

   - Update the keystoreFile parameter with the correct path and file name, typically USM_HOME\.keystore.
   - Update the keyAlias parameter with the *alias_name* that you specified when you created a keystore file (see page 1433) for CA Service Catalog.

6. Save and close the server.xml file.

You have edited the server.xml file. You can continue configuring CA Service Catalog (see page 1435) to use Secure Socket Layer (SSL).

Step 4 - (Optional) Configure CA Process Automation to Communicate with CA Service Catalog Using Secure Socket Layer

Configure CA Process Automation to communicate with CA Service Catalog using SSL.

Follow these steps:

1. On the CA Service Catalog GUI, select Administration, Configuration, CA Process Automation.

2. Complete the fields in this section as follows:
   For Host Name, specify the name of the host where CA Process Automation is installed.
   For Port Number, specify the CA Process Automation port where HTTPS is configured.
   For Enable HTTPS, specify Yes.

3. Recycle Catalog Component.

4. Click Test.
   The connection is tested, using the new values that you specified.
   If the connection fails, try using a different value.

5. Click Configure.
   The CA Process Automation configuration details are updated with the new values that you specified.

6. Perform this step if you are using content packs. Otherwise, you can skip this step.
   Edit the USM_HOME\build.xml file, and verify that the following parameters are correct. Update them, if applicable.

   - The file name and path name of the keystore
     For example, if the keystore is located in USM_HOME and the keystore file name is. mykeystore, update this line as follows:

     ```
     <sysproperty key="javax.net.ssl.trustStore" value="${env.USM_HOME}/.mykeystore" />
     ```

   - The keystore password
     For example, if the keystore password is mykeystorepw, update this line as follows:

     ```
     <sysproperty key="javax.net.ssl.trustPass" value="mykeystorepw" />
     ```

You have configured CA Process Automation to communicate with CA Service Catalog using SSL.

Step 5 - (Optional) Configure CA Business Intelligence to Communicate with CA Service Catalog Using Secure Socket Layer

As part of configuring CA Service Catalog to use Secure Socket Layer (SSL), you configure BusinessObjects Enterprise to communicate with CA Service Catalog using SSL.

Follow these steps:

1. Select Administration, Configuration, CA Business Intelligence, on the CA Service Catalog GUI.

2. Complete the fields in this section as follows:
   For Host Name, specify the computer name on which the Business Intelligence Launch Pad component of CA Business Intelligence is hosted.
   For Port Number, specify the port number on which CA Business Intelligence is running.
   For Enable HTTPS, specify Yes.

3. Recycle Catalog Component.

4. Click Launch.

5. The connection is tested, using the new values that you specified. If the connection fails, try using a different value.
   The BusinessObjects Enterprise configuration details are updated with the new values that you specified.

Step 6 - Add Self-Signed Certificates to the Keystore

When you use self-signed certificates for any computer that connects directly to CA Service Catalog or that CA Service Catalog connects to, add these certificates to the keystore. For example, suppose that you are using clustering with load balancing for CA Service Catalog. In that case, if you are using a self-signed certificate for the load balancing computer, add them to the keystore.

Note: If you are using trusted certificates for these computers, you do not need to add them to the keystore.

Follow these steps:

1. Verify the computer to be trusted, that is, the computer that has direct connection with CA Service Catalog.
   For example, suppose that you integrate CA Service Catalog with CA Service Desk Manager through a load balancing computer. In that case, CA Service Catalog connects directly to the load balancer (not CA Service Desk Manager). Therefore, the computer to be trusted is the load balancer (not the CA Service Desk Manager computer).

2. Go to a Catalog Component computer. Download the DER encoded binary X.509 file (the certificate) for the computer to be trusted.
   For example, use your web browser to visit the computer and obtain the certificate.

3. Open the CA Service Catalog command prompt and enter the following command:

   ```
   keytool -importcert -alias aliasname -file pathname-to-certificate -keystore
   USM_HOME\.keystore
   ```

   - ***alias_name***
     Specifies the logical name for the certificate that you are using for CA Service Catalog and possibly for other products.

   - ***pathname-to-certificate***
     Specifies the complete path name to the certificate file that you downloaded in the previous step.

   You are prompted to enter a password.

4. Perform one of the following actions:

   - Enter changeit as the keystore password.

   - Enter a different keystore password.

The password is saved.

5. Complete this step if you entered a different password than changeit in the previous step. Otherwise, skip this step.

    a. Open the viewService.conf file for editing.

    b. Find the line that contains the following phrase:

    ```
    -Djavax.net.ssl.trustPass=keystore-password
    ```

    a. Update the keystore-password to match the new password that you specified in the previous step.

    The viewService.conf file is updated with the new password.

6. Remain at this Catalog Component computer. Repeat the previous steps for every computer to be trusted which has self-signed certificates.
   The keystore file is updated with the new self-signed certificates from each applicable computer to be trusted.

7. Perform the following actions on of every other Catalog Component computer:

    a. Update the viewService.conf file to use a password other than *changeit*, if applicable.

    b. Copy the updated keystore file from this Catalog Component computer to all the remaining Catalog Component computers.

You have added self-signed certificates to the keystore.

Reconfigure the CA Service Catalog Computer using the Setup Utility

Run the CA Service Catalog setup utility to set up your database, reconfigure CA EEM, and reconfigure the product components. The product components are Catalog Component, Catalog Content, and Service Accounting Component.

Important! Run the CA Service Catalog setup utility on all CA Service Catalog computers in the correct sequence, as explained in this topic.

Follow these steps:

1. Run the setup utility on each CA Service Catalog computer, in the following sequence:

    a. The *first* (formerly *primary*) Service View computer

    b. All *additional* (formerly *secondary*) Service View computers

c. All other CA Service Catalog computers, in any order

Note: To run the setup utility, perform *all* the following steps on each computer, one computer at a time. For example, the first Service View computer is Host1, the additional Service View computers are Hosts 2 and 3, and the remaining CA Service Catalog computers are Hosts 4-6. First, run the setup utility on Host1. Next, run the setup utility on Hosts 2 and 3, one computer at a time, in any order. Third, run the setup utility on Hosts 4-6, one computer at a time, in any order.

2. Start the setup utility using one of the following methods:

   - Click the option to start the setup utility *after* you have run the installation or upgrade program on the last applicable computer. The last applicable computer is the final computer on which you run the installation or upgrade program for CA Service Catalog.
   - Start the setup utility from the Windows Start menu. For example, click Start, Programs, CA, Service Catalog, Setup Utility.

Note: If your browser blocks access to the setup utility web page for security reasons, add the CA Service Catalog computer to the trusted web sites for the browser. Use the following format for the CA Service Catalog computer: http://*hostname*:*port*.

3. Specify the following parameters and log in to the utility:

   - **Password**
     Specifies the password for logging in to the utility and running it using either of the methods in the previous step.

     Note: Record the password for reference, because the utility requires you to specify the password each time you start it.

     If necessary, you can reset the password, as follows:
     Enter the following command:

     ```
     USM_HOME\scripts\configurator.bat -resetpwd
     ```

     The Catalog system resets the password and prompts you to perform the next action: Restart the utility and specify the new password.

   - **Remote Configuration**
     (Optional) If you have run the utility successfully on another computer (a remote computer), you can use the same configuration on this computer (the local computer). To

do so, select this option and enter the URL of the remote computer. Use the following format: http://*server*:*port*/*context*. An example is http://localhost:8080/usm.
The database setup page appears.

4. Complete this step *only* if you selected the Remote Configuration option in the previous step. Otherwise, skip to the next step.
   Supply the password for the setup utility on the remote computer.
   The local setup utility copies configuration data from the remote computer and pre-populates the corresponding local fields with this data. The local utility copies the data for the database setup, CA EEM configuration, and the name of the top-level business unit. Therefore, you do not need to enter this data manually. However, you can optionally update the copied values, if necessary. This data appears on the remaining tabs of the local setup utility and is described in the remaining steps.
   You typically use the Remote Configuration option when you plan to install multiple instances of CA Service Catalog.

5. Reconfigure the Database (see page 1441)

6. Reconfigure CA EEM (see page 1445)

7. Reconfigure the CA Service Catalog Components (see page 1445)

You have completed the steps for running the setup utility on all CA Service Catalog computers.

Note: If you are installing CA Service Catalog for the first time on a computer, the setup utility pre-populates the fields that require input with default values. If you are re-installing or upgrading CA Service Catalog, the setup utility pre-populates these fields with the values from the current installation. The Remote Configuration option overwrites any default values or existing values with the values from the remote computer.

Reconfigure the Database

You can reconfigure database so that CA Service Catalog users and the Catalog system can function correctly.

Follow these steps:

1. Log in to the setup utility and click Database on the left menu.
   The utility displays the page for connecting to the database and configuring it.

2. Select the DBMS that you are using and provide the information to complete the fields.

3. Complete the fields for the Database Connectivity section.
   This step verifies that you can connect to the database. If the connection fails, perform these actions:

   a. Verify that the parameter values are correct. For more information about these parameter values, see Parameters for SQL Server (see page 1442) and Parameters for Oracle (see page 1439).

b. Verify that you prepared the catalog database and the DBMS (see page 582).

4. Specify the name of the CA Service Catalog database, typically MDB, in the Database Settings section.
   This step installs or upgrades the MDB, if necessary. This step also configures the CA Service Catalog database in the MDB.

5. Complete the remaining database fields.

6. Specify the details for the application user that you created earlier.

7. Save and confirm your updates.

8. (Optional) Review the log files, as follows:

   - For log information for SQL Server, see the following sources:
     - See the install_mdb.log file in your MDB target installation directory. This directory is specified in %TEMP%\MDB1.5, where %TEMP% is a Windows environment variable. If the MDB installation fails, review the log files in this location.
     - After a successful installation of the MDB, the install_mdb.log file is copied to the %ProgramFiles%\CA\SC\Mdb\Windows\logs folder. This log file is renamed to install_mdb_*mm-dd,hh_mm_ss*.log (for example, install_mdb_12-03,15_29_05.log).
     - See the view.log file. Its default location is the C:\Program Files\CA\Service Catalog\logs folder.
   - For log information for Oracle, see the following sources:
     - See the install_connectionID.log file in your MDB target installation directory. For example, if the connection ID is myhost_orcl, the install_connectionID.log file name is install_myhost_orcl.log. The MDB target installation directory is specified in %TEMP%\MDB1.5, where %TEMP% is a Windows environment variable. If the MDB installation fails, review the log files in this location.
     - After a successful installation of the MDB, the install_connectionID.log file is copied to %ProgramFiles%\CA\SC\Mdb\Windows\logs. This log file is renamed to install_connectionID_*mm-dd,hh_mm_ss*.log, for example, install_myhost_orcl_12-03,15_29_05.log.
     - See the view.log file. Its default location is the C:\Program Files\CA\Service Catalog\logs folder.

You have reconfigured the database.

Parameters for SQL Server

Before you install CA Service Catalog, you specify values for several parameters to establish the connection to an SQL Server database. The following parameters may require explanation:

Important! For a migration model upgrade, when you are prompted for information about the Catalog database, use the *existing* Catalog database specifications.

For the Database Connection

- **Host Name**
  Defines the computer name of the Microsoft SQL Server (SQL Server) server.

- **Port**
  Defines the TCP Port number of the database server.
  If you are using an instance name, verify the following requirements:

  - The instance name has a port number set.

  - Your implementation is *not* using dynamic ports.

- **User Name and Password fields**
  Define the user name and password of the SQL Server database administrator (DBA). The setup utility uses these credentials to set up the CA Service Catalog database.
  You can use the login credentials of either of the following users:

  - System administrator (sa). This user requires dbo as its default schema.

  - The user named installuser that you created. You can optionally create this user so that the setup utility uses this user (instead of sa) to set up the CA Service Catalog database.

- **Instance Name**
  Defines the SQL Server instance name for the MDB. For example, myinstance. You can specify either a primary instance or a named instance.

For the Database Configuration

- **Database Name**
  Specifies the name of the CA Service Catalog database: MDB.

  Important! The name of the Catalog database must be MDB. This requirement is especially important if you integrate CA Service Catalog with another CA product, such as CA Service Desk Manager, CA APM, or CA Process Automation.

Application User Settings

- **User Name and Password fields**
  Define the user name and password that CA Service Catalog uses for accessing this database. This user name and password are created in the database.
  This user is the first application user. For increased flexibility, you can optionally create a second application user.

Parameters for Oracle

Before you install CA Service Catalog, you specify values for several parameters to establish the connection to an Oracle database. The following parameters may require explanation:

Important! For a migration model upgrade, when you are prompted for information about the Catalog database, use the *existing* Catalog database specifications.

Note: These parameters apply to Oracle running on both Windows and Linux.

For the Database Connection

- **Host Name**
  Defines the computer name of the Oracle server.
- **Port**
  Defines the TCP Port number of the database.
- **User Name and Password fields**
  Define the user name and password of the Oracle database administrator (DBA).
- **Service Name**
  Defines the service name. Every Oracle database or service has a service name. The service name of an Oracle database is typically its global database name. Enter the service name of the database or other service that you want to access.
  A non-RAC deployment typically includes one service, one instance, and one database, each with the same name. However, in a RAC deployment, multiple instances can provide multiple services, all connecting to a single database.
- **Connection SID**
  Defines the connection ID (such as orcl) for connecting to the Oracle server, as follows:
  - For a local database, this value is typically the SID.
  - For a remote database, this value is typically the Net Service Name.

For the Database Configuration

- **Database Name**
  Specifies the name of the CA Service Catalog database: MDB.

Important! The name of the Catalog database must be MDB. This requirement is especially important if you integrate CA Service Catalog with another CA product, such as CA Service Desk Manager, CA APM, or CA Process Automation. CA Service Catalog embeds CA MDB r1.5.

- **Tablespace Path**
  Defines the complete path name of the tablespace for Oracle.

- **Data Tablespace Name**
  (Optional) Defines the tablespace name for the data.

- **Index Tablespace Name**
  (Optional) Defines the tablespace name for the indexes.
  The installer verifies whether the data and index tablespaces exist in the MDB. These tablespaces exist when either of the following conditions are met:

  - The MDB is being upgraded.

  - The CA Service Catalog database is being installed in an existing MDB, typically from an already installed CA product or group of products.

  If the data and index tablespaces exist, the installer displays their names. The installer also prompts you to specify whether to continue using the existing names or overwrite them with new names.

Application User Settings

- **User Name and Password fields**
  Define the user name and password that CA Service Catalog uses for accessing this database. This user name and password are created in the database.

Reconfigure CA EEM

You can reconfigure CA EEM for use with CA Service Catalog using the setup utility.

Note: Use the Setup Utility if you have only CA Service Catalog in your environment. Use the Service Management Administration, Common Configuration option to reconfigure CA EEM if you have integrated CA Service Catalog with at least one other CA Service Management product.

For more information, see Integrate CA Service Catalog with CA EEM Manually (see page 3292)

CA EEM has been reconfigured for use with CA Service Catalog.

Reconfigure the CA Service Catalog Components

You can reconfigure the CA Service Catalog product components that you want on this computer.

Note: If you are installing CA Service Catalog on this computer for the first time, you can use the utility to reconfigure the product components. However, if you are upgrading or installing CA Service Catalog on this computer a second time, this value is read-only and you cannot reconfigure the product components.

Follow these steps:

1. Log in to the setup utility and click Components in the the left menu.
2. Enter the name of the service provider business unit. It is the “root” business unit above all other business units. As a best practice, specify your company domain name or a short version of your company name for the business unit ID.
3. Select each component that you want to use on this computer:
   - **Catalog Component**
     Lets you create service options and service option groups, which you use to create services that users can request from the catalog.
     This option includes the Catalog Content, which supplies the predefined services in the catalog. Examples include services for requesting hardware, software, and other IT essentials from your business unit. You can use these services as-is, or you can copy and customize them.
     This option installs a Windows service named CA Service Catalog.
   - **Service Accounting Component**
     Lets you provide billing and chargeback for the services that users request from the catalog. You can also use Service Accounting Component to allocate costs, prepare budgets, and plan IT services.
     This option installs a Windows service named CA Service Accounting.
4. Click Save.
5. Follow the prompts and complete the setup.

Note: You can optionally review the installation log file, view.log. Its default location is the USM_HOME\logs folder. This log file is visible after you have completed all tasks of the installation or upgrade program and have closed the program. For information about uninstallation and aborted or canceled installations (when applicable), see the CA_Service_Catalog_Uninstallation.log file in the Windows Temp folder.

CA Service Catalog components have been reconfigured.

Configuration Files

The configuration files and locations are as follows:

- Database connection configuration file: USM_HOME\DBSource.properties
- CA EEM connectivity configuration file: USM_HOME\Eiam.properties
- IXUtil utility configuration file: USM_HOME\scripts\ixutil.cfg

USM_HOME is the documentation convention that specifies the local CA Service Catalog installation directory. For 32-bit computers, the default path name is C:\Program Files\CA\Service Catalog. For 64-bit computers, the default path name is C:\Program Files (x86)\CA\Service Catalog for 32-bit installations or C:\Program Files\CA\Service Catalog for 64-bit installations.

- Configuration Settings (see page 1447)
- Set CA Service Catalog Configuration Options (see page 1449)
- Set Accounting Configuration Options (see page 1461)
- Set Administration Configuration Options (see page 1477)

Configuration Settings

This article contains the following topics:

- Inheritance of Configuration Settings Through the Business Unit Hierarchy (see page 1447)
- Change the Business Unit (see page 1448)

After the CA Service Catalog installation is complete, verify the configuration settings. Doing so helps ensure that the product functions according to the needs of your organization.

Verify the settings by group, as follows:

- Set CA Service Catalog Configuration Options (see page 1449)
- Set Accounting Configuration Options (see page 1461)
- Set Administration Configuration Options (see page 1477)
  These include Integration-Specific Options (see page 1478)
- Location of shared files (filestore)

Important! With one exception, CA Service Catalog sends emails in HTML format only. To receive legible emails from CA Service Catalog, recipients must configure their email software to accept emails in HTML format. Otherwise, emails from CA Service Catalog display indecipherable messages when opened. The one exception to this HTML-only rule is invoice history. You can choose to view and email invoice history in HTML, CSV, or XML format. The HTML-only rule applies to all other invoice-related areas of CA Service Catalog, including invoice generation.

Inheritance of Configuration Settings Through the Business Unit Hierarchy

The following rules govern the relationship between parent and child business units (children), including the inheritance of configuration settings:

- The child business units directly under the top-level business unit (the service provider) are named super business units. Super business units *always* inherit their configuration settings from the service provider business unit.
- If the configuration parameter *Contains Sub Units* is enabled, a super business unit can have children.
- If the *Contains Sub Units* parameter of the super business unit is enabled, you *can* edit the configuration settings of the super business unit.
- If you edit the configuration settings of a super business unit, your changes do *not* apply to the super business unit. Instead, your changes apply to its children. A child "inherits" its configuration settings from its parent.
- You can optionally create unlimited levels of children under super business units. If the *Contains Sub Units* setting of the business unit is enabled, you can edit its configuration settings. Your configuration changes do *not* apply to the business unit itself but instead apply to its children. Conversely, if the *Contains Sub Units* setting of the business unit is disabled, you cannot edit its configuration settings.

Thus, the following summary applies to all business units except for the service provider:

- A business unit always inherits its configuration settings from its parent.
- You can edit the configuration settings of a business unit *only* if its Contains Sub Units setting is enabled. Your changes apply *only* to its children.

Change the Business Unit

By default, the Catalog system displays settings for the business unit that you logged in to. If your role permits, you can change to a different business unit.

When common multi-tenant administration is enabled, you can add tenants, delete tenants, or edit the common attributes *only* through CA Service Desk Manager. When common multi-tenant administration is enabled, you can *view* tenants and all their attributes in CA Service Catalog. But you can edit only the CA Service Catalog-specific attributes.

Follow these steps:

1. Click Catalog, Configuration.
2. Click the Change Business Unit button.
   The Search Business Units dialog appears.
3. Use the Expand and Collapse icons to navigate the business unit tree. Alternatively, use the selection criteria and Search button to locate the desired business unit.
   The list includes only the business units that your role permits you to access.
4. To select a business unit, click its name in the tree.
   The window closes, and the configuration settings for that business unit appear.

Set CA Service Catalog Configuration Options

You configure CA Service Catalog to customize settings for request management, access control, request emails, and so forth. These settings specify how the Catalog system processes requests in your organization.

Follow these steps:

1. Click Catalog, Configuration.
2. Perform one of the following actions:
   - To manage configuration options for a different business unit, change the business unit (see page 1448) before performing the next step.
   - To manage configuration options for the current business unit, go directly to the next step.
3. Click one of the following links for the category of options that you want to update:
   - Catalog Configuration (see page 1449)
   - Request Management Configuration (see page 1450)
   - System Configuration (see page 1461)
4. View the options for the category, and click the Modify icon for the option that you want to update.
5. Update the setting as required and click Update Configuration.

You have set the CA Service Catalog configuration options. These settings apply to the children of the business unit that you updated, according to the inheritance of configuration settings through the business unit hierarchy (see page 1447).

Catalog Configuration

As part of setting the CA Service Catalog configuration options (see page 1449), you specify the following Catalog Configuration options. These settings control the behavior of the catalog.

- **Default Effect of Service Option Element Changes**
  Specifies when to reflect changes to service option elements for accounts that have subscribed to or requested services that include them.
  Select one of the following options to use when the service option element changes:
  - **Specify when the Service Option Element Changes - Allow User to Choose**
    Enables the administrator to specify the effect of the change on existing subscribers or requestors.
  - **Beginning of Accounts' Current Billing Period - No Audit Trail**
    Implements the change retroactively to the beginning of the current billing period for existing subscribers or requestors. No audit trail applies.

- **Beginning of Accounts' Current Billing Period**
  Implements the change retroactively to the beginning of the current billing period for existing subscribers or requestors.

- **Beginning of Accounts' Next Billing Period**
  Implements the change at the beginning of the next billing period for existing subscribers or requestors.

- **Immediately during Accounts' Billing Period**
  Implements the change immediately for existing subscribers or requestors.

- **Specify a Future Effective Date**
  Enables the Administrator to specify a date on which the change takes effect for existing subscribers or requestors.

Default: Specify when the Service Option Element Changes - Allow User to Choose.

- **Pass Through Catalog**
  Specifies whether to include the catalog of the parent business unit.
  If you select this option, the parent catalog is passed down to the child business unit. This setting is useful in a multiple-level business unit organization. This setting applies only to the settings for a child business unit.
  Default: No

Request Management Configuration

As part of setting the CA Service Catalog configuration options (see page 1449), you specify the Request Management Configuration options. These settings that control the behavior of requests for the following groups of parameters:

- Access Control Parameters (see page 1450)
- Other Parameters (see page 1453)
- Request Email Parameters (see page 1458)

Access Control Parameters

As part of setting the CA Service Catalog configuration options (see page 1449), you specify the following Access Control parameters:

- **Access Control: Add Request**
  Specifies which user roles can add a request.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, End User, Catalog User, Request Manager, Catalog Administrator

- **Access Control: Edit Request**
  Specifies which user roles can edit a request. All users can edit their own requests, if the status of the request is in the not submitted range.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, End User, Catalog User, Request Manager, Catalog Administrator

- **Access Control: Delete Request**
  Specifies which user roles can delete a request or a requested service. All users can delete their own requests, if the status of the request is in the not submitted range. Once a requested service is in a canceled state, only users with Delete Request permission can delete a canceled service.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Cancel Request**
  Specifies which user roles can cancel a request.
  This parameter works together with the Allow Cancellation Through parameter, which is described later in this list.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Show Amount Column**
  Specifies which user roles can view the Amount Column when viewing a request.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Show Period Column**
  Specifies which user roles can view the Period Column when viewing a request or shopping cart.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Show Related Ticket Column**
  Specifies which user roles can view the Related Ticket Column when viewing a request or shopping cart.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Show General Information**
  Specifies which user roles can control whether the general information form is visible when you create a request.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator, Service Manager, End User, Catalog User

- **Access Control: Show Request Information**
  Specifies which user roles can control whether the request information form is visible when you create a request.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator, Service Manager, End User, Catalog User

- **Access Control: Save Cart As Request**
  Specifies which user roles can view the button allowing the user to save the shopping cart as a request, clearing the cart for reuse.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Proxy Request**
  Specifies which user roles can view the link to change the Requested For field from your own user ID or account to another user ID or account.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Proxy Action**
  Specifies which user roles can see the link to approve, reject, fulfill, or transfer requests pending action that is assigned to other users.

- **Access Control: Show Fulfillment Details**
  Specifies which user roles can view statistical information regarding the time that is required to fulfill a service option in the past.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Take/Return Request Pending Action**
  Specifies which user roles can take or return ownership of requests pending action. They can take ownership of requests pending action from the following options:

  - A group queue
  - The queue of another user in the same business unit or child business unit

  Similarly, they can return ownership of requests pending action from their own queue to their group queue.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Transfer Request Pending Action**
  Specifies which user roles can transfer ownership of requests pending action from the assigned user to either of the following options:

  - Another user in the same group
  - Another user in the same business unit or child business unit

  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Delegate Request Pending Action**
  Specifies which user roles can delegate ownership of requests pending action from a group queue to either of the following options:

  - A specific user in that group
  - Another user in the same business unit or child business unit

  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Push Through Requests**
  Specifies which user roles can push through ("force") a stuck request to the next level of approval or fulfillment.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator

- **Access Control: Display Request Warning**
  Specifies which user roles can view the warning icon indicating that a request is stuck. **Default:** Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator, End User, Catalog User

- **Access Control: Hold/Resume Request**
  Specifies which user roles can hold a request that is in progress and can resume a request that is in Hold status.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, Request Manager, Catalog Administrator, End User, Catalog User

Other Parameters

As part of setting the CA Service Catalog configuration options (see page 1449), you specify the following miscellaneous parameters:

- **Allow Attachments at Service Option Level**
  Lets users add attachments to individual service options. This setting must be Yes if you want to make attachments mandatory for any service option.

- **Allow Cancellation Through**
  Defines the status through which users can cancel requests. After the request moves to the next status, it cannot be canceled. This parameter works together with the *Access Control: Cancel Request* parameter.
  Default: Fulfilled

- **Allow Discrete Handling for Reject**
  Specifies the effect of the rejection of a single service or service option upon other services and service options in the same request, as follows:

  - **Yes**
    Specifies that when you reject a service or service option, the remaining services or service options can advance if they are approved. If the following options are approved, they can advance in the request life cycle:

    - Other services in the same request

    - Other service options in the same service

  - **No**

  Specifies that when you reject a service or service option, the entire request is rejected. All services in the same request are rejected and can no longer advance in the request life cycle, even if they were previously approved. Similarly, all service options in the same service are rejected and can no longer advance in the request life cycle, even if they were previously approved.

Default: No

Note: For more information about discrete request life cycle, see the Manage Discrete Request Life Cycle (see page 2120) section.

- **Allow Discrete Handling of Service Options After**
  Specifies the status at which request managers (approvers and fulfillers) can handle requests pending action (approval, rejection, or fulfillment) *discretely*. When the request reaches the status you specify, request managers can discretely approve, reject, or fulfill each service option in every service in the request.
  Use this parameter to specify that pending actions are assigned at the service option level, rather than the service level.
  The setting applies to the request *from* the starting status that you specify *through* the remainder of the request life cycle.
  Valid values: Submitted, Pending Fulfillment, or Completed.
  Default: Pending Fulfillment

  Note: For more information about using a discrete request life cycle, see the Manage Discrete Request Life Cycle (see page 2120) section.

- **Allow Discrete Request Life Cycle After**
  Specifies the status at which individual service options in a service and individual services in a request advance independently. *Independently* means *without* requiring or waiting for any other service option in the same service or any other service in the same request to advance its status. When the request reaches the specified status, the service options that you approve or fulfill can complete the remainder of the request life cycle. This condition exists even if other service options in the same service do not advance in status.
  As soon as the request reaches the specified status, the services that you approve or fulfill can complete the remainder of the request life cycle. This condition exists even if other services in the same request are rejected or are not updated.
  Valid values: Submitted, Pending Fulfillment, or Completed.
  Default: Completed
  The setting applies to the request *from* the starting status that you specify *through* the remainder of the request life cycle.

  Note: For more information about using a discrete request life cycle, including sample settings and their meanings, see the Manage Discrete Request Life Cycle (see page 2120) section.

- **Allow Multi Service/Service Option Approval**
  Lets users approve or reject multiple, selected services or service options (including all) with a single click. This ability is *multi-item approval*. Discrete approval is required to approve or reject service options using multi-item approval.

- **Allow Notes at Service Option Level**
  Controls whether a user can add notes at the service and service option levels.
  If this option is set to Yes, then the Add Note icon appears in the Action column for requests. Therefore, the user can add a note for a specific service or service option.
  If this option is set to No, then the user can add notes for the entire request but not for a specific service or service option.
  Default: No

- **Allow Only One Service Per Request**
  Specifies whether a user can include more than one service in a request or cart.
  If this option is set to Yes, then a user can have only one service in a cart or request. Also, the user must submit the cart or request before creating a new one.
  If this option is set to No, then a user can select multiple services from the catalog. The user can add them to the cart or request before submitting the request.
  Default: No

- **Browse Catalog Layout**
  Specifies the look-and-feel for the Requests page. On this page, users can create, customize, submit, and manage requests.
  Specify *one* of the following options. Click Home, Requests to verify the resulting look-and-feel on the Requests page.
  The Service View and Service View without Browse Section options provide the best performance. These options provide *links to* the requests, while the other options display the requests directly.

  - **Service View**
    Configures the Requests page to display the catalog, featured services, and a search-for-services field in boxes.
    A My Requests link opens a drop-down list. The list includes options to search requests, review open requests, and act on pending requests.

  - **Service View without Browse Section**
    Configures the Requests page to display the catalog alone. Featured services and the search-for-services field do *not* appear.
    A My Requests link appears, as described for the Service View option.

  - **Request View**
    Configures the Requests page to display the catalog (categories and lists of services) in a column on the left.
    Boxes to the right of the column enable users to do the following tasks:

    - Search for services.
    - View and request featured services.
    - Review their own recent requests and, if applicable, act on them.
    - Use links to review open, pending, and completed requests.
    - Search for requests.

- **Grid View**
  Configures the Requests page to display the catalog in a grid.
  Boxes surrounding the grid enable users to perform the same tasks as listed for the Request View option.

Default: Service View

- **Browse Catalog: Show Folder Icon**
  Specifies whether images associated with catalog folders appear in the Browse section of the Requests page.
  If this option is set to Yes, folder images appear in the Browse section. If this option is set to No, they do not appear.
  Default: No

- **Browse Catalog: Show Subfolders**
  Specifies whether the top-level subfolders under each catalog folder appear in the Browse section of the Requests page.
  If this option is set to Yes, the first level of subfolders appear under each catalog folder in the Browse section.
  If this option is set to No, only the catalog folders appear.
  Default: Yes

> **Note:** For any individual catalog folder, you can override this default by changing its folder details on the Catalog, Service Offerings page.

- **Default User for Request Actions**
  Specifies the user who must be assigned a pending action when no other user is available. This setting is typically used for request approvals when the user needs manager approval and no manager exists in the system for the user. When this setting is used with the system approval process, verify that this user has the highest authorization level.
  Default: spadmin

- **Display Service Health**
  This parameter applies *only* if you are integrating CA Service Catalog with CA Business Service Insight.
  Specifies whether to enable catalog users requesting a service to view actual, current data regarding the quality or "health" of a service. The health is based on the level of compliance of the service to its associated metrics. This data includes the contractual metrics, incentive metrics, and the SLA health period. This information is specified in the contract-specific details for the service option elements in the service being requested.
  The metric data includes both the performance criteria and the actual number of violations, including the time increments measured.
  If you enable this option, catalog users can view this actual and current metric data for the service they are requesting.

- **Edit Cancelled Requests**
  Specifies that if the value is set to **Yes**, you can edit a cancelled request. If the value is set to **No**, the cancelled request cannot be edited.

Notes: This parameter is available only if you have installed the CA Service Catalog 14.1.01 patch updates from CA Support.

- **Edit Completed Requests**
  Specifies that if the value is set to **Yes**, you can edit a completed request. If the value is set to **No**, the completed request cannot be edited.

  Notes: This parameter is available only if you have installed the CA Service Catalog 14.1.01 patch updates from CA Support.

- **Enable Delegation of Catalog**
  Specifies whether to enable the delegation of catalogs: Yes or No.
  When this option is enabled, no users are *required to* delegate use of their catalogs. But they can *optionally* do so.

  Note: The delegation of a catalog does *not* affect the Catalog configuration of the CA Service Catalog, such as the *Use Service Provider Catalog Only* and *Pass Through Catalog* configuration parameters. Similarly, the delegation of a catalog is *not* directly related to the configuration options such as *Access Control: Add Request* in this Request Management Configuration section. For more information about delegation of catalogs, see the Delegate Catalog (see page 2222) section.

- **Notify users when they complete their own pending actions**
  Specifies whether request managers receive a notification email every time they address a pending action by approving, rejecting, or fulfilling a service option, service, or request.
  If you specify Yes, request managers receive such emails confirming their own actions.
  If you specify No, request managers do not receive such emails.
  This setting is especially relevant if you are using discrete approval and the *Allow Request Life Cycle to Continue After* parameter is set to Submitted. If this parameter parameter is set to Yes, request managers are likely to receive several notification emails.
  For example, if a service has five service options and the request manager approves each option, the request manager receives five confirmation emails. To prevent request managers from receiving such emails, set *Notify users when they complete their own pending actions* to No.
  The Requested For users and Requested By users always receive these notification emails, regardless of the setting of these parameters.

- **Number of Requests per Page**
  For individual users (not administrators), specifies the maximum number of requests that appear on Request List pages. When a user moves to a new Request List page, the default setting replaces their custom settings. Users can optionally customize the display for each new Request List page they view.
  Request List pages appear when you click Home, Requests, and click any of the following options:

  - Open Requests
  - My Recent Requests

- Completed Requests
- Pending My Action

Advanced Search - after you search for requests and view the results.
Administrators can set the following options for all users: The individual columns that appear on Request List pages and the default maximum number of requests per page.

- **PDA Support: Enable**
  Specifies whether to enable PDA support.
  When you specify Yes, PDA users can click the links that are provided in PDA-compliant request approval emails to access the requests. The users can approve or reject them. Support for forms are limited when you enable PDA Approval.
  When you specify No, the links for accessing the requests and approving or rejecting them do *not* appear in the request approval emails that PDA users receive. The absence of such links implicitly guides PDA users to use an office computer to view, approve, and reject requests.

- **Request Details Link for E-Mail Notifications:**

  Notes: This parameter is available only if you have installed the CA Service Catalog 14.1.01 patch updates from CA Support.

  By default, value for this parameter is not configured. You can configure this parameter in the following format if CA Service Catalog is configured with USS:
  http://<USS HostName>:<PortNumber>/web/frontoffice/myrequest-catalog?ServiceCatalogRequestID=
  If you configure the Unified Self-Service (USS) URL for **Request Details Link for E-Mail Notifications**, clicking on the request details hyperlinks in the email notification will take you to the Unified Self-Service login page instead of CA Service Catalog login page. If this parameter is not configured, clicking on the hyperlinks in email notification with request details takes you to the CA Service Catalog login page.

- **Request Home Page: Include Request Information**
  Specifies which roles can view the Request Lookup and My Recent Requests sections on the Home or Requests menu option page.
  Default: Service Delivery Administrator, Super Business Unit Administrator, Administrator, End User, Catalog User, Request Manager, Catalog Administrator, Service Manager

- **Request General Information Column Configuration**
  Default: Name, ID, Requested For, Date Created, Date Required, Requested By, Priority, Last Modified, Status

Request Email Parameters

As part of setting the CA Service Catalog configuration options (see page 1449), you specify the following Request Email parameters:

- **Request Email: From Address**
  Specifies the email address from which the Catalog system sends emails about requests.

- **User Defined**
  Uses the email address that the user specifies. Selecting this option with no email address specified sets this setting to EMPTY.

- **Service Provider Email**
  Uses the email address for the service provider business unit.

Default: CatalogSystem@serviceprovider.com, where "*serviceprovider*" is the root business unit that is specified during installation.

- **Request Email: From Name**
  Specifies the email address *name* from which emails about requests are sent.
  Default: CatalogSystem

- **Request Email: To**
  Specifies the primary recipient email address to which emails about requests are sent.

  - **User Defined**
    Uses the email address that the user specifies. Multiple email addresses can be specified, separated by a semi-colon. Selecting this option with no email address specified sets this setting to EMPTY.

  - **Requested For User/Account Email**
    Uses the email address of the user or account to which this request applies.

  - **Requested By User/Account Email**
    Uses the email address of the user or account that created this request.

  Default: EMPTY, meaning this value is set when email options are used.

- **Request Email: CC**
  Specifies the "CC" recipient email address to which emails about requests are sent.

  - **User Defined**
    Uses the email address that the user specifies. Multiple email addresses can be specified, separated by a semi-colon. Selecting this option with no email address specified sets this setting to EMPTY.

  - **Requested For User/Account Email**
    Uses the email address of the user or account to which this request applies.

  - **Requested By User/Account Email**
    Uses the email address of the user or account that created this request.

  Default: EMPTY, meaning this value is set when email options are used.

- **Request Email: BCC**
  Specifies the "BCC" recipient email address to which emails about requests are sent.

- **User Defined**
  Uses the email address that the user specifies. Multiple email addresses can be specified, separated by a semi-colon. Selecting this option with no email address specified sets this setting to EMPTY.

- **Requested For User/Account Email**
  Uses the email address of the user or account to which this request applies.

- **Requested By User/Account Email**
  Uses the email address of the user or account that created this request.

Default: EMPTY, meaning this value is set when email options are used.

- **Request Email: Subject**
  Specifies the email subject that is used when emails about requests are sent.
  In addition to specific text, you can include dynamically substituted values in the subject text. The syntax for including dynamically substituted values is $Request.*variable_name*$.

  - ***variable_name***
    Specifies the name of the variable value to use.

  You can specify the following variables in the subject text:

  - **request_id**
    Specifies the internal Request ID, such as “10001”.

  - **name**
    Specifies the request name that the user specifies.

  - **status**
    Specifies the status of the request, such as “Pending Approval.”

  - **created_date**
    Specifies the date and time the request was created.

  - **modified_date**
    Specifies the date and time the request was last modified.

  - **completion_date**
    Specifies the date and time the request was completed.

  - **desired_date**
    Specifies the date and time in the Date Required field of the request.

  - **comments**
    Specifies the request Description that the user specifies.

  - **priority**
    Specifies the priority of the request.

  - **req_for_account_id**
    Specifies the internal account ID for the Requested For user or account.

- **req_by_account_id**
  Specifies the internal account ID for the Requested By user or account.

- **req_for_user_id**
  Specifies the user ID of the Requested For user, if the request is for a user not an account.

- **req_by_user_id**
  Specifies the user ID of the Requested By user.

Default: Email of Request ($Request.request_id$) - $Request.name$

- **Request Email: Message**
  Specifies the email message that is used when emails about requests are sent. You can override this text.
  In addition to specific text, you can include dynamically substituted values in the subject text. The syntax for including dynamically substituted values is $Request.*variable_name*$ where *variable_name* is the name of the variable value to use.The variables available for use are the same as in the *Request Email: Subject* setting.
  Default: Request ($Request.request_id$) created on $Request.created_date$

System Configuration

As part of setting the CA Service Catalog configuration options (see page 1449), you specify the following System Configuration parameters. These settings control the behavior of the system, regardless of business unit. This category is displayed *only* when you are logged in to the service provider (root) business unit.

- **Use Service Provider Configuration Only**
  Specifies whether a child business unit can have its own CA Service Catalog configuration settings.
  If this setting is Yes, the Catalog system ignores all CA Service Catalog configuration settings for a business unit. So, each business unit uses the configuration settings for the service provider.
  If this setting is No, then each business unit can have its own CA Service Catalog configuration settings.
  Default: No

- **Use Service Provider Catalog Only**
  Specifies whether the service provider business unit catalog is available to all business units in the hierarchy.
  If this setting is Yes, the subscribing or requesting user of a child business unit sees only the catalog of the service provider (root) business unit. That is, the child business unit cannot have its own catalog.
  If this setting is No, the child business unit can have its own catalog.
  Default: No

Set Accounting Configuration Options

You can optionally customize several options for accounting configuration. These options cover invoicing and subscription details, to meet the requirements of your organization.

Follow these steps:

1. Log in as a user with the Service Delivery Administrator role.

2. Click Accounting, Configuration.
3. Check for the name of the current business unit, and perform one of the following actions:
   - To set the accounting configuration options for a different business unit, change the business unit before performing the next step.
   - To set the accounting configuration options for the current business unit, go directly to the next step.
4. Click the link for the category of options that you want to update:
   - Accounting Profile Defaults (see page 1462)
   - Billing Cycles (see page 1466)
   - General (see page 1467)
   - Invoice Engine Configuration (see page 1467)
   - Invoice Methods (see page 1475)
   - Payment Methods (see page 1475)
   - Subscription Configuration (see page 1476)
5. View the options for the category, and click the Modify icon for the option that you want to update.
6. Update the setting as required and click Update Configuration.
7. Repeat the previous steps for each accounting configuration option that you want to update.

You have set the accounting configuration options. These settings apply to the children of the business unit that you updated, according to the inheritance of configuration settings through the business unit hierarchy (see page 1447).

Accounting Profile Defaults

As part of setting accounting configuration options (see page 1461), you specify the Accounting Profile Default settings. These settings indicate default values for newly created accounts for the current business unit. The following options require explanation:

- **Account Type**
  Specifies the type of account. This setting controls how outstanding balances are handled on invoices, as follows:
  - **Open Item**
    Specifies that every invoice is unique. Once a charge appears on an invoice, it does not appear on any future invoices.
  - **Balance Forward**
    Specifies that the remaining balance of a previous invoice is added to the next invoice.

- **Zero Balance**
  Specifies that the account is a zero balance account. A zero balance account can have charges appear on its invoice, but the total remaining balance is always zero. You cannot post payments to zero balance accounts.
  This option is commonly used when an aggregating account holds the charges for one or more zero balance accounts.

Default: Open Item

- **Aggregate**
  Specifies the role of the account in charge aggregation for invoicing, as follows:

  - **No**
    Specifies that the charges for the account appear *only* in the invoice of the account. The charges do *not* appear on an invoice for a related aggregating account.

  - **Yes**
    Specifies that the charges for the account appear in the invoices for all of the following options:

    - The original account

    - Each aggregating account in the same business unit or a parent business unit, up through the hierarchy of business units

  - **Aggregating Account**
    Specifies that the invoice for the account shows charges for all accounts in the same business unit or child business units. These business units must have Aggregate set to Yes or Aggregating Account.

    Note: To avoid double invoicing, do *not* specify more than one aggregating account in each business unit.

Default: No

- **Automatic Invoicing**
  Specifies whether to create an invoice for the account, as follows:

  - **Yes**
    Specifies that the account has an invoice that is generated during a bill run.

  - **No**
    Specifies that the account does not have an invoice that is generated during a bill run.

Default: Yes

- **Billing Cycle**
  Specifies the account invoicing cycle. Options are daily, weekly, and monthly.
  Note: This field works with the Billing Cycle Interval, which is described later in this topic.
  Default: Monthly

- **Period Start Date**
  Specifies how to set the start date for the invoice period for the account. Select from the following options:

  - **Business Unit Opened Date**
    Sets the start date as the date the business unit of the account was created (the Opened Date).

  - **Account Opened Date**
    Sets the start date as the date the account was opened (the Accounting Profile Opened Date).

  - **Current Date**
    Sets the start date to be the date that the accounting profile (account) was created.

  - **Current Date of Next Period**
    Sets the start date as the addition of both of the following options:

    - The date the accounting profile (account) was created.

    - The interval that the Billing Cycle and the Billing Cycle Interval determine.

  - **Day of Week**
    Sets the start date as the same day of the week on which the accounting profile (account) was created.

  - **Day of Month**
    Sets the start date as the same day of the month on which the accounting profile (account) was created.

  - **Day of Year**
    Sets the start date as the same day of the year on which the accounting profile (account) was created.

  - **Day of Week Adjusted from Current Date**
    Sets the start date as the specified day of the next week after the accounting profile (account) was created.

  - **Day of Month Adjusted from Current Date**
    Sets the start date as the specified day of the next month after the accounting profile (account) was created.

  - **Day of Year Adjusted from Current Date**
    Sets the start date as the specified day of the next year after the accounting profile (account) was created.

  - **Last Day of Current Month**
    Sets the start date as the last day of the month during which the accounting profile (account) was created.

  - **First Day of Next Month**
    Sets the start date as the first day of the next month after the accounting profile (account) was created.

- **Specify Date**
  Sets the start date as the date that you specify manually.

Default: Account Opened Date

- **Billing Cycle Interval**
  Specifies the number of billing cycles between invoices.
  For example, to bill the account quarterly, select a Billing Cycle of Monthly and a Billing Cycle Interval of 3. The Billing Cycle field is described earlier in this topic.
  Default: 1

- **Default Days Due**
  Specifies the number of days after the invoice date to use as the payment due date.
  Default: 10

- **Grace Days**
  Specifies the number of days that are permitted past the invoice date without a payment. If the invoice is not paid before the grace days expire, the account incurs extra fees and penalties.
  Default: 10

- **Invoice Method**
  Specifies how to send invoices. Select one of the following options:

  - **Email**
    Sends the invoice as an email attachment to the email address of the account.
    The Catalog system:

    - Uses the format that is specified in Invoice Output Type setting.
    - Uses the delivery mechanism that is specified in the Invoice Generation Email Attachment Type setting.
    - Saves the attachment in the Invoice Email Location server folder.

  - **Fax**
    Saves the invoice using the format that is specified in Invoice Output Type setting in the Invoice Fax Location server folder.

  - **Postal**
    Saves the invoice using the format that is specified in Invoice Output Type setting in the Invoice Postal Location server folder.

  - **Printer**
    Saves the invoice using the format that is specified in Invoice Output Type setting in the Invoice Printer Location server folder.

  Default: Email

- **Period End Date**
  Specifies how to set the end date for the invoice period for the account. Select one of the following options:

- **Compute from Start Date Using Billing Cycle**
  Specifies an end date that is based on the period start date, the billing cycle, and the billing cycle interval. Each of these settings is described earlier in this topic.

- ***other options***
  Specifies an end date equivalent to the options for period start date. That setting is described earlier in this topic.

The dates settings presume that each new day begins at a time of 00:00:00. Specify a Period End Date that includes the last full day. For example, to bill for the entire month of July, make your period 7/1/yyyy - 8/1/yyyy to include the entire last day of the month.
Default: Compute from Start Date Using Billing Cycle

- **Status**
  Specifies the status of the account when it is created: Closed, Opened, or Suspended. Invoicing occurs only when this setting is Opened.
  Default: Opened

- **Status Reason**
  Specifies the reason for the value of the Status option. You enter this text manually.
  Limit: 1024 characters
  Default: New account waiting approval

- **Taxable**
  Specifies whether the account is taxable.
  Specify Yes or No.
  Default: No

Billing Cycles

As part of setting accounting configuration options (see page 1461), you specify the settings for the billing cycles. You specify which billing cycle choices are available on the Accounting Profile of the account.

- **Daily**
  Specifies whether users can generate an invoice daily. If this option is set to Yes, Daily appears in the list of options for specifying the billing cycle.
  Default: Yes

- **Monthly**
  Specifies whether users can generate an invoice monthly. If this option is set to Yes, Monthly appears in the list of options for specifying the billing cycle.
  Default: Yes

- **Weekly**
  Specifies whether users can generate an invoice weekly. If this option is set to Yes, Weekly appears in the list of options for specifying the billing cycle.
  Default: Yes

General

As part of setting accounting configuration options (see page 1461), you specify the General settings. This value applies to all accounts in the current business unit.

- **Default Post Payment Method**
  Specifies the default option for posting a payment: cash, check, or credit card.
  Default: Check

Invoice Engine Configuration

As part of setting accounting configuration options (see page 1461), you specify the Invoice Engine Configuration settings. These settings control the behavior of the invoice engine during bill runs. These values apply to transactions and invoices for all accounts in the current business unit. The following settings require explanation:

- **Invoice Style for Aggregation**
  Specifies how totals appear on invoices for aggregating accounts.
  Select from the following options:

  - **All Details**
    Displays all details.
  - **Account Totals**
    Displays only the total of the aggregating account.
  - **Drill Down Account Totals**
    Displays subtotals by account by service. Users can drill down to view details for each account.
  - **Service by Account Totals**
    Displays subtotals by account by service, without drill-down functions.
  - **Service Totals**
    Displays subtotals by service for all accounts.
  - **Type by Account Totals**
    Displays subtotals by account by service option element type.
  - **Type Totals**
    Displays subtotals by service option element type.

  Default: All Details

- **Aggregate Advanced Charges**
  Specifies how advanced charges appear on an invoice. Advanced charges span multiple periods as defined by the period start and end dates in the Accounting Profile of the account.

  - **Yes**
    Displays the total of the advanced charges on one line.
  - **No**
    Displays the advanced charges individually on multiple lines.

For example, suppose that the cycle for a subscription is monthly and the billing cycle for an account is yearly. In this case, a Yes setting summarizes the charges on one line. Conversely, a No setting displays 12 lines instead.
Default: Yes

- **Aggregate Current Charges**
  Specifies how to present current charges on an invoice. Current charges apply only to the current period as defined by the period start and end dates in the Accounting Profile.

  - **Yes**
    Displays the total of the current charges on one line.

  - **No**
    Displays the current charges individually on multiple lines.

  This setting is similar to Aggregate Advanced Charges, but it applies to current charges instead.
  Default: Yes

- **Allow No Activity Invoices**
  Specifies whether to generate invoices for accounts with no charges.

  - **Yes**
    Generates invoices for *all* accounts, including accounts with no charges.

  - **No**
    Generates invoices *only* for accounts with charges.

  Default: No

- **Bill Run Capacity**
  Specifies the number of accounts to process for transaction and invoice generation until a commit is performed and all processing is persisted.
  The larger the value, the more server memory is required and the faster the invoices are processed. The smaller the value, the less server memory is required, and the slower the invoices are processed.
  Default: 100

- **Exclude Invoice Item**
  Specifies whether to include a chargeable item on an invoice if the quantity, unit cost, or both is 0. Select from the following options:

  - **Always Include**
    Invoices all items, regardless of the value for quantity and unit cost.

  - **Where Quantity is 0**
    Exclude items when the quantity is 0.

  - **Where Rate is 0**
    Exclude items when the unit cost is 0.

  - **Where Quantity and Rate are 0**
    Excludes items when *both* the quantity and unit cost are 0.

- **Where Quantity or Rate is 00**
  Excludes items where *either* the quantity or unit cost is 0.

Default: Always Include

- **Uninvoiced Transactions**
  Specifies whether to include a transaction on an invoice. The decision is based on a comparison of the transaction date with the period start date and end date on the Accounting Profile of the account.
  Select from the following options:

  - **Include All Uninvoiced Transactions**
    Includes all transactions that have not yet been invoiced, regardless of transaction date.

  - **Exclude Past Uninvoiced Transactions**
    Does not include transactions whose date is before the period start date, even if the transactions are not yet invoiced.

  - **Exclude Future Uninvoiced Transactions**
    Does not include transactions whose date is after the period end date, even if the transactions are not yet invoiced.

  - **Exclude Both Past and Future Uninvoiced Transactions**
    Does not include transactions whose date matches one of the following options, even if the transactions are not yet invoiced:

    - Before the period start date

    - After the period end date

    Both of these dates are outside the current period.

  Default: Include All Uninvoiced Transactions

- **Invoice From Address**
  Specifies the address for the "From" field on the invoice.
  Select from the following options: Service Provider Address and Business Unit Address.
  Business Unit Address is available for a child business unit only.
  Default: Service Provider Address

- **Invoice Generation Email Attachment Type**
  Specifies the delivery mechanism for the invoice when emails about invoices are sent.
  Select from the following options:

  - **Attachment**
    Includes the invoice as an attachment in the email. The format is specified in the Invoice Output Type setting.

  - **Inline**
    Includes the invoice in HTML format in the text of the email.

  - **Link**
    Includes a link to the invoice in the text of the email.

Default: Attachment

- **Invoice Generation Email Body Message**
  Specifies the body text for emails about invoices.
  You can specify both literal text and dynamically substituted values.
  The syntax for dynamically substituted values follows:

  - ***$object_name.variable_name$***
    Specifies the name of the variable.
    You can specify the following values:

    - "statements" object:
      statement_label - The label of the account plus an invoice statement ID, such as "acnt1: 10012"
      period_from - The Accounting Profile Period Start Date of the account
      period_to - The Accounting Profile Period End Date of the account
      due_date - The due date of the invoice

    - "billing_account" object:
      account_label - The label of the account, such as "acnt1"

  Limit: 1024 characters
  Default: Invoice Generated for $statements.statement_label$ for $statements.period_from$ - $statements.period_to$

- **Invoice Generation Email CC**
  Specifies the addresses of carbon copy (CC) recipients of emails about invoices.
  You can specify multiple email addresses. Separate each email address with a semi-colon.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice Generation Email From**
  Specifies the email address that sends emails about invoices.
  Select from the following options:

  - **User Defined**
    Specifies a custom email address that you enter manually. If you select this option but enter no email address, this setting changes to the literal value of EMPTY.

  - **Service Provider Email**
    Specifies the email address of the service provider business unit.

  - **System**
    Specifies that the Catalog system determines which one of the following email addresses to use: the Services Group or the super business unit.

  Default: Service Provider Email

- **Invoice Generation Email Subject**
  Specifies the text for the subject line of emails about invoices.
  You can specify both literal text and dynamically substituted values.
  The syntax for dynamically substituted values is the same as the Invoice Generation Email Body Message setting. That setting is described earlier in this topic.

Limits: 1024 characters
Default: Invoice: $statements.statement_label$ processed for account: $billing_account.account_label$, Due date: $statements.due_date$

- **Invoice Generation Email To**
  Specifies the primary recipient of emails about invoices.
  Select from the following options:

  - **System**
    Uses the email address of the Send Invoice To field in the Accounting Profile of the account.

  - **User Defined**
    Specifies a custom email address that you enter manually. If you select this option but enter no email address, this setting changes to the literal value of EMPTY.
    You can specify multiple email addresses. Separate each email address with a semi-colon.

  Default: System

- **Invoice History Email Attachment Type**
  Specifies the delivery mechanism for the invoice when you send emails from the Invoice History page.
  Select from the following options:

  - **Attachment**
    Includes the invoice as an attachment in the email. The format is specified in the Invoice Output Type setting.

  - **Inline**
    Includes the invoice in HTML format in the text of the email.

  - **Link**
    Includes a link to the invoice in the text of the email.

  Default: Attachment

- **Invoice History Email Body Message**
  Specifies the body text for emails about invoices, when you send these emails from the Invoice History page.
  You can specify both literal text and dynamically substituted values.
  The syntax for dynamically substituted values follows:

  - **$*object_name*.*variable_name*$**
    Specifies the name of the variable.

  You can specify the same variables as for the Invoice Generation Email Subject setting.
  In addition, you can specify the following variables:

  - "invoice_history" object:
    account_label - The label of the account

Limit: 1024 characters
Default: Invoices Generated During $invoice_history.start_date$ - $invoice_history.end_date$ total number of invoices: $invoice_history.num_invoices$ number of phases processed = $invoice_history.phases$

- **Invoice History Email CC**
  Specifies the addresses of carbon copy (CC) recipients of emails from the Invoice History page. You can specify multiple email addresses. Separate each email address with a semi-colon.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice History Email From**
  Specifies the email address that sends emails about invoice history.
  Select from the following options:

  - **User Defined**
    Specifies a custom email address that you enter manually. If you select this option but you enter no email address, this setting changes to the literal value of EMPTY.

  - **Service Provider Email**
    Specifies the email address of the service provider business unit.

  - **System**

  Specifies that the Catalog system determines which one of the following email addresses to use: the Services Group or the super business unit.
  Default: System

- **Invoice History Email Subject**
  Specifies the text for the subject of emails from the Invoice History page.
  You can specify both literal text and dynamically substituted values.
  The syntax for dynamically substituted values follows:

  - ***$object_name.variable_name$***
    Specifies the name of the variable.
    You can specify the same variables as for the Invoice Generation Email Subject setting.
    In addition, you can specify the following variables:

    - "invoice_history" object:
      account_label - The label of the account

  Limit: 1024 characters
  Default: Invoices Generated During $invoice_history.start_date$ - $invoice_history.end_date$

- **Invoice History Email To**
  Specifies the primary recipient email addresses when emails are sent from the Invoice History page. You can specify multiple email addresses, which are separated by a semi-colon.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice Email Location**
  Specifies a directory path on the local file system. This path stores invoices for the account when its Accounting Profile Invoice Method is set to Email.
  Each invoice file name includes the account label and invoice statement ID.
  For example, you could specify the following setting for a Windows environment:
  USM_HOME\accounting\outbox\email.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice Fax Location**
  Specifies a directory path on the local file system. This path stores invoices for the account when its Accounting Profile Invoice Method is set to Fax.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice Postal Location**
  Specifies a directory path on the local file system. This path stores invoices for the account when its Accounting Profile Invoice Method is set to Postal.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice Printer Location**
  Specifies a directory path on the local file system. This path stores invoices for the account when its Accounting Profile Invoice Method is set to Printer.
  Limit: 1024 characters
  Default: EMPTY

- **Invoice Output Type**
  Specifies the format to use when saving invoices as files.
  Select from the following options:

  - HTML
  - CSV
  - XML
  - HTML and CSV
  - HTML and XML

  The file format that you select is used for the previous two settings, Invoice Postal Location and Invoice Printer Location.
  Default: HTML

- **Invoice Style**
  Specifies the style to use for viewing an invoice through the user interface.
  Select from the following options:

  - Style 1 - One option for invoice format.
  - Style 2 - Another option for invoice format.

Default: Style 1

- **Invoice URL**
  Specifies an absolute URL path to the location that stores invoices for use by the Accounting, Invoices, Batch Printing menu option.
  Limit: 1024 characters
  Default: EMPTY

- **Output Invoices**
  Specifies whether to store the invoices for the account on the server file system, as follows:
  With either setting, you can view invoices through the user interface.

  - **Yes**
    Stores the invoices on the server file system. Depending on the Invoice Method setting, the invoices are stored in the locations that are indicated in the various "location" configuration settings.

  - **No**
    Does not store invoices on the server file system.

  Default: No

- **Payment Response**
  Specifies the text to print on an invoice when payment is posted.
  Limit: 1024 characters
  Default: Payment received - Thank you

- **Pro Rate Batch**
  Specifies whether to prorate invoice charges if the service start date does not align with the Accounting Profile period of the account.

  - **No**
    Charges the invoice *only* after a full charge period has passed.

  - **Yes**
    Prorates the charges.

  For example, suppose that both of the following options are true:

  - This setting is Yes

  - The charge and the Accounting Profile period of the account are both monthly

  In this example, if you generate an invoice half way through the billing period, only half the charge appears on the invoice.
  Default: Yes

- **Pro Rate Online**
  Specifies the same options as the previous setting (Pro Rate Batch), except that this setting applies to invoices that you view through the user interface.
  Default: Yes

- **Use Time (requires restart)**
  Specifies whether to use the time portion of a transaction date and time stamp when determining the period for which to bill a transaction.
  Default: Yes

Invoice Methods

As part of setting accounting configuration options (see page 1461), you specify the Invoice Methods settings. These settings specify which methods of sending invoices are available on the Accounting Profile of the account.

- **Email**
  Specifies whether users can send invoices through email. If this option is set to Yes, Email appears in the list of options for specifying the delivery mechanism.
  Default: Yes

- **Fax**
  Specifies whether users can send invoices through fax. If this option is set to Yes, Fax appears in the list of options for specifying the delivery mechanism.
  Default: Yes

- **Postal**
  Specifies whether users can send invoices through the postal service. If this option is set to Yes, Postal appears in the list of options for specifying the delivery mechanism.
  Default: Yes

- **Printer**
  Specifies whether users can send an invoice by printing. If this option is set to Yes, Printer appears in the list of options for specifying the delivery mechanism\.
  Default: Yes

Payment Methods

As part of setting accounting configuration options (see page 1461), you specify the Payment Methods settings. These settings specify which payment methods are available for applying a payment to an invoice.

- **Cash**
  Specifies whether Cash is a payment option for an invoice.
  Default: Yes

- **Check**
  Specifies whether Check is a payment option for an invoice.
  Default: Yes

- **Coupon**
  Specifies whether Coupon is a payment option for an invoice.
  Default: No

- **Credit Card**
  Specifies whether Credit Card is a payment option for an invoice.
  Default: Yes

- **Direct**
  Specifies whether Direct is a payment option for an invoice.
  Default: No

- **Tip**
  Specifies whether Tip is a payment option for an invoice.
  Default: No

Subscription Configuration

As part of setting accounting configuration options (see page 1461), you specify the Subscription Configuration settings. These settings specify how the Catalog system handles subscriptions.

- **Default Subscribe State**
  Specifies the status to which the selected service options are set when an account is subscribed to a service.

  - Completed
  - Pending

  Default: Completed

- **Default Cancellation State**
  Specifies the status to which the selected service options are set when the subscription of an account to a service is cancelled.
  Select from the following options:

  - Cancel - Charges for the current billing period do not appear on the next invoice.
  - Pending Cancellation - Charges for the current billing period appear on the next invoice, at which point the status is changed to Cancelled.

  Default: Pending Cancellation

- **Default Subscription Page**
  Specifies the initial page that is displayed when the Subscriptions tab is selected.
  Select from the following options:

  - Create New Subscriptions - Show catalog of services to which the account can subscribe.
  - Existing Subscriptions - Show services to which the account is subscribed.

  Default: Create New Subscriptions

- **Allow Instance Names**
  Specifies whether a name can be associated with a subscription instance.
  If this option is set to Yes, when an account is subscribed to a service, you can add some text to the subscription to name the instance.
  Default: No

- **Enable Subscription Notes**
  Specifies whether a note can be associated with a subscription instance.
  If this option is set to Yes, when an account is subscribed to a service, you can add notes to the subscription.
  This setting is available for the service provider business unit only, and it applies to all business units.
  Default: No

Set Administration Configuration Options

To meet the requirements of your organization, you can customize several administration configuration options. The options include those for integrations, portals, request SLAs, authentication, and others.

Follow these steps:

1. Log in as a user with the Service Delivery Administrator role. Updates to these options apply to the *entire* system. You *cannot* specify different administration configuration options for different business units.
2. Click Administration, Configuration.
3. Click the link for the category of options that you want to update:
   - Integration-specific options (see page 1478)
   - Event Manager (see page 1478)
   - File Store Information (see page 1479)
   - Mail Server (see page 1479)
   - Portal (see page 1480)
   - Request SLA (see page 1481)
   - Rule Engine (see page 1481)
   - Server Information (see page 1481)
   - Single Sign On Authentication (see page 1482)
   - System Information (see page 1483)
   - User Default (see page 1484)
4. View the options for the category, and click the Modify icon for the option that you want to update.
5. Update the setting as required and click Update Configuration.

6. Repeat the previous steps for each administration configuration option that you want to update.

You have set the administration configuration options. These settings apply to the children of the business unit that you updated, according to the inheritance of configuration settings through the business unit hierarchy (see page 1447).

Integration-Specific Options

If you are integrating CA Service Catalog with any of the following products, set the related configuration parameters to ensure CA Service Catalog and the integrating product work together correctly. This task is part of setting the administration configuration options (see page 1477).

- CA APM
- CA Business Intelligence

> **Note:** CA Business Intelligence packages and delivers BusinessObjects Enterprise. So, you use these CA Business Intelligence parameters to configure the integration of CA Service Catalog with BusinessObjects Enterprise.

- CMDB
- CMDB Visualizer
- CA Process Automation
- CA Business Service Insight
- CA Service Desk Manager
- Reservation Manager

> **Note:** For more information about setting these parameters, see the relevant sections in Integrating CA Service Catalog (see page 3425).

Event Manager

As part of setting the administration configuration options (see page 1477), you configure the following parameters for the Event Manager. The Event Manager processes events. An event occurs when one or more conditions that are specified in a rule are met.

For more information about events, rules, and actions, see the Manage Events-Rules-Actions (see page 3040) section.

- **Email From**
  Sends an email *from* this address if the Event Manager has a problem.
  Default: spadmin@*serviceprovider*, where "*serviceprovider*" is the root business unit that is specified during installation.

- **Email To**
  Sends an email *to* this address if the Event Manager has a problem.
  Default: spadmin@*serviceprovider*, where *serviceprovider* is the root business unit that is specified during installation.

- **Audit Trail Level**
  Indicates the level of detail that is logged in the audit trail tables. Typically, system performance decreases as the level of log detail increases. Conversely, system performance typically increases as the level of log detail decreases.
  Select one of the following options:

  - **No Audit Trail**
    Stores no information about the event in the database.

  - **Only Object ID**
    Stores the event information, including the object ID, in the usm_system_change table. This option stores only minimal information.

  - **Include Attributes**
    Stores the event information, including the object ID, in the usm_system_change table. This option stores detailed old and new values for the object attributes in the usm_system_change_detail table.

  - **Include Multiple Attributes**
    Stores the event information, including the object ID, in the usm_system_change table. This option stores detailed old and new values for the object attributes in the usm_system_change_detail table. If any attributes have multiple values, the old and new values are stored in the usm_system_change_detail_ext table.
    Default: Include Attributes.

File Store Information

As part of setting the administration configuration options (see page 1477), you configure the following parameter for the File Store Information. You can set up a custom location for shared files. Having a common location improves the accuracy and efficiency of sharing files between computers.

- **File Store Location**
  Specifies the UNC path name of the shared drive.
  Default: USM_HOME\filestore

Mail Server

Important! Any mail-related settings in custom rule actions override these mail server parameters. For more information about events, rules, and actions, see the section Manage Events-Rules-Actions (see page 3040).

As part of setting the administration configuration options (see page 1477), you configure the following parameters for the mail server. The mail server sends automated messages from CA Service Catalog. These settings apply to the children of the business unit that you updated, according to the inheritance of configuration settings through the business unit hierarchy (see page 1447).

- **From Address**
  Specifies the address that emails are sent from.
- **Host Name**
  Specifies the host name of the mail server.
- **Port Number**
  Specifies the port number on the mail server that listens for incoming calls from CA Service Catalog.
- **User ID**
  Specifies the user ID for accessing the mail server.
- **User Password**
  Specifies the password for accessing the mail server.

Note: Specify these parameters and click the Test button to verify the connection between CA Service Catalog and the mail server. If the test fails, review the view.log file in the USM_HOME\logs folder.

Portal

As part of setting the administration configuration options (see page 1477), you configure the following parameters for the Portal. The Portal settings specify how the dashboard library and document entries are made available.

- **Allow New Document Domain Namespaces**
  Specifies whether business units can have their own document name spaces. If this parameter is set to Yes, the Add A New Business Unit page contains the "Create Document Namespace" check box.
  If a business unit has its own document namespace, you can segregate documents in separate business units. This segregation allows only users in that business unit to have access to the document.
  Default: Yes
- **Allow New Library Namespaces**
  Specifies whether business units can have their own library name spaces.
  If this parameter is set to Yes, the Add A New Business Unit page contains the "Create Dashboard Library Namespace" check box.
  If a business unit has its own library namespace, you can segregate dashboard library content. This segregation allows only users in that business unit have access to the library content when they add a dashboard.
  Default: Yes

- **Show Resource Tree**
  Specifies whether the Resource Explorer appears in the dashboard library tree.
  If this parameter is set to Yes, the Resource Explorer appears in the dashboard library tree. This option applies *only* if CA Service Catalog is integrated with CA Business Service Insight.
  Default: Yes

Request SLA Processor

As part of setting the administration configuration options (see page 1477), you configure the following parameter for the request SLA processor. These settings specify how the Catalog system processes request SLAs.

For information about setting up request SLA processing, see the Manage Request SLAs (see page 2168) section .

- **Maximum Delay for Request SLA Alerts**
  Specifies how frequently the request SLA processor checks for SLA warnings or violations. This setting applies to all SLA instances managed by a Catalog Component computer.
  To minimize possible delays in SLA processing time when a Catalog Component clustered computer fails, configure this parameter. Therefore, set a smaller interval, such as one hour, to receive SLA warnings and violations quickly. Otherwise, set a larger interval, for example, one day, to receive them when the failed clustered computer is restored.

Rule Engine

As part of setting the administration configuration options (see page 1477), you configure the following parameter for the Rule Engine. Administrators use rules to define actions to take when a specific event occurs. These actions can be running scripts or Java programs, sending emails, and so forth. The rule engine manages the execution of the actions.

For information about events, rules, and actions, see the Manage Events-Rules-Actions (see page 3040 section.

- **Action Default Timeout (in seconds)**
  Specifies the default timeout value in seconds for rule actions.
  Default: 300

Server Information

As part of setting the administration configuration options (see page 1477), you configure the following parameters for the Catalog Component server. These settings apply *only* when you configure Catalog Component for use with HTTPS or for use as a load balancer in clustering. Otherwise, Catalog Component is configured automatically and the following parameters do *not* apply.

- **Enable HTTPS**
  Defines whether CA Service Catalog uses HTTPS when communicating with this Catalog Component computer.
  Default: No

- **Host Name**
  Specifies the host name accessible to catalog users, typically one of the following host names:

- The Catalog Component computer
- The load balancer computer (applies if you are clustering).
- The computer that redirects catalog users (applies if you are using DNS aliases for redirection).

- **Port Number**
  Specifies the port number for communicating with the host named in the previous parameter.

Important! If you use clustering, replace the host name and port number in the Server Information section with the host name and port number of the load balancer. If you use DNS aliases for redirection, replace the host name and port number in the Server Information section with the host name and port number of the computer that redirects catalog users.

Single Sign On Authentication

You configure the following single sign-on authentication parameters.

- **Allow Login with GET**
  Specifies whether users can log in using an HTTP GET request.
- **External Authentication Parameters**

  The external authentication parameters follow. To enable external authentication of users, configure these parameter values to match the external application that you are using.

  - **Artifact Name**
    Specifies the name of the cookie, header, or request parameter that contains the authenticated user ID. This name varies according to the external authentication system and your site-specific implementation.
    The default value is sm-user.
    For example, if you are using CA SiteMinder, select Header as the authentication type and sm-user as the artifact name. With this configuration, CA Service Catalog checks the header named sm-user whose value is the userid.
    When the Artifact Type is request, the artifact name is ignored.
  - **Artifact Type**
    Specifies the mechanism that the external application uses to send the authenticated user ID to CA Service Catalog, as follows:
    - Cookie: Cookie in the request
    - Header: Header in the request
    - Parameter: request parameter
    - Request: request user

- **Bypass Nodes**
  Specifies the GUI nodes that you want the authentication check to skip. These GUI nodes typically do not require the user to log in.
  Examples include the following: icguinode.login, icguinode.logout, iclaunchpad.launch, icguinode.changepwdlockout, and icguinode.lockout.

- **Login Page**
  Specifies the page that displays to the user when either the artifact type is set incorrectly or CA Service Catalog does not find an authenticated user.
  An example is wpf?Node=icguinode.login.

- **Single Sign-on Type**
  Specifies *one* of the following options:

  - Disabled: Specifies that CA Service Catalog does *not* use single sign-on.
  - Artifact Based Single Sign-on: Configures CA Service Catalog to use single sign-on based on the artifacts specified on this page.
  - NTLM (NT LAN Manager): Configures CA Service Catalog to use single sign-on based on Windows NT authentication.

System Information

As part of setting the administration configuration options (see page 1477), you configure the following settings that are related to common multi-tenant administration for CA Service Catalog business units:

Important! These settings apply *only* if you are *both* integrating CA Service Catalog with CA Service Desk Manager *and* using common multi-tenant administration of CA Service Catalog business units. For more information about setting up common multi-tenant administration, see the section Configure Common Tenant Administration (see page 1397).

- **Terms Of Usage Prompt Enabled**
  Specifies that common tenants in CA Service Catalog must implement the terms of use (if any) that are created and maintained in CA Service Desk Manager. The specific effect on users attempting to log in to CA Service Catalog depends on the terms of use settings that are specified in CA Service Desk Manager.
  If this setting is Yes, the users attempting to log in to CA Service Catalog receive the terms of use prompt. If the users do not accept the terms of use, they cannot access CA Service Catalog.
  If this setting is No, the users attempting to log in to CA Service Catalog are not prompted with terms of use, regardless of the terms of use settings that are specified in CA Service Desk Manager.

- **Common Multi-Tenant Administration Enabled**
  Specifies whether you manage CA Service Catalog business units with the common multi-tenant administration framework supplied through CA Service Desk Manager.
  When this option is set to No, you manage CA Service Catalog business units directly through CA Service Catalog, and these business units are not synchronized with CA Service Desk Manager.

When this option is set to Yes, you cannot manage CA Service Catalog business units directly through CA Service Catalog, except for CA Service Catalog-specific attributes. You use the tenant administration tool of CA Service Desk Manager to manage all business units of CA Service Catalog and CA Service Desk Manager and their common attributes.
You cannot set this option to Yes unless the Common Multi-Tenancy Model option is set to Yes.

- **Common Tenant Data Synchronized (read-only)**
  Specifies whether the CA Service Catalog tenant (business unit) structure is synchronized with the tenant structure of CA Service Desk Manager.
  CA Service Catalog sets this option to Yes when all of the following conditions are met:

  - CA Service Desk Manager is installed.
  - The common multi-tenancy merge utility has run successfully.
  - Since the utility was last run, no business unit has been created, deleted, or had a change in a common attribute through CA Service Catalog directly.

  Conversely, CA Service Catalog sets this option to No when one or more of the following conditions exist:

  - The common multi-tenancy merge utility has not run successfully.
  - Since the utility was last run, one or more business units have been created, deleted, or had a change in a common attribute through CA Service Catalog directly.

User Default

As part of setting the administration configuration options (see page 1477), you configure the following settings that are related to users, roles, searches, and sessions:

- **CA EEM Max Search Size**
  Defines the maximum number of users that are queried during searches in CA EEM.
- **Access Control: Allow Request Auto-Delegation via User Management**
  Defines which user roles are able to view and set auto-delegation for other users. Typically, administrator roles use this ability to set auto-delegation for users who are unable to set it for themselves. Examples of such employees:

  - Users who suddenly became unavailable due to emergency.
  - Users who left for a long absence without setting their own auto-delegation.
  - Users whose roles have no rights to set their own auto-delegation.

  The default value is the Service Delivery Administrator user role.
- **Access Control: Allow Request Auto-Delegation via User Profile**
  Defines which user roles have the Request Auto-Delegation setting appear on their User Profile window. Users with these roles can view and optionally configure this setting for themselves. The default value is all user roles, so that all users can change at minimum their own auto-delegation settings.

- **User Default Role**
  Defines the default business-unit role that is assigned to a user when an administrator creates or edits the user.
  If both of the following conditions are true, the Catalog system assigns the default role to the user logging in:

  - The user has an MDB record that is created by another product.
  - That MDB record has never been edited through CA Service Catalog.

  A change of this setting requires a restart of the Catalog Component service to take effect.
  The default value of this setting depends on the products installed:

  - If CA Service Catalog is installed, the default value for this setting is Catalog User.
  - If only Accounting Component is installed, the default value for this setting is End User.

- **User Search Scope**
  Defines how the scope of the "search user" functionality works for the Catalog User and End User roles. "Search user" functionality for these roles is available in the following areas:

  - When emailing a request, users can populate the To, CC, and BCC fields by searching from a list of users or accounts.
  - When editing the cart or a request, if the logged in user can create requests for other users or accounts (proxy requests), the user can override the Requested For value by choosing from a list of users or accounts.

Note: The scope of "search account" functionality for Catalog End Users and End Users includes *only* accounts in the same business unit as the logged in user. This scope does *not* include child business units.

Select one of the following options:

- Enterprise - All users who have a User ID specified without regard to the role of the user. This setting is suitable for enterprise customers where business units represent departments in one company.
  The scope of the "search user" functionality works as follows:

  - A user who can change the Requested For user for a cart or a request can select from all users.

  When a request is emailed, the list of users includes all users.

- Business Unit - All users who have a user ID and a role in the business unit of the logged in user. This setting is suitable for customers whose business units represent separate companies or departments within those companies.
  The scope of the "search user" functionality works as follows:

- A user who can change the Requested For user for a cart or a request can select from users who have a role in the same business unit as the logged in user.
- When a request is emailed, the list of users includes only users who have a role in the same business unit as the logged in user.

Default: Enterprise

- **Session Timeout**
  Defines the number of minutes of inactivity after which users are logged out. For the change to take effect, recycle the Windows service named CA Service Catalog.

Administering CA Service Catalog

This section contains the following articles:

Migrate Data Between CA Service Catalog Systems using the Import Export Utility

Administrators can use the Import Export utility to export CA Service Catalog data between two CA Service Catalog computers. This migration is primarily intended for either:

- Moving data from test to production, when both computers are running the same release of CA Service Catalog.
- Moving data from a computer running the previous release of CA Service Catalog to a computer running a newer release of CA Service Catalog.

Follow these steps:

Step 1 - Verify the Prerequisites for Data Migration using the Import Export Utility

Before you begin to migrate data between the CA Service Catalog systems:

- Verify that CA Service Catalog is installed and running.

- Integrate CA Service Catalog with CA Service Desk Manager or CA CMDB, to export services that have CMDB CI associations.
- Understand the different object type attributes (see page 1488) that can be exported or imported.

Step 2 - Export the Data

The Import Export utility exports the data in a proprietary XML format. The same XML format must be used in the data files when importing. You can determine the correct XML formats for each object type by examining an exported XML file.

Follow these steps:

1. Click Administration, Tools.
2. Select Import Export Utility from the left pane.
3. Select Export action in the Action and Object type.
4. In the Object Type drop-down list select the object for which, you want to export the data.
5. Specify the attributes (see page 1488) for the selected object.
6. Click Start Export.
   The exported data for the selected object type is saved as an XML file in the format: *ixutil_{object_name}_{YYYYMMDD}_{HHMMSS}.*xml.
   You have successfully exported the data between CA Service Catalog systems.

Step 3 - Import the Data

You can use the Import Export utility to migrate new and updated objects from one computer to another. All the object types that are exported can be imported.

Follow these steps:

1. Click Administration, Tools.
2. Select Import Export Utility from the left pane.
3. Select Import action in the Action and Object type.
4. Select the object type that you want to import in the Object Type drop-down list.
5. (Optional) Select Quick Import check box, if you do not want to specify any other attributes as inputs to import.
6. Specify the attributes (see page 1488) for the selected object, if you do not want to perform a Quick Import.
7. Click Browse and select the xml file as input for the selected object type.

Note: For the Service Offering object type, select the exported zip file, if, the Include Translations option was selected during import.

8. Click Start Import.
   The file is imported to the business unit specified in the file.

Important! If you export report data objects that are based external data sources, verify that they are imported correctly on the target computer. To verify, review the IXUtil log file in the USM_HOME\logs\install folder on the target computer. If necessary, recreate these report data objects on the target computer.

Note: The Import Export utility does *not* import *images* of offerings. The import fails because of the variation of the image file path names on the source and target computers. To retain such images, copy and paste them manually, after the initial migration is complete.

You have successfully imported the object type.

Step 4 - Verify the Exported or Imported Data

You can verify the imported data through the corresponding objects section in CA Service Catalog, or by querying the database.

Follow these steps:

1. Log in to CA Service Catalog on the computer where you imported the policies. If applicable, log in to the business unit to which you exported the policy or policies.
2. Click Catalog, Policies.
3. Expand the policy folders.
4. Verify that the CA Service Catalog imported the policy or policies as you want. Verify if the import was successful in Forms, Service Offerings, Events, Report Data, Business Units, and Configurations in Administration, Accounting, and Catalog.

Object Type Attributes

This article contains the following topics:

- Report Data Attributes (see page 1490)
- Service Offerings Attributes (see page 1491)

Depending on the selected object type to export or import, specify the information in the fields available for each attribute.

Business Unit Attribute

This section describes the business unit attribute.

- **Business Unit ID**
  Specifies the business unit login ID, the name that is used to log in to the business unit. When you use the business unit id attribute while exporting, verify that the business unit specified exists in the source. For importing a business unit, the parent business unit must exist in the target system. If it does not exist, the business unit being imported becomes a child business unit of the root business unit.
  When you import a business unit that has one or more sub-business units, first import all the business units. Then import all the accounts.

Configuration Attributes

This section describes the configuration attributes.

- **Group Name**
  Specifies the configurations that are grouped under various categories. Many groups are configured in the Administration Configurations, Accounting Configurations, Catalog Configurations, and Custom Configurations. The Configuration name to be provided as input in the Group Name text box is displayed in brackets beside the configuration name in the header section. You can import or export multiple groups at the same time. To export multiple groups, separate the names with commas.
  For example, to export a CMDB configuration group, provide the input as CMDB. All the configurations under this group are exported or imported. Leave this field blank to export all the configurations irrespective of the group.

- **Business Unit ID**
  Specifies the configurations of a group of Business Units that are exported or imported as a group. Leave this field blank to export all the configurations of the groups irrespective of the Business Unit.

Event Attributes

This section describes the event attributes.

- **Event Name**
  Specifies the name of the event as seen in the Event Type list. This option is used to export and import an event information about the specified event type.

- **Rule Name**
  Specifies the name of the rule as seen in the Rule Type list. This option is used to export and import a rule information about the specified event type.

- **Action Name**
  Specifies the name of the action as seen in the Action Type list. This option is used to export and import action information about the specified event type.

Form Attributes

The form attributes export either an individual Form Designer form or all Form Designer forms from a specified folder.

- **Form Designer Folder Name**
  Exports all the Form Designer forms from a specific folder.

- **Form Designer Form Name**
  Exports an individual Form Designer form.

  Note: For Form Designer forms and folders, use only the form name or folder name; path name is not applicable.

- **Business Unit ID**
  Specifies the business unit login ID, the name that is used to log in to the business unit. Use this option to export all forms in a domain. If you omit this option, IXUtil exports all forms in all domains.
  For example, if the business unit ID is subBud, specify subBud in the text box.

Policy Attributes

This section describes the policy attributes.

- **Folder Name**
  Specifies the folder name. To export multiple folders, separate the names with commas.

- **Policy Name**
  Specifies the policy name. To export multiple policies, separate the names with commas.

- **Business Unit ID**
  Specifies the business unit login id that contains the policies being exported. If you are exporting all policies in all the business units, omit this attribute. Otherwise, this attribute is required.
  To import the policy files, optionally specify this parameter to import all the policies into a single business unit.
  If the specified business unit does not exist, the policies that are assigned to it are instead assigned to the root business unit.

Report Data Attributes

This section describes the report data attributes.

- **Folder Name**
  Specfies the folder name. To export multiple folders, separate the names with a comma.

- **ID**
  Specifies an identification of the data objects. To export multiple data objects, separate the id's with a comma.

Service Offerings Attributes

This section describes the service offering attributes.

- **Object Classifier**
  Specifies whether the folders or Service offerings are chosen specifically.

- **Business Unit ID**
  Specifies the business unit login id that contains the folders or service offerings being exported. To export all folders or service offerings in all business units, omit this attribute; otherwise, this attribute is required.
  To import folders or service offerings files, you can specify this parameter to import all the folders or service offerings into a single business unit.
  If the specified business unit does not exist, the folders or service offerings that is assigned to it is instead assigned to the root business unit.

- **Include Forms**
  Associates export of the included forms, with the export of service offerings.

- **Include CMDB CI Mapping**
  Specifies that the associations between CA Service Catalog services and CMDB configuration items are exported.
  This option applies *only* when you have integrated CA Service Catalog with CMDB.

  Important! Verify that the CMDB configuration items are already present on the target computer *before* you export. Also verify that the UUIDs of these configuration items are the same on both the source and target computers. For more information about how to copy the configuration items and verify the UUIDs, see your CMDB documentation.

- **Include Permissions**
  Exports or Imports the permissions for each service (offering) while exporting or importing services through service offerings.

- **Include Request SLA**
  Exports or imports the associated request SLAs for each service (offering) while exporting or importing services.

- **Include Service Hour**
  Exports or imports the associated service hours (outage calendars and business hours) for each service (offering) while exporting or importing services through service offerings.

- **Include Resource Type**
  Exports or Imports the resource type that is associated with the service (offering).

- **Include Application Metric**
  Exports or Imports the application and its metric, along with the definition of the service that is associated with the Application Rate item.

- **Include Associated Policies and Actions**
  Exports or imports the associated policies and actions for each service (offering) while exporting or importing services through service offerings.

- **Include Translations**
  Creates the output as a zip file instead of xml file during export. The zip file includes the default properties file associated with the xml file.
  During Import, if you select this option, provide the zip file as input (instead of single xml file). The zip file internally must contain the properties files corresponding to different locales with the xml file.

Archive and Purge Historical Data

Administrators can archive and purge historical data concerning requests and audits from the CA Service Catalog database. Purging historical data regularly helps improve the performance of CA Service Catalog and the database.

Important! Once you archive the data, you cannot restore the data to production tables.

Follow these steps:

1. Step 1 - Complete the Prerequisites (see page 1492)
2. Step 2 - Prepare the MDB for Archive and Purge for the First Time (see page 1493)
3. Step 3 - Archive the Data (see page 1493)
4. Step 4 - Purge the Data (see page 1495)

Step 1 - Complete the Prerequisites

Complete these prerequisites so that you can archive and purge data successfully.

Follow these steps:

1. Understand the database-related terms that are used in this scenario, as follows:
   When you install CA Service Catalog, you install the Catalog database. The Catalog database includes the following tables:

   - The CA Management Database (MDB) tables that apply to CA Service Catalog. The names of such tables typically begin with a CA_ prefix. The MDB is the common, shared database for CA Technologies products. The MDB provides the database schema for CA Service Catalog and other CA Technologies products.

- The CA Service Catalog-specific tables. The names of such tables typically begin with a USM_ prefix.

2. Back up the Catalog database.

> **Note:** Log in to the Catalog database as the database application user; the user name is typically usm_user or mdbadmin.

3. Configure your DBMS to run with a minimal level of logging. This configuration helps expedite database processing for CA Service Catalog.

> **Note:** For more information about backup procedures and how to set logging levels, see your DBMS documentation.

4. (Optional) Stop all antivirus services.

Step 2 - Prepare the MDB

To improve the performance of archive and purge activity, prepare the Catalog database. This procedure creates an index that helps the database fetch the records faster.

> **Important!** Before you archive or purge data *for the first time*, perform this procedure *once* . Repeating this procedure is unnecessary. For information about how to prepare the MDB, see *Optimize the System Change Detail Tables* in Prepare for Upgrade (see page 580) section.

Step 3 - Archive the Data

Archiving the data moves the archival data from production tables to archival tables. After you archive the data, the data does not appear in CA Service Catalog UI.

> **Important!** The data in archival tables cannot be restored to production tables. So, ensure that you no longer need the data you want to archive.

Use one of the following procedures:

- Archive the Data in SQL Server 2008 (see page 1494)

- Archive the Data in Oracle (see page 1495)

Archive the Data in SQL Server 2008

This section describes archiving the data in SQL Server 2008.

Note: We recommend that you Use MS SQL Server Management Studio to execute the stored procedure.

Follow these steps:

1. Log in to MDB as usm_user or sa using MS SQL Server Management Studio.
2. Click New Query and enter the following code in the new query window.

```
USE [<mdb instance name>]
GO
DECLARE    @return_value int
EXEC    @return_value = [dbo].[usm_sp_archive_data]
        @p_object_type = N'< Object Type >',
        @p_date = N'<Completion Date on or before  -  yyyy-mm-dd>',
        @p_bu = N'<Business Unit>'

SELECT    'Return Value' = @return_value
GO
```

   Replace the values inside the carets (< >) with the required data.

   - **MDB Instance Name**
     Specifies the MDB instance name that CA Service Catalog uses.
   - **Object Type**
     Specifies the type of objects to archive and purge, as follows:
     - **Request**
       Archives or purges requests that are in completed status and related data (including audit data).
     - **Audit**
       Archives or purges audit entries for all objects.
   - **Completion Date on or before - yyyy-mm-dd**
     Archives or purges only requests that are completed on or before this date.
   - **Business Unit**
     Archives or purges the records of this business unit.

3. Click Execute.
   The result appears on the Messages tab.

The data is archived.

Archive the Data in Oracle

This section describes archiving the data in Oracle.

Note: We recommend that you use Oracle SQL Developer to execute the stored procedure.

Follow these steps:

1. Log in to MDB as usm_user or sa using Oracle SQL Developer.
2. Navigate to Connections, connection name, Procedures.
   a.
      - USM_SP_ARCHIVE_DATA
      - USM_SP_PURGE_DATA
3. Right-click one of the procedures and select Run.
4. In the Run PL/SQL window, replace the values inside the carets (< >) with required data.

   Note: If you are using SQLPlus on command prompt, execute the SET SERVEROUT ON statement before executing the stored procedure.

```
DECLARE
  P_OBJECT_TYPE VARCHAR2(200);
  P_DATE DATE;
  P_BU VARCHAR2(200);
BEGIN
  P_OBJECT_TYPE := '<Object Type>';
  P_DATE := '<Completion Date on or before  -  DD-MON-YYYY>';
  P_BU := '<Business Unit>';

  USM_SP_ARCHIVE_DATA(
    P_OBJECT_TYPE => P_OBJECT_TYPE,
    P_DATE => P_DATE,
    P_BU => P_BU
  );
END;
```

5. Click OK.
6. The result is displayed in the Running - Log tab.

The data is archived.

Step 4 - Purge the Data

You can purge the data to remove the archived data permanently from the database.

Follow these steps:

1. Follow the instructions in the Archive the Data procedure and replace the USM_SP_ARCHIVE_DATA stored procedure with USM_SP_PURGE_DATA procedure. When the stored procedure is successfully completed, the data is purged.

Diagnose the Health of the Product

Administrators can use the diagnostic framework to assess the health of CA Service Catalog in a clustered environment. The diagnostic framework includes web service methods, CA Remote Engineer, and the JMX client.

Follow these steps:

Step 1 - Verify the Prerequisites (see page 1496)

Step 2 - Implement the Web Service Methods (see page 1496)

Step 3 - Download and Run CA Remote Engineer (see page 1499)

Step 4 - Use JMX Client to Monitor Status (see page 1500)

Step 5 - Verify the Diagnostic Framework (see page 1500)

Step 1 - Verify the Prerequisites

Before you use the diagnostic framework, meet the following prerequisites for each component:

- For web services, a utility to connect to the web services is required. Examples include Java Client and Simple Object Access Protocol client.
- For CA Remote Engineer, the Java Runtime Environment (JRE) version for CA Service Catalog is required. This JRE version is installed automatically when you install CA Service Catalog.
- For JVM Metrics, a Java Management Extension (JMX) client is required. An example is JConsole, which is included in the Java Development Kit (JDK).

Step 2 - Implement the Web Service Methods

Web service methods help you diagnose problems by verifying the health of the connection between CA Service Catalog and its components. The following web service methods apply during the connection time between CA Service Catalog and its components:

- Web service method for CA Embedded Entitlements Manager (see page)
- Web service method for the database (see page)
- Web service method for CA Process Automation (see page 1498)

Web Service Method for CA Embedded Entitlements Manager

This web service method tests the connectivity of CA Service Catalog with Embedded Entitlements Manager server.

Web Service Method

```
long getEEMConnectionStatus()
```

Input Parameter

None

Return Parameter

Time that is taken in milliseconds by CA Service Catalog to connect to Embedded Entitlements Manager. If the connectivity fails, then an exception is displayed.

Pseudocode to use Embedded Entitlements Manager connectivity web service

```
URL endpoint1 = null;
AdministratorServiceSoapBindingStub adminStub = null;
endpoint1 =
new java.net.URL("http://catalog:8080/usm/services/AdministratorService");
adminStub = (AdministratorServiceSoapBindingStub) new AdminServiceImplService

long eemLatency;
try {
        eemLatency = adminStub.getEEMConnectionStatus();
        System.out.println("Connection successful. Time taken(milliseconds):

} catch (Exception ex) {
        System.out.println("Connection to EEM failed. " + ex.getMessage());
}
```

Web Service Method for the Database

This web service method tests the connectivity of CA Service Catalog with the database server.

Web Service Method

```
long getDBConnectionStatus()
```

Input Parameter

None

Return Parameter

Time that is taken in milliseconds by CA Service Catalog to connect to Database. If the connectivity fails, then an exception is displayed.

Pseudocode to use database connectivity web service

```
URL endpoint1 = null;
AdministratorServiceSoapBindingStub adminStub = null;
endpoint1 =
new java.net.URL("http://catalog:8080/usm/services/AdministratorService");
adminStub = (AdministratorServiceSoapBindingStub) new AdminServiceImplService
```

```
long dbLatency;
try {
        dbLatency = adminStub.getDBConnectionStatus();
        System.out.println("Connection successful. Time taken(milliseconds):

} catch (Exception ex) {
        System.out.println("Connection to database failed. " + ex.getMessage(

}
```

Web Service Method for CA Process Automation

This web service method tests two-way connectivity from CA Service Catalog to CA Process Automation.

Web Service Method

```
long getITPAMConnectionStatus(String configName, String nodeUrl)
```

Input Parameter

- **configName**
  (Optional) Defines the configuration name, which is the group name of CA Process Automation as defined in Administration, Configuration, CA Process Automation. You can remove this parameter to test the default configuration.

- **nodeURL**
  (Optional) Specifies the value for connecting from CA Process Automation to CA Service Catalog. Use this parameter in a clustered setup to verify the connection to an individual node.

  Note: To use this parameter, enable the HTTP connector port that is disabled while setting up a cluster. Disable the HTTP connector port again once the diagnosis is complete.

  If the nodeURL parameter is ignored, it picks CA Service Catalog URL configured with CA Process Automation.

For example:

```
http://host_name:port_no
```

For Secure Sockets Layer (SSL):

```
https://host_name:port_no
```

Return Parameter

Returns an array of the time in milliseconds taken to connect to CA Process Automation and CA Service Catalog respectively. A value of -1 is returned if there are exceptions while connecting.

Pseudocode to use CA Process Automation connectivity web service

```
URL endpoint1 = null;
AdministratorServiceSoapBindingStub adminStub = null;
endpoint1 =
new java.net.URL("http://catalog:8080/usm/services/AdministratorService");
```

```
adminStub = (AdministratorServiceSoapBindingStub) new AdminServiceImplService

long[] millSecs = new long[2];
try {
        millSecs = adminStub.getITPAMConnectionStatus("subton", null);
        System.out.println(String.format("Time taken for connection from Cata

} catch (Exception ex) {
        System.out.println("Connection to ITPAM failed. " + ex.getMessage());

}
```

Step 3 - Download and Run CA Remote Engineer

CA Remote Engineer collects the following product-specific critical diagnostic information and uploads it to CA Technologies:

- Log files
- Product configuration
- Hardware and software information
- A list of Microsoft installed products
- A list of CA installed products with an XML representation of the Windows registry

Note: The information in this topic is based on CA Remote Engineer Release 2.0 (the current release at publication time). If the version that you download is different, the steps can be different.

Follow these steps:

1. Download CA Remote Engineer from http://ca.com/support (http://www.ca.com/support) to the CA Service Catalog computer.
2. Unzip the utility.
3. Run the re.cmd file. This file is in the RemoteEngineer folder in the location where you unzipped the utility. This file opens a command-line utility. To use the UI-based alternative instead, run the RemoteEngineer.cmd file.
4. Follow the prompts and enter the requested information.

   Important! Specify *Service_Catalog* as the CA product name.

   For more information about the prompts, see the help file in the RemoteEngineer\help folder.

5. When prompted to verify the information that you entered, enter Yes or No.
   The utility proceeds as follows:

   - If you enter Yes, the utility collects the required information from your computer and zips it.
     Specify whether the utility must upload the zip file to CA Technologies through FTP. Alternatively, you can keep the zip file for reference or you can send to CA Technologies through another means. For example, email.

   - If you enter No, the utility aborts.

6. Close CA Remote Engineer.

Note: If you are using clustering, repeat the steps for all cluster nodes.

You have downloaded and run CA Remote Engineer.

Step 4 - JMX Client to Monitor Status

Configure the default Tomcat in CA Service Catalog to monitor the health of catalog instances with the JMX client. You can use JVM metrics to monitor the status information such as memory usage, CPU usage, and number of threads.

Note: This facility is not available if CA Service Catalog is deployed as web archive.

Follow these steps:

1. Enable the JMX remote monitoring without any security options. Use a free port of your choice.

2. Open the viewservice.conf wrapper configuration file from the *view**conf*\ location in an editor.

3. Uncomment the following three lines in the file for the JMX remote monitor.

   ```
   wrapper.java.additional.22=-Dcom.sun.management.jmxremote.port=9091
   wrapper.java.additional.23=-Dcom.sun.management.jmxremote.ssl=false
   wrapper.java.additional.24=-Dcom.sun.management.jmxremote.authenticate=false
   ```

4. Save and close the file.

Step 5 - Verify the Diagnostic Framework

The following results indicate a successful implementation of the diagnostic framework:

- The web service methods are called without any errors from the client.
- The web services run without errors.
- CA Remote Engineer collects product-specific data.
- The health of CA Service Catalog instances is monitored using the JMX client.

Deploy CA Service Catalog on a Custom Web Server

Deploying CA Service Catalog on a custom web server lets you use CA Service Catalog with another supported web server instead of the default Tomcat web server. Such a deployment also lets you use the same instance of the web server for multiple applications. For example, CA Service Catalog and CA RCM are installed on the same computer. You can use the same instance of the JBoss web server for CA Service Catalog and CA RCM. Such sharing helps your environment run more efficiently.

To deploy CA Service Catalog on the custom web server, follow this process:

- Step 1 - Verify the Prerequisites (see page 1501)
- Step 2 - Review the Limitations (see page 1502)
- Step 3 - Create the WAR File (see page 1502)
- Step 4 - Deploy the WAR File (see page 1503)
- Step 5 - Disable the Default Tomcat Instance (see page 1504)
- Step 6 - Verify the Deployment (see page 1504)

Step 1 - Verify the Prerequisites

Verify that you have met the following prerequisites, so that you can deploy the WAR file successfully:

- Install or upgrade the following applications on the same computer:
  - CA Service Catalog
    The applications with which you want to share the instance of the custom web server as CA Service Catalog, for example, CA RCM
  - The custom web server
    You can use one of the following options as your custom web server:
    - Tomcat 6 or 7
    - JBoss 5.1

    You can use either a new or existing installation of a supported web server, one of the following options:
    - A version that was supplied by installing another application. For example, CA RCM installs JBoss 5.1.
      In this case, this entire scenario applies, including the procedure to deploy the WAR file (see page).

- A stand-alone version that you installed manually. For example, you can download a supported web server from the Apache web site or the JBoss web site.
  In this case, this entire scenario applies, *except for* the procedure to deploy the WAR file. Instead, see your web server documentation for instructions to deploy the WAR file.

- Be an experienced administrator for the web server and database that you are using with CA Service Catalog.

Step 2 - Review the Limitations

Understand the following limitations:

- You *cannot* use the same custom web server for both CA Service Catalog and CA Process Automation.

- Stop, start, or restart the web server, to stop, start, or restart CA Service Catalog. You cannot stop, start, or restart CA Service Catalog by itself. However, you can individually restart other products that use the web server.
  For example, CA Service Catalog and CA RCM use the same web server. You can restart CA RCM alone, but you cannot restart CA Service Catalog alone. To restart CA Service Catalog, you restart the web server, which restarts *both* products.

- JMX Diagnosis is not available for war deployment.

Step 3 - Create the WAR File

Create the war file from CA Service Catalog.

Note: The war file that is generated from a computer must be deployed on the same computer. For example, in a clustered set-up, generate the war file on each node. Now deploy the war file on the nodes.

Follow these steps:

Click Start, Programs, CA, CA Service Catalog Command Prompt.

- (Optional) Run the following command if the custom web server is running on a port other than the port used for installation of CA Service Catalog (typically 8080).

  ```
  ant update-usm-host
  ```

  You are prompted to enter the new port number. Enter the port number of the custom web server.

- Run the following command at the command prompt:

  ```
  ant create-war
  ```

- Select one of the following options from the list:

- **Tomcat**
  Creates the war file for Tomcat 6 or 7.

- **JBoss**
  Creates the war file for JBoss 5.1

- **Other**
  Do not use this option as it is reserved for future use.
  For Tomcat, the usm.war file is generated in the USM_HOME\war folder.
  For JBoss, the usm.war folder is created.

- (Optional) Change the war file name to reflect the name of the catalog, business unit (tenant), or other meaningful entity:

  1. In Windows, manually rename the usm.war file, for example, to catalog.war or FinanceBU.war.

  2. Update the file name in the synchronization utility properties file: Specify the new name *without the .war extension* in the EIAMUser.Context=*filename* parameter in the syncuputil.properties file. This file resides in the USM_HOME folder.

  3. For example, if the new file name is FinanceBU.war, then the updated entry is EIAMUser.Context=FinanceBU.

  4. Update the file name in the administration configuration settings on the UI: Log in to CA Service Catalog as a Service Delivery administrator (for example, spadmin). Then select Administration, Configuration, Server Information, Context Path, and specify the new file name.
     The war file is created and available for deployment.

- If you are migrating or upgrading CA Service Catalog, follow these steps:

  1. Apply the patch on the installed CA Service Catalog before generating the war file.

  2. Deploy the WAR file on the same web server.

Step 4 - Deploy the WAR File

Deploy the war file so that you can use the custom web server for CA Service Catalog with other applications. Using the same web server for CA Service Catalog and other applications helps your system run more efficiently. This procedure uses CA RCM for illustration. Follow this procedure as a model for deploying your WAR file with other applications.

Follow these steps:

1. Copy the usm.war folder to the *RCM_HOME*\Server\eurekify-jboss\server\eurekify\deploy folder.
   RCM_HOME is the CA RCM installation folder; the default is C:\Program Files\CA\RCM.

2. Edit the *RCM_HOME*\Server\eurekify-jboss\bin\run.bat file, as follows:

   a. Locate the *set PATH=* statement.

b. At the end of this statement, add the path name of the database client, for example:

- The default path name for SQL 2008 R2 is C:\Program Files\Microsoft SQL Server\100\Tools\Binn.
- The default path name for Oracle 11g is C:\app\Administrator\product\11.2.0 \dbhome_1\BIN.

Troubleshooting

After you deploy the war file with CA RCM and you cannot start it, you see the following error message:

```
Provider org.apache.xalan.xsltc.trax.TransformerFactoryImpl not found" in eurekify.
log"
```

Note: The log files reside in this folder: C:\Program Files\CA\RCM\Server\eurekify-jboss\server\eurekify\log\eurekify.log.

If you are not able to start CA RCM, follow these steps:

1. If the xalan-x.x.x.jar and serilizer.jar files exist in the following folder, delete them.

   ```
   RCM_HOME\Server\eurekify-jboss\server\eurekify\deploy\eurekify.war\WEB-INF\lib
   ```

2. Copy the xalan-2.7.0.jar and serilizer.jar files from the following folder:

   ```
   RCM_HOME\Server\eurekify-jboss\server\eurekify\deploy\usm.war\WEB-INF\lib
   ```

   to the following folder:

   ```
   RCM_HOME\Server\eurekify-jboss\server\eurekify\deploy\eurekify.war\WEB-INF\lib
   ```

3. Restart the JBoss server.

Step 5 - Disable the Default Tomcat Instance

After you deploy the war file on the custom web server, stop the CA Service Catalog Windows service. Stopping the CA Service Catalog service disables the default Tomcat instance. Optionally, you can disable the service to prevent it from starting automatically.

Note: The CA Service Accounting service needs no modifications.

Step 6 - Verify the Deployment

After you deploy the custom web server, you can verify whether the deployment is successful.

Follow these steps:

1. Access the following catalog URL: http://*computer_name:port/context*

   - **Computer name**
     Defines the name of the computer on which CA Service Catalog is installed.

   - **Port**
     Defines the port number on which the web server is configured to run.

   - **Context**
     Defines the name of the war file that is created during deployment. The default is usm.war.

   If you renamed the war file, use the new name here.

2. Verify that you can access CA Service Catalog, for example, by creating, submitting, and acting on requests.
   You have verified the deployment.

Deploy and Undeploy Components from the Command Line

This article contains the following topics:

CA Service Catalog allows you to deploy and undeploy components from the command line.

Prerequisites

Fulfill the following prerequisites before deploying:

To deploy CA EEM:

The following columns must be filled in config.properties file.

- eem.configured = true
- eiam.backend =
- eiam.application =
- eiam.admin.username = EiamAdmin
- eiam.admin.password =

To deploy the MDB:

The following columns must be filled in config.properties file.

- mdb.configured = true
  Mandatory parameters for the command line interface.
- mdb.deploy.vendor =
- mdb.deploy.host =
- mdb.deploy.port =
- mdb.deploy.user =
- mdb.deploy.password =
- mdb.deploy.dbinstance =
  Mandatory parameter specific to Oracle
- mdb.deploy.connectionid =
  MDB Configuration
- mdb.deploy.dbname =
- mdb.deploy.mdbadminpwd =
- mdb.deploy.usmuser =
- mdb.deploy.usmpassword =

Note: For a SQL database, fill only the columns that are related to SQL.

To deploy a component:

- component.catalog = true
- component.accounting = true
- component.webserver = true
- application.service = true
- corporate.service = true
- facilities.service = true
- it.service = true
- network.service = true
- personnel.service = true
- project.service = true

- reservation.service =true

To run all the commands:

All the columns that are mentioned must be filled in config.properties. Note that the Oracle and SQL columns must not be filled at the same time. If the database is Oracle then only the Oracle columns must be filled. The same criteria holds true for SQL database.

Deploy Components

Deploy the CA Service Catalog components such as the MDB, CA EEM from the command line using the config.properties file. The config.properties file is an input file and must be located outside the USM_HOME. The file accepts passwords in plain text format only.

Note: You can also deploy the components from the CA Service Catalog User Interface.

Follow these steps:

1. Open the CA Service Catalog command prompt by clicking Start, Programs, CA, Service Catalog, CA Service Catalog Command Prompt.
2. Go to the Scripts path in the USM folder.
3. Enter one or more of the following commands:
   - To deploy MDB, enter the following command:

     ```
     Configurator.bat  - c mdb  - p "path to config.properties"
     ```

     For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - c mdb - p "C:\config.properties"
   - To deploy CA EEM, enter the following command:

     ```
     Configurator.bat  - c eem  - p "path to config.properties"
     ```

     For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - c eem - p "C:\config.properties"
   - To deploy component, enter the following command:

     ```
     Configurator.bat  - c component  - p "path to config.properties"
     ```

     For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - c component - p "C:\config.properties"
   - To deploy all CA Service Catalog components, enter the following command:

```
Configurator.bat  - c all  - p "path to config.properties"
```

For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - c all - p "C:\config.properties"

Important! Stop and start the tomcat service for the changes to take effect.

You have deployed the CA Service Catalog components using the command line.

Undeploy Components

CA Service Catalog allows you to undeploy the MDB, CA EEM, and other components individually from the command line. Undeploy these components in reverse order.

Follow these steps:

1. Open the CA Service Catalog command prompt by clicking Start, Programs, CA, Service Catalog, CA Service Catalog Command Prompt.
2. Go to the Scripts path in the USM folder.
3. Enter one or more of the following commands:
   - To undeploy all CA Service Catalog components, enter the following command:

     ```
     Configurator.bat  - u all  - p "path to config.properties"
     ```

     For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - u all - p "C:\config.properties"
   - To undeploy component, enter the following command:

     ```
     Configurator.bat  - u component  - p "path to config.properties"
     ```

     For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - u component - p "C:\config.properties"
   - To undeploy MDB, enter the following command:

     ```
     Configurator.bat  - u mdb  - p "path to config.properties"
     ```

     For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - u mdb - p "C:\config.properties"
   - To undeploy CA EEM, enter the following command:

     ```
     Configurator.bat  - u eem  - p "path to config.properties"
     ```

For Example: C:\Program Files\ca\service catalog\scripts>Configurator.bat - u eem - p "C:\config.properties"

Important! Stop and start the tomcat service for the changes to take effect.

You have undeployed the CA Service Catalog components using the command line.

Perform Maintenance

You can perform the following maintenance tasks:

- CA Service Catalog files are updated during use. Backup such files regularly. For more information about file location on the CA Service Catalog component. You can perform maintenance by backing up files regularly that are updated when you use CA Service Catalog. You can change the name of of the host computer running CA EEM for security compliance. You can also change the names of the applications whose access control you manage through CA EEM. To change these names, you run the setup utility on every computer that has a CA Service Catalog component.
- You can also change the database settings like host name, port number, instance name, or service name. CA Service catalog components use the database settings for communication.
- You can also use the operating system (not the ant update-usm-host command) to change the host name. You can make use of the ant command to propagate this change for catalog systems.
- Run the setup utility to change the password of the database user, to comply with security, governance, or other requirements. CA Service Catalog components use the logon credentials (user name and password) of the database user to access the database.

Perform the following maintenance tasks:

- Files to Back Up Regularly (see page 1509)
- Update the CA EEM Host Name and Application Names (see page 1510)
- Update the Database Host, Password, Instance, Service Name, or Port (see page 1511)
- Update the Host Name and Port Number Using the ant Command (see page 1513)
- Update the Password of the Database User (see page 1514)

Files to Back Up Regularly

Several CA Service Catalog files are updated during use. Back up such files regularly.

The following table identifies the features that use the files on the Catalog Component server and their locations:

Feature	Folder
Request Attachments	USM_HOME\filestore\documents\requests
CA Service Catalog Images for services	USM_HOME\filestore\images\offerings

Feature	Folder
Documents	USM_HOME\filestore\documents
CA Service Catalog Forms	USM_HOME\filestore\forms
Data Objects and Data Views	USM_HOME\filestore\reporting
Offline Data Objects and Data View	USM_HOME\filestore\reporting\offline
Custom files for CA Service Catalog, including custom images, data fields for business units, accounts, and users. You can optionally store these files in a filestore.	USM_HOME\filestore\custom **Example:** Suppose you customized data fields for business units, accounts, and users. Sample folder name: USM_HOME\filestore\custom\locale\icusen (for English). Suppose you customized images for service option groups. Sample folder name: USM_HOME\filestore\custom\images\rateplans
Data Mediation	USM_HOME\filestore\DataMediation
CA Service Repository Agent files (also known as Data Mediation Data Repository Agent)	USM_HOME\repagent. This folder contains these sub folders: \conf, \log, and \data

Administrators who have installed CA Service Catalog on multiple computers must keep files synchronized on all servers. Otherwise, an error can occur.

The following table identifies the features that use files on multiple computers and the folders where those files are located:

Feature	Folder
Attachments	USM_HOME\view\documents
CA Service Catalog Images	USM_HOME\FileStore\images\offerings
Documents	USM_HOME\view\documents
CA Service Catalog Forms	USM_HOME\view\forms

Update the CA EEM Host Name and Application Names

To comply with security, governance, or other requirements, you can change the name of the host computer running CA EEM. You can also change the names of the applications whose access control you manage through CA EEM. To change these names, you run the setup utility on *every* computer that has a CA Service Catalog component. This utility updates these names globally to ensure that CA Service Catalog, CA EEM, and the integrated products run efficiently.

The *application names* are the CA EEM policies for managing user access control and other resources to these products. The application name *Service Delivery* in CA EEM refers to the policies governing user access control in CA Service Catalog. CA EEM includes a *Global* application name that you can apply in part or in whole to one or more products.

Follow these steps:

1. Enter the following URL in your browser for the CA Service Catalog installation that you want to update:

`http://hostname:portnumber/usm/config`

2. Enter the password to log in to the setup utility.
   The setup utility opens on the Database tab.

3. Click the Security tab, and specify new values for the settings that you want to change, as follows:

   - The host name of the CA EEM computer.
     If you change the host name, a “Backup and restore” option appears. To back up the CA EEM data on the current computer and restore it on the new computer, select this option. If you select the Backup and restore option, specify the password of the administrator on the old CA EEM computer.
   - The name of the CA EEM application instance.
   - The password of the CA EEM application instance.

4. Save your changes.

5. Restart the Windows services for Accounting Component and CA Service Catalog to make your updates take effect.

6. Make the same updates on all remaining CA Service Catalog computers in your environment.

7. Verify that CA Service Catalog is running correctly, as follows:

   a. Log in to CA Service Catalog.

   b. Perform administrative tasks. Create Services. Also, create and process requests.

The new or updated host name and application names are updated in the Windows registry.

Note: As a best practice, back up the Windows registry after you update the host name and application names. For more information, see your Windows documentation.

Update the Database Host, Password, Instance, Service Name, or Port

To comply with changes in your environment or for other reasons, you can change the following database settings: host name, port number, instance name, or service name. CA Service Catalog components use these settings to communicate with each other and the database.

Follow these steps:

1. Perform the following prerequisite tasks:

   a. To update the database host name, update the operating system computer name of the computer which has the database. For more information, see your operating system documentation.

b. Update the database settings in your DBMS software (Oracle or SQL Server). For more information, see your DBMS documentation.

c. Verify that the updated DBMS is accessible from every DBMS client on every CA Service Catalog computer. Use your DBMS client software (not CA Service Catalog) to perform this step.

2. Enter the following URL in your browser for the CA Service Catalog installation that you want to update:

   `http://hostname:portnumber/usm/config`

3. Enter the password to log in to the setup utility.
   The setup utility opens on the Database tab.

4. Enter the new password for the database user in the Application User Settings section only if *both* of the following conditions exist.

   - You are using SQL Server.
   - The database was backed up and restored on a new computer.

   Confirm the password and save your changes.

5. (Optional) When you are prompted for your password, specify your existing password to continue using it.

6. Specify new values for the settings that you want to change, as follows:
   SQL Server
   If applicable update the instance name for the MDB.
   Default: MSSQLSERVER
   Oracle
   If applicable, update the service name. Every Oracle database or service has a service name. The service name of an Oracle database is typically its global database name. Enter the service name of the Oracle database or other service that you want to access.

7. If applicable, update the port number.

8. Save your changes.

9. Restart the Windows services for CA Service Catalog to make your updates take effect.

10. Make the same updates on all remaining CA Service Catalog computers in your environment.

11. Verify that CA Service Catalog is running correctly, as follows:

    a. Log in to CA Service Catalog.

    b. Perform administrative tasks. Create services. Also, create and process requests.

Update the Host Name and Port Number Using the ant Command

If applicable, you use the operating system (not the ant update-usm-host command) to change the host name. Afterwards, you use the ant command to propagate that host name change throughout the catalog system. Use the ant command to both update the port number directly *and* propagate that change throughout the catalog system.

You perform these steps *only* on the computer whose host name or port number has changed. You do not perform these steps on *other* computers.

Follow these steps:

1. Stop the CA Service Catalog services on the computer being updated.

   Important! Stop these services on *all* CA Service Catalog computers in your environment *before* proceeding to the next step. Use the Windows Control Panel to stop the services.

2. Perform the following actions:

   a. Open the CA Service Catalog command prompt from the CA Service Catalog portion of the Windows Start menu.

   b. Enter the following command at the CA Service Catalog command prompt:

      ```
      ant update-usm-host
      ```

      Note: For a list of ant commands and their descriptions, enter ant -p.

      The utility displays the current settings for the host name and port number.

   c. Update each setting that you want to change, and record all updated settings for reference.

The command utility performs the following actions:

- Updates the host name and port number settings in your DBMS (Oracle or SQL Server) and in configuration files
- Records the actions that it performs in the maintenance.log file.
  This log file and the backed-up configuration files are stored in the USM_HOME\conf-backup*date-time* folder. The name of the *date-time* subfolder is based on when the ant update-usm-host command was run. Thus, this subfolder name is different on each computer in the environment. The utility writes the name of the subfolder to the screen as soon as the backup is completed.

3. Perform the following actions:

    a. View the maintenance.log file in the USM_HOME\conf-backup*date-time* folder for a record of the actions performed.

    b. Record the name of this folder for future reference.

4. Verify that you have finished updating the host name and port number on the current computer. Update the host name and port number on the next computer, if necessary.

5. Verify that you have updated the required settings on *all* CA Service Catalog computers.

6. Log in to CA Service Catalog.

7. Verify that CA Service Catalog is running correctly, as follows:

    a. Log in to CA Service Catalog.

    b. Perform administrative tasks. Create services. Create and process requests.

The new or updated host name and application names are updated in the Windows registry.

Update the Password of the Database User

You can run the setup utility to change the password of the database user, to comply with security, governance, or other requirements. CA Service Catalog components use the logon credentials (user name and password) of the database user to access the database. The setup utility updates these password references globally to help CA Service Catalog continue to run efficiently throughout your environment. You run the setup utility on *every* computer in your environment that has a CA Service Catalog component installed.

Follow these steps:

1. Start the setup utility by entering the following URL in your browser for the CA Service Catalog installation that you want to update: http://*hostname:portnumber*/usm/config.

2. Enter the password to log in to the setup utility.
   The setup utility opens on the Database tab.

3. Enter the new password for the database user in the Application User Settings section. Confirm the password and save your changes.

4. Restart the Windows services for CA Service Catalog to make your updates take effect.

5. Update the password on all remaining CA Service Catalog computers in your environment.

6. Verify that CA Service Catalog is running correctly, as follows:

    a. Log in to CA Service Catalog.

    b. Create services, create and process requests, and perform administrative tasks.

Configuring CA Asset Portfolio Management

This section contains the following articles:

Configurations

As an administrator, you can configure the user interface to simplify how users enter, manage, and search for data. You can also protect users from performing unauthorized tasks, ensure that you conform to your IT asset management practices. When you configure the user interface, you, and all users affected by your configuration changes, immediately see the changes. For example, you do not want anyone, except the asset manager, to see any information for sites and companies. Therefore, you hide the Site and Company tabs and specify that only users in the asset manager role can see those tabs.

When configuring the user interface, use the following types of configurations:

- **Global configuration**. Configure the product for all users, regardless of their role.
  A *global configuration* lets you modify the functionality of your product implementation. You focus on configuring the pages, objects, fields for your specific implementation. You need not worry about making configuration changes for all possible users and roles.
  For example, you do not want to use the contact management functionality. Therefore you define a global configuration on the Contact page, hide this functionality from all users, and save the global configuration. As a result, users do not see the Contact page, unless you define a local configuration to override the global configuration.
  A global configuration can apply to all asset families or legal templates or to a specific family or template. You can have only one global configuration that applies to all families or templates or that applies to a specific family or template.

  
  If you do not want to make any global user interface changes for your implementation, you do not have to define a global configuration. You can define a local configuration without defining a global configuration.

- **Local configuration**. Configure the product for specific users and roles.
  Use a *local configuration* to configure the user interface pages based on the requirements of the different users and roles.

  
  Local configuration changes override global configuration changes.

For example, you define a global configuration to hide the contact management functionality in your implementation. However, there are users in a specific role who must be able to see and update contact information. Therefore, you define a local configuration on the Contact page, make the contact information appear, and save the local configuration. When you assign the local configuration to the users in the role, they see the contact information.
A local configuration can apply to all asset families or legal templates or to a specific family or template. You can have multiple local configurations that apply to all families or templates or that apply to a specific family or template. You can assign to a role only one local configuration that applies to all families or templates or that applies to a specific family or template.

You cannot assign a global configuration to a role. By default, a global configuration is assigned to all roles when the users log in and the security permissions for the roles are determined. You can only assign a local configuration to a role.

A global configuration is always assigned to all roles, even when you assign the role to a local configuration. Any permission from the global configuration that a local configuration does not override is applied to the role. Global configurations are used to configure the product for every user (except for the system administrator role, *uapmadmin*). To configure the user interface on a more detailed level by role, add a local configuration. In this situation, all users in all roles will see the configured interface based on the global configuration changes, and users assigned to a local configuration will see the additional changes to the interface.

If a user is assigned to a local configuration, the local configuration is assigned to the role when the user logs in.

Page Configuration by Asset Families and Legal Templates

This article contains the following topics:

For most objects, you configure the user interface, save the configuration, and all users in the role that is assigned to the selected configuration see the page that way. No additional configuration options are available. For certain objects (assets, models, and legal documents) you can provide a more specific configuration by selecting a particular *asset family* or *legal template, or all asset families or legal templates*.

You can manage pages in the following ways:

- Configure the model or asset page by asset family (see page 1518).
- Configure the legal document page by legal template (see page 1519).

Example: Configure for a Hardware and Software Asset

- (Hardware Asset) Configure the page for assets by moving important fields (asset name, model name, quantity, serial number, operating system, purchase order number, and service status) to the top of the page and making the fields required. In addition, remove the Host Name field. When you save the configuration, select the asset family *Hardware*. As a result, when users assigned to the configuration enter a hardware asset, they see the page as you have configured it.

- (Software Asset) Configure the page for assets by moving important fields (asset name, model name, quantity, serial number, department, cost center, and purchase order number) to the top of the page and making the fields required. In addition, remove the Service Status and Service Status Date fields. When you save the configuration, select the asset family *Software*. As a result, when users assigned to the configuration enter a software asset, they see the page as you have configured it.

Example: Configure Across All Asset Families

Configure the page for assets in all asset families by making the Requisition ID and Purchase Order ID fields read only for all users except the asset fulfiller. The asset fulfiller can edit these two fields. To achieve this result, you create two configurations:

1. A global configuration that makes the Requisition ID and Purchase Order ID fields read only. Select Across all families for this configuration so that the fields are read only on the Asset page for all asset families. This global configuration applies to all users.

2. A local configuration that allows users to edit the Requisition ID and Purchase Order ID fields. Select Across all families for this configuration, also, so that the fields can be edited on the Asset page for all asset families. This local configuration is assigned to users in the asset fulfiller role.

As a result, users who are not asset fulfillers cannot edit the Requisition ID and Purchase Order ID fields on the Asset page for any asset family. However, users in the asset fulfiller role can edit the two fields on the Asset page for all asset families.

Example: Configure for a Confidentiality Agreement

Configure the page for legal documents by moving important fields (Document Identifier, Effective Date, Termination Date, and Negotiator) to the top of the page and making the fields required. In addition, remove the Status and Status Date fields. When you save the configuration, select the legal template *Confidentiality Agreement*. As a result, when users assigned to the configuration enter a confidentiality agreement, they see the page as you have configured it.

Custom Asset Families

You can extend the product by creating additional asset families (see page) to track products other than hardware and software. *Custom asset families* let you track information about almost any classification of asset in your IT environment. For example, you can create asset families for telecommunications, services. After you create a custom asset family, configure the page and save the configuration for the custom asset family. As a result, a user assigned to the configuration for the custom asset family sees the page as you configure.

Configure the Model and Asset Page by Asset Family

You can configure the Model or Asset page for a specific asset family (for example, hardware asset and software asset) or for all asset families. Users in the role assigned to the configuration see the page as you have configured it.

Follow these steps:

1. Click the Model or Asset tab.
2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.
3. In the Configuration Information area of the page, select an asset family or select Across all families.

   If you are creating a global configuration and a global configuration already exists across all families, the Across all families field does not appear.

4. Specify the information for the new global or local configuration (see page 1515), or select an existing configuration that you want to change.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles that are assigned to the selected configuration.

5. Complete any of the following steps:
   - Change a field label.
   - Move a field to a new location.
   - Make a field read-only, required, or optional.
   - Hide a field.
   - Make a previously hidden field appear.
   - Add a field.
6. Click Save Configuration.
   When you assign a configuration to a role, users in the role see the page as you have configured it.

Configure the Legal Document Page by Legal Template

You can configure the Legal Document page for a specific legal template or for all legal templates. Users in the role that is assigned to the configuration see the page as you have configured it.

Follow these steps:

1. Click the Legal Document page.
2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.
3. In the Configuration Information area of the page, select a legal template or select Across all templates.

   If you are creating a global configuration and a global configuration already exists across all templates, the Across all templates field does not appear.

4. Specify the information for the new global or local configuration (see page 1515), or select an existing configuration that you want to change.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles that are assigned to the selected configuration.

5. Complete any of the following steps:
   - Change a field label.
   - Move a field to a new location.
   - Make a field read-only, required, or optional.
   - Hide a field.
   - Make a previously hidden field appear.
   - Add a field.
6. Click Save Configuration.
   When you assign a configuration to a role, users in the role see the page as you have configured it.

How to Configure the User Interface

To configure the user interface, complete the following tasks:

- Protect the users from performing unauthorized tasks using object access configuration and tab and menu configuration.
- Make it easier for users to enter information for the objects they manage using field configuration.
- Validate and enforce the field format and data entry requirements using field data validation configuration (see page 1526).
- Protect the users from performing unauthorized tasks using hyperlink and button configuration.
- Extend the repository to store more data using extended field configuration (see page 1524).
- Extend the product and enhance how users enter information for the objects they manage using reference field configuration.
- Extend the product and track more information and detail about an object using hierarchy configuration (see page 1528).
- Make it easier for users to enter model, asset, and legal document information by family and legal template using page configuration (see page 1516).
- Make it easier for users to find the objects they manage in searches using search configuration.
- Make it easier for users to enter information for legal documents using legal template configuration (see page 1530).
- Alert users about upcoming events and verify that the appropriate tasks are performed in the correct order at the right time using event and notification configuration (see page 1522).
- Make it easier for users to select the correct items from lists using list management (see page 1532 .
- Extend the product and enhance how users manage object information using custom relationships (see page 1520).

Custom Relationships

Custom relationships are links between two related objects. The relationship describes and provides information about the interdependencies between the objects. Through a custom relationship, you can navigate from one object to the other object. You can locate, retrieve, and modify information about the objects.

Manage Custom Relationships

You can define and update custom relationships between two objects. In a custom relationship, one of the objects is a primary object and the other object is a secondary object.

You cannot delete a custom relationship that you define and save.

Follow these steps:

1. Define a custom relationship.
    a. Click the tab and optional subtab for the object for which you want to define a custom relationship.
    b. Select CONFIGURE: ON from the search results page.
    c. Select a global configuration across all families or templates or create and save a global configuration.

You cannot define a custom relationship for a local configuration.

    d. Click Add Custom Relationship.
    The Add Custom Relationship dialog opens.
    e. Specify a name for the primary object relationship and secondary object relationship.
    f. Select the secondary object.

For assets, models, and legal documents, select a family or template or select across all types.

    g. Click Save.
    The new custom relationships are displayed under the Custom Relationship menu for the primary and secondary objects.
    h. (Optional) Add simple or reference extended fields to the custom relationship.
2. Update a custom relationship.
    a. Click the tab and optional subtab for the object for which you want to update a custom relationship.
    b. Select CONFIGURE: ON from the search results page.
    c. Select a global configuration across all families or templates.
    d. Select the relationship under the Custom Relationship menu.

e. Modify the information for the custom relationship and click Save.

Event and Notification Configuration

This article contains the following topics:

An *event* represents an activity related to a field (default or extended) for an object. When you define an event, you specify the criteria that must be met before the event occurs. For example, you want to know when the data in a particular field changes. You can define an event that detects the data change. An event works in combination with a *notification*, which the workflow provider (for example, CA Process Automation) creates to alert your team members that an important event has occurred for a specific field or object. By using events and notifications, you alert people about upcoming events and help ensure that the appropriate tasks are performed in the correct order at the right time.

A notification is triggered when an event that you define occurs. For example, you define a date event on the Termination Date field for a legal document to notify the contract manager 15 days before a legal contract expires. The contract manager uses the 15 days to review and possibly negotiate a better contract. When the date arrives (that is, 15 days before the contract expires), the event occurs and the notification process is triggered through the workflow provider. The workflow provider constructs, issues, and manages the notification based on the configuration that you provided in the workflow provider and in CA APM.

The default notification method in CA APM supports email notifications using a workflow provider. You can send an email notification to any user or distribution list that is defined in your internal email system, even if the user is not a CA APM user. In addition, you can send an email to any external email address, if permitted by your email system.

You can also configure the notification process in the workflow provider to trigger any type of process. For example, you can set up the notification process to perform certain actions in another application when an event occurs in CA APM. For information about setting up different notification processes, see your workflow provider documentation.

You can define the following types of events to track and manage important changes to fields or objects:

- Date events. Monitor a date field for an object and have the workflow provider notify you that an important date is approaching or has passed.
- Change events. Monitor a field for an object and have the workflow provider notify you that the field value has changed.
- Watch events. Monitor a field for an object and have the workflow provider notify you about a potential obstruction to completing a task.

How to Configure Events and Notifications

Events work in combination with notifications, which the workflow provider (for example, CA Process Automation) creates, to communicate information to your team members about important events and activity. To configure events and notifications, complete the following steps:

1. Administrators grant permissions to users to manage events.

2. Users with the correct permissions open an existing configuration and define date events, change events, and watch events. For more information about defining events, see Events and Notifications (see page 2376).

3. Users, when defining an event, map all workflow provider process parameters to a CA APM object attribute. For more information, see Workflow Provider Process Parameters (see page 2376).

4. The workflow provider initiates the notification process.

5. Users View an Audit History of Events (see page 2340).

Grant Permissions to Manage Events

You can grant permissions to users so they can configure the user interface and can define an event.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.

3. In the Configuration Information area of the page, select an existing global or local configuration (see page 1515).

   Important! Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles that are assigned to the selected configuration.

4. In the Permissions area of the page, move Manage Events to the Granted Permissions list.

5. (Optional) Select the Inherit Permissions from Parent Object check box to apply any security permissions from a top-level (parent) object to the lower-level (child) object using the same configuration.

   For example, you create a local configuration for an Organization. In the configuration, you deny permissions to change field labels, move fields, make fields required, and hide fields. After you save the configuration, you open Attachments under Organization and select the Inherit Permissions from Parent Object check box. All permissions from the Organization are applied to Attachments. In this example, because permissions to change field labels, move fields, make fields required, and hide fields are applied to the Organization, the permissions are also applied to the Attachment.

6. Click Save Configuration.
   When you assign a configuration to a role, users in the role have permissions to define an event.

Extended Field Configuration

Contents

You can design your own fields (extended fields) and can add them to objects. Extended fields are additional fields to help you capture data in your repository critical to the asset management at your site. If you are not able to find an appropriate field in your repository to store key data, define an extended field for the data.

You can define extended fields for models, assets, legal documents, costs, payments, model parts and pricing, contacts, companies, organizations, locations, and sites. You can use extended fields when searching and for reports.

You can add an extended field that you created for an asset cost to a legal document cost. Under Legal Document, click Add Existing Fields on the Costs configuration page.

Extended fields are shared with the products integrating with CA APM (CA Service Desk Manager and CA Service Catalog). Any changes that are made to the extended field values in the integrating products are immediately reflected in CA APM. And, any changes you make to the extended field values in CA APM are reflected in the integrated products.

Define an Extended Field

You can define an extended field to help you capture all data in your repository that is critical to your asset management program. For example, when entering an asset for a blade server, there is no way to enter the chipset. Define an extended field that is named *chipset,* which adds the field to the Asset Details page. Users can enter the chipset information (for example, Intel 5520) with the other information such as the asset name, serial number, memory, processor, operating system.

Important!: These steps work only the first-time you complete the wizard and define the extended field for the object. Before you define the extended field, verify that you have the following information for reference: table name, label, format (character, boolean, currency, date, decimal, or integer), field name, attribute name, field size, and whether an entry for the extended field is required. After you complete the wizard, you can configure the extended field like any field.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.

3. In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global configuration (see page 1515), or select an existing global configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object. Changes do not apply to the other parts of the object.

You can only define an extended field for a global configuration. You cannot define an extended field for a local configuration.

4. Click Save Configuration to create the global configuration.

5. Click Add Extension.
   A wizard appears.

6. To enter the information for the extended field, select the Simple Field option and follow the on-screen instructions.

To change the default object label for the extended field, change the label in the Object Label field. For example, change the default label *asset hardware Extension* to *Hardware Extension*.

7. Click Save Configuration.
   All users see the extended field on the page.

Note: After you add a field and define an extended field, and save the field to a local or global configuration, users can define an event for the field. For more information about managing events, see Event and Notification Configuration (see page 1522).

Grant Permissions to Define an Extension

You can grant permissions to users so an Add Extension link appears to define an extension.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.

3. In the Configuration Information area of the page, specify the information for the new global configuration (see page 1515). You can select an existing global configuration that you want to change.

   You can only define an extended field for a global configuration. You cannot define an extended field for a local configuration.

4. In the Permissions area of the page, move Extend Object to the Granted Permissions list.

5. (Optional) Select the Inherit Permissions from Parent Object check box to apply any security permissions from a top-level (parent) object to the lower-level (child) object using the same configuration.

   For example, you create a local configuration for an Organization. In the configuration, you deny permissions to change field labels, move fields, make fields required, and hide fields. After you save the configuration, you open Attachments under Organization and select the Inherit Permissions from Parent Object check box. All permissions from the Organization are applied to Attachments. In this example, because permissions to change field labels, move fields, make fields required, and hide fields are applied to the Organization, the permissions are also applied to the Attachment.

6. Click Save Configuration.
   When you assign a configuration to a role, users in the role have permissions to define an extension.

Field Data Validation Configuration

You can create field data validation configurations to validate the data entry in fields. These field data validations ensure that users enter data in the correct format and enforce your organizational business rules.

The data validation affects new data that is added. Existing data records are validated only when you access the data record and you save the record.

For example, you want to ensure that users enter asset names using only alphanumeric characters (no special characters). Create a data validation for the Asset Name field on the New Asset or Asset Details page. Specify that the field allows only alphanumeric entries. Users receive an error message if the characters they use are not alphanumeric.

Add a Data Validation for a Text Field

You can validate the data entry in text fields (for example, contact name, email address, or telephone number) to enforce specific format requirements. You create the data validations for text fields by defining the regular expressions that apply to the different types of text fields.

A *regular expression* is a text string that describes a particular pattern or format. Regular expressions are used to validate text to ensure that the text matches a predefined format. For example, create a regular expression to specify the correct format for an email address, telephone number, or IP address.

Compose and test your regular expression before creating the text field data validation. You can find resources on the Web for creating, analyzing, and testing regular expressions.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.
2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.
3. In the Configuration Information area of the page, complete the following steps:
   a. Specify the information for the new global or local configuration, or select an existing configuration that you want to change.

      Permissions for data validation are allowed by default. You can deny data validation permissions for the current configuration. The users that are assigned to the configuration do not then see the Data Validation icon and cannot add data validations.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
      For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles that are assigned to the selected configuration.

4. Next to the text field that you want to validate, click the Data Validation icon.
5. Enter the regular expression that applies to the type of field (for example, telephone number, email address) and click OK.

Verify that you selected the correct regular expression for the field type and that you entered the regular expression accurately.

To modify or delete an existing data validation, complete one of the following steps:

- To modify the validation, edit the regular expression in the text entry field and click OK.
- To delete the validation, clear the regular expression in the text entry field and click OK.

6. Click Save Configuration.
   When you assign the configuration to a role, users in the role receive data validation messages if their text entries do not match the defined format.

Hierarchy Configuration

In the product, a *hierarchy* is a way to establish a logical relationship to an object field. You can define a hierarchy to extend the product and track more information and detail about an object. You can define a hierarchy for any object.

Example: Create a Hierarchy to Locate an Asset

In CA APM, when you enter an asset, use the Location Name field to enter generic asset information. Information can be the location of an asset (city and address). However, for a hardware asset family, you need a more detailed way to track the asset location. To locate an asset for maintenance and repair, find the specific office number, building number, floor number, and cubicle number. Define the following hierarchy:

```
Pittsburgh Office
   Building 3
    Fourth Floor
        Cubicle 49466
```

In the previous hierarchy, each field is related to the field above it. If you change the information for a parent field, the information for the child field is changed. However, changing a child field (Fourth Floor) does not change the parent field (Building 3).

By defining this hierarchy, you know and can track the exact location of the asset. CA APM manages the fields that you define in the hierarchy so they can be used in searches and reports.

Define a Hierarchy

You can define a hierarchy to extend the product and track more information and detail about an object. For example, define a location hierarchy for an asset to track the asset to a specific location. When asset location with an established hierarchy for the asset family is selected, a list appears inside the location section. Each location hierarchy extended field has one list. If the location selected has values for the hierarchy, the values are populated in the drop-down list.

Before you define a hierarchy, verify that you have the following reference information: table name, label, format, field name, attribute name, field size. Also verify, if an entry for the extended field in the hierarchy is required.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.
2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.
3. In the Configuration Information area of the page, complete the following steps:
   a. Specify the information for the new global configuration (see page 1515), or select an existing global configuration that you want to change.
   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Permission changes that you make apply only to that part of the object. For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object.

   You can only define a hierarchy for a global configuration. You cannot define a hierarchy for a local configuration.
4. (Optional) Click Save Configuration to create the global configuration.

5. Click Add Extension.
   A wizard appears.

6. To define the hierarchy, select the Hierarchy option and follow the on-screen instructions. The following fields require explanation:

   - **Object Label**
     Specify the default object label for the hierarchy. You can change this label to meet your requirements. For example, change the default label Asset Extensions to Asset.

   - **Object Table Name**
     Specify the database table name for the hierarchy.

   - **Object Tenancy**
     If multi-tenancy is enabled, specify how multi-tenancy works for the hierarchy by selecting one of the following options. The option that you select is applied to all levels in the hierarchy.

     - **Untenanted**
       Defines objects without a tenant attribute. All data in these objects is public, and any user can create and update untenanted public data.

     - **Tenant Required**
       Defines objects with a tenant attribute that cannot be null (enforced by CA APM, not the DBMS). All data in these objects is associated with individual tenants; there is no public data.

     - **Tenant Optional**
       Defines objects with a tenant attribute that can be null. You can either create these objects as tenanted or public. When you select a tenant in a tenant drop-down to create an object, the object becomes a tenanted object. However, when you select the Public Data option in a tenant drop-down, the object becomes a tenanted public object. A tenant drop-down does not appear for users assigned to a role that only exposes a single tenant when entering data.

   - **Begin with existing field**
     Select an existing field as the basis for fields in the first hierarchy level.

   - **Begin with a new field**
     Select to start the hierarchy with a new field you define. Define at least two levels for the hierarchy.

7. Click Save Configuration.
   All users see the hierarchy on the page.

Legal Template Configuration

This article contains the following topics:

A *legal template* provides the group of attributes that belong to a particular type of legal document. You typically set up and maintain legal templates, while users create legal document records based on the legal templates. When you create a legal document record, you first select a legal template on which to base the document. The legal document record inherits the attributes from the legal template.

Each legal template has *terms and conditions* that typically apply to the legal document type. For example, a legal template for an invoice includes information about the terms of payment.

You can use the product to define legal templates and change the attributes of a legal template. To change the terms and conditions assigned to a legal template, you can remove them or add new ones from the master list of terms and conditions.

A legal template cannot be deleted until all legal documents based on the template are deleted. In addition, you can search for legal documents by the legal template name, and you can use legal template names to select records to include in reports.

Define a Legal Template

You can define a legal template to group attributes that belong to a particular type of legal document. Administrators or users with appropriate privileges can define legal templates.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Legal Document Lists and click Legal Template.
   The list of templates appears on the right.
3. Click New, enter a name for the template, and click Save.
   The new template appears in the list.
4. Click the Edit Record icon for the new template.
5. Click the View Assigned Ts & Cs hyperlink.
6. Click Select New and select the terms and conditions for the new template.
7. Click Save.
   Users can select the new template when they define legal documents.

Change the Terms and Conditions for a Legal Template

You can change the terms and conditions for a legal template. Administrators or users with appropriate privileges can change the terms and conditions.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Legal Document Lists and click Legal Template.
   The list of templates appears on the right.

3. Click the Edit Record icon for the legal template.

4. Click the View Assigned Ts & Cs hyperlink.
   All terms and conditions for the legal template appear.

5. Select any of the following options:

   - Click Select New and select the terms and conditions for the template.

   - Click the Delete icon to remove the term and condition from the template.

6. Click Save.
   The updated terms and conditions are applied to the template.

List Management

This article contains the following topics:

You can define the items that appear in lists to help make it easier for users to select the correct information from lists for the objects they manage. For example, when defining a new contact, the user can specify a contact type. You define the items that appear in the contact type list. In addition, when defining a legal document, the user must specify a legal template. You define the items that appear in the legal template list.

You can manage items in the following lists and in the reference fields you define:

- Assets
- Companies
- Contacts
- Legal Documents
- Locations
- Models
- Organizations
- Searches
- Normalization

Define List Items

You can define, update, and delete list items to help make it easier for users to select the correct information from lists when managing objects. For example, you can change the name and description of a cost center to make it easier for users to select a cost center. You can also delete a general ledger code so that users cannot select that code when they define assets.

When you delete a list item, users cannot select the item when defining an object. Instead of deleting the list item, you can make the list item inactive. Then, if you need the list item in the future, you can make the item active again. You do not have to redefine the item.

By default, all the items in a list are displayed. However, if you have large number of list items, you can search for specific items. The search criteria depends on the properties of the list. For example, for **Cost Type** you can search the items based on **Value, Status**, and the **Description** of the cost type.

Note: This feature will only be available if you apply a patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

Follow these steps:

1. Click Directory, List Management.
2. On the left, select the list that you want to manage.
3. Click New.
4. Enter the information for the list item.

   When multi-tenancy is enabled, select the tenant for the list item.

5. Click Save.

Define List Management Access

As an Administrator, you can define who accesses List Management. You can also determine the list items that different users can access. For example, a Contract Manager requires information related to legal document lists, company lists, and contact lists but not Asset lists. So, as an Administrator, you configure the access rights to Contract Manager role accordingly.

> **Note:** This feature will only be available if you apply a patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

Follow these steps:

1. Click Administration, User/Role Management.
2. Click the role for which you want to configure List Management access.
3. To configure which list items the role access, select the appropriate check box.
   For example, to restrict asset list access to a Contract Manager, ensure clear the Asset Lists Access check box.
4. To enable or disable List Management, select or clear List Management Access.
5. Save the configuration changes.

Define the Class and Subclass Lists for an Asset Family

You can define the class and subclass lists for an asset family to help make it easier for users to select the correct information when defining models and assets. For example, you can define the class "printer" and the subclass "laser". Then when users create or search for printer assets, this additional information helps them to define or identify the correct assets.

Follow these steps:

1. Click Directory, List Management.
2. On the left, click Asset Lists, Asset Family.
3. Complete the following steps to define the class list:
   a. Click the Edit Record icon next to the asset family for which you want to define the class.
   b. Click the Class List hyperlink.
   c. Define the class record for the asset family.
   d. Click Save.
4. Complete the following steps to define the subclass list:
   a. Click the Edit Record icon next to the class record for which you want to define the subclass.
   b. Click the Subclass List hyperlink.
   c. Define the subclass record for the asset family.
   d. Click Save.

Define Legal Document Terms and Conditions

You can define the terms and conditions that apply to legal document lists. Users can then apply the correct terms and conditions when they define legal templates or legal documents.

Follow these steps:

1. Click Directory, List Management.
2. On the left, expand Legal Document Lists and select Terms and Conditions.
3. Click New.
4. Enter the information for the new list item.

   To make the new item apply to date-specific terms and conditions lists only, select the Date Specific Key check box.

5. Click Save.

Exclude an Asset Family

You can exclude an asset family so that it is not available for users. If you exclude an asset family, a user who creates or modifies a model cannot select that asset family. Also, the excluded asset family is not available for managing filters, data imports, or configurations. For example, if CA APM is integrated with CA Service Desk Manager, the asset families from CA Service Desk Manager are also available to CA APM users. If you do not require the CA Service Desk Manager asset families, you can exclude them so that they are not available to users.

If a model was already associated with an asset family before you excluded the family, you can still access and edit that model. You can also still use that model to create assets. However, you cannot change the asset family for that model to another excluded asset family.

You can change the asset family for a model only if the model does not have associated assets.

Follow these steps:

1. Click Directory, List Management.
2. On the left, select Asset Family under Asset Lists or Model Lists.
3. Click the Edit Record icon for the family that you want to exclude.
4. Clear the Is ITAM check box and click the Complete Record Edit icon.

> Do not select the Inactive check box. This action makes the asset family inactive for all products that are integrated with the CA MDB.

5. Click Save.

This feature will only be available if you apply a patch for CA Service Management Release 14.1.01. Find the patch and the download details from CA Support Online.

Manage Buttons

You can configure the button access to help prevent users from performing unauthorized tasks. You can configure buttons in the following ways:

- Hide a button when you do not want users to be able to see and use the New menu option and the Save, Copy, and Delete buttons. For example, you do not want a user to be able to copy or delete an asset. Therefore, you hide the Copy and Delete buttons on the Asset page.
- Make a previously hidden button appear when users must be able to see and use the New menu option and the Save, Copy, and Delete buttons. For example, you hid the Copy button for the Asset page, but the button appears. Therefore, you make the Copy button appear.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the page is enabled.

   In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global or local configuration, or select an existing configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

> Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. In the Permissions area of the page, complete the following steps in the Granted and Denied Permissions lists:

- To hide the New option and Save button, move Create to the Denied Permissions list.
- To hide the Copy button, move Copy to the Denied Permissions list.
- To hide the Delete button, move Delete to the Denied Permissions list.
- To make the New option and Save button appear, move Create to the Granted Permissions list.
- To make the Copy button appear, move Copy to the Granted Permissions list.
- To make the Delete button appear, move Delete to the Granted Permissions list.

3. (Optional) Select the Inherit Permissions from Parent Object check box to apply any security permissions from a top-level (parent) object to the lower-level (child) object using the same configuration.

   For example, you create a local configuration for an Organization. In the configuration, you deny permissions to change field labels, move fields, make fields required, and hide fields. After you save the configuration, you open Attachments under Organization and select the Inherit Permissions from Parent Object check box. All permissions from the Organization are applied to Attachments. In this example, because permissions to change field labels, move fields, make fields required, and hide fields are applied to the Organization, the permissions are also applied to the Attachment.

4. Click Save Configuration.

Manage Fields

This article contains the following topics:

You can change the display and attributes of field information on the page to meet your asset management practices and help make it easier for users to enter information for the objects they manage. In the product, these fields are referred to as *configured fields*.

You can manage fields in the following ways:

- Change a field label to help make the field more familiar to users and conform to your IT asset management practices.
- Move a field to a new location to help make it easier for users to find the field on the page.
- Hide a field from display when users should not be able to view a particular field on the page.
- Make a field appear when users must be able to see a field that you previously hid. For example, you previously hid the Capacity field. Users must be able to see that field because it is required. Add the field back so users can enter a value when defining an asset.

- Make a field read-only, required, or optional (see page 1540).
- Add a field (see page 1539).
- Manage field permissions (see page 1541).

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

   On the left, click CONFIGURE: ON.

   The configuration of the page is enabled.

   In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global or local configuration, or select an existing configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. To change a field label, complete the following steps:

   a. Click the field label and enter the new label.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role see the new field label.

3. To move a filed to a new location, complete the following steps:

   a. Drag-and-drop the field to a new location in the current section.

   You cannot move a field from one section of the page to another. For example, you cannot move a field from the Additional Information section to the Basic Information section.

b. Click Save Configuration.
When you assign a configuration to a role, users in the role see the fields in the new location.

4. To hide a field, complete the following steps:

a. Next to the field, click the Remove Field icon.

b. Click Save Configuration.
When you assign a configuration to a role, users in the role do not see the field. If an event is defined for the hidden field, users still receive notifications. However, any mapped attribute that is not accessible in the workflow process associated with the event is not sent as part of the notification.

5. To make a previously hidden field appear, complete the following steps:

a. Click Expose Hidden Fields.

b. To add the field to the page, follow the on-screen instructions.

c. Click Save Configuration.
When you assign a configuration to a role, users in the role see the field on the page.

After you make a previously-hidden field appear, users can define an event for the field. You do not have to save the configuration because the field has already been added to the configuration. For more information about managing events, see Events and Notifications (see page 2376).

Add a Field

You can add a field to the page when users must be able to see a field that exists in the repository but is not part of a global configuration, or any field that has been removed and you have denied access. For example, you previously removed an extended field that is named chipset from the Asset Details page. Users must be able to see and enter a value for this field, so you add the field back onto the page. In addition, if you previously added an extension but did not save the global configuration, use these steps to add the extended field to the page.

When you add a field to an object having multiple asset families (Assets and Models) and legal templates (Legal Documents), the field is added to all families and templates for the object, regardless of the family or template to which you added the field. For example, you add a field for the Hardware asset family. The field is added to all other asset families, including Computer, Other, Projects, Service, and Software.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration to the page is enabled.

3. In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global configuration (see page 1515), or select an existing global configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make apply only to that part of the object. For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object.

You can only add a field for a global configuration. You cannot add a field for a local configuration.

4. Click Save Configuration to create the global configuration.

5. Click Add Existing Fields.
   A wizard appears.

6. To add to the page, select the fields.

For extended fields, a link appears that matches the object label that is specified when defining an extended field. To add to the page, click the link and select the extended fields.

7. Click Save Configuration.
   All users see the field on the page.

Note: After you add a field and define an extended field, and save the field to a local or global configuration, users can define an event for the field. For more information about managing events, see Event and Notification Configuration (see page 1522).

Make a Field Read-Only, Required, or Optional

A *required field* is a field that must contain a value to save the record. When you configure a field or create an extended field, you can make the field read-only, required, or optional. Making a field that is required is useful for fields that contain key pieces of data.

When making a new required field, saved records may not have data in the field. When you save the record in the future, you must enter data into the new required field. You must also enter data when a pre-existing record is updated by an application you write using the web services. Your client application must verify that the required field contains data, or provides data for the field. If not, the record will not be updated.

We recommend that before you make a field required, you populate the field for all existing records. You can search to locate all occurrences of blank values in the field by searching for NULL or space (clear the value field).

To make a field read-only, required, or optional

1. Click the tab and optional subtab for the object that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the page is enabled.

   In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global or local configuration, or select an existing configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. Next to the field, click the appropriate icon to make the field read-only, required, or optional.

3. Click Save Configuration.
   When you assign a configuration to a role, users in the role see the fields as read-only, required, or optional.

Manage Field Permissions

You can grant permissions to users so they can configure the user interface to change a field label, move a field, make a field required, and hide a field.

You can also grant permissions to users so they can configure the user interface and can perform mass changes on a field. You can perform mass changes on fields that are associated with the following objects:

- Asset
- Model
- Legal document
- Organization
- Contact
- Company
- Location
- Site

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.
2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.
3. In the Configuration Information area of the page, specify the information for the new global or local configuration (see page 1515), or select an existing configuration that you want to change.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

4. In the Permissions area of the page, do one the following:
   - To grant permissions to change a field label, move Modify Labels to the Granted Permissions list.
   - To grant permissions to move a field, move Order Fields to the Granted Permissions list.
   - To grant permissions to make a field required, move Requiredto the Granted Permissions list.
   - To grant permissions to hide a field, move Secure (Read-Only and Access)to the Granted Permissions list.

- To grant permissions to perform mass changes on a field, move Mass Changeto the Granted Permissions list.

5. (Optional) Select the Inherit Permissions from Parent Object check box to apply any security permissions from a top-level (parent) object to the lower-level (child) object using the same configuration.

   For example, you create a local configuration for an Organization. In the configuration, you deny permissions to change field labels, move fields, make fields required, and hide fields. After you save the configuration, you open Attachments under Organization and select the Inherit Permissions from Parent Object check box. All permissions from the Organization are applied to Attachments. In this example, because permissions to change field labels, move fields, make fields required, and hide fields are applied to the Organization, the permissions are also applied to the Attachment.

6. Click Save Configuration.
   When you assign a configuration to a role, users in the role have permissions to perform the respective configuration.

View Field Information

You can view the information about any field, including extended fields, to see database-related field attributes. For any field, you can view the object label, database table name, database field name, attribute name, data type, description, and size. Use this information in the following ways:

- You want to view CA APM data outside of the product using an external reporting solution and must understand database-level information. For example, you want to know the database table name, field name, attribute name, data type, description, or field size for a particular default field or user-defined extended field.

- You have changed a field label or moved a field to a new location on the page. Use the field information to understand how the field is represented in the database. This field information can be helpful when you work with Technical Support to understand any specific configuration changes you have made to the product.

Follow these steps:

1. Click the tab and optional subtab for an object.

2. On the left, click CONFIGURE: ON.
   The configuration of the object is enabled.

3. Next to the field, click the View Details icon.
   The field information appears.

Manage Hyperlinks

You can configure hyperlink access to help prevent users from performing unauthorized tasks and only see the information appropriate for their particular job function. You can configure hyperlinks in the following ways:

- Hide a hyperlink when users should not be able to see a particular hyperlink. For example, you do not want a user to be able to see the audit history for an object. Therefore, you hide the View Audit History hyperlink.

- Make a previously hidden hyperlink appear when users must be able to see a hyperlink that you previous hid. For example, you hid the View Audit History hyperlink, but the hyperlink should now appear. Therefore, you make the View Audit History hyperlink appear.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the page is enabled.

   In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global or local configuration, or select an existing configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. To hide a hyperlink, complete the following steps:

   a. Next to the hyperlink, click the Access Granted icon.
   The Access Denied icon appears for the hyperlink.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role do not see the hyperlink.

3. To make a previously hidden hyperlink appear, complete the following steps:

   a. If the hyperlink is already hidden, click the Access Denied icon next to the hyperlink.
   The Access Granted icon appears for the hyperlink.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role can see and use the hyperlink.

Manage Menu Options

You can configure the tab and menu access to:

- Help protect the integrity of the data for your objects.
- Prevent the users from performing unauthorized tasks such as adding or deleting object information.
- Support separation of duties so users only see the information appropriate for their particular job function.

For assets, models, and legal documents, you provide a specific configuration by specifying the *asset family* and *legal template*.

You can configure the menu access in the following ways:

- Hide a menu option when users should not be able to see all, or a particular menu option.
  For example, you do not want a user to be able to view model dependencies. Therefore, you hide the Dependencies menu option.
- Make a menu option appear when users should be able to see all, or a particular menu option.
  For example, you want a user to be able to view model dependencies. Therefore, you make the Dependencies menu option appear.
- Make a menu option read-only when users should be able to see, but not use a particular menu option.
  For example, you do not want a user to change any notes for a model. Therefore, you make the Notes menu option read-only.
- Make a menu option accessible when users should be able to see, and use a particular menu option.
  For example, you want a user to be able to change the generic configuration for a model. Therefore, you make the Model Configuration menu option accessible.

Combine the tab and menu configuration and field configuration to enforce more granular levels of access.

Follow these steps:

1. Click the tab and optional subtab for the object access that you want to configure. On the left, click **CONFIGURE: ON**.

   The configuration of the object access is enabled.

   In the Configuration Information area of the page, specify the information for the new global or local configuration, or select an existing configuration that you want to change.

Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. To hide a menu option, complete the following steps:

    a. On the menu or menu option, click the Access Granted icon.
    The Access Denied icon appears for the menu or menu option.

    b. Click Save Configuration.
    When you assign a configuration to a role, users in the role cannot see the menu option.

3. To make a menu option appear, complete the following steps:

    a. If the menu or menu option is already hidden, click the Access Denied icon on the menu or menu option.
    The Access Granted icon appears for the menu or menu option.

    b. Click Save Configuration.
    When you assign a configuration to a role, users in the role can see and use the menu option.

4. To make a menu option read-only, complete the following steps:

    a. On the menu or menu option, click the Editable icon.
    The Read Only icon appears for the menu option.

    b. Click Save Configuration.
    When you assign a configuration to a role, users in the role can see, but not use, the menu option.

5. To me a menu option accessible, complete the following steps:

    a. If the menu or menu option is already read-only, click the Read Only icon on the menu or menu option.
    The Editable icon appears for the menu option.

    b. Click Save Configuration.
    When you assign a configuration to a role, users in the role can see, and can use the menu option.

Manage Object Access

You can configure object access to help protect the integrity of the data, prevent users from performing unauthorized tasks, and provide users with only the information appropriate for their job functions. You can configure object access in the following ways:

- Hide an object to prevent users from seeing a particular area of the page for the object.
  For example, you do not want a user to be able to see pricing information for models. Therefore, you hide the Parts and Pricing area of the Models page.

- Make an object appear when users should be able to see a particular object.
  For example, you want a user to be able to see pricing information for models. Therefore, you make the Parts and Pricing area of the Models page appear.

- Make an object read-only when users should be able to see, but not change the information about a particular object.
  For example, you want a user to be able to see, but not change, pricing information for models. Therefore, you make the Parts and Pricing area of the Models page read-only.

- Make an object accessible when users should be able to see and change the information about a particular object.
  For example, you want a user to be able to see, and edit, pricing information for models. Therefore, you make the Parts and Pricing area of the Models page accessible.

- Grant permission to users to secure objects.

Combine object access and field configuration to enforce more granular levels of access.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure. On the left, click CONFIGURE: ON.

   The configuration of the page is enabled.

   In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global or local configuration, or select an existing configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. To hide an object, complete the following steps:

   a. On the right, next to the title for the area of the page (for example, Models page, Parts and Pricing) click the Access Granted icon.
   The Access Denied icon appears for the object.

b. Click Save Configuration.
When you assign a configuration to a role, users in the role cannot see the object information.

3. To make an object appear, complete the following steps:

   a. If access is already denied for the object, click the Access Denied icon on the right, next to the title for the area of the page (for example, Models page, Parts and Pricing).
   The Access Granted icon appears for the object.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role can see the object information.

4. To make an object read-only, complete the following steps:

   a. On the right, next to the title for the area of the page (for example, Models page, Parts and Pricing) click the Editable icon.
   The Read Only icon appears for the object.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role can see, but not change the object information.

5. To make an object accessible, complete the following steps:

   a. If the object is already read-only, click the Read Only icon on the right, next to the title for the area of the page (for example, Models page, Parts and Pricing).
   The Editable icon appears for the object.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role can access the object information.

Grant Permissions to Secure Objects

You can grant permissions to users so they can configure the user interface and hide objects, make objects appear, make objects read-only, and make objects accessible.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON to enable the configuration of the page.

3. In the Configuration Information area of the page, specify the information for the new global or local configuration (see page 1515), or select an existing configuration that you want to change.

Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

4. In the Permissions area of the page, move Secure (Read-Only And Access)to the Granted Permissions list.

5. (Optional) Select the Inherit Permissions from Parent Object check box to apply any security permissions from a top-level (parent) object to the lower-level (child) object using the same configuration.

   For example, you create a local configuration for an Organization. In the configuration, you deny permissions to change field labels, move fields, make fields required, and hide fields. After you save the configuration, you open Attachments under Organization and select the Inherit Permissions from Parent Object check box. All permissions from the Organization are applied to Attachments. In this example, because permissions to change field labels, move fields, make fields required, and hide fields are applied to the Organization, the permissions are also applied to the Attachment.

6. Click Save Configuration.
   When you assign a configuration to a role, users in the role have permissions to hide objects, make objects appear, make objects read-only, and make objects accessible.

Manage Tabs

You can configure tab access to help protect the integrity of the data for your objects, prevent users from performing unauthorized tasks such as adding or deleting object information, and to support separation of duties so users only see the information appropriate for their particular job function.

For assets, models, and legal documents, you provide a specific configuration by specifying the *asset family* (assets and models) and *legal template* (legal documents).

You can configure tab access in the following ways:

- Hide a tab when users should not be able to see a particular tab.
  For example, you do not want a user to be able to see any information for legal documents. Therefore, you hide the Legal Document tab.

- Make a tab appear when users should be able to see a particular tab.
  For example, you want a user to be able to see all information for legal documents. Therefore, you make the Legal Document tab appear.

- Make a tab read-only when users should be able to see, but not change the information on a particular tab.
  For example, you want a user to be able to see, but not change, the information for a model. Therefore, you make the Model tab read-only.

- Make a tab accessible when users should be able to view and change the information on a tab. For example, you want a user to be able to see, and edit, all information for a model. Therefore, you make the Model tab accessible.

Follow these steps:

1. Click the tab and optional subtab for the object access that you want to configure. On the left, click **CONFIGURE: ON**.

   The configuration of the object access is enabled.

   In the Configuration Information area of the page, specify the information for the new global or local configuration, or select an existing configuration that you want to change.

   > Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

2. To hide a tab, complete the following steps:

   a. On the tab, click the Access Granted icon.
   The Access Denied icon appears for the tab.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role cannot see the tab.

3. To make a tab appear, complete the following steps:

   a. If the tab is already hidden, click the Access Denied icon on the tab.
   The Access Granted icon appears for the tab.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role can see the tab.

4. To make a tab read-only, complete the following steps:

   a. On the tab, click the Editable icon.
   The Read Only icon appears for the tab.

   b. Click Save Configuration.
   When you assign a configuration to a role, users in the role cannot change the information on the tab.

5. To make a tab accessible, complete the following steps:

   a. If the tab is already read-only, click the Read Only icon on the tab.
   The Editable icon appears for the tab.

b. Click Save Configuration.
When you assign a configuration to a role, users in the role can access the information on the tab.

Reference Field Configuration

This article contains the following topics:

You can define your own *reference fields* and add them to objects to extend the product and enhance how users enter information for the objects that they manage. When you define a reference field, you can reference an existing object, or define a new object.

- Define a reference field (see page 1551) to an *existing object* to standardize on a common set of values that the user can select when defining an object. For example, when defining an asset, you want users to select the specific terms and conditions for an asset and select an approved general ledger code. In this example, you define two reference fields to standardize the terms and conditions and general ledger codes the user can select when defining the asset.

- Define a reference field (see page 1551) to a *new object* to establish a relationship between people, companies, assets, and so forth. For example, when defining and managing vendors, you want the user to assign a service rating to each vendor and select a quality rating (one through five stars). In this example, you define one reference field to record the quality rating when defining and managing vendors.

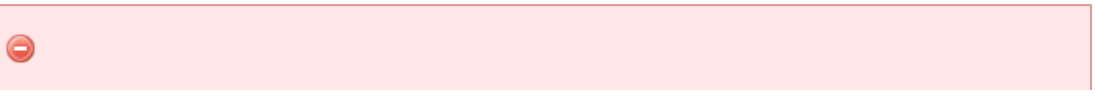
You can define reference fields for models, assets, legal documents, costs, payments, model parts and pricing, contacts, companies, organizations, locations, and sites.

After you define a reference field, you can configure the reference field (see page 1554) by completing the following tasks:

- Add a field to the reference field criteria and results
- Remove a field from the reference field lookup criteria and results
- Make a previously-hidden reference field appear
- Move a reference field to a new location

Define a Reference Field

You can define your own *reference fields* and add them to objects to extend the product and enhance how users enter information for the objects they manage. When you define a reference field, you can reference an existing object, or define a new object. For example, when defining an asset, you want users to select the specific terms and conditions for an asset and select an approved general ledger code. In this example, you define a reference field to an existing object and standardize the terms and conditions and general ledger codes the user can select when defining the asset.



Important!: These steps work only the first-time you complete the wizard and define the reference field. Before you define the reference field, verify that you have the following information for reference: table name, label, format (character, boolean, currency, date, decimal, or integer), field name, attribute name, field size, and whether an entry for the field is required. After you complete the wizard, you can configure the reference field by adding and removing fields, making a previously-hidden reference field appear, and moving a reference field to a new location.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.

3. In the Configuration Information area of the page, complete the following steps:

   a. Specify the information for the new global configuration (see page 1515), or select an existing global configuration that you want to change.

   b. (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
   For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

   You can only define a reference field for a global configuration. You cannot define a reference field for a local configuration.

4. (Optional) Click Save Configuration to create the global configuration.

5. Click Add Extension.
   A wizard appears.

6. Select the Reference Field option and follow the on-screen instructions to enter the information for the reference field. The following fields require explanation:

   - **Object Label**
     Displays the default reference field object label to appear when you add a field to the reference field criteria and results, and make a previously-hidden reference field appear. You can change this label to meet your requirements. For example, change the default label Location Extensions to Location.

   - **Label**
     Enter the label for the reference field that you want to appear in list management.

- **Service provider eligible**
  Determines if field values from the service provider are included in the reference field. When you select this check box, public data and service provider objects are included in the reference field.

- **Based on current object**
  Select an existing object on which to base the reference field you are defining.

  
  When you select this option, the reference field for the object already exists and the multi-tenancy options for the object are applied.

- **Object table name**
  Specify the database table name for the reference field.

- **Object Tenancy**
  If multi-tenancy is enabled, specify how multi-tenancy works for the reference field by selecting one of the following options:

  - **Untenanted**
    Defines objects without a tenant attribute. All data in these objects is public, and any user can create and update untenanted public data.

  - **Tenant Required**
    Defines objects with a tenant attribute that cannot be null (enforced by CA APM, not the DBMS). All data in these objects is associated with individual tenants; there is no public data.

  - **Tenant Optional**
    Defines objects with a tenant attribute that can be null. You can either create these objects as tenanted or public. When you select a tenant in a tenant drop-down to create an object, the object becomes a tenanted object. However, when you select the Public Data option in a tenant drop-down, the object becomes a tenanted public object. Users assigned to a role that only exposes a single tenant will not see a tenant drop-down when entering data.

  
  When multi-tenancy is disabled, you do not see the Object Tenancy drop-down for the reference field. However, the product applies the Tenant Optional setting to the reference field. The product works this way so that if you enable multi-tenancy, the Tenant Optional setting is applied to the reference field.

7. Click Save Configuration.
   All users see the reference field on the page. When you define a reference field based on a new object, the reference field appears as a list item that can be managed using list management (see page 1532).

Manage Reference Fields

After you define a reference field, you can configure the field in the following ways:

- Add additional fields to extend the information that appears in your reference field criteria and results. For example, when users add an asset, they can search by model name and description to find the model describing the asset. You can configure the model reference field and add the Asset Family, Class, and Company Name fields to the reference field criteria and results to make it easier for users to find the model when defining the asset.

- Remove a field when you do not want a particular field included in the reference field criteria and results. For example, you previously configured the model reference field by adding the Asset Family, Class, Company Name, and GL Code fields. To protect users from viewing sensitive information, you remove the GL Code field from the model reference field.

- Make a reference field appear when users must be able to see a reference field that you previously hid. For example, you previously configured the model reference field by removing the Inactive field. Add the field back to the model reference field so users can find and not select inactive models when adding an asset.

- Move a reference field to a new location to help make it easier for users to find the reference field. For example, you configure the model reference field and add the Asset Family, Class, and Company Name fields to the reference field criteria and results to make it easier for users to find the model when defining an asset. You move the Company Name field to the top of the model reference field so users can find models in a particular company.

You can complete the tasks only when your assigned role has permissions to configure the object.

Follow these steps:

1. Click the tab and optional subtab for the object that you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.

3. In the Configuration Information area of the page, complete the following steps:

   - Specify the information for the new global or local configuration, or select an existing configuration that you want to change.
     (Optional) In the Object drop-down list, select the part of the object that you want to configure. Any permission changes you make (for example, deny permissions to move a field) apply only to that part of the object.
     For example, when configuring a legal document, you select Legaldoc Status History in the Object drop-down list. You deny permissions to move fields for that part of the object (the status history). The permission changes apply only to the status history part of the object, and not to the other parts of the object.

Important!: Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

4. Click Save Configuration.

5. Next to the field, click the Lookup Field icon.
   A list of fields in the reference field criteria and results appears.

6. To add a field to the reference field criteria and results, complete the following steps:

   a. (Global configurations only) Click Add Fields.

   b. Select the fields to add to the reference field criteria, results, or both.

   c. Click Save.

   d. Click Save Configuration.
      The field appears in the reference field criteria and results.

7. To remove a field from the reference field criteria and results, complete the following steps:

   a. Click the Mark for Deletion icon next to the field you want to remove from the reference field criteria and results.

   b. Click Save.

   c. Click Save Configuration.
      The field does not appear in the reference field criteria and results.

8. To make a previously-hidden reference field appear, complete the following steps:

   a. Click Expose Hidden Fields.

   b. Select the fields to add to the reference field criteria, results, or both.

   c. Click Save.

   d. Click Save Configuration.
      When you assign a configuration to a role, users in the role see the field in the reference field criteria and results.

9. To move a reference field to a new location, complete the following steps:

   a. Drag-and-drop the reference field to a new location in the reference field criteria and results.

   b. Click Save.

   c. Click Save Configuration.
      When you assign a configuration to a role, users in the role see the fields in the new location.

Search Configuration

This article contains the following topics:

You can configure searches to simplify how users search for information in the repository and export the results. To configure searches, complete the following tasks:

- Set a search result limit.
- Make it easier to search by assigning a default search for a role.
- Make it easier to specify search criteria by completing the following tasks:
  - Adding fields
  - Removing fields
  - Moving fields
  - Changing the field name
  - Replacing fields
- Make it easier to find information in the search results by completing the following tasks:
  - Managing Columns in Search Results (see page 1562).
  - Adding sort fields
  - Preventing duplicate records from appearing
  - Preventing the ability to open records
- Make it easier to search by allowing users to save searches.

- Make it easier to use search results in spreadsheets by allowing users to export search results.
- Delete a search that you do not need.

Set a Search Result Limit

When you search for an object and the results are difficult to manage because too many object records appear, you can set a limit. For example, when you search for assets, over 2,000 assets appear in the search results. The results are difficult to navigate, you cannot find the assets you want, and the performance is negatively impacted. Therefore, you set a maximum of 50 object records to return.

Follow these steps:

1. Click the tab and optional subtab for the search that you want to configure.

   On the left, click Manage Searches.
   A list of saved searches displays. Click a search in the list.

2. In the Additional Settings, Maximum Search Results Returning area, specify the total number of objects to appear.

   For performance reasons, we recommend that you set this value to less than 500.

3. Click Go.
   The limited search results appear and help you see the impact on the results before you save the limit. All future search results are limited to the specified number or percentage.

Assign a Default Search for a Role

You can assign a default search for a role so that all users in the role have the same default search when they click a tab or subtab. For example, all users responsible for reviewing and negotiating contracts, agreements, and services belong to the Contract and Vendor Management role. To simplify the search setup for users so they do not have to specify a default search for themselves, you configure the default legal document search. You assign the configured legal document search as the default for all users in the Contract and Vendor Management role. When users in this role click the Legal Document tab, they see the configured legal document search as their default, rather than the default legal document search provided by the product.

Consider the following information when assigning a default search for a role:

If you do not assign a default search for a role, the default search for the object appears when users in the role click the tab or subtab.

- You can assign multiple default searches for a role. However, you can only assign one default search for a particular object type (for example, model, asset, legal document, and so forth) to a role.

- When a user saves a search as their default, that search is the default for the user, even when you assign a different search as the default for the role. For example, a user in the Asset Technician role sets their default search as the asset search provided by the product. You configure the default asset search by adding a field to the search criteria and removing a field from the search results. You then assign the configured asset search as the default search for the Asset Technician role, to which the user belongs. The default asset search is the default for the user, even when you have assigned the configured asset search as the default for the role.

- A search must be available to a role before you can assign the search as the default for the role. For example, you create a legal document search. To make the search available to the Contract and Vendor Management role, assign the Contract and Vendor Management role to the search. You can then assign the legal document search as the default for the Contract and Vendor Management role.

  
  For more information about assigning a role to a search, see Search Security.

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the Role Management menu.
3. Click Role Search.
4. Search for and select a role.
   The role details appear.
5. In the Default Searches area of the page, click Select New.
6. Select the default search for the role.
   The default search is added to the Default Searches list.
7. Click Save.
   The search is saved as the default for all users in the role.

Add a Field

CA APM lets you extend the information that appears in your search criteria and results by adding additional fields. For example, you can add the DNS Name field to the asset search. You can add fields to a new and saved search. You cannot add fields to the default searches provided by the product.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.
2. On the left, click Manage Searches.

   A list of saved searches displays.
3. Click a search in the list.

4. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

5. Click Add Fields.
   The Add Fields dialog appears.

6. Select the fields to add to the search criteria, results, or both.

7. At the top of the page, click CONFIGURE SEARCH: OFF.
   The configuration of the search is complete.

8. Click Save.
   The field appears in the search criteria and results.

Remove a Field

CA APM lets you remove a field when you do not want a particular field included in the search criteria. For example, you can remove the DNS Name field from the asset search.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.

2. On the left, click Manage Searches.
   A list of saved searches appears.

3. Click a search in the list.

4. Complete the following steps:

   a. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

   a. Click the appropriate icon next to the field in the search criteria.

   b. At the top of the page, click CONFIGURE SEARCH: OFF.

   The configuration of the search is complete.

5. (Optional). Complete the following steps:

   a. In the search criteria area of the page, click Advanced.

   b. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

   a. Click the Mark for Deletion icon next to the field you want to remove from the search criteria.

   b. At the top of the page, click CONFIGURE SEARCH: OFF.

The configuration of the search is complete.

6. Click Save.
   The field is removed from the page and does not appear in the search criteria.

Move a Field

CA APM lets you move a field in the search criteria to a new location to help make it easier for you to enter your search criteria. For example, you can move the Bar Code Number field so that the field appears before the Serial Number field.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.
2. On the left, click Manage Searches.

   A list of saved searches displays.
3. Click a search in the list.
4. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.
   Drag-and-drop the field to a new location in the search criteria.
5. At the top of the page, click CONFIGURE SEARCH: OFF.
   The configuration of the search is complete.
6. Click Save.
   The new location of the field is saved.

Change the Field Name

CA APM lets you change the label for a field to help make the field name more familiar in your search criteria. For example, you can change the label *Asset Quantity* to *Quantity*.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.
2. On the left, click Manage Searches.
   A list of saved searches appears.
3. Click a search in the list.
4. Complete the following steps:

   a. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

   a. In the search criteria, click the field label and enter the new label.

b. At the top of the page, click CONFIGURE SEARCH: OFF.

The configuration of the search is complete.

5. (Optional). Complete the following steps:

   a. In the search criteria area of the page, click Advanced.

   b. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

   a. Click the Edit Record icon next to the field for which you want to change the label.

   b. Enter the new field label.

   c. Click the Complete Record Edit icon.

   d. At the top of the page, click CONFIGURE SEARCH: OFF.

   The configuration of the search is complete.

6. Click Save.
   The new field label appears in the search criteria.

Replace a Field

CA APM lets you replace an existing field in your *advanced* search criteria with a different field. For example, when searching for companies, you can replace the field *Company ID* with *Company Name*.

You can replace fields only in a custom search that you created. You cannot replace fields in the product default search.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.

2. On the left, click Manage Searches.
   A list of saved searches appears.

3. Click a search in the list.

4. Complete the following steps:

   a. In the search criteria area of the page, click Advanced.

   b. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

a. Click the Search icon next to the field that you want to replace with a different field.
The Add Fields dialog appears.

b. Select the replacement field and click OK.

c. At the top of the page, click CONFIGURE SEARCH: OFF.

The configuration of the search is complete.

5. Click Save.
The existing field is replaced in the search criteria.

Manage Columns in Search Results

You can configure search results columns in the following ways:

- Add a new column to the search results to help make it easier for you to find the information you need in search result lists. For example, you have several people in your enterprise with the name John Smith. Their first and last names are the same, but their additional contact information (email address, supervisor, department, and so forth) is different.
You can add columns to a new and saved search. You cannot add columns to the default searches provided by the product.

- Move a column to a new location to help make it easier for you to find the information you need in the search results. For example, you can move the Asset ID column so that the column appears before the Asset Name column.

- Change the label for a column heading to help make the label more familiar in your search results. For example, you can change the label *Asset Quantity* to *Quantity*.

- Remove a column when you do not want a particular column included in the search results. For example, you can remove the Mac Address column from the search results.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.

2. On the left, click Manage Searches.

   A list of saved searches displays.

3. Click a search in the list. At the top of the page, click CONFIGURE SEARCH: ON.

   The configuration of the search is enabled.

4. To add a column to the search results, complete the following steps:

   a. Click Add Fields.

   b. Select the fields to add to the search results.

   c. At the top of the page, click CONFIGURE SEARCH: OFF.

d. Click Save.
The column is added to the search results.

5. To move a column to a new location, complete the following steps:

   a. In the search results list, drag-and-drop the column to a new location.

   b. At the top of the page, click CONFIGURE SEARCH: OFF.

   c. Click Save.
   The new location of the column is saved.

6. To change a column heading label, complete the following steps:

   a. In the search results, select the column heading and enter the new label.

   b. At the top of the page, click CONFIGURE SEARCH: OFF.

   c. Click Save.
   The new column label appears in the search results.

7. To remove a column, complete the following steps:

   a. In the search results, click the appropriate icon next to the column.

   b. At the top of the page, click CONFIGURE SEARCH: OFF.

   c. Click Save.
   The column is removed from the page and the search results.

Add a Sorting Field

CA APM lets you add sorting fields to the search results and extend the default sort of a single column using either ascending or descending order. For example, you currently sort assets by asset name. You can add asset family to the sorting so that you can sort on both asset name and asset family.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.

   a. On the left, click Manage Searches.

   b. A list of saved searches displays.

   c. Click a search in the list.

   d. At the top of the page, click CONFIGURE SEARCH: ON.

   e. The configuration of the search is enabled.

2. Click a search in the list.

3. In the Additional Settings, Search Result Sorting area, add the additional field for sorting.

4. Click Go.
   The results appear with the extended sorting and help you see the impact on the results before you save the sorting. The new field is added and you can use the field to sort the search results.

Prevent Duplicate Object Records

CA APM lets you prevent duplicate object records from appearing in the search results. For example, you have several people in your enterprise with the name John Smith. Their first and last names are the same, but their additional contact information (email address, supervisor, department, and so forth) is different.

You have a saved contact search in which only the first and last name of the contact appears in the results. When you search using the saved contact search and specify *John* as the first name and *Smith* as the last name, two instances of John Smith appear in the search results. When you prevent duplicate records from appearing, only one instance of John Smith appears.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.

   a. On the left, click Manage Searches.

   b. A list of saved searches displays.

   c. Click a search in the list.

   d. At the top of the page, click CONFIGURE SEARCH: ON.

   e. The configuration of the search is enabled.

2. Click the search for which you want to prevent duplicate records from appearing.

3. In the Additional Settings, Unique Search Characteristics area, select the Make Results Unique check box.

4. Click Go.
   The results appear without the duplicate records and help you see the impact on the results before you save your settings. The DISTINCT argument is added to the SQL statement, preventing duplicate records from appearing in the search results.

Prevent Opening Records

CA APM lets you disable the ability to open individual records from the search results. For example, you do not want users to open and display contact information from the contact search results.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.

   a. On the left, click Manage Searches.

b. A list of saved searches displays.

c. Click a search in the list.

d. At the top of the page, click CONFIGURE SEARCH: ON.

e. The configuration of the search is enabled.

2. Click a search in the list.

3. In the Additional Settings, Unique Search Characteristics area, clear the Allow Selection of Results check box.

4. Click Save.
A hyperlink does not appear in the search results to open the object.

Allow Users to Save Searches

You can grant permissions to users so a Save button appears to save searches.

Follow these steps:

1. Click the tab and optional sub tab for the object you want to configure.

2. On the left, click CONFIGURE: ON.
The configuration of the page is enabled.

3. In the Configuration Information area of the page, specify the information for the new global or local configuration (see page 1515), or select an existing configuration that you want to change.

Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

4. In the Permissions area of the page, complete the following steps in the Granted and Denied Permissions lists:

When you grant any combination of the following permissions, the user can save searches.

a. To allow only the current user who is logged in to save a search, move Save Search to User to the Granted Permissions list.

b. To allow the current user who is logged in and specific configurations to save a search, move Save Search to Configuration to the Granted Permissions list. The search is available to the current user and all users that you select for the configuration.

c. To allow the current user who is logged in and specific roles to save a search, move Save Search to Role to the Granted Permissions list. The search is available to the current user and all users in the roles you select.

5. Click Save Configuration.
   The configuration is saved. Verify that you correctly assign a configuration to a role.

Allow Users to Export Search Results

You can grant permissions to users so they can save exported search results.

Follow these steps:

1. Click the tab and optional subtab for the object you want to configure.

2. On the left, click CONFIGURE: ON.
   The configuration of the page is enabled.

3. In the Configuration Information area of the page, specify the information for the new global or local configuration (see page 1515), or select an existing configuration that you want to change.

   Global configuration changes affect all users, regardless of their role. Local configuration changes only affect users in the roles assigned to the selected configuration.

4. In the Permissions area of the page, complete the following steps in the Granted and Denied Permissions lists:

   When you grant any combination of the following permissions, the user can save exported search results.

   a. To allow only the current user who is logged in to save the exported search results, move Export for User to the Granted Permissions list.

      When this is the only permission granted to a user, the user cannot select the Export to All Configurations assigned on Search and Export to All Roles assigned on Search check boxes when scheduling search requests. For information about scheduling search requests, see Search Results Export

(see page 2439). An email is sent to the current user only. The email includes a link to the CSV file or specifies the name of the database view, depending on the type of export.

b. To allow the current user who is logged in and specific configurations to save the exported search results, move Export for Configuration to the Granted Permissions list. The export is available to the current user and all users in the selected configurations assigned to the search used by the export.

When this permission is granted to a user, the user can select the Export to All Configurations assigned on Search check box when scheduling search requests. For information about scheduling search requests, see Search Results Export (see page 2439). An email is sent to all users in the selected configurations. The email includes a link to the CSV file or specifies the name of the database view, depending on the type of export.

c. To allow the current user who is logged in and specific roles to save the exported search results, move Export for Role to the Granted Permissions list. The export is available to the current user and all users in the selected roles assigned to the search used by the export.

When this permission is granted to a user, the user can select the Export to All Roles assigned on Search check box when scheduling search requests. For information about scheduling search requests, see Search Results Export (see page 2439). An email is sent to all users in the selected roles. The email includes a link to the CSV file or specifies the name of the database view, depending on the type of export.

5. (Optional) Select the Inherit Permissions from Parent Object check box to apply any security permissions from a top-level (parent) object to the lower-level (child) object using the same configuration.

   For example, you create a local configuration for an Organization. In the configuration, you deny permissions to change field labels, move fields, make fields required, and hide fields. After you save the configuration, you open Attachments under Organization and select the Inherit Permissions from Parent Object check box. All permissions from the Organization are applied to Attachments. In this example, because permissions to change field labels, move fields, make fields required, and hide fields are applied to the Organization, the permissions are also applied to the Attachment.

6. Click Save Configuration.
   The configuration is saved. Verify that you can correctly assign a configuration to a role.

Delete Saved Searches

As an Administrator, you can delete user-defined searches if they are not in use for long time.

Note: You cannot delete searches that are out-of-box.

Follow these steps:

1. Click the tab and optional sub tab for the object that you want to find.
2. On the left, click Manage Searches.
3. Under Search Results, select the user-defined search you want delete.
4. Click Delete.

Administering CA Asset Portfolio Management

This section contains the following articles:

Administration

The overall administration of CA APM involves setting up security, configuring the user interface, managing hardware reconciliation, and optionally changing configuration settings for product components. The product administration is flexible and you can complete the following administration tasks in any order that you want.

After you complete the following tasks, provide the CA APM URL and login credentials to all users so that they can log in to the product.

- **Security**
  You define security to control user access to the product and features. For example, you can provide one user with access to models and assets, and another user with access to legal documents.

  
  For more information, see Security (see page 1570).

- **User Interface Configuration**
  You configure the user interface to simplify how users enter, manage, and search for data. In addition, you secure and protect users from performing unauthorized tasks and ensure that you conform to your IT asset management practices. For example, you can globally hide the Contact page from all CA APM users. However, there are some users who must be able to see and update contact information. Therefore, you make the Contact page appear for those users. User interface configuration is flexible, and you can configure almost all aspects of the user interface.

  
  For more information, see How to Configure the User Interface (see page 1520).

- **Hardware Reconciliation**
  You use hardware reconciliation to match *discovered assets* to their corresponding *owned assets* from different logical repositories and manage your assets. You can identify unauthorized, missing, under-utilized, and over-utilized assets, which helps you to optimize your hardware asset base.

  
  For more information, see Hardware Reconciliation (see page 2404).

- **Product Components**
  You can change the product component configurations that were set up during the product installation. For example, you can change the listening port for Oracle. You can also add components to additional servers to maintain product performance and enable product scalability. For example, you can add a Hardware Reconciliation Engine on an additional server. The configuration is flexible, and you can change many component settings.

  
  For more information, see Configure a Product Component (see page 1586) and Add Component Servers (see page 1568).

Log In to CA APM

After the product is installed, your implementer verifies that all services are started and starts the web interface to verify that CA APM is ready to use. The implementer provides you with the URL and credentials to log in to the product. You can then prepare the product for users to manage assets.

By default, the login credentials (username and password) for the default System Administrator user are uapmadmin. You can change the password to meet your requirements by changing the settings for the CA EEM component.

The default password can also be changed during the installation process.

Maintaining Security

This article contains the following topics:

Security

Before you allow user access to CA APM, set up security to control access to the product, protect your repository from unauthorized or inaccurate changes, and make necessary data available to users. For example, you can provide one user with access to models and assets, and another user with access to legal documents.

Setting up security involves the following tasks:

1. Users (see page 1571). Define the users who can access the product.

2. User Roles (see page 1574). Define groups of users who perform similar tasks.
3. Authentication (see page 1581). Define how users are authenticated when they log in.
4. Searches (see page 1583). Define which users can use searches.
5. Configuration. Protect users from performing unauthorized tasks.

One or more system administrators perform these security tasks in CA APM. A system administrator with the user ID *uapmadmin* acts as a global system administrator, with complete control over all security aspects of the product.

You enforce security across the enterprise by using the web interface. Minimal database skills are required to perform these tasks.

Users

You establish user security when you add new users to the product and assign a user ID and password. If a user does not have a valid user ID and password, they cannot log in. For each person, a user record is established, and the record is associated with a contact in the ca_contact table.

You can add users to the product in the following ways:

1. Import them.
2. Manually define them.

When manually defining users, you can immediately authorize them to use the product. However, when you import users, import them first, and then you can authorize them.

When you define a user manually, a corresponding CA EEM user is also created. CA EEM verifies the user name and password when the user logs in to CA APM.

After you define all CA APM users, assign each user to a *user role* and assign the entire role access rights to determine what they see and can access when they log in.

Best Practices (Users and Roles)

Use the following best practices to effectively manage users and roles:

- A user must have a valid user ID and password, and be authorized, to log in.
- Remove a user from a role before assigning a new role to the user.

  The product does not allow you to assign a user to more than one role.

- Verify that there are no users assigned to a role before deleting the role.

- Delete users before deleting a role.

Import and Synchronize Users

Important! Verify that the user completing this task belongs to a role in which user management access is enabled.

You can import a list of users from an external user store such as an active directory through CA EEM, and synchronize them to be saved as contacts in CA APM. Importing users helps you to save time when defining your users, and helps ensure the accuracy of the user information. After you import and save the users, authorize them to access the product.

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the User Management menu.
3. Click LDAP Data Import and Sync.
4. If multi-tenancy is enabled, select a tenant from the drop-down list.
5. Click Start LDAP Data Import and Sync.
   The import process begins and users are imported from the external store. If multi-tenancy is enabled, users are imported for the selected tenant as contacts into the ca_contact table. You can then authorize the imported users to access the product.

The LDAP Data Import and Sync works for user names that begin with a letter or number. User names that begin with a special character are not imported.

Define a User

Important! Verify that the user completing this task belongs to a role in which user management access is enabled.

You define all users of CA APM and provide them with access to the product. After you define a user, assign a role to the user.

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the User Management menu.

3. Click New User.
4. Enter the information for the new user and the contact-related information.
5. (Optional) Specify if you want to authorize the user to access to the product.
6. Click Save.
   The user is defined.

Authorize a User

Important! Verify that the user completing this task belongs to a role in which user management access is enabled.

You can authorize a user so they can log in and use the product. Before you can authorize a user, save the user as a contact.

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the User Management menu.
3. Click Authorize Users.
4. Search to find the list of available users.
5. Select the user you want to authorize and click OK.
   The user appears in the Authorized Users list.
6. Click the Edit icon next to the user name.
7. (Optional) Select a contact to assign a user with contact details.

   If you do not select a contact, a new contact is created for the user.

8. (Optional) Select a role to assign to the user.
9. Click Authorize.
   The selected user is authorized to log in to the product.

Deny a User Access

> **Important!** Verify that the user completing this task belongs to a role in which user management access is enabled.

You can deny a user access and prevent them from logging in to the product. For example, you hire a new asset technician and want to prevent them from using the product until they have received proper training. When you deny a user access, the contact information for the user is not deleted from the product.

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the User Management menu.
3. Click Authorize Users.
4. Select the user for which you want to deny access from the Authorized Users list.
5. Click De-Authorize.
   The user is prevented from logging in to the product.

User Roles

A *user role* is the primary record that controls security and user interface navigation in the product. Each role defines a focused view of the product by exposing only the functionality necessary for users to perform the tasks that are assigned to their business roles. The default role for a user and the associated user interface configuration determine the data and functions that are available to the user. A user can belong to only a single role.

Define user roles to apply functional and field-level repository access rights. You determine and assign the level of access that is required for each role. Group the users with the same job function and assign them the corresponding role. Role assignment prevents the users from performing unauthorized tasks, such as adding or deleting data. For example, users in an Administrator role need full access to all records, while users in an Asset Technician role need limited access to fewer records.

> The product contains predefined System Administrator and user roles that you can use as the basis for user management.

You can perform several tasks to set up and manage user roles:

- Define a role.
- Assign a role to a user.

- Remove a user from a role.
- Update a role.
- Delete a role.
- Assign a configuration to a role.

Predefined Roles

The product provides a System Administrator role, which has complete control and access to all objects and tenant data. This role is associated with the System Administrator contact and cannot be deleted. A user in this role can define, update, and delete objects, in addition to defining and updating more roles to meet your business requirements. You cannot assign a configuration to the System Administrator role.

The product also provides the following predefined user roles to help you manage users:

- CA APM Asset Technician - Provides access to the data and functions that are required for working with asset information only.
- CA APM Contract Manager - Provides access to the data and functions that are required for working with legal documents and the contract management process only.
- CA APM Default User - Provides read-only access to a limited view of the product. This role can view most of the data in the product. However, this role cannot modify the product data.
- CA APM Fulfiller - Provides access to the data and functions that are required for asset fulfillment tasks only.
- CA APM Receiving - Provides access to the data and functions that are required for updating assets that are received from a fulfillment process only.

Each predefined user role has associated configurations, which provide access to the data that is required to complete the particular function. You can modify the configurations that are associated with each predefined role. The predefined roles are available only after a new installation.

Define a User Role

Important! Verify that the user completing this task belongs to a role in which role management access is enabled.

You can define customized user roles to meet your site-specific business requirements. For example, you can define one role with access to reconciliation management, and another with access to asset fulfillment.

Follow these steps:

1. Click Administration, User/Role Management.

2. On the left, expand the Role Management menu.

3. Click New Role.

4. Enter the information for the role.

   - **User Management Access**
     Select this check box so a user assigned to the role can access the user management functionality (Administration, User/Role Management, User Management). The User/Role Management subtab is available only when the role has access to the user management functionality, the role management functionality, or both.

   - **Role Management Access**
     Select this check box so a user assigned to the role can access the role management functionality (Administration, User/Role Management, Role Management). The User/Role Management subtab is available only when the role has access to the user management functionality, the role management functionality, or both.

   - **System Configuration Access**
     Select this check box so a user assigned to the role can access the system configuration functionality (Administration, System Configuration).

   - **Web Services Access**
     Select this check box so a user assigned to the role can access the CA APM web services documentation and WSDL (Administration, Web Services). If this check box is not selected and a user in the role attempts to access the web services from an external client application, the user receives a login error.

   - **Filter Management Access**
     Select this check box so a user assigned to the role can access the filter management functionality (Administration, Filter Management).

   - **Other Information Configuration Access**
     Select this check box so a user assigned to the role can access the Other Information Configuration functionality. This function allows the user to access additional related information for selected objects. The user can access this additional information by selecting menu items under Relationships on the left side of the page.

   - **Data Importer User Access**
     Select this check box so a user assigned to the role can access the Data Importer functionality (Administration, Data Importer) with user permissions. Users can create imports and can modify or delete their own imports. Users can also view any import that was created by another user.

   - **Data Importer Admin Access**
     Select this check box so a user assigned to the role can access the Data Importer functionality (Administration, Data Importer) with administrator permissions. Administrators can create imports and can modify or delete any import that was created by any user.

   - **Reconciliation Management Access**
     Select this check box so a user assigned to the role can access the reconciliation rules management functionality (Administration, Reconciliation Management).

- **Asset Fulfillment Access**
  Select this check box so a CA Service Catalog user assigned to the role can perform asset fulfillment using CA Service Catalog.

- **Tenancy Admin Access**
  Select this check box so a user assigned to the role can access the multi-tenancy administration functionality to enable multi-tenancy, define tenants, define subtenants, and define tenant groups (Administration, Tenancy Management).

- **Normalization Access**
  Select this check box so a user assigned to the role can access the normalization rules management functionality (Directory, List Management, Normalization).

- **Mass Change Utilities Access**
  Select this check box so a user assigned to the role can access the Mass Change Utilities functionality. This function allows the user to change the asset family for a model and also to change the model for an asset.

5. (Optional) Specify the read/write permissions for tenants. Multi-tenancy expands the purpose of the role to control the tenant or tenant group that a user within the role can access. When multi-tenancy is enabled, the Tenant Information section includes Tenant Access Read and Tenant Access Write drop-down lists.

   The Tenant Information section is visible only when multi-tenancy is enabled. For information about how to enable multi-tenancy, see Implementing Multi-Tenancy (see page 1606). In addition, users associated with a tenant other than the service provider can only create or update objects associated with their own tenant. Only users associated with the service provider are permitted to create or update objects belonging to tenants other than their own.

   - **All Tenants**
     Contains no tenant restrictions. A user in a role with this access can view any object in the database (including public objects). In addition, a user associated with the service provider can update or create objects associated with any tenant. When a service provider user with this access creates an object, the product requires the user to select the tenant of the new object.

   - **Contact's Tenant**
     (Default value) Associates the role with the tenant of the contact. The product restricts a user in a role with this access to viewing, creating, and updating only those objects associated with their own tenant (and to view public objects). When a user with this access creates an object, the user cannot select a tenant. The tenant is automatically set to the tenant for the contact.

   - **Contact's Tenant Group**
     Associates the role with the tenant group of the contact. The product restricts a user in a role with this access to viewing, creating, and updating only those objects associated with the tenants in their tenant group (and to view public objects). When a user with this access creates an object, the user can select any tenant belonging to the tenant group.

- **Single Tenant**
  Associates the role with a named tenant. When you select this option, select a specific tenant in either the Tenant Write or Tenant Read field. The product restricts a user in a role with this access to viewing, creating, and updating only those objects associated with the tenant you select (and to viewing public objects). When a user with this access creates an object, the user cannot select a tenant. The tenant is automatically set to the tenant you select.

  Note: Only a service provider user can create or update data for a tenant other than their own. A tenant user in a role with single tenant access to another tenant is restricted to read access.

- **Tenant Group**
  Associates the role with a named tenant group. When you select this option, select a specific tenant group in either the Tenant Group Write or Tenant Group Read field. The product restricts a user in a role with this access to viewing only those objects that belong to any tenant in the tenant group. In addition, a user associated with the service provider can update or create objects associated with any tenant in the group. When a service provider user with this access creates an object, the product requires the user to select the tenant for the new object.

- **Update Public (check box)**
  Available only when you select All Tenants. Select this check box to authorize a user in the role to create or delete tenanted public data.

6. Click Save.
   The role is defined and you can assign users to the role.

Assign a Role to a User

Important! Verify that the user completing this task belongs to a role in which role management access is enabled. In addition, if you do not assign a role to a user, the Administration tab is hidden from the user.

You can assign a role to a user to define a focused view of the product and determine what they see when they log in. For example, assign an administrator to the system configuration role. You can assign a user to only a single role. Save a user as a contact before you assign the user to a role.

Note: Remove a user from their previous role before assigning a new role to the user.

Follow these steps:

1. Click Administration, User/Role Management.

2. On the left, expand the Role Management menu.
3. Click Role Search.
4. In the Role Contact area of the page, click Assign Contact.
   All users not assigned to a role appear.
5. Select the user for which you want to assign the role.
6. Click OK.
7. Click Save.
   The role is assigned to the user.

Remove a User from a Role

Important! Verify that the user completing this task belongs to a role in which role management access is enabled.

You can restrict the access rights for a user by removing them from a role. For example, an administrator is transferred to a different department and you remove them from the system configuration role. Remove a user from a role before assigning them to another role, or if they are no longer a part of your site or organization.

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the Role Management menu.
3. Click Role Search.
4. Click the delete icon next to the user you want to remove from the role.
5. Click Save.
   The user is removed from the role.

Update a User Role

Important! Verify that the user completing this task belongs to a role in which role management access is enabled.

At any time, you can update a user role to change what the user sees when they log in to the product. For example, the users in a particular role no longer perform tenancy management functions. In this situation, remove the tenancy management access for the role.

Important! You can delete a role that is no longer active in your site or organization, or when the role functions are no longer required. You cannot delete the predefined System Administrator role (see page 1575).

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the Role Management menu.
3. Click Role Search.
4. Search for and select a role.
5. To update the user role, change the information for the role and click Save.
   The role is updated.
6. To delete the user role, click Delete.
   The role is deleted.

Assign a Configuration to a Role

Important! Verify that the user completing this task belongs to a role in which role management access is enabled.

You can configure the user interface to simplify how users enter, manage, and search for data. When you assign a configuration to a role, you help ensure that any user assigned to the role sees the product as you have configured it for them.

Example: Assign a configuration to an asset manager

In this example, an asset manager must quickly view, and monitor the most important information that has been entered into the product for an asset. This information is used for reporting, cost analysis, and inventory control. The administrator configures the search results to display the asset name, model name, quantity, serial number, operating system, purchase order number, and cost center. The administrator saves the configuration and assigns it to the asset manager role. When an asset manager logs in to the product, the configuration for the asset manager role is selected and appears.

For more information about configurations, see How to Configure the User Interface (see page 1520).

Follow these steps:

1. Click Administration, User/Role Management.
2. On the left, expand the Role Management menu.
3. Click Role Search.
4. Search for and select a role.
5. Click Role Configuration.
6. Click Select New.
   The list of saved configurations appears.
7. Select the configuration you want to assign to the role.
8. Click OK.
9. Click Save.
   The configuration is assigned to the role. Any user assigned to the role sees the configuration when they log in to the product.

Authentication

Authentication is the process of obtaining identification credentials from a user such as name and password to validate their credentials to verify that the user exists. If the credentials are valid, the user is authenticated. After a user is authenticated, the authorization process determines whether the user can log in to the product.

Note: CA APM uses CA EEM to process user authentication.

The following types of authentication are supported:

- Form Authentication. A user is prompted for a user name and password to log in to the product.

  Form authentication is the default authentication type.

- Windows Integrated Authentication. A user already logged in to the Windows domain can access the product without having to provide additional login credentials.

You can provide additional security by defining tab and menu configuration in the product to restrict the pages and tabs that a user can access.

Configure Form Authentication

Verify that the user completing this task belongs to a role in which system configuration access is enabled.

You can configure form authentication so a user is prompted for a user name and password when logging in.

Follow these steps:

1. Click Administration, System Configuration.
2. On the left, click EEM.
3. Select Form from the Authentication Type drop-down list.
4. Click Save.
   Form authentication is enabled.

Configure Windows Integrated Authentication

Verify that the user completing this task belongs to a role in which system configuration access is enabled.

You can configure Windows integrated authentication and reference the CA EEM server to the active directory used for authentication. With Windows integrated authentication enabled, a user already logged in to the Windows domain can access the product without having to provide any additional login credentials.

You can also configure Windows integrated authentication with CA EEM and CA SiteMinder. CA SiteMinder uses the active directory for authentication. For information about this configuration, see the CA EEM product documentation.

For Windows integrated authentication to work, the CA EEM server, the Active Directory, and the client computer making the authentication request must belong to the same domain.

In addition, when you create and authorize a user in the CA EEM local store with a user name that exists in the Active Directory, the corresponding Active Directory user is automatically authorized.

Follow these steps:

1. On the computer where CA EEM is installed, configure the CA EEM server to reference your Active Directory or LDAP system.

For information about performing these functions, see the CA EEM product documentation.

2. In CA APM, click Administration, System Configuration.
3. On the left, click EEM.
4. Select Windows Integrated from the Authentication Type drop-down list.
5. Click Save.
   Windows integrated authentication is enabled.

Single Sign-On

Single sign-on is an authentication process where the user can enter one user ID and password and access a number of resources within the organization. Single sign-on eliminates the need to enter additional authentication credentials when switching from one solution to another.

Single sign-on lets users log in to the product automatically using Windows login information. After you add the user ID to any role, the product verifies the login credentials and displays the appropriate home page to the user.

For single sign-on to work correctly, configure Windows user accounts as domain user accounts, and not as the local user accounts.

Search Security

Default searches let you find objects in the repository. For example, use the default searches to find assets, models, contacts, and so forth. The security for the default searches makes them available to all users and configurations. You can use these searches to create additional searches.

In contrast, you can apply security to the searches that you create to limit who can use the search. When you save a configured search, you can select specific user roles and configurations (restricted to administrators). By default, the security for the searches you create makes them available to all users and configurations. By applying unique security to your searches, you help ensure that certain users cannot view sensitive information that a search returns.

Consider the following information when applying security to searches:

- You can access all searches (default and user-defined searches) so that you can configure and troubleshoot searches for users.
- You can access all scheduled searches and exports so that you can configure and troubleshoot scheduled searches and exports for users.

- All users that are assigned to a role and configuration can access the default searches and the user-defined searches that are assigned to the role and configuration. However, the search results that users see for the default searches do not display information and fields that you hide and secure.

- When a default and user-defined search becomes invalid because of configuration changes, you may not need the search. You can delete any default and user-defined search in CA APM.

Troubleshooting Search Security

Troubleshooting tips related to search security help you when working with configured searches.

- Role Cannot Be Assigned to a Configured Search (see page 1584)

- Configuration Cannot Be Assigned to a Configured Search (see page 1584)

Role Cannot Be Assigned to a Configured Search

Valid on all supported operating environments.

Symptom:

When attempting to provide a role with access to a configured search, I receive an error similar to one of the following errors:

You cannot assign role <role name> to the search because the role cannot access the following field (s): <field name> on Asset Type <asset family>

You cannot assign role <role name> to the search because the role cannot access the Asset Type <asset family>

You cannot assign role <role name> to the search because the configuration cannot access the following field(s): <field name>, <field name>

Solution:

Use any of the following solutions to resolve this error:

1. Update the configuration and provide the role or user with access to the search.

2. Update the configuration and remove the hidden field from the search.

3. Do not allow the role to access the search.

4. Remove the configuration from the role.

Configuration Cannot Be Assigned to a Configured Search

Valid on all supported operating environments.

Symptom:

When attempting to provide a global or local configuration with access to a configured search, I receive an error similar to one of the following errors:

You cannot assign configuration <configuration name> to the search because the configuration cannot access the following field(s): <field name> on Asset Type <asset family>

You cannot assign configuration <configuration name> to the search because the configuration cannot access the Asset Type <asset family>

You cannot assign configuration <configuration name> to the search because the configuration cannot access the following field(s): <field name>, <field name>

Solution:

Use any of the following solutions to resolve this error:

1. Update the configuration and make the hidden field available to the search.
2. Update the configuration and remove the hidden field from the search.
3. Do not allow the configuration to access the search.

Managing Product Components

This article contains the following topics:

- Modify the Debugging Level for Component Service Log Files (see page 1605)

Product Components

After you install CA APM, you can manually configure many of the product components. In addition, you can add components to additional servers to maintain optimum performance and enable scalability. For example, you can add a Hardware Reconciliation Engine or an additional component server. The configuration is flexible, and you can change many component settings.

For a description of each product component, see the Step 9: Configure Product Components (see page 319).

Configure a Product Component

Verify that the user completing this task belongs to a role in which system configuration access is enabled.

You can change the component configurations that were set up during the product installation. For example, you can change the name of the SMTP server that is used to send email.

Follow these steps:

1. Click Administration, System Configuration.
2. On the left, select the product component.
3. Enter the new configuration settings for the component:
   - Database
     - Oracle (see page 1587)
     - SQL Server (see page 1589)
   - Web Server (see page 1590)
   - Application Server (see page 1592)
   - Hardware Reconciliation Engine (see page 1593)
   - CA EEM (see page 1594)
   - Export Service (see page 1595)
   - Data Importer (see page 1596)

- Data Importer Engine (see page 1596)
- LDAP Data Import and Sync Service (see page 1597)
- CORA (see page 1597)
- Storage Manager Service (see page 1598)
- Event Service (see page 1598)
- Common Asset Viewer (see page 1600)
- WCF Service (see page 1601)
- SAM - Import Driver (see page 1601)
- Software Asset Management (see page 1602)

4. Click Save.
   The configuration settings are saved.

Oracle Database Configuration Settings

After you install the product, if you are using Oracle as the database for the CA MDB, you can change the settings for the Oracle database server.

The following fields require explanation:

- **DBA User Name**
  The user name for connecting to the target database. The user name must be for a privileged user.
  Default: sys

- **Listen Port**
  The database connection port.
  Default: 1521

- **Oracle Service Name**
  The service name for the target database.
  Default: orcl

- **Oracle Net Service Name**
  The net service name for the target database.
  Default: orcl

- **Tablespace Path**
  The location of the Oracle tablespaces.
  Default: c:\oracle\product\10.2.0\oradata\orcl

- **Data Tablespace Name**
  The name of the data tablespace.
  Default: MDB_DATA

- **Data Tablespace Size**
  The amount of disk space to be allocated for the data tablespace.
  Default: 400 MB

- **Index Tablespace Name**
  The name of the index tablespace.
  Default: MDB_INDEX

- **Index Tablespace Size**
  The amount of disk space to be allocated for the index tablespace.
  Default: 100 MB

- **mdbadmin Password**
  The password that is associated with the mdbadmin user. If a new CA MDB is being created, this is the password that is assigned to the mdbadmin user.

- **Command Timeout**
  The maximum amount of time that the application waits for a response from the database.

- **Stored Procedure Command Timeout**
  The maximum amount of time that the application waits for a response from the database stored procedures.

- **Max Connection Pool Size**
  The maximum number of requests that the database can process simultaneously.

- **Enable CORA Connection Pooling**
  Placeholder for the flag that enables CORA connection pooling. Currently, CORA does not support connection pooling.

- **CORA Connection Pool Lifetime**
  Placeholder for the lifetime of the CORA connection pool. Currently, CORA does not support connection pooling.

- **CORA Connection Pool Size**
  Placeholder for the size of the CORA connection pool. Currently, CORA does not support connection pooling.

- **Last Run Date Option**
  Determines if the imported data should update the existing CA APM data. CA APM receives discovered hardware data imports and uses the data to match ownership and discovery data. CA APM determines if the imported data is more current than the existing data by comparing their inventory dates. Then CA APM decides whether the imported data should update the existing CA APM data.

  Default: 2
  See the following table for a description of all valid options.

Option	Definition
1	Always update the existing CA APM data with the imported data.
2	

Option	Definition
	(Default) Update the existing CA APM data only if the inventory date of the imported asset is more current than the inventory date of the existing asset. If the imported asset does not have an inventory date, an error occurs and the imported asset data does not update the existing CA APM data.
3	Update the existing CA APM data only if the inventory date of the imported asset is more current than the inventory date of the existing asset. If the imported asset does not have an inventory date, update the existing CA APM data with the imported data.

SQL Server Database Configuration Settings

After you install the product, if you are using SQL Server as the database for the CA MDB, you can change the settings for the SQL Server database server.

The following fields require explanation:

- **SQL Server Login**
  The user name for connecting to the target database. The user name must have sysadmin role privileges assigned in SQL Server.
  Default: sa

- **SQL Server TCP/IP Port**
  The database connection port.
  Default: 1433

- **Command Timeout**
  The maximum amount of time that the product waits for a response from the database.

- **Stored Procedure Command Timeout**
  The maximum amount of time that the product waits for a response from the database stored procedures.

- **Max Connection Pool Size**
  The maximum number of requests that the database can process simultaneously.

- **Enable CORA Connection Pooling**
  Placeholder for the flag that enables CORA connection pooling. Currently, CORA does not support connection pooling.

- **CORA Connection Pool Lifetime**
  Placeholder for the lifetime of the CORA connection pool. Currently, CORA does not support connection pooling.

- **CORA Connection Pool Size**
  Placeholder for the size of the CORA connection pool. Currently, CORA does not support connection pooling.

- **SQL Server Host Name**
  The host name of the server that is used for SQL Server.

- **Last Run Date Option**
  Determines if the imported data should update the existing CA APM data. CA APM receives discovered hardware data imports and uses the data to match ownership and discovery data. CA APM determines if the imported data is more current than the existing data by comparing their inventory dates. Then CA APM decides whether the imported data should update the existing CA APM data.

  Default: 2
  See the following table for a description of all valid options.

Option	Definition
1	Always update the existing CA APM data with the imported data.
2	(Default) Update the existing CA APM data only if the inventory date of the imported asset is more current than the inventory date of the existing asset. If the imported asset does not have an inventory date, an error occurs and the imported asset data does not update the existing CA APM data.
3	Update the existing CA APM data only if the inventory date of the imported asset is more current than the inventory date of the existing asset. If the imported asset does not have an inventory date, update the existing CA APM data with the imported data.

Web Server Configuration Settings

After you install the product, you can change the settings for the web server.

The following fields require explanation:

- **Web Server or Load Balancer IP/Host**

  The CA APM installation, by default, sets this field to the web server host name.

  - In a single web server environment, you can enter the web server host name, or the web server IP address.
  - In a multiple web server environment, you can enter either the web server host name, or the IP address of the Load Balancer.

  Note: The web server can be registered with a different name in the Domain Name System (DNS) than what is registered as the web server host name. In this situation, specify the different name in this field.

- **Authentication Timeout**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the product and must log in again.
  Default: 3600000 (6 minutes)

- **State Data**
  The temporary view data that is stored at the server side for each user until the user logs off. This data can be stored either in the database or on the web server file system. The value of State Data can be SERVER (FileSystem) or DATABASE.

- **Cache Timeout**
  The elapsed time-out period for cached files to be deleted from the store.
  When a user logs in, along with view data, documents are stored in system memory (Cache). If the user is not referring to these documents, the documents become stale. After some time, these documents are deleted. The time limit is the Cache Timeout.

- **Auto complete Result Count**
  The number of values to display in the Auto Complete drop-down lists. In fields with lists, the user can start to type a value and the product provides a list of matching values. The user can then select a value from this Auto Complete list.

  Note: If you set a low number for this parameter, the Auto Complete list may not be useful since the user will have to type most of the value before finding it in the list. If you set a high number for this parameter, the list could perform slowly.

- **Homepage**
  The default CA APM home page that is opened after the user logs in.

- **SM Web Service Protocol**
  The protocol that is used to access the Storage Manager Service.
  The Storage Manager Service provides file storage facility to other product components. When the other components want to interact with the Storage Manager Service, the components use this protocol.

- **SM Web Service Port**
  The port on which the Storage Manager Service is running.
  This port is the HTTP port on which the Storage Manager Service is hosted. The default port is 80. If the Storage Manager Service is configured to host on a different port, that port number is shown.

- **EEM Backend**
  The name of the server where CA EEM is installed. This value is populated during installation.

- **Reporting Web Service Server**
  The CA Business Intelligence server name and port. This value is populated during installation.

- **Reporting Timeout**
  The time-out in seconds for a connection to the CA Business Intelligence (reporting) web service.

- **Reporting Name**
  The name of the CA Business Intelligence (reporting) engine. This name is always "Allegheny Reporting Engine".

- **Reporting User**
  The CA Business Intelligence (reporting) user with administrative privileges.

- **Reporting Password**
  The password for the Reporting User.

- **External AuthHeader**
  This header works with the External setting of Authentication Type on the CA EEM configuration. The external authentication mechanism sets information in the HTTP header for the CA APM web pages to receive. One piece of information is the User Id. The External AuthHeader is the name of the variable external authentication that sets the User Id value. The External AuthHeader setting must match the configured setting in the external authentication for which the User Id is provided.

- **From Address**
  The From email address for the notifications that are sent from the Event Service.

- **To List**
  The list of recipients who receive the email notifications about issues from the Event Service.

- **Cc List**
  The list of recipients in the Cc list who receive the email notifications about issues from the Event Service.

- **Bcc List**
  The list of recipients in the Bcc list who receive the email notifications about issues from the Event Service.

- **Email Subject**
  The subject line in the email notification about issues that the Event Service sends to the recipients in the To List, Cc List, and Bcc List.

Note: If you change the setting on Administration, System Configuration, Web Server for the Web Server Protocol or the Web Server or Load Balancer IP/Host, you must restart the Windows service for CA Asset Portfolio Management - Export Service.

Application Server Configuration Settings

After you install the product, you can change the settings for the application server.

The following fields require explanation:

- **Application Server or Load Balancer IP/Host**

  The CA APM installation, by default, sets this field to the application server host name.

  - In a single application server environment, you can enter the application server host name, or the application server IP address.

  - In a multiple application server environment, you can enter either the application server host name, or the IP address of the Load Balancer.

The application server can be registered with a different name in the Domain Name System (DNS) than what is registered as the application server host name. In this situation, specify the different name in this field.

- **Authentication Timeout**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the product and must log in again.
  Default: 3600000 (6 minutes)

- **EEM Backend**
  The name of the server where CA EEM is installed. This value is populated during installation.

- **USM Web Service URL**
  The URL for the USM web service. This value is used when the product is integrated with CA Service Catalog or CA Service Desk Manager.

If you change the setting on Administration, System Configuration, Application Server for the Web Service Protocol or the Application Server or Load Balancer IP/Host, you must restart the following Windows services:

- CA Asset Portfolio Management - Export Service
- CA Asset Portfolio Management - Event Service
- CA Asset Portfolio Management - HW Reconciliation Engine
- CA Asset Portfolio Management - LDAP Import Service

Hardware Reconciliation Engine Configuration Settings

After you install the product, you can change the settings for the Hardware Reconciliation Engine.

The following fields require explanation:

- **Message Queue Retention**
  Number of days that records remain in the message queue before the Hardware Reconciliation Engine purges them.
  Default: 7

- **Refresh Lock Record Count**
  Engine performance tuning setting that works with the Lock Stale Interval setting. The number of records that the Hardware Reconciliation Engine adds or updates before refreshing the lock on the reconciliation rule record. If the lock refresh does not happen within the number of seconds specified in the Lock Stale Interval setting, the reconciliation rule record is available to another Hardware Reconciliation Engine.
  Default: 100

- **Lock Stale Interval**
  Engine performance tuning setting that works with the Refresh Lock Record Count setting. If the lock refresh does not happen on the reconciliation rule, the amount of time, in seconds, after which a reconciliation rule record is available to another Hardware Reconciliation Engine.
  Default: 600

- **Web Service Authentication Timeout**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the service and must log in again.
  Default: 3600000 (6 minutes)

- **Processing Mode**
  Specifies whether the Hardware Reconciliation Engine processes continuously. The product supports the following option:

  - **0**
    Process in continuous reconciliation mode.

- **Engine Snooze Time**
  Amount of time, in milliseconds, that the Hardware Reconciliation Engine waits between processing cycles.
  Default: 300000 (5 minutes)

- **Connection Retry Time**
  Amount of time, in milliseconds, that the Hardware Reconciliation Engine waits between attempts to connect to the database.
  Default: 60000 (1 minute)

- **Engine Debug Level**
  Debug level for the message queue. The levels are Fatal, Error, Warning, Info, and Debug.
  Default: Fatal

- **Web Service Batch Size**
  Number of records that are sent to the web service at one time for update processing.
  Default: 50

- **Pending Modification Retention**
  Number of days that pending modification requests remain in the queue before the Hardware Reconciliation Engine purges them. This setting affects any tenant that is processed by the Hardware Reconciliation Engine.
  Default: 7

CA EEM Configuration Settings

After you install the product, you can change the settings for CA EEM.

The following fields require explanation:

- **Authentication Type**
  Type of authentication allowed:

  - **Form**. A user is prompted for a user name and password to log in to the product.

- **Windows Integrated**. A user who is already logged in to the Windows domain can access the product without having to provide additional login credentials.

- **External**. A user is authenticated by an external access management system, for example, CA SiteMinder.

Default: Form

- **uapmadmin Password**
  Password for the uapmadmin user to access the web and application servers.

Export Service Configuration Settings

After you install the product, you can change the settings for the Export Service.

The following fields require explanation:

- **On Demand Request Period**
  Amount of time, in milliseconds, that the Export Service waits between On Demand Request processing cycles.
  Default: 5000 (5 seconds)

- **On Demand Maximum Threads**
  Number of On Demand Request processing threads.
  Default: 2

- **Scheduled Requests Period**
  Frequency, in milliseconds, of Scheduled Requests processing cycles.
  Default: 7200000 (2 hours)

- **SMTP Server**
  Email server name.

- **Authentication Timeout**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the product and must log in again.
  Default: 360000 (6 minutes)

- **Purge Start Time**
  Time of day, in 24-hour format (Universal Time) when the purge thread starts.
  Default: 5 (5:00 a.m. Universal Time)

- **Search Batch Size**
  Maximum number of data records returned for each search in a single export request. Changing the default value may affect performance. For example, a lower value may increase the number of web service calls that are needed to retrieve all the data, and a higher value may require a longer period of time to gather all the records.
  Default: 2000

- **SM Web Service Protocol**
  The protocol that is used to access the Storage Manager Service.

- **SM Web Service Port**
  The port on which the Storage Manager Service is running.

- **Export Service Email Address**
  The email address that is used by the Export Service for notifications.

Data Importer Configuration Settings

After you install the product, you can change the settings for the Data Importer.

The following fields require explanation:

- **Authentication Timeout**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the component and must log in again.
  Default: 3600000 (6 minutes)

- **Maximum Batch Record Size**
  Maximum number of records in a Data Importer batch.
  Default: 50

Data Importer Engine Configuration Settings

After you install the product, you can change the settings for the Data Importer Engine.

The following fields require explanation:

- **SMTP Server Value**
  The email server name.

- **Scheduled Requests Period**
  The amount of time that the Data Importer Engine waits before checking for pending scheduled import requests. This value applies to scheduled data imports only.
  Default: 60000 (60 seconds)

- **On Demand Request Period**
  The amount of time that the Data Importer Engine waits before checking for pending on demand import requests. This value applies to on demand data imports only.
  Default: 60000 (60 seconds)

- **Max Batch Record Size**
  Maximum number of records in a Data Importer Engine batch.
  Default: 100

- **Max Job Threads**
  The maximum number of Data Importer Engine threads that can be running simultaneously for one import job.
  Default: 5

- **Max Import Threads**
  The maximum number of Data Importer Engine threads that can be running simultaneously for all import jobs.
  Default: 5

LDAP Data Import and Sync Service Configuration Settings

After you install the product, you can change the settings for the LDAP Data Import and Sync Service.

The following fields require explanation:

- **DB Check Time**
  Amount of time, in milliseconds, that the service checks the status (active or sleep mode). If the status is active, the service starts importing data.

- **EEM Backend**
  The name of the server where CA EEM is installed. This value is populated during installation.

CORA Configuration Settings

After you install the product, you can change the settings for CORA (CA APM Registration Service).

The following fields require explanation:

Note: Changes to the Common parameters affect the Web Server, WCF Service, Hardware Reconciliation, and Application Server components. Changes to the Registration Service parameters affect the Registration Service component.

- **(Common) Enable CORA**
  Enables Common Object Registration API features for the Web Server, WCF Service, Hardware Reconciliation, and Application Server components.
  Default: False

- **(Common) Enable CORA ID Generation**
  Allows the CORA tables to get the next CORA ID for a new record for the Web Server, WCF Service, Hardware Reconciliation, and Application Server components.
  Default: True

- **(Registration Service) Enable CORA**
  Enables the Common Object Registration API features using the Registration Service for all CA APM components.
  Default: True

- **(Registration Service) Enable CORA ID Generation**
  Allows the CORA tables to get the next CORA ID for a new record using the Registration Service for all CA APM components.
  Default: False

Storage Manager Service Configuration Settings

After you install the product, you can change the settings for the Storage Manager Service.

The following fields require explanation:

- **Purge Start Time**
  Time of day, in 24-hour format, when the Storage Manager Service starts to delete unused files.

- **Authentication Timeout**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the service and must log in again.
  Default: 3600000 (6 minutes)

Event Service Configuration Settings

After you install the product, you can change the settings for the Event Service.

The following fields require explanation:

- **Provider URL**
  The URL for accessing the workflow provider (for example, CA Process Automation).
  Example: The following URL is the default CA Process Automation workflow web services URL:

  ```
  http://<wf_hostname>:<wf_tomcat_port>/itpam/soap
  ```

- **Provider Authentication Type**
  The type of authentication (user or CA EEM) to be used with the Event Service.
  Default: User (CA EEM authentication is not currently supported for the Event Service.)

- **Provider User Name**
  The user ID for logging in to the workflow provider.

- **Provider Password**
  The user password for logging in to the workflow provider.

- **Provider Process Path**
  The path for accessing the start request forms for the workflow provider. These forms must be available for the CA APM integration with the workflow provider. For more information, see your workflow provider documentation.
  Default:/

- **Number of Events to be Processed**
  The maximum number of events to be processed in one Web Service call.
  Default: 2000

- **Time of the day for Event purge (in hours, GMT)**
  The time of day, in 24-hour format (GMT), when CA APM starts to purge event definitions that are marked for deletion.
  Default: 5 (5:00 a.m. GMT)

- **CMDB Audit Share Required**
  The indicator that enables audit sharing with the CMDB.
  The CMDB common database tables can be used by multiple applications. For example, the ca_contact table is used by CA APM, CA Service Catalog, and CA Service Desk Manager when they are integrated. An audit table maintains the changes that are made to these common tables. When there is a change to any of the CMDB objects in CA APM and this value is set to true, the change audit is posted to the CMDB audit table.

- **From Address**
  The From email address for the notifications that are sent from the Event Service.

- **To List**
  The list of recipients who receive the email notifications about issues from the Event Service.

- **Cc List**
  The list of recipients in the Cc list who receive the email notifications about issues from the Event Service.

- **Bcc List**
  The list of recipients in the Bcc list who receive the email notifications about issues from the Event Service.

- **Email Subject**
  The subject line in the email notification about issues that the Event Service sends to the recipients in the To List, Cc List, and Bcc List.

- **Interval between Event Occurrence check (in milliseconds)**
  The amount of time, in milliseconds, that CA APM waits between database checks for field changes related to defined events.
  If SAM capabilities are enabled, verify that this parameter is set to 30000. If SAM capabilities are not enabled, verify that this value matches the setting in the Event Service configuration file.
  Default (without CA SAM implementation): 3600000 (1 hour)
  Default (with CA SAM implementation): 30000 (30 seconds)

- **Interval between triggering events check (in milliseconds)**
  Amount of time, in milliseconds, that CA APM waits between database checks for triggered events that need to be sent to the workflow provider.
  If SAM capabilities are enabled, verify that this parameter is set to 60000. If SAM capabilities are not enabled, verify that this value matches the setting in the Event Service configuration file.
  Default (without CA SAM implementation): 3600000 (1 hour)
  Default (with CA SAM implementation): 60000 (60 seconds)

- **Interval between triggered events status update (in milliseconds)**
  The amount of time, in milliseconds, that CA APM waits between updates to the status of triggered events that were sent to the workflow provider.
  If SAM capabilities are enabled, verify that this parameter is set to 60000. If SAM capabilities are not enabled, verify that this value matches the setting in the Event Service configuration file.
  Default (without CA SAM implementation): 3600000 (1 hour)
  Default (with CA SAM implementation): 60000 (60 seconds)

- **Interval between asset contact update (in milliseconds)**
  The amount of time, in milliseconds, that CA APM waits between updates to asset contacts in the CA CMDB.
  Default: 43200000 (12 hours)

- **CA SAM Status Update Frequency**
  The frequency for updating the status of CA SAM import jobs in the MDB (in milliseconds).
  Default: 120000 (120 seconds)

- **On Demand Max Threads**
  The maximum number of threads for processing the data synchronization between CA APM and CA SAM. The default (zero) indicates that the system creates the required number of threads, depending on the system hardware configuration. Any value other than the default value uses the same number of threads, regardless of the system configuration.
  Default: 0

- **CA SAM Events Notification Email**
  The CA APM administrator email address for receiving notifications about the CA SAM data synchronization.

- **Authorization Token**
  The token that establishes communication between the CA APM Event Service and the CA SAM Import and Export Service. This value must match the CA SAM Import and Export Service configuration setting.

  If you change this value, you must update the value of the Authorization Token for the CA SAM Import and Export Service on the CA SAM server to match this value.

For more information about events and notifications, see Events and Notifications (see page 2376).

Common Asset Viewer

After you install the product, you can change the settings for the Common Asset Viewer.

The Tomcat port number for CA APM defaults to 9080. If another product that is integrated with CA APM uses this port number, change the port number in CA APM so that you do not have a conflict.

The following fields require explanation:

- **Tomcat Port**
  Port that should be used for the Apache Tomcat server that is processing the Common Asset Viewer.
  Default: 9080

  You must first update the port in the Apache Tomcat configuration file before you change the setting in the product. For information about updating the Apache Tomcat configuration file, see Update the Apache Tomcat Configuration File (see page 314).

WCF Service Configuration Settings

After you install the product, you can change the settings for the Windows Communications Foundation (WCF) Service component.

The following fields require explanation:

- **WCF Service Load Balancer IP/Host**

  The CA APM installation, by default, sets this field to the WCF Service server host name.

  - In a single WCF Service server environment, you can enter the WCF Service server host name, or the WCF Service server IP address.
  - In a multiple WCF Service server environment, you can enter either the WCF Service server host name, or the IP address of the Load Balancer.

  Note: The WCF Service server can be registered with a different name in the Domain Name System (DNS) than what is registered as the WCF Service server host name. In this situation, specify the different name in this field.

- **Authentication Timeout (in milliseconds)**
  Amount of time, in milliseconds, that users can be inactive before they are automatically logged out of the service and must log in again.
  Default: 3600000 (6 minutes)

- **Operation Threshold**
  The maximum number of records that can be sent by or returned to the client or server. When you call the Search method from a WCF client program, this value represents the maximum number of records that can be returned to you. If you call the Create method, this value represents the maximum number of records that you can send at one time.

- **EEM Backend**
  The name of the server where CA EEM is installed. This value is populated during installation.

SAM - Import Driver Configuration Settings

After you install the product, you can change the settings for the CA SAM Import Driver.

The following fields require explanation:

- **Server**
  The name of the server where the CA SAM Import Driver component is installed.
- **Username**
  The user name that is required for adding, changing, or deleting records with the Data Importer.
- **ITAM Root Path**
  The path to the root location where the product is installed.
- **File Path**
  The path to the root location where CA SAM export files are imported.
  Example:*[ITAM Root Path]*\ITAM\Import Driver\Input
- **Data Importer Executable Path**
  The path to the Data Importer executable file (ITAM Data Importer.exe).
  Example:*[ITAM Root Path]*\ITAM\Data Importer\ITAM Data Importer.exe
- **CA SAM Server Name**
  The name of the server where CA SAM is installed.

Software Asset Management Configuration Settings

After you install the product, you can configure the settings for software asset management. After you configure these settings, restart the Apache Tomcat Common Asset Viewer service.

Also restart the Apache Tomcat Common Asset Viewer service if you change the entries in any of the following fields at a later time:

- CA SAM Web Service WSDL URL
- CA SAM Web Service Login
- CA SAM Web Service Password

The following fields require explanation:

- **CA SAM Web Client URL**

  Specifies the URL for the CA SAM home page.

  Note: You can copy the web client URL from the CA SAM home page after you log in.

  CA SAM Import Export Webservice URL

  Specifies the URL for the CA SAM web service. Use the following format:

```
http://[CA SAM System Name]:[Port Number]/SAMImportExportService/Service.svc
```

- Replace [CA SAM System Name] with the name of the CA SAM server.
- Replace [Port Number] with the port number where the CA SAM Import and Export Service is hosted.

Enable SAM Capabilities

Specifies that software asset management capabilities are enabled. If you previously had CA SCM fields on the CA APM user interface, they are removed after you select this check box.

CA SAM Web Service WSDL URL

The URL for the CA SAM Web Service Definition Language (WSDL). This URL is used to access the CA SAM web service. Use the following format:

```
http://[CA SAM System Name]:[Port Number]/prod/soap/dyn_server.php
```

- Replace [CA SAM System Name] with the name of the CA SAM server.
- Replace [Port Number] with the port number where the CA SAM Web Service is hosted.

CA SAM Web Service Login

Login name for the CA SAM web service.

Note: Verify that this login name and the CA SAM Web Service Password match the login name and password in the config_soap.inc file. This file is found in the following CA SAM installation folder path:

```
app\includes\prod\st\config_soap.inc
```

Important! The default content of the config_soap.inc file is commented. Remove the comment delimiters (/* */) and configure the login name and password.

CA SAM Web Service Password

Login password for the CA SAM web service.

CA SAM SSO Encryption Algorithm

Specifies the encryption algorithm to be used for single sign-on access to CA SAM from the CA IT Asset Manager common home page.

This entry must match the entry in CA SAM System Configuration for the security_auth_token_cipher field.

Note: For more information about CA SAM single sign-on, see the description of single sign-on in the *CA Software Asset Manager Administration Manual.*

CA SAM SSO Authentication Mechanism

Specifies the mechanism to be used for logging in to CA SAM.

This entry must match the entry in CA SAM System Configuration for the security_auth_method field.

Note: We recommend that you select auth_token_password for this mechanism. The auth_token mechanism disables the login for other CA SAM users.

CA SAM SSO Field to Authenticate User

Specifies the type of unique identifier (import ID or email address) that is used to authenticate the user.

This entry must match the entry in CA SAM System Configuration for the security_auth_token_user_identifier field.

CA SAM SSO Secret Key

Specifies the key that CA APM and CA SAM share and that is used to encrypt and decrypt the user authentication. This key ensures that CA APM users who do not have the proper authentication cannot access CA SAM.

This entry must match the entry in CA SAM System Configuration for the security_auth_token_key field.

Enable SSO from CA Asset Portfolio Management to CA Service Desk Manager

CA Service Management allows you to enable SSO from CA Asset Portfolio Management (CA APM) to CA Service Desk Manager. For more information, see Enable Single Sign-On (SSO) from CA Asset Portfolio Management to CA Service Desk Manager (see page 3251).

Add Component Servers

Verify that the user completing this task belongs to a role in which system configuration access is enabled.

After the product is installed, you can add components to additional servers to maintain optimum performance and enable scalability as your enterprise grows. You can install the following components on one or more servers:

- Web server
- Application server
- Hardware Reconciliation Engine
- Data Importer
- WCF
- Data Importer Engine

Follow these steps:

1. Click Administration, System Configuration.
2. On the left, select the product component.
3. Specify the required server connection information in the Add Component to Server section, including the administrator username and password for the server.
4. Click Add.
   The server is added to the Component Server List.
5. Enter the configuration settings for the new component server:
   - Web Server
   - Application Server
   - Hardware Engine
   - Data Importer
6. Click Save.

Install CA APM on the server you just added. For information about installing, see Implementing CA IT Asset Manager (see page 301).

Modify the Debugging Level for Component Service Log Files

The product components have corresponding Windows services. These services create log files that allow you to verify the service status and review error details. The amount of detail information in a log file depends on the specified debugging level. The default debugging level for the service log files is Fatal. You can change the default level for the Windows services by editing the log configuration file for each component.

Follow these steps:

1. Navigate to a component folder on the application server where CA APM is installed.
   Example:

   ```
   [ITAM Root Path]\ITAM\Hardware Engine
   ```

2. Open the logging.config file in a text editor (for example, Notepad).
3. Locate the debugging level value statements.
4. Edit the statements to include your debugging levels.

   The log configuration files contain comments that explain the different debugging level values.

5. Save the log configuration file.

Implementing Multi-Tenancy

This article contains the following topics:

Multi-Tenancy

Multi-tenancy is the ability for multiple independent tenants (and their users) to share a single implementation of CA APM. Tenants only interact with each other in defined ways, as specified by their roles and tenant hierarchies. Typically, unless granted access by a role or tenant hierarchy, each tenant views the CA APM implementation as solely for its own use and cannot update or view the data for another tenant.

Multi-tenancy allows tenants to share hardware and application support resources, which reduces the cost of both, while gaining many benefits of an independent implementation.

Multi-tenancy is installed automatically during the CA APM installation. After you have installed CA APM, follow the steps in this section to implement multi-tenancy.

If you integrated CA Software Asset Management (CA SAM), you can also implement CA APM multi-tenancy with CA SAM. For more information, see How to Implement Multi-tenancy with CA SAM (see page 390).

Service Provider

The *service provider* is the primary tenant (owner) in a CA APM multi-tenancy implementation. The first tenant added to a CA APM implementation is always the service provider tenant. The service provider tenant cannot have a parent tenant.

CA APM associates the privileged user (typically, uapmadmin) with the service provider tenant.

Only the service provider tenant can perform any of the following CA APM tasks:

- Define, edit, or delete tenants.
- Allow tenants to have subtenants.
- Update tenanted public data.

The CA APM administrator can grant tenant users access to data other than their own. In addition, a user role can specify separate read and write access to certain tenant groups for users within that role.

How Multi-Tenancy Works

When you enable multi-tenancy, you can grant each contact access to all tenants (public), a single tenant, or a tenant group (user-defined or product-maintained). The role for a contact controls access, which specifies read and write access independently.

If multi-tenancy is enabled, most CA APM objects include a tenant attribute that specifies the tenant that owns the object. Objects are categorized into three groups, depending on their tenant attribute and how the object is used:

- **Untenanted**

Defines objects without a tenant attribute. All data in these objects is public, and any user can create and update untenanted public data.

Tenant Required

Defines objects with a tenant attribute that cannot be null (enforced by CA APM, not the DBMS). All data in these objects is associated with individual tenants; there is no public data.

Tenant Optional

Defines objects with a tenant attribute that can be null. You can either create these objects as tenanted or public. When you select a tenant in a tenant drop-down to create an object, the object becomes a tenanted object. However, when you select the Public Data option in a tenant drop-down, the object becomes a tenanted public object. Users assigned to a role that only exposes a single tenant do not see a tenant drop-down when entering data.

When a user queries the database, the product restricts the results to objects belonging to tenants that the user is authorized to access. As a result, you never see data in tenant required tables except for the data that belongs to tenants that you are permitted to access. If the data is tenanted public data, you can see the data in tenant optional tables because the data is also public data.

When a tenant user asks to create or update a database object, the product verifies that the object belongs to a tenant that the current role for the user can update. The product also verifies that all references from the object to other objects are to public (untenanted) objects, to objects from the same tenant, or to objects from tenants in the tenant hierarchy above the tenant for the object. That is, a tenanted object is allowed to reference objects belonging to its parent tenant, to the parent of the parent, and so on.

If a user who creates an object has update access to multiple tenants, the user must specify the tenant explicitly, either directly or indirectly.

The referenced objects restriction has one exception. Certain references are permitted to reference objects that belong to tenants in the tenant hierarchy of their containing object. These references are designated as SERVICE_PROVIDER_ELIGIBLE in the CA APM object schema. The SERVICE_PROVIDER_ELIGIBLE setting makes a difference only if the service provider tenant is not in the tenant hierarchy above the tenant for the object; if the service provider tenant is in the hierarchy, tenant validation rules permit service provider references.

A service provider user asking to create or update an object is subject to the same restrictions as tenant users, except that service provider users can be authorized to create or update tenanted public objects. The defined role of the service provider user controls this authorization. A service provider user with authorization to multiple tenants who is creating a tenanted object must specify the tenant directly or indirectly.

User Interface Impact

Implementing multi-tenancy changes the user interface, depending on the authorization and tenant access associated with the role for the user.

Tenant Users

A tenant user who is restricted to a single tenant and who is not an administrator has the following user interface changes:

- Any user belonging to more than one tenant can select a tenant in a drop-down list when entering information and when generating a report.

  If you do not want a user to select a tenant when generating a report, you can remove the tenant drop-down list from the report. For more information about removing the tenant drop-down list, see Remove the Tenant Drop-Down List (see page 2430).

- Any user having read access to more than one tenant has a Tenant Name column in search results.

How to Implement Multi-Tenancy

Multi-tenancy is the ability for multiple independent tenants (and their users) to share a single implementation of CA APM. Tenants only interact with each other in defined ways, as specified by their roles and tenant hierarchies. Typically, unless granted access by a role or hierarchy, each tenant views the CA APM implementation as solely for its own use and cannot update or view data for another tenant.

To implement multi-tenancy in CA APM, complete the following steps:

1. Verify that the CA CASM service is started.
2. Verify that the user implementing multi-tenancy is assigned to a role in which multi-tenancy administration access is enabled.
3. Enable multi-tenancy.
4. Define tenants, subtenants, and tenant groups.
5. Restart the CA APM web server and application server.
6. Log in to the product using the privileged username (typically *uapmadmin*) and complete the following steps:
   a. Define user roles with tenant access.
   b. Define contacts, or import and synchronize users.
   c. Authorize users to use the product.
   d. Assign contacts to user roles.
7. Log in to the product using the privileged username and verify that the multi-tenancy restrictions are enforced.

Enable Multi-Tenancy

Enable multi-tenancy so multiple independent tenants (and their users) can share a single implementation of CA APM. Before you enable multi-tenancy, define tenants, subtenants, tenant groups, and create user roles and assign users to roles. As soon as you enable multi-tenancy, multi-tenancy enforcement is enabled. Multi-tenancy enforcement means that when an object is tenant-required, you cannot save a record without meeting the tenant restrictions.

To enable multi-tenancy

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.
2. Click Edit.
3. In the Status drop-down list, select one of the following options:
   - **off**
     Disables multi-tenancy.
   - **on**
     Enables multi-tenancy.
4. In the Maximum Tenant Depth field, specify the maximum depth allowed for a tenant hierarchy.
5. Click Save.
   Multi-tenancy is enabled.
6. Restart the web server and application server.

Tenant, Subtenant, and Tenant Group Administration

Define the tenants, tenant groups, and subtenants to share a single implementation of CA APM. Multi-tenancy allows tenants to share hardware and application support resources, which reduces the cost of both, while gaining many benefits of an independent implementation.

Define a Tenant

You can define as many tenants as required to manage multiple separate enterprises that provide support to clients. Define a tenant before an instance of a tenant-required object can be updated.

The first created tenant, the service provider, is the primary tenant (owner) in a CA APM multi-tenancy implementation. The service provider tenant cannot have a parent tenant. After you define the service provider tenant, log out of the product and log in again as a member of the service provider. We recommend that you log in as the privileged user (uapmadmin), because this user automatically belongs to the service provider tenant.

To define a tenant

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.

2. On the left, click Tenant.

   The Tenants page appears.

3. Click Create Tenant.
   The Create New Tenant page appears.

4. Enter the tenant information. The following fields require explanation:

   - **Tenant Number**
     (Information Only) Displays the tenant number. CA APM does not use this field.

   - **Record Status**
     Sets the tenant to active or inactive. After you define the service provider tenant, this option is read-only for the tenant.

   - **Terms of Usage**
     (Information Only) Displays the terms of usage statement for the tenant. CA APM does not use this field.

   - **Parent Tenant**
     Specifies another tenant above this tenant, making this tenant a *subtenant* in a tenant hierarchy.

   - **Subtenants Allowed**
     Allows this tenant to have subtenants. The tenant cannot modify the setting.

   - **Tenant Depth**
     (Information Only) Indicates the tenant depth of this tenant.

   - **Logo**
     (Information Only) Displays the URL for an image file that contains the logo for the tenant, which can be any web image type. CA APM does not use this field.

   - **Contact**
     Displays the Contact lookup page.

   - **Location**
     Displays the Location lookup page.

5. Click Save.
   The tenant is defined.

Update a Tenant

When necessary, you can update the information for an existing tenant.

To update a tenant

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.

2. On the left, click Tenant.
   The Tenants page appears.

3. Search to find the tenant that you want to update.
   All tenants matching the search criteria appear in the Tenant List.

4. Click the tenant that you want to update.
   The tenant information appears.

5. Click Edit.

6. Enter the new information for the tenant.

7. Click Save.
   The tenant is updated.

Make a Tenant Active

When users must see and enter information for a particular tenant that is inactive, you can make the tenant active. For example, the service provider did not receive payment for services provided to a particular tenant. Based on the service agreement, the service provider makes the tenant inactive and stops offering services until payment is made. After the tenant provides payment for the services, the service provider makes the tenant active.

To make a tenant active

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.

2. On the left, click Tenant.
   The Tenants page appears.

3. Search to find the tenant that you want to make active.
   All tenants matching the search criteria appear in the Tenant List.

4. Click the tenant that you want to make active.
   The tenant information appears.

5. Click Edit.

6. In the Record Status drop-down list, select Active.

7. Click Save.
   The tenant is active.

How to Initialize a New Tenant

As the service provider, you can define a standard set of data for a new tenant, such as cost centers, cost types, and departments. For information about how to import data for tenants, see Import Data (see page 1622).

Define a Tenant Group

You can define a tenant group to classify, manage, and control access to tenants. For example, you can assign asset managers to a tenant group containing tenants belonging to a particular geographic location.

To define a tenant group

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.

2. On the left, click Tenant Group.
   The Tenant Groups page appears.

3. Click Create Tenant Group.
   The New Tenant Group Detail page appears.

4. Enter the tenant group information.

5. Click Save.
   The tenant group is defined.

6. Click Assign Tenants.
   The Tenant Search page appears.

7. Search and select the tenant that you want to add to the group.
   The tenant is added to the group.

Update a Tenant Group

You can update a tenant group to manage the group members and detail information.

To update a tenant group

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.

2. On the left, click Tenant Group.
   The Tenant Groups page appears.

3. Search to find the tenant group that you want to update.
   All tenant groups matching the search criteria appear in the Tenant Group List.

4. Click the tenant group in the list.
   The Tenant Group Detail page appears.

5. Click Edit.

6. Enter the new information for the tenant group.

7. (Optional) Click Assign Tenants to add a tenant to the group.

   Adding or removing a tenant also adds or removes the subtenants of that tenant.

8. Click Save.
   The tenant group is updated.

Tenant Hierarchies

A *tenant hierarchy* is a structured tenant group that is system-created or modified when you assign a parent tenant to a tenant. The tenant becomes a subtenant of the parent and higher tenants (if any) in that hierarchy.

The service provider can create multiple unrelated hierarchies, or none. Even in a system with tenant hierarchies, you can define standalone tenants.

CA APM supports a tenant hierarchy of unlimited depth. However, the service provider can specify a limit on the total number of tenants and the depth of tenant hierarchies (default is four levels). The service provider also determines whether individual tenants can have subtenants.

Note: Although not required, the service provider can participate in tenant hierarchies. The service provider cannot have a parent tenant.

Define a Subtenant

Subtenancy allows you to define and modify tenant hierarchies for organizational and data-sharing purposes. To place a tenant into a tenant hierarchy, you specify a parent tenant for the tenant.

To define a subtenant

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.

2. On the left, click Tenant.
   The Tenants page appears.

3. Click Create Tenant.
   The Create New Tenant page appears.

4. Enter the subtenant information. The following fields require explanation:

- **Parent Tenant**
  Specifies another tenant above this tenant, making this tenant a *subtenant* in a tenant hierarchy.

The Parent Tenant drop-down only displays tenants that are allowed to have subtenants.

5. Click Save.
   The tenant is a subtenant of the parent tenant.
   Note: When a tenant becomes a subtenant, the tenant belongs to the subtenant group of the parent tenant, in addition to its other subtenants (if any), and so on. The parent tenant joins the supertenant group of its new subtenant, in addition to its other supertenants (if any), and so on. Each joins the related tenants group of the other.

Update a Subtenant

When necessary, you can update the information for an existing subtenant.

To update a subtenant

1. Click Administration, Tenancy Management.
   The Multi-Tenancy Administration page appears.
2. On the left, click Tenant.
   The Tenants page appears.
3. Search to find the tenant that you want to update.
   All tenants matching the search criteria appear in the Tenant List.
4. Click the tenant in the list. The subtenant name appears in the Name column of the Tenant List.
   The tenant information appears.
5. Click Edit.
6. Enter the new information for the subtenant.
7. Click Save.
   The subtenant is updated.

Product-Maintained Tenant Groups

The product generates and maintains the following tenant groups automatically for each tenant in a tenant hierarchy (*tenant* is the tenant name):

- *tenant*_subtenants (tenant, its *child* tenants, and their lower subtenants)
- *tenant*_supertenants (tenant, parent tenant and its higher supertenants)

- *tenant*_relatedtenants (entire single hierarchy)

System-maintained groups can be used like user-defined tenant groups. However, only the name and description can be modified.

How to Secure CA APM Data with Filters

You can set up CA APM data security by creating data filters. You use the data filters to limit the data that users and user roles can view, create, or modify. Users can view, create, or modify only the data that the filter specifies. You can create filters for any of the primary objects:

- Asset
- Model
- Legal Document
- Contact
- Company
- Location
- Organization
- Site

You cannot create a filter for a secondary object that is included in List Management. For example, you can filter assets (primary object) based on the cost center (secondary object) so that you only see assets that belong to a specific cost center. However, all cost centers are still accessible. To restrict access to cost centers (or other secondary objects), assign the user to a configuration that does not allow access to these objects.

As a system administrator, you define filters that limit data access in the following ways:

- Limit data based on the current user (contact).
  For example, define a filter that limits assets by the cost center of the contact. If you apply the filter to all users, the assets dynamically filter based on each user cost center. If the contact cost center is changed, the product filters the assets for the new cost center automatically.

- Limit data based on fixed values.
  For example, allow a user to view assets in the Development cost center. Development is a fixed value. If the cost center changes, the cost center is not automatically changed in the filter.

The data that matches the filter criteria is accessible to filter users.

Note: You can also set up CA APM security by configuring the user interface. Through this configuration, you can control user access to the different functions in CA APM.

In this scenario, the system administrator defines the filters. However, the administrator can grant filter management permissions to any CA APM user role.

To filter CA APM data, perform these steps:

1. Review the Prerequisites (see page 1617).
2. Define and Apply a Filter (see page 1617).
3. Verify the Filter (see page 1620).

Example: Filter Asset Data by Cost Center

Sam, the CA APM system administrator at Document Management Company, wants to ensure that organizational data security requirements are met. Sam wants to limit user access to the company asset records so that users see only their own cost center data. Sam creates a filter for Asset (All Families) and assigns the filter to particular users. Sam verifies that the filter works to ensure the organizational data security.

Review the Prerequisites

To ensure that you can successfully filter data, verify that you have completed the following prerequisites:

1. Identify the product data that you want to limit by user or role.
2. Identify the users and roles that have limited data access.

Define and Apply a Filter

Define a filter and assign the filter to a role, a user, or a combination of roles and users. The product displays only the data that the user is authorized to access.

Follow these steps:

1. Click Administration, Filter Management.
2. On the left, click New Filter.
3. In the Filter Information area, enter the required and optional (if needed) information. The following fields require explanation:

   - **Object**
     Specifies the object data that you want to filter. The object that you select determines the fields that you can use as criteria in the Filter Criteria area.

If you select Model or Asset, select a family, also. If you select Legal Document, select a template, also. The filter is applied to objects that belong to the family or template that you select. For example, a filter for the hardware asset object does not apply to any other asset family.

You cannot change the object or the object family or template after you specify filter criteria or after you save the filter. Delete the filter criteria to change the object.

- **Family or Legal Template**
  Specifies the family for the Model or Asset object or specifies the template for the Legal Document object.

4. In the Filter Security area, enter information for role or user security.

   If you save your filter without selecting a user or role in the Filter Security area, your filter is not applied to any users.

5. In the Filter Criteria area, click Add Fields.

6. Select a field from the dialog and click OK.
   The criterion is shown in the Filter Criteria list.

7. Click the Edit Record icon next to the criterion you added.

8. Enter information to define the filter criterion for a selected field. The following fields require explanation:

   - **Left Parenthesis**
     Specifies the first criterion in a group of criteria. You can define groups of criteria to control the logic of the filter.

     If you select Left Parenthesis to define the first criterion in a group, select Right Parenthesis for the last criterion in the group.

     For example, you can filter for assets with the asset name OE001 or with both the asset family Computer and the asset name Dell. In this example, the group consists of two criteria. The Left Parenthesis is selected for the first criterion, which states that the asset family is Computer. The Right Parenthesis is selected for the second criterion, which states that the asset name is Dell.

   - **Field Name**
     Specifies the field data that is filtered.

- **Operator**
  Specifies the filter operator to use to filter object data. For all operators except Has Value and Has No Value, enter a value in the Value field.
  For example, you can filter assets in which the asset name is not equal to OE001 and the asset family is equal to Computer.

  If you specify an Operator and Value, the filter limits data based on a fixed value for the Field Name. In this type of filter, the Use Contact's Value field is not applicable.

- **Use Contact's Value**
  Specifies that the filter uses the Field Name value that is associated with the current user. For example, if you select this check box and you select cost center for Field Name, the users can access product data for their cost centers only. If you apply the filter to all users in the product, the data dynamically filters based on each user cost center. If the cost center changes, the product filters the data for the new cost center automatically.

  If you select this check box, the filter limits data based on the Field Name value that is associated with the current user. In this type of filter, the Operator and Value fields are not applicable.

- **Right Parenthesis**
  Specifies the last criterion in a group of criteria. You can define groups of criteria to control the logic of the filter.

  If you select Right Parenthesis to define the last criterion in a group, select Left Parenthesis for the first criterion in the group.

  For example, you can filter for assets with the asset name OE001 or with both the asset family Computer and the asset name Dell. In this example, the group consists of two criteria. The Left Parenthesis is selected for the first criterion, which states that the asset family is Computer. The Right Parenthesis is selected for the second criterion, which states that the asset name is Dell.

- **Connector**
  Specifies the connector between a set of two criteria:

  - And - Filters the data if the current criterion and the next criterion in the list are valid.
  - Or - Filters the data if either the current criterion or the next criterion in the list is valid.

  For example, you can filter for assets with an asset family of Computer and an asset name of Dell.

- **Value**
  Specifies the field value that you want to filter. If you specify a value, select an Operator in the Operator field. If a Search icon appears next to this field, you can also select a value by clicking the Search icon.
  For example, you can filter an asset with an asset name of OE001.

  If you specify an Operator and Value, the filter limits data based on a fixed value for the Field Name. In this type of filter, the Use Contact's Value field is not applicable.

9. Click the Complete Record Edit icon.
10. (Optional) Click Add Fields to define more filter criteria.
11. Click Save after you have completed all filter criteria.
    The filter is defined and applied to users and roles. The data that matches the filter criteria is accessible to filter users.

Example: Filter Asset Data by User Cost Center

As the system administrator, Sam defines a filter that restricts users to the asset data for their own cost centers. To define this filter, Sam makes the following selections:

1. In the Filter Information area, Sam selects Asset in the Object field and (All Families) in the Family field.
2. In the Filter Security area, Sam selects the users who are associated with the filter.
3. In the Filter Criteria area, Sam creates a criterion by performing these steps:
   a. Sam selects Cost Center in the Field Name field.
   b. Sam selects the Use Contact's Value check box.
4. Sam saves the filter.

Verify the Filter

Verify that your filter works to ensure the security of your organizational data.

Follow these steps:

1. Log in to the product as a user who was assigned to the filter.
2. View some of the data that the filter allows for the user.

3. Attempt to view some of the data that the filter does not allow for the user.
   For example, log in as another user who has access to data that is not allowed for the filter user. Copy the URL for a page that displays some data that the filter user cannot access. Paste the URL in the browser of the filter user.
   An error message appears.

4. Attempt to modify some of the data that the filter does not allow for the user.
   For example, identify a text entry field on a page. Enter data that the user cannot access (such as a specific company name that the filter does not allow) and click Save.
   An error message appears.

Example: Verify that the Data Filter Limits Asset Data

Sam created a filter for Asset (All Families) data and assigned the filter to a particular user. With the filter, the user can access only the assets that are in the user cost center. Sam then performs these steps to verify that the filter works:

1. Logs in as the assigned user and validates that assets are available on the Asset Search page.

2. Logs in as a second user with access to assets that are outside of the first user cost center.

3. Views an asset that is outside of the first user cost center and copies the URL of the asset.

4. Logs in as the first user (who was assigned the filter) and pastes the copied asset URL in the browser.
   An error message states that the asset does not exist.

How to Delete Unused Files from CA APM

The files that you use while working with the product are stored on the CA APM application server where the Storage Manager Service is installed. These files include attachment files and Data Importer source data files and legacy map files.

When you delete an attachment, you delete only the reference to the attachment in the object record. If the deleted attachment is a file, the file remains in the file system on the CA APM application server. In similar fashion, when you delete an import that uses a specific data file, you do not delete the data file from the CA APM server.

If a specific attachment file, import data file, or legacy map file is no longer needed, you can delete the file from the CA APM server. Before you delete the file, verify that the file does not have any associations.

To delete unused files, perform these steps:

1. Review the Prerequisites (see page 1622).

2. Query the CA MDB (see page 1622).

3. Locate and Delete the Unused Files (see page 1622).

Review the Prerequisites

To ensure that you can successfully delete the unused files, identify the names of the unused files that you want to delete.

Query the CA MDB

If a specific attachment file, import data file, or legacy map file is no longer needed, you can delete the file from the CA APM application server. Before you delete the file, verify that the file does not have any associations in CA APM (for example, a file attached to a legal document or an import data file associated with a data import).

Follow these steps:

1. Access the CA MDB that is associated with your CA APM installation.

2. Query the al_file_storage table to search for the file name and the associated tenant if applicable. The following statement is an example query:

   ```
   select COUNT(0) from al_file_storage where attachment_url = 'filename.txt'
   ```

   If no records are returned, no records are associated with the specified file name. You can delete the file.

Locate and Delete the Unused Files

After you verify that the files do not have any associations in CA APM, you can locate and delete the files.

Follow these steps:

1. On the CA APM application server where the Storage Manager Service is installed, navigate to one of the following locations, depending on whether you are using multi-tenancy:

   ```
   [ITAM Root Path]/Storage/Common Store/Attachments
   [ITAM Root Path]/Storage/Tenant_Name/Attachments
   [ITAM Root Path]/Storage/Common Store/Import
   [ITAM Root Path]/Storage/Tenant_Name/Import
   ```

2. Locate and delete the unused files.

Import Data

This section contains the following articles:

How to Delete Data with the Data Importer

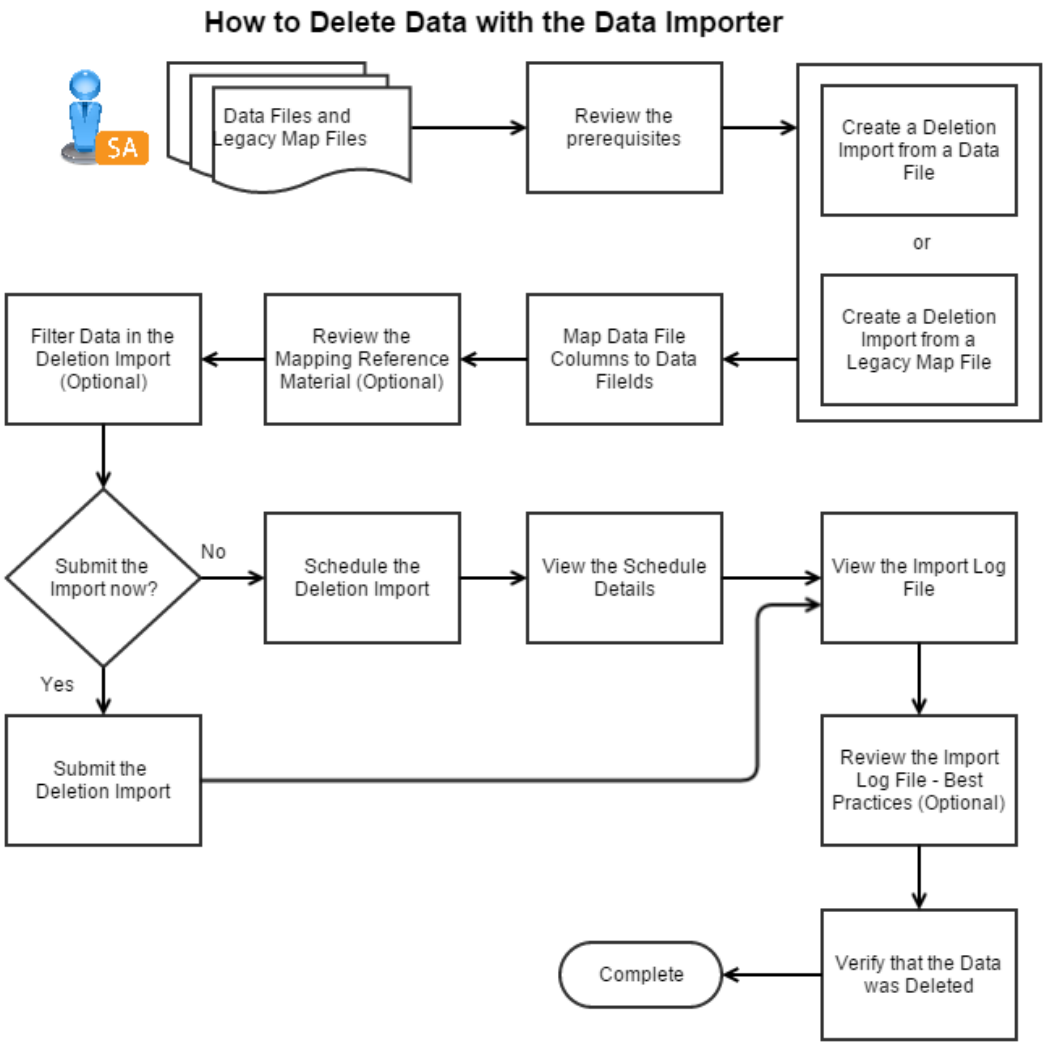
When data is no longer valid for your implementation, delete the data from CA APM using the Data Importer. In most situations, however, it is considered good IT asset management practice to keep the data in the repository with a status of inactive. This method allows you to access the data for historical and audit purposes. However, in some cases, the data was created by mistake. In these cases, you want to delete the data.

In this scenario, the system administrator performs the data deletion. However, the administrator can grant Data Importer User Access or Data Importer Admin Access to any CA APM user role. User access allows users to create imports, modify or delete their own imports, and view any import that was created by another user. Admin access allows users to create imports and modify or delete any import that was created by any user.

You can delete primary objects and can remove the relationships to their secondary objects. For example, you delete an asset (primary object) and you remove its relationship to a legal document (secondary object).

When you delete a primary object and its relationship to a secondary object, the secondary object is not deleted. The primary object is deleted, and the relationship between the primary and secondary object is removed. For example, if you delete an asset and its associated legal document relationship, the asset is deleted but the legal document is not deleted. Only the relationship between the asset and the legal document is removed.

The following diagram illustrates how a system administrator deletes data.



To delete CA APM data, perform these steps:

1. Review the Prerequisites. (see page 1625)
2. Create a Deletion Import from a Data File (see page 1626) or Create a Deletion Import from a Legacy Map File (see page 1629).
3. Map Data File Columns to Data Fields. (see page 1631)
4. Review the Mapping Reference Material. (see page 1650)
   - Primary and Secondary Lookup Combinations (see page 1650)
   - Hard-Coded Values (see page 1652)
   - Multiple Values for a Single Field (see page 1653)
5. Filter Data in the Deletion Import (see page 1635).

6. Submit the Deletion Import (see page 1636) or Schedule the Deletion Import (see page 1637).
7. View the Schedule Details (see page 1656).
8. View the Import Log File. (see page 1657)
9. Review the Import Log File - Best Practices (see page 1657).
10. Verify that the Data was Deleted (see page 1640).

Example: Delete Laptops

Miriam, the CA APM system administrator at Document Management Company, wants to delete several laptops that have been retired and recycled. Miriam also wants to delete the associations with legal documents that were made for these laptops. Miriam has a data file that identifies the laptop names, the manufacturers, and the model names. Using the Data Importer and the source data file, Miriam creates a deletion import. After Miriam runs the import, she views the import statistics, import log file, and user interface to verify the deletions.

Review the Prerequisites

To ensure that you can successfully delete the data, verify that you have completed the following tasks:

- Prepare a source data file in delimited text format (for example, tab or comma) containing the data that you want to delete.
  We recommend that you include the main destination object in the name of the source data file. This file naming convention helps you locate your data files when you create your import.

  A value of NULL in your source data file clears the corresponding destination field value. An empty field in your source data file leaves the corresponding destination field value unchanged.

  If a data value in your source data file contains the selected delimiter, you must use double quotation marks around the data value. For example, you select a comma as the delimiter to import companies. You want to include the data value Document Management Company, Inc. in your source data file. Specify this data value with double quotation marks: "Document Management Company, Inc".

- (Optional) Copy your source data files from your local server to one of the following locations. You can access these locations on the CA APM application server where the Storage Manager Service is installed. The location depends on whether you are using multi-tenancy.

  ```
  [ITAM Root Path]\Storage\Common Store\Import

  [ITAM Root Path]\Storage\Tenant_Name\Import
  ```

If you copy the data file before you create an import, you can then specify the file name when you create the import. If you do not copy the data file first, you can upload the file from your local server when you create the import.

- (Optional) Copy your legacy map files from a previous product release (if you have these files) from your local server to one of the following locations. You can access these locations on the CA APM application server where the Storage Manager Service is installed. The location depends on whether you are using multi-tenancy.

```
[ITAM Root Path]\Storage\Common Store\Import

[ITAM Root Path]\Storage\Tenant_Name\Import
```

Create a Deletion Import from a Data File

You can delete data using a source data file (delimited text file) that contains the data that you want to delete. You select the file, configure the import parameters, and specify the delimiter (for example, a comma) that separates the data in the file.

You can also create a deletion import using a legacy map file from a previous product release. For more information, see creating a deletion import from a legacy map file (see page 1629).

Follow these steps:

1. Log in to CA APM as the administrator.

   In this scenario, the system administrator performs the deletion import. However, the administrator can grant Data Importer User Access or Data Importer Admin Access to any CA APM user role. User access allows users to create imports, modify or delete their own imports, and view any import that was created by another user. Admin access allows users to create imports and modify or delete any import that was created by any user.

2. Click Administration, Data Importer.

3. Click New Import.

4. Enter the required information in the Basic Information area and supply optional information as needed. The following fields require explanation:

   - **Data File**
     Specifies the source data file.
     If this file is available on the CA APM application server, search for the data file and select the file. If this file is not available on the application server, upload the file.

   - **Upload File**
     Browse on your local server for a source data file or a legacy map file that you want to use to create mappings. This file is uploaded to the CA APM application server.

Note: The file size is limited by the product environmental settings. For more information, contact your administrator.

- **Main Destination Object**
  Specifies the main object for the deletion import.
  Asset and Model objects are listed with their corresponding families. You can also specify All Families. Legal Document objects are listed according to legal template. You can also specify All Templates. The objects include all objects that can be imported or deleted.

  For assets or models that include multiple asset family types or legal documents that include multiple legal templates, use the following selections for this field. Specify the particular family or template for each record in your source data file.

  - For an asset, select Asset (All Families).
  - For a model, select Model (All Families).
  - For a legal document, select Legal Document (All Templates).

  Ensure that you select the correct main destination object. You cannot change the main destination object after you save or copy an import.

- **First Row Has Column Names**
  Specifies whether the first row in the source data file contains the column names. If the first row does not contain the column names, the names display as generic names, such as Field 1 and Field 2.

- **Tenant**
  Specifies the tenant that applies to the import (if you are using multi-tenancy).
  You can select a tenant only when multi-tenancy is enabled in CA APM and you are authorized to access different tenants. If you have access to public data and you have multiple tenants, you can select all tenants.
  If you specify all tenants, your source data file must have a tenant name column that you map to the Tenant Name field.

  If you specify one tenant, verify that all data in your source data file belongs to your selected tenant. If you have data for more than one tenant, data for all tenants is applied to the selected tenant.

- **Data Delimiter**
  Specifies the delimiter (for example, comma or tab) that you used in the source data file.

If a data value in your source data file contains the selected delimiter, you must use double quotation marks around the data value. For example, you select a comma as the delimiter to import companies. You want to include the data value Document Management Company, Inc. in your source data file. Specify this data value with double quotation marks: "Document Management Company, Inc".

- **Data File Locale**
  Specifies the locale for the source data file. This setting determines the date and time format.

5. Enter the required information in the Advanced Settings area and supply optional information as needed.
   The following fields require explanation:

   - **Maximum Error Threshold (in %)**
     Defines the number of errors after which the import stops. The threshold is based on the percentage of records processed. We recommend a minimum threshold of 15 percent.

     The Data Importer processes the number of records that are specified on Administration, System Configuration, Data Importer (Maximum Batch Record Size field) before calculating if the error threshold has been reached.

   - **Primary Lookup Object Processing Type**
     Specifies the type of import activity. Select one of the following options:

     - **Delete Primary Objects and Associated Relationships**
       Select this option to delete primary objects and the relationships to their associated secondary objects. For example, you delete a company (primary object) and you remove the relationship to an associated asset allocation (secondary object).
       When you select this option, verify that your mapping rules specify the primary objects only. Do not include any mapping rules for secondary objects.
       Note: The secondary object that is associated with a primary object is not deleted. The relationship between the primary object and the secondary object is removed. For example, you have a primary object Company1 with an associated acquired company Company2 (secondary object). When you delete Company1, the relationship to Company2 is removed. The secondary object Company2 is not deleted.

     - **Delete Relationships Only**
       Select this option to remove the relationships between secondary objects and their primary objects. When you select this option, verify that your mapping rules specify the primary and secondary objects only. You include a mapping rule for a secondary object; however, do not select the Primary Lookup check box for this rule.
       Note: A secondary object that is associated with a primary object is not deleted. The relationship between the primary and secondary object is removed.

   - **Normalization Behavior**
     Specifies whether to normalize the data or write an error message in the log file without normalizing the data.

This field appears only if you have defined normalization rules.

- **Error on Normalization**
  Writes an error message to the Data Importer log file when data that can be normalized is found in the data that you are deleting. The data involved is not deleted. The log file error message includes the details about the data.
  For example, your data includes the company name Microsoft. The company normalization rules that you created identify Microsoft as a collected (nonauthoritative) value and specify Microsoft Corporation as the normalized (authoritative) value. If you select this option when deleting your data, the object with the company name Microsoft is not deleted and an error message is written to the log file.

- **Apply Normalization without Error**
  Uses the normalization rules to normalize the data that you are deleting. If data that can be normalized is found, the data is normalized and deleted. No error message about the data is written to the log file.
  For example, your data includes the company name Microsoft. The company normalization rules you created identify Microsoft as a collected (nonauthoritative) value and specify Microsoft Corporation as the normalized (authoritative) value. If you select this option when deleting your data, the object with company name Microsoft is normalized. In this example, the company name is changed to Microsoft Corporation and the associated object is deleted.

6. Click Save.
   The deletion import is saved. The Mapping, Exclusion Filter, and Schedule areas of the page are now available for your input.

Example: Create a Deletion Import from a Data File

Miriam, the CA APM system administrator, performs the following actions to create the deletion import:

1. Navigates to Administration, Data Importer and clicks New Import.

2. Enters Hardware Deletions.csv in the Data File field.
   This CSV file is the source data file that contains the laptop deletions.

3. Selects Asset (Hardware) for the Main Destination Object and comma for the Data Delimiter.

4. Selects Delete Primary Objects and Associated Relationships in the Primary Lookup Object Processing Type field and clicks Save.

Create a Deletion Import from a Legacy Map File

You can create a deletion import using a legacy map file from a previous CA APM release. The map file defines the corresponding data file and the import parameter settings.

Note: We recommend that you copy your legacy map files and corresponding data files to the CA APM application server before you create the deletion imports. However, if necessary, you can use the optional steps to upload a legacy map file.

You can also create a deletion import using a data file only. For more information, see creating a deletion import from a data file (see page 1626).

Follow these steps:

1. Click Administration, Data Importer, New Import.
2. Click Search and Load Map to select a legacy map file that is already available on the CA APM application server.

   The corresponding data file must also be available on the CA APM application server.

   If the legacy map file is not available on the CA APM application server, upload the file using the Upload File field.
3. (Optional) Upload a legacy map file that is not available on the CA APM application server using the following steps:

   a. In the Upload File field, browse on your local server and select a legacy map file.
   The legacy map file is uploaded and is displayed in the Upload File field.

   b. Click Search and Load Map and select the legacy map file that you uploaded.
   The legacy map file is displayed in the Legacy Map File field.
   The Basic Information is loaded.

   Note: If you receive a warning about the source data file, upload the data file using the Upload File field.
4. Specify the Advanced Settings and click Save.
   The Exclusion Filter and Mapping data mapping are loaded. The Mapping, Exclusion Filter, and Schedule areas of the page are now available for your input. The Mapping and Exclusion Filter areas display the data from the legacy map file.

   Note: For information about specifying the Advanced Settings, see creating a deletion import from a data file (see page 1626).

Map Data File Columns to Data Fields

You can map the columns in your source data file to product fields. You perform column mapping to specify which data is deleted. You can select most objects and associated fields as destination fields during column mapping.

> If you created your deletion import from a legacy map file, the column mapping exists. You can edit the existing mapping rules if you want to change the values. You can also add new mapping rules.

When you log in, the user role that your administrator assigned to you determines the objects and fields that you can see and use. If your role specifies that you do not have permissions for an object field, the field is not available for a mapping. You can only create a mapping and import or delete data for the objects and fields for which you have permissions.

Follow these steps:

1. On the Administration tab, Data Importer page, in the Mapping area for a selected deletion import, click New or click Load Source Fields.
   - New allows you to select the source fields individually from the source data file.
   - Load Source Fields adds all source fields from the source data file.

   > If you have existing mappings, Load Source Fields allows you to replace those mappings with the source fields in the source data file. This option also allows you to add the source fields from the source data file that you do not already have in your mappings.

   a. If you clicked Load Source Fields, click the Edit Record icon next to a field.

2. Click the Select icon next to Source Field (if this field is empty), select a column from your data source, and click OK.
   If this field already contains a source field (because you loaded all source fields), you can skip this step.

3. Click the Select icon next to Destination Field, select a Destination Field for the selected Source Field, and click OK.
   The destination fields that appear are based on your selected main destination object.

   >

> The destination fields display in hierarchical order. For example, the fields that are listed under Asset Type Hierarchy are Asset Family, Class, and Subclass. The order of the fields represents the field hierarchy. Follow the field hierarchy when you specify mapping rules. For example, for Asset Type Hierarchy, specify a rule for Class before you specify Subclass.

4. Select the Primary Lookup and Secondary Lookup check boxes as required.

    a. Select a Primary Lookup check box for each destination field that you want to use to find the primary object. Use the following guidelines when selecting this check box:

    - Select at least one Primary Lookup check box in the column mapping for an import.
    - Do not select this check box if the Destination Field is Note Text (under the Note object). The database data type for the Note Text field does not allow it to function as a lookup field.

    b. Select a Secondary Lookup check box for each destination field that you want to use to find the secondary object. Use the following guidelines when selecting this check box:

    - Do not select this check box if the destination field is not one of your lookup fields for the secondary object.
    - Do not select this check box if the Destination Field is Note Text (under the Note object). The database data type for the Note Text field does not allow it to function as a lookup field.

5. Click the Complete Record Edit icon.

6. (Optional) Click New again, or click the Edit Record icon next to another source field, to specify more mapping rules.

> ⚠ To delete a specific mapping rule from the list of mapped columns, click the Delete icon next to the mapping rule. The column mapping rule is removed from the list.

7. Click Save.
   Your column mapping is saved.

Example: Map Data File Columns to Data Fields

Miriam performs the following steps to map the columns in the source data file to the CA APM data fields:

1. Clicks New in the Mapping area of the Import Details page.

2. Selects %Hardware Name% in the Source Field by clicking the Select icon next to Source Field and selecting this item from the dialog.
   The items that are listed in the dialog are the columns from the source data file.

3. Selects Asset Name in the Destination Field by clicking the Select icon next to Destination Field and selecting this object from the dialog.

4. Selects the Primary Lookup check box.

5. Clicks the Complete Record Edit icon and clicks Save.

Review the Mapping Reference Material

Reference the following information when setting up the column mapping for importing or deleting data.

Primary and Secondary Lookup Combinations

The fields that you select as the primary and secondary lookup in your column mapping are used to search for data in the product database.

- **Simple mapping**
  In simple mapping, you specify only the primary lookup. For example, you are importing or deleting a set of company records from a text file into the product database. You specify the Company Name as the primary lookup. If a company with a particular name does not exist in the database when you are importing data, a record is created for the company. The following table shows an example of the lookup for a simple mapping.

Source Field	Destination Field	Primary Lookup	Secondary Lookup
%Company Name%	Company.Company Name	Yes	No

- **Reference field mapping**
  In reference field mapping, you specify primary and secondary lookup values. To search for a unique object, specify more than one primary lookup. For example, to search for a company, you can specify Company Name, Parent Company, and Company Type as primary lookup values. In this example, the Data Importer searches for a company with the specified name, the specified parent company, and of the specified company type. If the object does not exist and you are importing data, the record is created (depending on the insert or update option you selected in Advanced Settings). The following table shows an example of the lookup for reference field mapping.

Source Field	Destination Field	Primary Lookup	Secondary Lookup
%Company Name%	Company.Company Name	Yes	No
%Parent Company%	Company.Parent Company.Company Name	Yes	Yes
%Company Type%	Company.Company Type.Value	Yes	Yes

This mapping has both the Primary Lookup and the Secondary Lookup check boxes selected for Parent Company and Company Type. The Data Importer uses the Company Name to look up the parent company and uses the Parent Company to look up the company name.

- **Secondary object mapping**
  If a mapping rule maps to a secondary object property, the primary lookup values establish a relationship between a secondary object and the reference fields. The following table shows examples of the lookup for a secondary object mapping.

Source Field	Destination Field	Primary Lookup	Secondary Lookup
%Comment%	Legal Document.Legal Party.Comment	No	Yes
%Legal Document ID%	Legal Document.Document Identifier	Yes	No
%Company Name%	Legal Document.Legal Party.Legal Party. Company Name	Yes	Yes
%Legal Template%	Legal Document.Legal Template.Template	Yes	Yes

In the first mapping rule, Legal Document is the primary object, and Legal Party is the secondary object. Comment is a property of Legal Party.

In the third mapping rule, Legal Document is the primary object, and Legal Party is the secondary object. In addition, Legal Party has a reference field in the Company table. The Secondary Lookup check box indicates that the Company Name is used to look up the Company object. The Primary Lookup check box indicates that the Company object is used to look up the Legal Party object.

Hard-Coded Values

In the column mapping, the percent signs that appear before and after column names identify the names as column headers in your source data file. You can also specify a hard-coded value in the Source Field that you want to apply to all records in your source data file. You can then map the hard-coded value to a Destination Field. The hard-coded values do not display with percent signs to distinguish these values from the source data file column names.

1. Source data file column header
2. Hard-coded value

You can define a hard-coded value in the Source Field to expand your source data and to ensure that you include all required fields. Hard-coded values typically do not begin and end with a percent sign (%). If you have hard-coded values with percent signs, the values cannot match the field names in your source data file.

Example: Use hard-coded values for asset family

In this example, the assets in your source data file do not contain asset family, which is required when creating an asset. You can add a hard-coded value to your mapping. If all of your assets are hardware, you can enter Hardware in the Source Field. You can map this value to the Asset Family field. If your assets belong to different families, add a column to your source data file with the corresponding asset families before importing or deleting data.

The following information illustrates the difference between values from your source data file and values that are added through hard-coded values:

- You have an Asset Family column in your source data file. The selection in the Source Field is %asset family%.
- You do not have an Asset Family column in your source data file. However, all of your assets are hardware assets. You specify a hard-coded value of Hardware in the Source Field.

You can also use the Main Destination Object to specify that all records in your source data file belong to a particular family or template. For example, the Asset (Hardware) selection for Main Destination Object specifies that all source records belong to the hardware asset family.

Multiple Values for a Single Field

You can add a mapping with multiple Source Field values that are mapped to a single Destination Field.

Example: Use multiple values for a single field

Your source data file has two columns with the names Manufacturer and Catalog Name. Combine these columns by selecting both in the Source Field. In this example, the Source Field selection is %Manufacturer% %Catalog Name%.

You can also enter multiple hard-coded values in the Source Field (for example, Document Management Company %model name% IT Department).

Filter Data in the Deletion Import

You can identify a subset of records in your source data file that you want to exclude from the deletion import. The Data Importer exclusion filter allows you to filter a part of your data source using exclusion filter rules.

Example: Define an exclusion filter to process returned assets

A CSV file that you receive from your hardware vendor includes assets that were ordered and returned to the vendor. You want to delete the assets that were returned to the vendor, so you want to process those records only. You define an exclusion filter to exclude records that do not have a status of Returned.

Follow these steps:

1. On the Administration tab, Data Importer page, Exclusion Filter area for a selected deletion import, select the Filter Type.

- **And**
  Excludes a record from the source data file only if all the rules that you specify are valid for the record.

- **Or**
  Excludes a record from the source data file if any of the rules that you specify is valid for the record.

2. Click New.

3. Click the Select icon next to Source Field, select a column from your source data file, and click OK.

   The percent signs before and after the column name identify the name as a column from your source data file.

4. Select the Operator.

   To specify "not equal to", select the "<>" operator.

5. Enter a Filter Value for the rule.

   You can use special characters and wildcards in the filter value. The rules can process text, numeric, and date fields.

6. Click the Complete Record Edit icon.

7. (Optional) Click New and specify more exclusion filter rules.

8. Click Save.
   The exclusion filter rules are saved and are applied when the deletion import processes.

Submit the Deletion Import

To start a deletion import immediately, click Submit in the Schedule area of the page. The data source records from the data file for the selected deletion import are processed.

You can specify a data file other than the default (from the Basic Information) if you want to use a different file.

You can also schedule the deletion import for a particular day and time. For more information, see schedule the deletion import (see page 1637).

To view the import jobs for your current selected deletion import, click Associated Jobs on the left side of the page. To view all import jobs for all imports, click Import Jobs. In the list of import jobs that appears, click Status Message to view the status of an import.

You can also view the log file for more information about the import activity. In the list of import jobs, click View Logs for the selected import.

Schedule the Deletion Import

You can schedule a deletion import for a specific time and you can specify the interval for the deletion import (for example, daily or weekly). You can schedule multiple deletion imports to process simultaneously.

Follow these steps:

1. On the Administration tab, Data Importer page, in the Schedule area for a selected deletion import, select the Is Scheduled check box.

2. Provide the information for the schedule. The following fields require explanation:

   - **Run Time**
     Specifies the time of the day, in 24-hour format, to process the deletion import. When you schedule imports, use the local time zone on the CA APM application server.

   - **Interval Day**
     Specifies the day during the Interval Type to process the deletion import. For example, if the Interval Type is Month and the Interval Day is 1, the import is processed on the first day of the month.

   - **Data File**
     Specifies a data file name other than the default (from the Basic Information) if you want to use a different file.
     If this file is available on the application server, you can search and select the file. If this file is not available on the application server, you can locate and upload the file.

   - **Upload Data File**
     Browse for the source data file. This file is uploaded to the application server.

   - **First Run Date**
     Specifies the date when the first deletion import starts to process.

   - **Interval Type**
     Specifies the type of interval for the deletion import (for example, Day, Month, Quarter, Week, or Year).

   - **Interval**
     Specifies how often the deletion import processes. This interval is based on the specified Interval Type. For example, if the Interval Type is Weekly and the Interval is 2, the import processes every two weeks.

- **Last Day of Interval**
  Specifies that the deletion import processes on the last day of the selected Interval Type. If you select this check box, any previous value that you added to the Interval Day field is removed, and the Interval Day field is disabled.

3. Click Submit.
   The deletion import is scheduled for the specified date and time.

Examples: Using the Schedule Settings

The following examples illustrate the use of the schedule settings.

- Select Day for Interval Type and 2 for Interval. The import processes every other day.
- Select Week for Interval Type, 1 for Interval Day, and 3 for Interval. The import processes every three weeks on the first day (Sunday) of the week.
- Select Month for Interval Type, 15 for Interval Day, and 2 for Interval. The import processes every two months on the 15th day of the month.
- Select Quarter for Interval Type and select Last Day of Interval. The import processes every quarter (every three months) on the last day of the last month in the quarter.
- Select Year for Interval Type, 1 for Interval Day, and 1 for Interval. The import processes on January 1 of every year.

To view the import jobs for your current selected deletion import, click Associated Jobs on the left side of the page. To view all import jobs for all imports, click Import Jobs. In the list of import jobs that appears, click Status Message to view the status of an import.

You can also view the log file for more information about the import activity. In the list of import jobs, click View Logs for the selected import.

View the Schedule Details

You can view the schedule details for a scheduled import job that you created.

First, open the list of import jobs.

- To view the scheduled import jobs for your currently selected import, click Associated Jobs on the left side of the page, select the Scheduled check box, and click Go.
- To view all import jobs for all imports, click Import Jobs on the left side of the page, select the Scheduled check box, and click Go.

In the list of import jobs that appears, click Schedule Details for a selected import.

View the Import Log Files

You can view the Data Importer log files to see the details of all CA-provided and user-defined imports that have completed. The Data Importer creates a log file for each import that you run, including imports that were submitted immediately or scheduled for a future time. All import activities are saved in the log files.

To view the log files, first open the list of import jobs.

- To view the import jobs for your current selected import, click Associated Jobs on the left side of the page.
- To view all import jobs for all imports, click Import Jobs.

In the list of import jobs, click View Logs for a selected import. If more than one log file is available (for example, for a scheduled import that has completed a few times already), all files are listed with their corresponding creation dates.

You can view any available LDAP Import Sync log file. If you click Start LDAP Data Import and Sync on the LDAP Data Import and Sync page (Administration, User/Role Management), an import job ID is displayed. Use this job ID to locate the job in the Data Importer list of import jobs. Then click View Logs for that job.

You can also locate and view the import log files in the following location on the CA APM application server:

```
[ITAM Root Path]\Storage\Common Store\Import\Logs
```

Review the Import Log File - Best Practices

The Data Importer log file contains information and error messages regarding the processing of import jobs. To help you understand the results of your import and to troubleshoot any errors, use the information in this log file. This section contains some recommended best practices for working with the Data Importer log file.

Match the row number in the data file with the error message in the log file.

A log file error message identifies the corresponding row number from your data file. You can also find the data file row number in the row above or below the error message in the log file.

Sometimes the error message in the log file does not show the data file row number. In this situation, the actual data file values are shown immediately after the error message in the log file.

Count the number of error messages in your log file.

1. Search for the following phrases in your log file to find the error messages in the file. These phrases are included with the error messages.

   ```
   Web Service threw exception
   Error at record
   ```

2. After you find a type of error message, search for that error in the log file and count the number of occurrences.

3. Identify and search for more error types that appear in your log file and count the number of occurrences.

4. Compare the count of all errors in your log file with the statistics that the Data Importer generated for the associated import. To view these statistics, click Status Message on the Associated Jobs list or Import Jobs list. This comparison helps you account for all relevant errors and identify error messages that are not valid and can be ignored.

Verify that the Data was Deleted

You verify that your deletion import succeeded by viewing your data in CA APM and by reviewing the Data Importer statistics.

- **Review the Data Importer Statistics.** To review the statistics for your current selected deletion import, click Associated Jobs on the left side of the page. In the list of import jobs that appears, click Status Message for your import.
  You can also view the log file for more information about the import activity. In the list of import jobs, click View Logs for the selected import.

- **View the Data in CA APM.** To view the data in CA APM, navigate to the tab and subtab, if necessary, for the object that you deleted (for example, asset, company, or contact). Search for the objects that you deleted and verify that the objects are not available.

Example: Verify the Deletion of Laptops

After Miriam runs the deletion import, she performs the following steps to verify that the laptops were deleted:

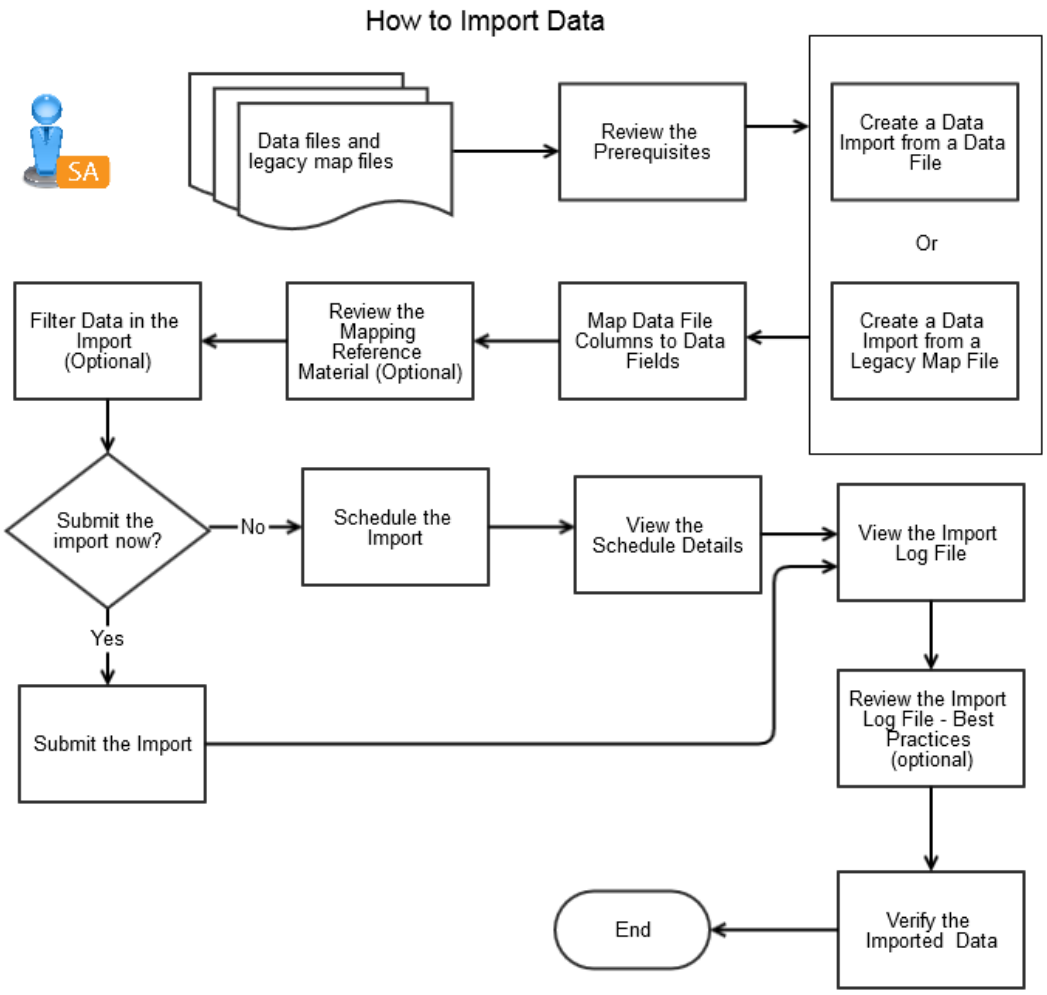
1. Checks the import statistics.
   - Clicks Associated Jobs or Import Jobs on the left side of the Data Importer page.
   - Clicks Status Message for the deletion import and reviews the statistics.
2. Views the import log file and the user interface.
   - Clicks View Logs in the list of import jobs and reviews the contents of the log file.
   - Navigates to the Asset tab. Searches for the deleted laptops and verifies that the deleted laptops are not available.

How to Import Data

When you want to add or update data, import it into CA APM using the Data Importer. The data that you import is inserted, or updates existing data, in the CA MDB.

In this scenario, the system administrator performs the data import. However, the administrator can grant Data Importer User Access or Data Importer Admin Access to any CA APM user role. User access allows users to create imports, modify or delete their own imports, and view any import that was created by another user. Admin access allows users to create imports and modify or delete any import that was created by any user.

The following diagram illustrates how a system administrator imports data.



To import CA APM data, perform these steps:

1. Review the Prerequisites (see page 1642).
2. Create a Data Import from a Data File (see page 1643) or Create a Data Import from a Legacy Map File (see page 1647).
3. Map Data File Columns to Data Fields (see page 1648).
4. Review the Mapping Reference Material (see page 1650).
   - Primary and Secondary Lookup Combinations (see page 1650)
   - Hard-Coded Values (see page 1652)
   - Multiple Values for a Single Field (see page 1653)
5. Filter Data in the Import (see page 1653).

6. Submit the Import (see page 1655).
7. Schedule the Import (see page 1655).
8. View the Schedule Details (see page 1656).
9. View the Import Log File (see page 1657).
10. Review the Import Log File Best Practices (see page 1657).
11. Verify the Imported Data (see page 1658).

Example: Import New Employees

Sam, the CA APM system administrator at Document Management Company, wants to import a group of new employees. The new employees use the product to manage hardware assets. Sam received a comma-separated value (CSV) source data file from Human Resources that contains the employee information. All of the new asset manager employees belong to the IT department and work at the company headquarters. However, the source data file also contains data about some new employees who work at other locations and do not belong to the IT department.

Sam only wants to import the data for the IT employees at headquarters. Using the Data Importer and the source data file, Sam creates a data import to incorporate the new employees into the CA MDB. To ensure that only employees in the IT department at headquarters are imported, Sam creates an exclusion filter. After Sam runs the import, he checks the import statistics and the import log file and user interface to verify that the import was successful.

Review the Prerequisites

To ensure that you can successfully import the data, verify that you have completed the following tasks:

- Prepare a source data file in delimited text format (for example, tab or comma). This file contains the data that you want to import.

We recommend that you include the main destination object in the name of the source data file. This file naming convention helps you locate your data files when you create your import.**Note:** A value of NULL in your source data file clears the corresponding destination field value. An empty field in your source data file leaves the corresponding destination field value unchanged.

If a data value in your source data file contains the selected delimiter, you must use double quotation marks around the data value. For example, you select a comma as the delimiter to import companies. You want to include the data value Document Management Company, Inc. in your source data file. Specify this data value with double quotation marks: "Document Management Company, Inc".

- (Optional) Copy your source data files from your local server to one of the following locations. You can access these locations on the CA APM application server where the Storage Manager Service is installed. The location depends on whether you are using multi-tenancy.

```
[ITAM Root Path]\Storage\Common Store\Import

[ITAM Root Path]\Storage\Tenant_Name\Import
```

If you copy the data file before you create an import, you can then specify the file name when you create the import. If you do not copy the data file first, you can upload the file from your local server when you create the import.

- (Optional) Copy your legacy map files from a previous product release (if you have these files) from your local server to one of the following locations. You can access these locations on the CA APM application server where the Storage Manager Service is installed. The location depends on whether you are using multi-tenancy.

```
[ITAM Root Path]\Storage\Common Store\Import

[ITAM Root Path]\Storage\Tenant_Name\Import
```

Create a Data Import from a Data File

You create a data import using a source data file (delimited text file) that contains the data that you want to import. You select the file, configure the import parameters, and specify the delimiter (for example, a comma or a tab) that separates the data in the file.

You can also create a data import using a legacy map file from a previous product release. For more information, see creating a data import from a legacy map file (see page 1647).

Follow these steps:

1. Log in to CA APM as the administrator.

In this scenario, the system administrator performs the data import. However, the administrator can grant Data Importer User Access or Data Importer Admin Access to any CA APM user role. User access allows users to create imports, modify or delete their own imports, and view any import that was created by another user. Admin access allows users to create imports and modify or delete any import that was created by any user.

2. Click Administration, Data Importer.

3. Click New Import.

4. Enter the required information in the Basic Information area and supply optional information as needed. The following fields require explanation:

- **Data File**
  Specifies the source data file that you want to import.
  If this file is available on the CA APM application server, search for the data file and select the file. If this file is not available on the application server, upload the file.

- **Upload File**
  Browse on your local server for a source data file that you want to import or a legacy map file that you want to use to create mappings. This file is uploaded to the CA APM application server.

  The file size is limited by the product environmental settings. For more information, contact your administrator.

- **Main Destination Object**
  Specifies the main object for the import.
  Asset and Model objects are listed with their corresponding families. You can also specify All Families. Legal Document objects are listed according to legal template. You can also specify All Templates. The objects include all objects that can be imported.

  For assets or models that include multiple asset family types or legal documents that include multiple legal templates, use the following selections for this field. Specify the particular family or template for each record in your source data file.

  - For an asset, select Asset (All Families).
  - For a model, select Model (All Families).
  - For a legal document, select Legal Document (All Templates).

  Important! Ensure that you select the correct main destination object for your import. You cannot change the main destination object after you save or copy an import.

- **First Row Has Column Names**
  Specifies whether the first row in the source data file contains the column names. If the first row does not contain the column names, the names display as generic names, such as Field 1 and Field 2.

- **Tenant**
  Specifies the tenant that applies to the import (if you are using multi-tenancy).
  You can select a tenant only when multi-tenancy is enabled in CA APM and you are authorized to access different tenants. If you have access to public data and you have multiple tenants, you can select all tenants.

If you specify all tenants, your source data file must have a tenant name column that you map to the Tenant Name field.

If you specify one tenant, verify that all data in your source data file belongs to your selected tenant. If you have data for more than one tenant, data for all tenants is imported into the selected tenant.

- **Data Delimiter**
  Specifies the delimiter (for example, comma or tab) that you used in the source data file.

  If a data value in your source data file contains the selected delimiter, you must use double quotation marks around the data value. For example, you select a comma as the delimiter to import companies. You want to include the data value Document Management Company, Inc. in your source data file. Specify this data value with double quotation marks:

  "Document Management Company, Inc"

- **Data File Locale**
  Specifies the locale for the source data file. This setting determines the date and time format.

5. Enter the required information in the Advanced Settings area and supply optional information as needed. The following fields require explanation:

   - **Maximum Error Threshold (in %)**
     Defines the number of errors after which the import stops. The threshold is based on the percentage of records processed. We recommend a minimum threshold of 15 percent.

     The Data Importer processes the number of records that are specified on Administration, System Configuration, Data Importer (Maximum Batch Record Size field) before calculating if the error threshold has been reached.

   - **Primary Lookup Object Processing Type**
     Specifies the type of import activity (for example, insert or update).

   - **Create Secondary Lookup Object**
     Creates new secondary lookup objects during the import process. If this option is not selected and a secondary object does not exist, an error occurs.

   - **Update Secondary Lookup Object**
     Updates the existing secondary lookup objects during the import process. If a secondary object does not exist, an error occurs.

- **Error on Secondary Lookup Object Errors**
  Indicates that the Data Importer does not process a primary object insert or update if the secondary object process fails. If a secondary object insert or update process fails and this check box is selected, the insert or update for the primary object also fails. If this check box is not selected, the primary object is created or updated (as long as the object is not dependent on the secondary object). However, the secondary object value is not created or changed. In both situations, the secondary object error is logged in the import log file.
  Example: You import a location and the location has a country. If the import fails while trying to update the country object and this check box is selected, the location record is not created. If this check box is not selected, the location record is created, and the country information is not updated.

- **Normalization Behavior**
  Specifies whether to normalize the data or write an error message in the log file without normalizing the data.

  
  This field appears only if you have defined normalization rules.

  - **Error on Normalization**
    Writes an error message to the Data Importer log file when data that can be normalized is found in the data that you are importing. The data involved is not imported. The log file error message includes the details about the data.
    For example, your data includes the company name Microsoft. The company normalization rules that you created identify Microsoft as a collected (nonauthoritative) value and specify Microsoft Corporation as the normalized (authoritative) value. If you select this option when importing your data, the object with the company name Microsoft is not imported and an error message is written to the log file.

  - **Apply Normalization without Error**
    Uses the normalization rules to normalize the data that you are importing. If data that can be normalized is found, the data is normalized and imported. No error message about the data is written to the log file.
    For example, your data includes the company name Microsoft. The company normalization rules you created identify Microsoft as a collected (nonauthoritative) value and specify Microsoft Corporation as the normalized (authoritative) value. If you select this option when importing your data, the object with company name Microsoft is normalized. In this example, the company name is changed to Microsoft Corporation and the associated object is imported.

6. Click Save.
   The import is saved. The Mapping, Exclusion Filter, and Schedule areas of the page are now available for your input.

Example: Create a Data Import of New Employees from a Data File

Sam, the CA APM system administrator, performs the following actions to create the data import:

1. Navigates to Administration, Data Importer and clicks New Import.

2. Enters New Employees.csv in the Data File field.
   This CSV file is the source data file that Sam received from Human Resources with the new employee information.

3. Selects Contact for the Main Destination Object and comma for Data Delimiter.

4. Selects Insert or Update in the Primary Lookup Object Processing Type field and clicks Save.

Create a Data Import from a Legacy Map File

You can create a data import using a legacy map file from a previous CA APM release. The map file defines the corresponding data file and the import parameter settings.

We recommend that you copy your legacy map files and corresponding data files to the CA APM application server before you create the data imports. However, if necessary, you can use the optional steps to upload a legacy map file.

You can also create a data import using a data file only. For more information, see creating a data import from a data file (see page 1643).

Follow these steps:

1. Click Administration, Data Importer, New Import.

2. Click Search and Load Map to select a legacy map file that is already available on the CA APM application server.

   The corresponding data file must also be available on the CA APM application server.

   If the legacy map file is not available on the CA APM application server, upload the file using the Upload File field.

3. (Optional) Upload a legacy map file that is not available on the CA APM application server using the following steps:

   a. In the Upload File field, browse on your local server and select a legacy map file.
      The legacy map file is uploaded and is displayed in the Upload File field.

   b. Click Search and Load Map and select the legacy map file that you uploaded.
      The legacy map file is displayed in the Legacy Map File field.
      The Basic Information is loaded.

If you receive a warning about the source data file, upload the data file using the Upload File field.

4. Specify the Advanced Settings and click Save.
   The Exclusion Filter and Mapping data mapping are loaded. The Mapping, Exclusion Filter, and Schedule areas of the page are now available for your input. The Mapping and Exclusion Filter areas display the data from the legacy map file.

   For information about specifying the Advanced Settings, see creating a data import from a data file (see page 1643).

Map Data File Columns to Data Fields

You can map the columns in your source data file to fields in CA APM. You perform column mapping to specify where the source data is imported. You can select most objects and associated fields as destination fields during column mapping.

If you created your data import from a legacy map file, the column mapping exists. If you want to change the values, you can edit the existing mapping rules. You can also add or remove mapping rules and filters.

When you log in, the user role that your administrator assigned to you determines the objects and fields that you can see and use. If your role specifies that you do not have permissions for an object field, the field is not available for a mapping. You can only create a mapping and import data for the objects and fields for which you have permissions.

Note: We recommend that, before you map data, you review the CA APM user interface to determine the required information for a mapping. For example, review the Asset page to see that the asset name, asset family, model, and class are required. Because a model is required to create an asset, you review the Model page to see that the model name and asset family are required. By reviewing the user interface before you create a mapping, you ensure that you have all required information to create a mapping.

Follow these steps:

1. On the Administration tab, Data Importer page, in the Mapping area for a selected import, click New or click Load Source Fields.

   - New allows you to select the source fields individually from the source data file.

- Load Source Fields adds all source fields from the source data file.

> If you have existing mappings, Load Source Fields allows you to replace those mappings with the source fields in the source data file. This option also allows you to add the source fields from the source data file that you do not already have in your mappings.

a. If you clicked Load Source Fields, click the Edit Record icon next to a field.

2. Click the Select icon next to Source Field (if this field is empty), select a column from your data source, and click OK.
   If this field already contains a source field (because you loaded all source fields), you can skip this step.

> The percent signs that appear before and after the column names identify the names as column headers in your source data file. You can also specify a hard-coded value in the Source Field that you want to apply to all records in your source data file. You can then map the hard-coded value to a Destination Field. The hard-coded values do not display with percent signs so that they can be distinguished from the source data file column names. For more information, see hard-coded values (see page 1652).

3. Click the Select icon next to Destination Field, select a Destination Field for the selected Source Field, and click OK.
   The destination fields that appear are based on your selected main destination object.

> The destination fields display in hierarchical order. For example, the fields that are listed under Asset Type Hierarchy are Asset Family, Class, and Subclass. The order of the fields in the list represents the field hierarchy. Follow the field hierarchy when you specify mapping rules. For example, for Asset Type Hierarchy, specify a rule for Class before you specify Subclass.

4. Select the Primary Lookup and Secondary Lookup check boxes as required.

   a. Select a Primary Lookup check box for each destination field that you want to use to find the primary object. Use the following guidelines when selecting this check box:

      - Select at least one Primary Lookup check box in the column mapping for an import.
      - Do not select this check box if the Destination Field is Note Text (under the Note object). The database data type for the Note Text field does not allow it to function as a lookup field.

b. Select a Secondary Lookup check box for each destination field that you want to use to find the secondary objects. Use the following guidelines when selecting this check box:

   - Do not select this check box if the destination field is not one of your lookup fields for the secondary object.
   - Do not select this check box if the Destination Field is Note Text (under the Note object). The database data type for the Note Text field does not allow it to function as a lookup field.

5. Click the Complete Record Edit icon.
6. Click New again, or click the Edit Record icon next to another source field, to specify more mapping rules.

   To delete a specific mapping rule from the list of mapped columns, click the Deletion icon next to the mapping rule. The column mapping rule is removed from the list.

7. Click Save.
   Your column mapping is saved.

Example: Map Data File Columns to Data Fields

Sam performs the following steps to map the data file columns in the source data file to the CA APM data fields:

1. Clicks New in the Mapping area of the Import Details page.
2. Selects %Login ID% in the Source Field by clicking the Select icon next to Source Field and selecting this item from the dialog.
   The items that are listed in the dialog are the columns from the source data file.
3. Selects User ID in the Destination Field by clicking the Select icon next to Destination Field and selecting this object from the dialog.
4. Selects the Primary Lookup check box.
5. Continues to map the remaining columns in the source data file with CA APM data fields and clicks Save when finished.

Review the Mapping Reference Material

Reference the following information when setting up the column mapping for importing or deleting data.

Primary and Secondary Lookup Combinations

The fields that you select as the primary and secondary lookup in your column mapping are used to search for data in the product database.

- **Simple mapping**
  In simple mapping, you specify only the primary lookup. For example, you are importing or deleting a set of company records from a text file into the product database. You specify the Company Name as the primary lookup. If a company with a particular name does not exist in the database when you are importing data, a record is created for the company. The following table shows an example of the lookup for a simple mapping.

Source Field	Destination Field	Primary Lookup	Secondary Lookup
%Company Name%	Company.Company Name	Yes	No

- **Reference field mapping**
  In reference field mapping, you specify primary and secondary lookup values. To search for a unique object, specify more than one primary lookup. For example, to search for a company, you can specify Company Name, Parent Company, and Company Type as primary lookup values. In this example, the Data Importer searches for a company with the specified name, the specified parent company, and of the specified company type. If the object does not exist and you are importing data, the record is created (depending on the insert or update option you selected in Advanced Settings). The following table shows an example of the lookup for reference field mapping.

Source Field	Destination Field	Primary Lookup	Secondary Lookup
%Company Name%	Company.Company Name	Yes	No
%Parent Company%	Company.Parent Company.Company Name	Yes	Yes
%Company Type%	Company.Company Type.Value	Yes	Yes

This mapping has both the Primary Lookup and the Secondary Lookup check boxes selected for Parent Company and Company Type. The Data Importer uses the Company Name to look up the parent company and uses the Parent Company to look up the company name.

- **Secondary object mapping**
  If a mapping rule maps to a secondary object property, the primary lookup values establish a relationship between a secondary object and the reference fields. The following table shows examples of the lookup for a secondary object mapping.

Source Field	Destination Field	Primary Lookup	Secondary Lookup
%Comment%	Legal Document.Legal Party.Comment	No	Yes
%Legal Document ID%	Legal Document.Document Identifier	Yes	No
%Company Name%	Legal Document.Legal Party.Legal Party. Company Name	Yes	Yes
%Legal Template%	Legal Document.Legal Template.Template	Yes	Yes

In the first mapping rule, Legal Document is the primary object, and Legal Party is the secondary object. Comment is a property of Legal Party.

In the third mapping rule, Legal Document is the primary object, and Legal Party is the secondary object. In addition, Legal Party has a reference field in the Company table. The Secondary Lookup check box indicates that the Company Name is used to look up the Company object. The Primary Lookup check box indicates that the Company object is used to look up the Legal Party object.

Hard-Coded Values

In the column mapping, the percent signs that appear before and after column names identify the names as column headers in your source data file. You can also specify a hard-coded value in the Source Field that you want to apply to all records in your source data file. You can then map the hard-coded value to a Destination Field. The hard-coded values do not display with percent signs to distinguish these values from the source data file column names.

1. Source data file column header
2. Hard-coded value

You can define a hard-coded value in the Source Field to expand your source data and to ensure that you include all required fields. Hard-coded values typically do not begin and end with a percent sign (%). If you have hard-coded values with percent signs, the values cannot match the field names in your source data file.

Example: Use hard-coded values for asset family

In this example, the assets in your source data file do not contain asset family, which is required when creating an asset. You can add a hard-coded value to your mapping. If all of your assets are hardware, you can enter Hardware in the Source Field. You can map this value to the Asset Family field. If your assets belong to different families, add a column to your source data file with the corresponding asset families before importing or deleting data.

The following information illustrates the difference between values from your source data file and values that are added through hard-coded values:

- You have an Asset Family column in your source data file. The selection in the Source Field is % asset family%.

You do not have an Asset Family column in your source data file. However, all of your assets are hardware assets. You specify a hard-coded value of Hardware in the Source Field.

You can also use the Main Destination Object to specify that all records in your source data file belong to a particular family or template. For example, the Asset (Hardware) selection for Main Destination Object specifies that all source records belong to the hardware asset family.

Multiple Values for a Single Field

You can add a mapping with multiple Source Field values that are mapped to a single Destination Field.

Example: Use multiple values for a single field

Your source data file has two columns with the names Manufacturer and Catalog Name. Combine these columns by selecting both in the Source Field. In this example, the Source Field selection is %Manufacturer% %Catalog Name%.

You can also enter multiple hard-coded values in the Source Field (for example, Document Management Company %model name% IT Department).

Filter Data in the Import

You can identify a subset of records in your source data file that you want to exclude from the import. The Data Importer exclusion filter allows you to filter a part of your data source using exclusion filter rules.

Example: Define an exclusion filter to process returned assets

A CSV file that you receive from your hardware vendor includes assets that were ordered and returned to the vendor. You want to process only the returned assets, so you want to import data to update those records only. You define an exclusion filter to exclude records that do not have a status of Returned.

Follow these steps:

1. On the Administration tab, Data Importer page, Exclusion Filter area for a selected import, select the Filter Type.
   - **And**
     Excludes a record from the source data file only if all the rules that you specify are valid for the record.
   - **Or**
     Excludes a record from the source data file if any of the rules that you specify is valid for the record.
2. Click New.
3. Click the Select icon next to Source Field, select a column from your source data file, and click OK.

The percent signs before and after the column names identify the names as columns from your source data file.

4. Select the Operator.

   To specify "not equal to", select the "<>" operator.

5. Enter a Filter Value for the rule.

   You can use special characters and wildcards in the filter value. The rules can process text, numeric, and date fields.

6. Click the Complete Record Edit icon.
7. (Optional) Click New and specify more exclusion filter rules.
8. Click Save.
   The exclusion filter rules are saved and are applied when the import processes.

Example: Create an Exclusion Filter

Sam performs the following steps to create an exclusion filter. The filter eliminates non-IT employees and employees who do not work at the company headquarters from the data import.

1. Selects And for the Filter Type and clicks New in the Exclusion Filter area of the Import Details page.
2. Selects %Department% for the Source Field.
3. Selects <> for the Operator.
4. Enters IT for the Filter Value.
5. Clicks the Complete Record Edit icon and clicks New.
6. Selects %Location% for the Source Field.
7. Selects <> for the Operator.
8. Enters Headquarters for the Filter Value.
9. Clicks the Complete Record Edit icon and clicks Save.

Submit the Import

To start an import immediately, click Submit in the Schedule area of the page. The data source records from the data file for the selected import are processed.

You can specify a data file other than the default (from the Basic Information) if you want to use a different file.

You can also schedule the import for a particular day and time. For more information, see schedule the import (see page 1655).

To view the import jobs for your current selected import, click Associated Jobs on the left side of the page. To view all import jobs for all imports, click Import Jobs on the left side of the page. In the list of import jobs that appears, click Status Message to view the status of an import.

You can also view the log file for more information about the import activity. In the list of import jobs, click View Logs for the selected import.

Schedule the Import

You can schedule an import for a specific time and you can specify the interval for the import (for example, daily or weekly). You can schedule multiple imports to process simultaneously.

Follow these steps:

1. On the Administration tab, Data Importer page, in the Schedule area for a selected import, select the Is Scheduled check box.

2. Provide the information for the schedule. The following fields require explanation:

   - **Run Time**
     Specifies the time of the day, in 24-hour format, to process the import. When you schedule imports, use the local time zone on the CA APM application server.

   - **Interval Day**
     Specifies the day during the Interval Type to process the import. For example, if the Interval Type is Month and the Interval Day is 1, the import is processed on the first day of the month.

   - **Data File**
     Specifies a data file name other than the default (from the Basic Information) if you want to use a different file.
     If this file is available on the application server, you can search and select the file. If this file is not available on the application server, you can locate and upload the file.

   - **Upload Data File**
     Browse for the source data file that you want to import. This file is uploaded to the application server.

- **First Run Date**
  Specifies the date when the first import starts to process.

- **Interval Type**
  Specifies the type of interval for the import (for example, Day, Month, Quarter, Week, or Year).

- **Interval**
  Specifies how often the import processes. This interval is based on the specified Interval Type. For example, if the Interval Type is Weekly and the Interval is 2, the import processes every two weeks.

- **Last Day of Interval**
  Specifies that the import processes on the last day of the selected Interval Type. If you select this check box, any previous value that you added to the Interval Day field is removed, and the Interval Day field is disabled.

3. Click Submit.
   The data import is scheduled for the specified date and time.

Examples: Using the Schedule Settings

The following examples illustrate the use of the schedule settings.

- Select Day for Interval Type and 2 for Interval. The import processes every other day.
- Select Week for Interval Type, 1 for Interval Day, and 3 for Interval. The import processes every three weeks on the first day of the week (Sunday).
- Select Month for Interval Type, 15 for Interval Day, and 2 for Interval. The import processes every two months on the 15th day of the month.
- Select Quarter for Interval Type and select Last Day of Interval. The import processes every quarter (every three months) on the last day of the last month in the quarter.
- Select Year for Interval Type, 1 for Interval Day, and 1 for Interval. The import processes on January 1 of every year.

To view the import jobs for your current selected import, click Associated Jobs on the left side of the page. To view all import jobs for all imports, click Import Jobs on the left side of the page. In the list of import jobs that appears, click Status Message to view the status of an import.

You can also view the log file for more information about the import activity. In the list of import jobs, click View Logs for the selected import.

View the Schedule Details

You can view the schedule details for a scheduled import job that you created.

First, open the list of import jobs.

- To view the scheduled import jobs for your currently selected import, click Associated Jobs on the left side of the page, select the Scheduled check box, and click Go.

- To view all import jobs for all imports, click Import Jobs on the left side of the page, select the Scheduled check box, and click Go.

In the list of import jobs that appears, click Schedule Details for a selected import.

View the Import Log Files

You can view the Data Importer log files to see the details of all CA-provided and user-defined imports that have completed. The Data Importer creates a log file for each import that you run, including imports that were submitted immediately or scheduled for a future time. All import activities are saved in the log files.

To view the log files, first open the list of import jobs.

- To view the import jobs for your current selected import, click Associated Jobs on the left side of the page.
- To view all import jobs for all imports, click Import Jobs.

In the list of import jobs, click View Logs for a selected import. If more than one log file is available (for example, for a scheduled import that has completed a few times already), all files are listed with their corresponding creation dates.

You can view any available LDAP Import Sync log file. If you click Start LDAP Data Import and Sync on the LDAP Data Import and Sync page (Administration, User/Role Management), an import job ID is displayed. Use this job ID to locate the job in the Data Importer list of import jobs. Then click View Logs for that job.

You can also locate and view the import log files in the following location on the CA APM application server:

```
[ITAM Root Path]\Storage\Common Store\Import\Logs
```

Review the Import Log File - Best Practices

The Data Importer log file contains information and error messages regarding the processing of import jobs. To help you understand the results of your import and to troubleshoot any errors, use the information in this log file. This section contains some recommended best practices for working with the Data Importer log file.

Match the row number in the data file with the error message in the log file.

A log file error message identifies the corresponding row number from your data file. You can also find the data file row number in the row above or below the error message in the log file.

Sometimes the error message in the log file does not show the data file row number. In this situation, the actual data file values are shown immediately after the error message in the log file.

Count the number of error messages in your log file.

1. Search for the following phrases in your log file to find the error messages in the file. These phrases are included with the error messages.

   ```
   Web Service threw exception
   Error at record
   ```

2. After you find a type of error message, search for that error in the log file and count the number of occurrences.

3. Identify and search for more error types that appear in your log file and count the number of occurrences.

4. Compare the count of all errors in your log file with the statistics that the Data Importer generated for the associated import. To view these statistics, click Status Message on the Associated Jobs list or Import Jobs list. This comparison helps you account for all relevant errors and identify error messages that are not valid and can be ignored.

Verify the Imported Data

You verify that your data import succeeded by viewing your data in CA APM and by reviewing the Data Importer statistics.

- **Review the Data Importer Statistics.** To review the statistics for your current selected import, click Associated Jobs on the left side of the page. In the list of import jobs that appears, click Status Message for your import.
  You can also view the log file for more information about the import activity. In the list of import jobs, click View Logs for the selected import.

- **View the Imported Data in CA APM.** To view the imported data, navigate to the tab and subtab, if necessary, for the object that you imported (for example, asset, company, or contact). Search for the objects that you imported and verify that the objects are available.

Example: Verify the Data Import of New Employees

After Sam runs the import, he performs the following steps to verify the data import of new employees:

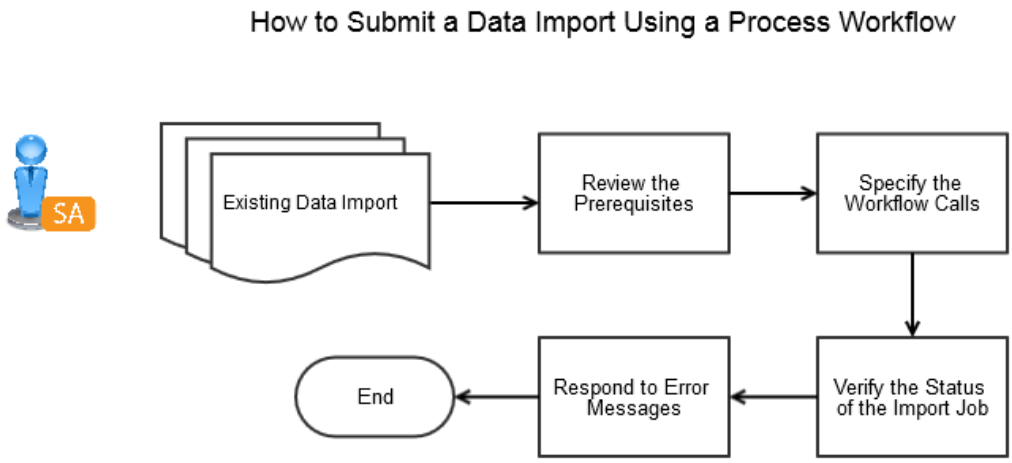
1. Checks the import statistics.
   - Clicks Associated Jobs or Import Jobs on the left side of the Data Importer page.
   - Clicks Status Message for the import and reviews the statistics.
2. Views the import log file and the user interface.
   - Clicks View Logs in the list of import jobs and reviews the contents of the log file.
   - Navigates to Directory, Contact on the CA APM user interface. Searches for the new employees. Verifies that the non-IT employees and employees who do not work at company headquarters are not available.

How to Submit a Data Import Using a Process Workflow

You can use a process workflow (for example, CA Process Automation) to submit a Data Importer data import for processing instead of using the CA APM user interface.

You can create a data import process workflow using a company-provided sample XML file and integrating with CA Process Automation. For more information about this integration, see Implementing CA IT Asset Manager (see page 301).

The following diagram illustrates how a system administrator submits a data import using a process workflow:



To submit a data import using a process workflow, perform these steps:

1. Review the Prerequisites (see page 1660).
2. Specify the Workflow Calls (see page 1660).
3. Verify the Status of the Import Job (see page 1662).
4. (Optional) Respond to Error Messages (see page 1662).

Example: Import New Hardware Devices through a Process Workflow

Sam, the CA APM system administrator at Document Management Company, has defined a business process workflow. The workflow discovers new hardware devices, adds the new devices to the company data repository, and runs reports about the new devices. Sam has already created a data import in CA APM that adds the new hardware devices to the data repository. Sam wants to execute that data import at a specific point in his overall workflow. He wants to integrate the data import with his overall business process workflow. Sam wants the data import to execute at the time that the workflow specifies without the user logging in to the product user interface. Sam updates his business process workflow to include calls to the CA APM web service operations for the Data Importer.

Review the Prerequisites

To ensure that you can successfully submit a data import using a process workflow, verify that you have completed the following prerequisites:

1. Define a data import with all mappings and settings through the CA APM user interface.
2. Verify that the data file path (if you are specifying a path) is accessible from the server where the Import Service is running. Also, the Network Service (application pool identity) user requires access to this path.
3. Define a process workflow using a workflow provider (such as CA Process Automation).

Specify the Workflow Calls

To launch the Data Importer and execute a data import from a process workflow, you provide specific workflow calls to CA APM web service operations. These operations perform the following functions:

- Login operation - Logging in to CA APM.
- Submitting a data import using one of the following ways of providing a data file:
  - SubmitImportwithfilepath Operation - The data file is available on a specified file path. This file path must be accessible from the server where the Import Service is running. The web service operation uploads the file.
  - SubmitImport Operation - The data file content has been converted to byte array binary format. The web service operation receives the byte array content from an application and submits the content to the Data Importer.

    To use this way of providing a data file, create an application, if one is not already available, to convert the data file content to byte array format. The application then sends the content to the web service operation.

Incorporate the calls to these operations into your business process workflow.

For information about creating a process workflow, see the product documentation for your workflow provider.

Login Operation

This operation logs in to CA APM using the specified CA APM user ID and password. The output of this operation is the login token. The login token is used as input to other data import workflow operations.

- **Input Parameters**
  ItamUserName - CA APM user ID
  ItamUserPassword - CA APM user password

- **Output Parameters**
  loginToken - Token that is returned after the CA APM login.

SubmitImport Operation

This operation receives data file content that has been converted to byte array format and submits the content with the data import to the Data Importer. To use this operation, create an application, if one is not already available, to convert the data file content to byte array format. The application then sends the content to this web service operation.

This operation returns a data import job ID, which is used to verify the status of the import job.

- **Input Parameters**
  loginToken - Token that is returned after the CA APM login.
  ImportName - Name of the data import.
  Datafilename - Name of the data file that is associated with the data import.
  Datafilestream - Data file content in byte array format.
  Caprovided - (Optional) Indicator that specifies a product-provided data import. Set this parameter to one (1) to specify a product-provided import.
  Tenant - (Multi-tenancy only) Name of the tenant to which the import applies.

- **Output Parameters**
  Job ID - ID that is returned after a data import is submitted successfully. The GetJobStatus operation uses this ID to verify the status of an import job.

SubmitImportwithfilepath Operation

This operation uploads a data file from a specified file path and submits the data file with the data import to the Data Importer. This file path must be accessible from the server where the Import Service is running.

The operation returns a data import job ID, which is used to verify the status of the import job.

- **Input Parameters**
  loginToken - Token that is returned after the CA APM login.
  ImportName - Name of the data import.
  Datafilepath - Complete path and name of the data file that is associated with the data import. This path must be accessible from the server where the Import Service is running. Also, the Network Service (application pool identity) user requires access to this path.

  If the data file location is a shared path, the CA APM server and the shared computer must be in the same domain.Caprovided - (Optional) Indicator that specifies a product-provided data import. Set this parameter to one (1) to specify a product-provided import.

  Tenant - (Multi-tenancy only) Name of the tenant to which the import applies.

- **Output Parameters**
  Job ID - ID that is returned after a data import is submitted successfully. The GetJobStatus operation uses this ID to verify the status of an import job.

Verify the Status of the Import Job

The Data Importer provides a status summary of each submitted data import job. Your process workflow can include a call to the CA APM web service operation that retrieves the status of a submitted data import job. Incorporate the call to this operation into your process workflow.

GetJobStatus Operation

This operation uses the data import job ID to verify the status of an import job.

- **Input Parameters**
  loginToken - Token that is returned after the CA APM login.
  Job ID - ID that is returned after a data import is submitted successfully.

- **Output Parameters**
  Job Status - Status of the import job.

Respond to Error Messages

If errors occur during the data import workflow process, you can receive error messages. The following messages require explanation:

- **20002 - Cannot access the data import because of user permissions. Contact your administrator.**
  The user role requires Data Importer Admin access or Data Importer User access to submit a data import.

- **20005 - Cannot connect to the Import service. Contact your administrator.**
  Verify the Import Service URL in the ImportProcessor.config file, or contact your administrator.

- **21002 - The data import name is invalid.**
  The data import does not exist, or the user does not have access to the data import. If the data import is product-provided, specify a value of 1 for the Caprovided parameter.

- **21004 - The data file failed to upload.**
  This message can result from a configuration error. Review the Storage Manager Service log files.

- **21005 - No mappings are defined for the data import.**
  Define mappings and resubmit the data import.

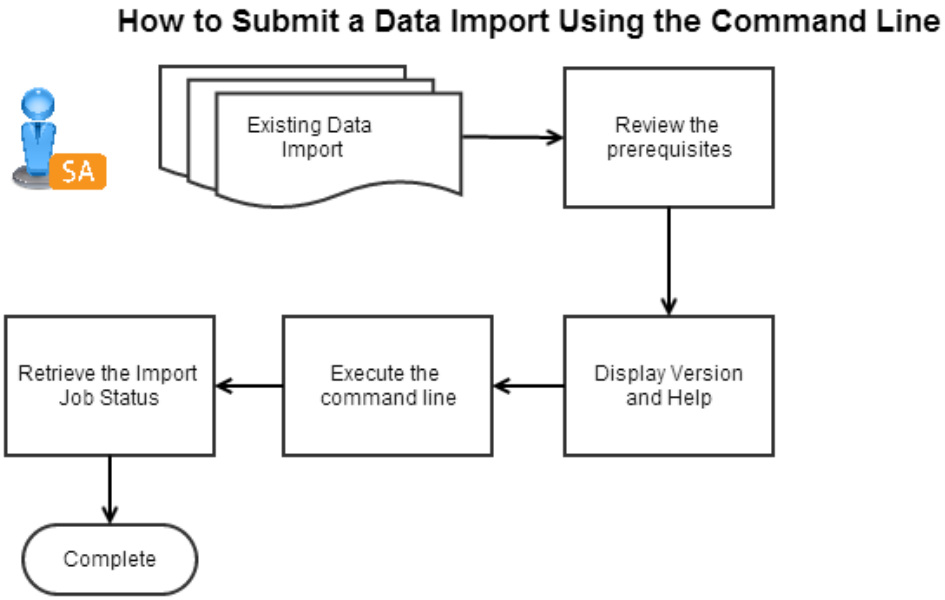
- **22001 - The data import job ID is invalid. Verify the job ID and try to execute the import again.**
  Verify the job ID by logging in to CA APM and locating the data import job. Resubmit the data import with the valid job ID.

How to Submit a Data Import Using the Command Line

You can use a command line to submit a Data Importer data import for processing instead of using the CA APM user interface. You can execute the command line from the Import Processor folder on the application server where the product is installed. You can also copy the Import Processor folder to another computer. The users of that computer can then execute the command line, also.

The data import is submitted immediately and is executed by the Data Importer Engine with other import jobs from the CA APM user interface. You cannot schedule a data import to execute at a particular time using the command line. However, you can use a scheduler (such as the operating system scheduler) to specify dates and times to run the data import.

The following diagram illustrates how a system administrator submits a data import using the command line:



To submit a data import using the command line, perform these steps:

1. Review the Prerequisites (see page 1663).
2. (Optional) Display Version and Help (see page 1664).
3. Execute the Command Line (see page 1664).
4. Retrieve the Import Job Status (see page 1665).

Example: Import New Hardware Devices

Sam, the CA APM system administrator at Document Management Company, has an existing data import that adds new hardware devices to the data repository. Sam wants to execute that data import daily. Sam also wants to verify the status of the submitted import job. However, he does not want to log in to the product to perform the import because he does not always perform other product functions on a daily basis. Sam uses the command line to submit the data import and then verify the status.

Review the Prerequisites

To ensure that you can successfully submit a data import using the command line, verify that you have completed the following prerequisites:

1. Verify that Microsoft .NET Framework 4.0 is installed on the computer where you are executing the command line.

2. Define a data import with all mappings and settings through the CA APM user interface.

3. (Optional) If you change the Import Service URL, modify the ImportProcessor.exe.config file to reflect the new URL. You can locate the ImportProcessor.exe.config file in the Import Processor folder. Update the endpoint address value.
   Example: The following statements show an example of the endpoint address value that you modify to change the Import Service URL.

```
<endpoint address="http://localhost/ImportService/ImportService.svc"
    binding="basicHttpBinding" bindingConfiguration="
BasicHttpBinding_ImportService"
    contract="IImportService" name="BasicHttpBinding_ImportService" />
```

Display Version and Help

Specify the command line parameters to display the command line version and usage help.

Follow these steps:

1. Log in to the application server where you installed CA APM or to a computer that has the Import Processor folder.

2. Access the Import Processor folder.

   On the application server, the Import Processor folder is located in the CA APM installation path.

3. Open a command prompt window and execute the following command:

```
importerprocessor -H | -V
```

   - **-H**
     Displays the command line version number and usage help for the command line parameters.

   - **-V**
     Displays the command line version number.

Execute the Command Line

Specify the command line parameters to submit a data import.

Follow these steps:

1. Log in to the application server where you installed CA APM or to a computer that has the Import Processor folder.

2. Access the Import Processor folder.

   On the application server, the Import Processor folder is located in the CA APM installation path.

3. Open a command prompt window and execute the following command:

```
importerprocessor -usr "user_name" -pwd "password" -i "import_name"
 - df  "data_file_absolute_path" -t "tenant_name"  - ts -c
```

   - **-usr**
     Specifies the CA APM login user name.
   - **-pwd**
     Specifies the CA APM login password.
   - **-i**
     Specifies the name of the data import that was created previously through the CA APM user interface.
   - **-df**
     Specifies the absolute path of the data file that is associated with the data import. The Data Importer Engine uses this file to process the import.
   - **-t**
     (Required for multi-tenancy) Specifies the name of the tenant that is associated with the data import.
   - **-ts**
     (Optional) Specifies that the command line parameters are recorded in the Import Processor log file.

     The Import Processor log file is located in the Import Processor folder.

   - **-c**
     (Optional) Identifies whether the data import was provided with the product or was created by a user.
     Valid values: 1 (product provided) or 0 (created by a user)
     Default: 0

Retrieve the Import Job Status

Specify the command line parameters to verify the status of an import job.

Follow these steps:

1. Log in to the application server where you installed CA APM or to a computer that has the Import Processor folder.

2. Access the Import Processor folder.

   On the application server, the Import Processor folder is located in the CA APM installation path.

3. Open a command prompt window and execute the following command:

   ```
   importerprocessor -usr "user_name" -pwd "password" -j "job_id"  - ts
   ```

   - **-usr**
     Specifies the CA APM login user name.

   - **-pwd**
     Specifies the CA APM login password.

   - **-j**
     Specifies the import job ID.

   - **-ts**
     (Optional) Specifies that the command line parameters are recorded in the Import Processor log file.

     The Import Processor log file is located in the Import Processor folder.

Managing Product-Provided Data Imports

This article contains the following topics:

Product-Provided Data Import Types

The product provides a set of predefined data imports that already contain all mappings and settings. These imports help you get started with data management. The two types of product-provided data imports allow you to perform the following functions:

- Read-only data imports - Allow you to monitor internal system functions, such as the LDAP Sync import of contacts.

- Object imports - Allow you to perform imports of common objects, such as locations, contacts, and assets.

You cannot modify the mappings and settings in the product-provided data imports. However, you can copy the imports and modify the copies.

Monitor the Status of Product-Provided Read-Only Data Imports

The read-only data imports perform internal system functions. You can monitor the status of the read-only imports, but you cannot submit these imports. You can copy the read-only imports and modify the copies to create your own imports.

Follow these steps:

1. Navigate to Administration, Data Importer.
2. Click one of the product-provided read-only data imports (not the object data imports). The following fields require explanation:
   - **CA APM - LDAP Sync Import**
     Submits a data import with the data file that CA EEM generated. This data import creates contacts through the LDAP Sync component.
   - **CA APM - Device Delete Import**
     Submits a data import with the data file that CA SAM generated. This data import deletes the information that is associated with deleted discovered assets.
   - **CA APM - Device Insert or Update Import**
     Submits a data import with the data file that CA SAM generated. This data import adds or updates the information that is associated with discovered assets.
3. Click Associated Jobs on the left side of the page.
4. Click Status Message in the list of import jobs to view the status of an import.

Submit the Product-Provided Object Data Imports

The product-provided object data imports perform imports of common objects. You can submit these imports, and you can monitor the status of these imports. To submit a product-provided object data import, verify that data was added to the associated data files. You can also specify your own data file. However, the column headers in your data file must match the column headers in the product-provided data file.

You can also copy these imports and modify the copies to create your own imports.

In a multi-tenanted environment, these imports add to or update the data in the Public Data tenant.

Follow these steps:

1. Navigate to Administration, Data Importer.

2. Click one of the product-provided object data imports (not the read-only imports). The following fields require explanation:

   - **CA APM - Company Import**
     Creates and updates companies.
   - **CA APM - Cost Center Import**
     Creates and updates cost centers.
   - **CA APM - Location Import**
     Creates and updates locations.
   - **CA APM - Contact Import**
     Creates and updates contacts.

     If you are using multi-tenancy, you cannot submit this import. Copy this import, add a mapping for the tenant, and submit your new contact import.

   - **CA APM - HW Model Import**
     Creates and updates hardware models.
   - **CA APM - HW Asset Import**
     Creates and updates hardware assets.
   - **CA APM - Unreconciled Discovered Assets Import**
     Creates and updates discovered assets.

     A CA Business Intelligence report about unreconciled discovered assets provides input for this data import. This CA Business Intelligence report does not include the Class and Status fields. Add these fields to the data file that corresponds to this import.

3. Specify your own data file in the Schedule area or use the product-provided data file.

   The product-provided data file does not contain data. Add the data that you want to import into the product-provided data file before you submit the import. You can find the product-provided data files at the following locations on the CA APM application server where the Storage Manager Service is installed.

   ```
   [ITAM Root Path]\Storage\Common Store\Import
   ```

4. Click Submit.

CA APM Environment Promotion

The CA Asset Portfolio Management Environment Promotion lets you promote the changes across environments with minimal manual effort. As a system administrator, you can promote any change across development, test, pre-production, and production environments.

Initiate CA Asset Portfolio Management Environment Promotion either through the user interface (UI) or command-line interface (CLI).

This article contains the following topics:

Prerequisites for Environment Promotion

1. Ensure that you meet the CA APM Environment Prerequisites (see page 686).
2. To promote content from the source to the target system, ensure that CA APM 14.1.02 patch is applied on CA APM 14.1 or CA APM 14.1.1.
3. During import, stop all CA APM services and resume them after the import is completed.

How Environment Promotion Works

- Environment Promotion involves the creation of an export package by promoting the configurations and content from the source system.
- To promote content to the target system, the system administrator must copy the export package and perform a dryrun and import.

Important! Initiate Environment Promotion to promote the custom changes.

Operations that are i nitiated through the command-line interface must be performed on the CA APM component server (First application server).

Supported Operations

Note: The supported operations must be executed after you change the directory to CA APM Promotion folder.

The following table lists the supported operations for CLI and CA APM UI:

Operation	Purpose	CLI	CA APM UI
Export	Create an export package to promote the configurations and content from the source system.	Yes	Yes *
DryRun	Validate the compatibility of the export package in the target system without actually importing it.	Yes	No
Import	Import the exported package in the target system.	Yes	No
History	Provide end-to-end execution history details such as package content, change initiator, and reason for change in the production environment.	Yes	No
Help	Display a list of commands applicable for Environment Promotion.	Yes	No
Version	Display the CA APM version that is installed with the patch levels.	Yes	No

* Indicates that only object-level filtering capability is supported.

Important! We recommend that you initiate the export operation through the CA APM UI.

Environment Promotable Objects

The following objects are eligible for Environment Promotion:

- List Management Data
- Configuration (Global and Local)
- Roles
- Search Definition
- Export Definition
- Reconciliation Rule
- Data Filter Definition
- Event Definition
- Data Import Definition

Support for Multi-Tenancy

Important! Before you initiate CA APM Environment Promotion, we recommend that you manually verify tenant hierarchy between the source and the target system.

- Before you promote the content, ensure that the tenant in the source and the target system is the same.
- Environment Promotion does not create, update, or delete any tenant on the target system.
- Before you promote the source content to the target system, Environment Promotion verifies if the tenant name and tenant group on the target system matches with that of the source. If the verification fails, the source content is not promoted to the target.

How to Promote Configurations and Content from the Source to the Target Systems

Syntax for Supported Operations

The following table lists the supported operation and its syntax:

Operation	Command Line Syntax	Command Line Syntax (Target Directory)
Export	>apmp -a export	apmp -a export -fp <File_Path>
Dryrun	>apmp -a dryrun -p <export_pkg_name>.zip	>apmp -a dryrun -fp <File_Path> -p <export_pkg_name>.zip
Import	>apmp -a import -p <export_pkg_name>.zip	>apmp -a import -fp <File_Path> -p <export_pkg_name>.zip
History	>apmp -a history	
Help	>apmp -help	
Version	>apmp -version / -v	

To promote custom configurations and content from the source to the target systems, perform the following tasks:

- Export (see page 1671)
  - Verify Prerequisites (see page 1671)
  - How to Perform Export (see page 1672)
  - Verify the Export (see page 1673)
  - How to Cancel Export (see page 1673)
- DryRun (see page 1673)
  - How to Perform DryRun (see page 1674)
  - DryRun Status Definition (see page 1674)
- Import (see page 1675)
  - Verify Prerequisites (see page 1675)
  - How to Perform Import (see page 1675)
  - Verify the Import (see page 1675)

Export

Verify Prerequisites

- You must have the CA APM administrator account name and password.

- Ensure that you have sufficient disk space (at least 500 MB) on the system where you plan to export.
- Ensure that CA Asset Portfolio Management - Export Service is running.
- While exporting to a shared location, ensure that you have sufficient write permissions and sufficient disk space (at least 500 MB) for the shared path.

How to Perform Export

To promote the configurations and content from the source system, use the **Environment Promotion** option in the CA APM UI.

Note: You can initiate multiple exports. However, only one job can be processed at a time and the other jobs are scheduled in the queue.

Follow these steps:

1. Log in to CA APM as a system administrator.
2. Navigate to **Administration, Environment Promotion**.
3. (Optional) Define the following filter values:
   - From Date
   - To Date
   - Last Modified User
4. Click **Go.**
5. Select the object(s) from the list of **Object Type**.
6. (Optional) Click the magnifying glass icon to sub-select from the list of **Object Type**.
7. Click **Export**.
8. (Optional) Add a comment and click **Submit**.
9. Navigate to **Administration**, **Environment Promotion**, **View Jobs**, **View Log** to view the status of the submitted export package. The status can be any one of the following:
   - **Not Started**: Specifies that the export package is scheduled in the queue.
   - **Running**: Specifies that the export package is running.
   - **Complete**: Specifies that the export package is exported successfully.

- **Canceled:** Specifies that the export is cancelled. Displayed when a user cancels any running operation using the **Cancel** button.
- **Failed:** Specifies that the export job fails.
- **Interrupted:** Specifies that the export job is interrupted.

Verify the Export

- After completion, you can view the exported package in the *Root/APM Promotion/Export* folder. Check the apmp_export_time stamp.zip export package.
- To verify errors or failures encountered during the export process, check the *apmp.log* in the Root */APM Promotion/logs* folder.

How to Cancel Export

You can cancel an export job only if the status is **Not Started**.

Follow these steps:

1. Log in to CA APM as a system administrator.
2. Navigate to **Administration** tab, **Environment Promotion**, **View Jobs**.
3. Select the export job that you want to cancel and click **Cancel Job.**
   The confirmation dialog appears.
4. Click **Ok**.
   The export is cancelled and the job status changes to Canceled.

DryRun

Perform a DryRun to validate the compatibility of the export package in the target system without actually importing it.

For example, Visibility is a property of the foreign key search configuration attribute. The visibility of the foreign key search configuration attribute in the source is promoted to the target environment.

If the source target attributes visibility is set to **Search Criteria** and on the target system it is set to **Search Results,** after Environment Promotion the target environment attributes visibility changes to **Search Criteria**.

Important! We recommend that you perform a DryRun before initiating the import to ensure that the changes are promoted without any failure.

How to Perform DryRun

We recommend that you initiate DryRun before executing the Import process.

Follow these steps:

1. Copy the export package from the source system to target system and paste this package in the *Root/APM Promotion/Import* folder.
2. Click Start, Run to open the command prompt (cmd) window.
3. Change the directory to the CA APM Promotion folder.
4. Execute the DryRun command (see page 1671).
5. Enter the CA APM System Administrator User Name and press Enter.
6. Enter the CA APM System Administrator Password and press Enter.
   The DryRun operation is completed and a summary report is created.
7. Press Enter to exit the console.
8. Navigate to the *Root/APM Promotion/DryRun* folder.
9. Access the apmp_dryrun_timestamp.csv file.
10. Sort the file by status, and take corrective measure for the records with status **Conflict**.

> **Important!** For a successful import, we recommend that you take corrective measure for the records with status **Conflict**.

DryRun Status Definition

The following table lists the DryRun status definition:

Status	Definition
New	The source content does not exist on the target system and hence it is promoted to the target system.
Update	The source content matches the target content and hence it is promoted to the target system.
Skip	The source content is not promoted to the target system as the dependent content does not exist on the target system.
Conflict	Due to a conflict with the target content, the source content is not promoted to the target system. For example, the source and target system **global configuration** names are the same, however the object types/sub-types are different .

Status	Definition
Conditional	The source content is promoted only when the dependent content is available on the target system while importing.

Import

Verify Prerequisites

- Back up your system database (MDB). This ensures safe data recovery if any problems are encountered.
- You must have the CA APM administrator account name and password.
- The target environment must be at the same patch level as the source environment.
- Copy the export package from the source system to target system and paste this package in the *Root/APM Promotion/Import* folder.
- Ensure that you have sufficient disk space (atleast 500 MB) on the target system where you plan to import.
- The DB server (Oracle or MS SQL) on the source and target system must be the same.

How to Perform Import

After a successful DryRun, initiate the Import process to promote the content to the target system.

Follow these steps:

1. Click Start, Run to open the command prompt (cmd) window.
2. Change the directory to the CA APM Promotion folder.
3. Execute the Import command (see page 1671).
4. Enter the CA APM System Administrator User Name and press Enter.
5. Enter the CA APM System Administrator Password and press Enter.
   After a while the import operation completes.
6. Execute the following command to stop and restart IIS:

   ```
   iisreset
   ```

7. Press Enter to exit the console.
8. Copy the Data Importer dependent files from the source system to the target system in the *Root/Storage/Common Store/Import* and *Root/Storage/Tenant Name/Import* folders.

Verify the Import

After importing the content to the target system, verify the changes are reflected on the target system.

1. A summary report is generated in the *Root/APM Promotion/Import* folder. Check the *apmp_import_timestamp.txt* file.

2. If any failures are encountered during import, rerun the import process using the same package.
   The import process restarts from the point of failure.

> **Note:** To verify errors or failures encountered during the import process, check the *apmp.log* in the Root */APM Promotion/logs* folder.

CA APM Environment Promotion Limitations

The following limitation applies to CA APM Environment Promotion:

- The new data importer definitions are promoted, however the job schedules are not promoted.
- The new data importer definitions are promoted, however the related data files and legacy map files are not promoted.

Object Status After Mapping from Source to Target Systems

This article describes the Environment Promotion behavior at an object level.

List Management Data

For example, when the source and target system contain the same list management data and tenant name, then the object is promoted to the target system with operation status as Skip.

List Management Data	Tenant Name	Operation
Same	Same	Skip
Same	Different	New
Different		New

Configuration

For example, when the source and target system contain the same global configuration and type /subtype, then the object is promoted to the target system with operation status as Update

Configuration Name	Global Configuration	Type /Subtype	Operation
Same	Yes	Same	Update
Same	Yes	Different	Conflict
Same	No	Same	Update
Same	No	Different	Conflict
Different	Yes	Same	Conflict
Different	Yes	Different	New
Different	No	Same	New
Different	No	Different	New

Roles

For example, when the source and target system contain the same roles, then the object is promoted to the target system with operation status as Update.

Roles	Operation
Same	Update
Different	New

Search Definition

For example, when the source and target system contain the same search definition name and type /subtype, then the object is promoted to the target system with operation status as Update.

Search Name	Type/Subtype	Operation
Same	Same	Update
Same	Different	Conflict
Different		New

Export Definition

For example, when the source and target system contain the same export definition and tenant name, then the object is promoted to the target system with operation status as Update.

Export Definition	Tenant Name	Operation
Same	Same	Update
Same	Different	Conflict
Different		New

Reconciliation Rule

Source reconciliation rules overwrite the target reconciliation rules.

Data Filter Definition

For example, when the source and target system contain the same data filter definition and type /subtype, then the object is promoted to the target system with operation status as Update.

Data Filter Definition	Type/Subtype	Operation
Same	Same	Update
Same	Different	Conflict
Different		New

Event Definition

For example, when the source and target system contain the same event definition and PAM workflow name, then the object is promoted to the target system with operation status as Update.

Event Definition	PAM Workflow Name	Operation
Same	Same	Update
Same	Different	New
Different		New

Data Import Definition

For example, when the source and target system contain the same data import definition and tenant name, then the object is promoted to the target system with operation status as Skip.

Data Import Definition	Tenant Name	Operation
Same	Same	Skip
Same	Different	New
Different		New

Extended Field

For example, when the source and target system contain the same extended field and type/subtype, then the object is promoted to the target system with operation status as Skip.

Extended Field	Type /Subtype	Operation
Same	Same	Skip
Same	Different	Skip
Different		New

Configuring Unified Self-Service

This section contains the following articles:

Onboard Tenants

This article contains the following topics:

After the Unified Self-Service installation, create tenants by onboarding them. Tenants are your customers or partners who share Unified Self-Service environment and can use the Unified Self-Service capabilities.

Create a Tenant

Create a unique tenant in Unified Self-Service so that the tenant can access the Unified Self-Service capabilities.

Follow these steps:

1. Log in to the following URL as the administrator:

   ```
   http://Web Host:Tomcat Port/web/guest/onboarding
   ```

   Note: On Windows you can also select Start, Program, All Programs, CA, Unified Self-Service, Onboarding to create a tenant.

2. Provide the following details:

- **Company Name**
  Specifies the company name of the tenant that you want to onboard. Depending on your input for this field, Web ID, Mail Domain, and Company Host fields are pre-populated. You can modify these pre-populated fields according to your organization requirements.
  Example: Company Inc

- **Web ID**
  Specifies the web domain of the tenant. This ID is a user-generated ID for the instance. A web ID must be unique.
  Example: company.com

- **Mail Domain**
  Specifies the mail domain of the tenant that you are boarding. Unified Self-Service uses this information to send email notifications from the portal. This mail domain is a domain part of the email address. If your email is someone@company.com, then company.com is the mail domain.
  Example: company.com

- **Company Host**
  Specifies a unique host name for the tenant. There can be multiple examples within the same domain. For example, Finance.company.com, HR.company.com. Here, Finance or HR are tenant host names.
  Example: test.company.com

  Note: The Web ID, Mail Domain, and Company Host must not contain special characters.

3. Click **Next**.

4. Provide the login credentials of the tenant administrator.

   - **Admin ID**
     Specifies the user name of the tenant administrator.

   - **Password**
     Specifies the password for the tenant administrator.

   - **Confirm Password**
     Enter the password again.

5. Click **Next**.
   The OnBoarding summary page is displayed.

6. Click **Start Onboarding**.
   The OnBoarding page is displayed.

> **Note:** Add an entry in the DNS server with the Company Host of the new tenant pointing to the Unified Self-Service server. For the testing purpose, you can add an entry in the C:\Windows\System32\drivers\etc\hosts on the client machine for the onboarded tenant.

Format: <*Unified_Self_Service_Server_IP_Address*> <*Company_Host*>

Example: 10.131.87.34 test.company.com (http://test.company.com)

7. Click **Go to Company Portal**.
   The Company portal opens. Share this portal detail with the tenant. After you create a tenant, the onboarding process creates a set of default users with different roles.

8. Log in to the Unified Self-Service tenant control panel as a tenant administrator.
   Example: http://<*Company_Host_Name*>:8686/group/control_panel

9. Navigate to Control Panel, Users and Organizations.
   The default users are listed. The default users are created with the password aquila.

Disable Onboarded Tenant

An administrator can disable an onboarded tenant from the Unified Self-Service control panel. This action cannot be performed by the tenant administrator from the Unified Self-Service tenant control panel.

Note: A default tenant cannot be disabled.

Follow these steps:

1. Log in to the Unified Self-Service control panel as the administrator.
   Example: http://<*Unified_Self_Service_Server_Name*>:8686/group/control_panel

2. Select Server, Portal Instances, and click on the Web ID of the onboarded tenant.
   The onboarded tenant details are displayed.

3. Clear the **Active** check box and click **Save**.
   The tenant is disabled.

Authenticate Users

You can authenticate Unified Self-Service users using one of the following methods:

- Configure CA EEM Authentication (see page 1682)
- Configure CA EEM With NTLM Authentication (see page 1683)
- Configure CA SiteMinder Authentication (see page 1684)
- Configure CA SiteMinder With CA EEM Authentication (see page 1686)

- Import Users from LDAP (see page 1687)

Configure CA EEM Authentication

If you have an existing installation of CA EEM, you can use the same for authenticating Unified Self-Service users. For more information about installing and configuring CA EEM, see the CA EEM documentation. Specify the EEM authentication details in Unified Self-Service for CA EEM users to log in to Unified Self-Service.

Follow these steps:

1. Log in to the Unified Self-Service tenant control panel as a tenant administrator.
   Example: http://<*Company_Host_Name*>:8686/group/control_panel

   Note: To configure the CA EEM authentication for a default tenant, login to the http://<*Unified_Self_Service_Server_Name*>:8686/group/control_panel URL as the administrator.

2. Under Portal, select Portal Settings, Authentication, EEM.

3. Select the Enabled check box to use CA EEM authentication and enter the following information:

   - **EEM Server Name**
     Specifies the host name of the CA EEM server.

   - **EEM Administrator Username**
     Specifies the CA EEM Admin username.

   - **EEM Administrator Password**
     Specifies the password for the **EEM Administrator Username**.

   - **EEM Application Administrator Group**
     Specifies the CA EEM group whose members are to be imported as administrators in Unified Self-Service.

     Important! This field is pre-populated with the OpenSpaceAdminGroup name, which you can modify. Ensure that a group is created in CA EEM with this **EEM Application Administrator Group** name and all your CA EEM users (who are intended to be Unified Self-Service administrators) are added to this group. All the users who are part of this group are considered as administrators of Unified Self-Service.

   - **EEM Default User Role (Optional)**
     Specifies the CA EEM role (Administrator or Business User) who is added after the authentication.

Important! If this role is not specified, then all the users are imported to Unified Self-Service as Business Users.

- **EEM Application Name (Optional)**
  Specifies the application within a CA EEM server, which is used for authentication.

- **EEM User Default Organization (Optional)**
  Specifies the default organization of the user. Enter the name of the organization (Web ID) that you specified during onboarding.

4. If you want to configure CA EEM with NTLM authentication, select the **Enable NTLM(v1) Authentication** check box. For more information about the CA EEM with NTLM authentication, see the Configure CA EEM With NTLM Authentication (see page 1683) topic.

5. Click **Save**.
   CA EEM authentication is configured.

Note: If the users are unable to log in Unified Self-Service using the CA EEM authentication, disable the CA EEM authentication (see page 1683).

Disable the CA EEM Authentication

If the users are unable to log in Unified Self-Service using the CA EEM authentication (this may happen because of incorrect or modified CA EEM server name) disable this authentication.

Follow these steps:

1. Log in to the Unified Self-Service server.

2. Open the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory.

3. Add the <*tenant-web-id*>.eem.authentication.enabled.override flag to true and save the file.
   For example, tenantA.eem.authentication.enabled.override=true. This Web ID can be obtained from the Portal Instances page of the Unified Self-Service control panel.
   The CA EEM authentication settings for that tenant are ignored by Unified Self-Service. The Enabled check box on Unified Self-Service tenant control panel may still be checked, but it does not affect the CA EEM authentication if the flag is set to true.

Configure CA EEM With NTLM Authentication

Configure the CA EEM with NTLM authentication for a logged in domain user to silently (SSO) log in to Unified Self-Service.

Follow these steps:

1. Ensure the following considerations:

- Unified Self-Service server and CA Service Catalog server must be in the same domain where you want to use the windows authentication. CA EEM server must be configured with Active Directory of the same domain.
- Active Directory users should be able to login to the client machine present in this domain.

2. Log in to the Unified Self-Service tenant control panel as a tenant administrator.
   Example: http://<*Company_Host_Name*>:8686/group/control_panel

   Note: To configure the CA EEM with NTLM authentication for a default tenant, login to the http://<*Unified_Self_Service_Server_Name*>:8686/group/control_panel URL as the administrator.

3. Select Portal Settings, Authentication, EEM.
4. Configure CA EEM Authentication (see page 1682) for the Unified Self-Service server.
5. Verify the CA EEM with NTLM authentication:
   a. Ensure that CA SDM and CA Service Catalog data sources integrated with Unified Self-Service. For more information, see the Configure Data Sources (see page 1687) topic.
   b. Ensure that the integrated CA SDM and CA Service Catalog data sources are also authenticated with NTLM for the CA SDM details and CA Service Catalog widgets to appear on Unified Self-Service. For more information, see the respective product documentation.
   c. Enter the Unified Self-Service URL.

   Windows users should be able to log in without being asked for the credentials.
6. (Optional) To use the NTLM authentication on the Mozilla Firefox browser, complete the following steps:
   a. Enter about:config on the Firefox browser.
   b. Search for ntlm.
   c. Enter the Unified Self-Service URL (that is to be authenticated with NTLM) and CA Service Catalog URL as the network.automatic-ntlm-auth-trusted-uris value, separated by comma.

Configure CA SiteMinder Authentication

Specify the CA SiteMinder authentication details in Unified Self-Service so that users with CA SiteMinder credentials can log in to Unified Self-Service.

Follow these steps:

1. Install the Apache server and install CA SiteMinder agent on the Apache server.

2. Open the httpd.conf file located in conf folder the Apache server.
   Example: C:\Program Files (x86)\Apache Software Foundation\Apache2.2\conf\

3. Ensure that the httpd.conf file has the following configuration:

```
<IfModule proxy_module>
    ProxyRequests Off
    <Proxy *>
         Order deny,allow
         Allow from all
     </Proxy>

    # This is important -
    # Don't forward URIs which starts with /siteminderagent to open space
server.
    ProxyPass /siteminderagent !

    #Forward all URI to given urls
     ProxyPass / http://<web-id-of-the-company:port>/
    ProxyPassReverse / http://<web-id-of-the-company:port>/
       ProxyPreserveHost Off
     ProxyErrorOverride On
</IfModule>
```

4. Ensure that you have enabled the following modules in the conf file:

```
LoadModule proxy_module modules/mod_proxy.so
LoadModule deflate_module modules/mod_deflate.so
LoadModule headers_module modules/mod_headers.so
LoadModule proxy_ajp_module modules/mod_proxy_ajp.so
LoadModule proxy_http_module modules/mod_proxy_http.so
LoadModule rewrite_module modules/mod_rewrite.so
```

5. Stop the Apache server, wait till LLAWP.exe is killed, and start the Apache server.
   The Apache server is configured with the reverse proxy pointing to the Unified Self-Service server.

6. If you are not using a default tenant for CA SiteMinder authentication, add an entry in the DNS server with the Company Host of the new tenant pointing to the Unified Self-Service server. For testing purpose, you can add an entry in the C:\Windows\System32\drivers\etc\hosts on the Apache web server machine for the onboarded tenant.
   Format: *Unified_Self_Service_Server_IP_Address Company Host*
   Example: 10.131.87.34 test.company.com

7. Log in to the Unified Self-Service server and add the following configuration details in the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory:

```
#### Reverse Proxy Configuration
web.server.protocol=http
```

```
web.server.http.port=80
web.server.https.port=-1
web.server.host=<apache-host-name>
```

8. Log in to the Unified Self-Service tenant control panel as a tenant administrator.
   Example: http://<*Company_Host_Name*>:8686/group/control_panel

   Note: To configure CA SiteMinder authentication for a default tenant, login to the http://<*Unified_Self_Service_Server_Name*>:8686/group/control_panel URL as the administrator.

9. Select **Portal Settings**, **Authentication**, **SiteMinder**.

10. Select the **Enabled** check box.

11. Import Users from LDAP (see page 1687) and select the **Import Users from LDAP** check box.
    CA SiteMinder authentication is configured.

12. Verify the CA SiteMinder authentication:

    a. Log in to any machine and access the Apache server using the http:// *Apache_Server_Host_ Name*:*Apache Port Number* URL.

    b. Enter the CA SiteMinder credentials on the CA SiteMinder authentication window.
    The Unified Self-Service Home page is displayed.

Configure CA SiteMinder With CA EEM Authentication

Specify the CA SiteMinder with CA EEM authentication details in Unified Self-Service for CA SiteMinder and CA EEM users to log in to Unified Self-Service.

Follow these steps:

1. Ensure that CA SiteMinder is configured with the same LDAP directory that is configured with CA EEM and Unified Self-Service.

2. Ensure that CA Service Catalog should be configured with the same CA EEM and CA SiteMinder for the users to view the CA Service Catalog widgets in Unified Self-Service.

3. Configure CA SiteMinder Authentication (see page 1684) for the Unified Self-Service server.

4. Use the CA SiteMinder server policy configuration to ignore the /usm/services URL from the configuration object of the CA Service Catalog Agent. For more information about how to ignore the URL, see the CA SiteMinder documentation.

5. For users to access the ITSM mobile application, skip the following URLs to ignore the CA SiteMinder authentication:

   - /rest/ (to skip the REST API URLs)

- /itsm/ (to access the mobile application without any CA SiteMinder authentication).

Import Users from LDAP

Import the users from LDAP to Unified Self-Service.

Follow these steps:

1. Log in to the Unified Self-Service tenant control panel as a tenant administrator.
   Example: http://*<Company_Host_Name>*:8686/group/control_panel

   Note: For a default tenant, login to the http://*<Unified_Self_Service_Server_Name>*:8686/group/control_panel URL as the administrator.

2. Click Portal Settings, Authentication, LDAP.
3. Select Enabled and Import Enabled check boxes.
4. Click Add to enter the LDAP details.
5. Click Save.
   The LDAP users are imported to the database.

Note: For more information about importing users from LDAP, see the Liferay documentation.

Configure Data Sources

Unified Self-Service integrates with several data sources to provide rich search results and extended application functionality. You can integrate Unified Self-Service with the following data sources:

- CA Service Desk Manager
- CA Service Catalog
- Google
- Microsoft SharePoint

To learn how to configure the data sources, see the following articles:

- How to Configure CA SDM Data Source (see page 1688)
- How to Configure the CA Service Catalog Data Source (see page 1692)
- How to Configure the Google Data Source (see page 1693)
- How to Configure the Microsoft SharePoint Data Source (see page 1694)

How to Configure CA SDM Data Source

Configure the CA SDM data source for the users to create, review, and update their requests directly within Unified Self-Service, and search knowledge base articles within the CA SDM Knowledge Base. In addition, you can enable Live Chat in the Unified Self-Service interface to allow users to chat with an IT analyst and also allow users to access the CA SDM mobile application.

Follow these steps:

1. Verify Prerequisites (see page).
2. Configure CA SDM Data Source (see page).

Verify Prerequisites

Verify the following prerequisites before configuring the CA SDM data source:

- CA SDM 12.6, 12.7, or 12.9 must be installed and configured with Unified Self-Service.
- Create or use DEFAULT Web Services Access Policy from CA SDM. Ensure that you select the Allow Impersonate check box and you enter the Proxy Contact detail for this policy.
- Generate an authentication certificate for the Access Policy. CA SDM provides a server-side utility that can generate a certificate. Execute the following command from the CA SDM server to generate the certificate for the access policy:

  ```
  pdm_pki -p policy_name
  ```

  This command generates an authentication certificate file *policy_name*.p12. Upload this file during the CA SDM data source configuration with Unified Self-Service.
- Ensure that the Unified Self-Service users available in CA SDM have the same User ID and email address for a successful configuration.
- For Unified Self-Service users to use CA SDM live chat, Support Automation must be set up in CA SDM. For more information, see Support Automation (see page 2821).

Customize CA SDM Data Source Property

As an administrator, define the maximum number of CA SDM fields that a user can configure in the Unified Self-Service (USS) console.

Follow these steps:

1. Log in to Unified Self-Service server as an administrator.
2. Navigate to the OSOP folder and edit the file: *portal-ext.properties*
3. In the *sdm.configFields.maxFieldsToShowInConfigOptionsPage* property, define the maximum number of CA SDM fields that you want to configure on the USS console.
   The default value is 10.

4. (Optional) In a tenanted environment, you can set the maximum number of fields for each tenant using the *someCompany.com.sdm.configFields.maxFieldsToShowInConfigOptionsPage* property.

    a. Replace *someCompany.com with the* Web ID of the tenant.

    You can obtain the Web ID from the Portal Instance in the Control Panel: *http (s)://server-name:<port-no>/group/control panel > Portal Instances*
    For example, *ca.com.sdm.configFields.maxFieldsToShowInConfigOptionsPage=20*

    > **Note:** The value in the *sdm.configFields. maxFieldsToShowInConfigOptionsPage* property is overridden by the tenant specific values.

5. Save the file and restart (see page 1704) the services.

Configure CA SDM Data Source

Configure CA SDM data source for the users to create, review, and search information from CA SDM directly in Unified Self-Service.

Follow these steps:

1. Log in to Unified Self-Service as an administrator.
2. In the menu, click Settings, Data Sources.
3. Click the arrow for the CA SDM data source and enter the following configuration information:

    - **NAME**
      Specifies the name for the CA SDM data source. This name is displayed in the header for search results from the CA SDM Knowledge Base.
    - **TICKET TYPE**
      Indicates the type of Help desk tickets that are implemented in your organization.
    - **LABEL FOR TICKET TYPE**
      Specifies the label that you want to associate with the selected ticket type.
    - **DEFAULT PRIORITY**
      Specifies the default priority level for new requests.
    - **URGENT PRIORITY**
      Specifies the priority level for urgent requests.
    - **BASE URL**
      Specifies the CA SDM server URL. To verify this value, enter the URL in a browser. If you see the CA SDM interface, then the value is correct.
      Format: http://*<CA_SDM_Server_Hostname>:<Port_Number>*/
      Example: http://servicedesk.test.com:8080

- **WSDL URL**
  Specifies the relative URL of the web services endpoint on the CA SDM server. By default, this URL is generated for you. For some CA SDM deployment configurations, you may have to override this value with a value provided to you by CA Support.
  To verify this value, enter the complete URL in a browser, that is, the Base URL plus the WSDL URL. If the value is correct, you see an XML document (the WSDL).
  Example: http://servicedesk.test.com:8080/axis/services/USD_R11_WebService?wsdl

- **SERVER HOST NAME**
  Specifies the servlet server as defined in CA SDM for Service Desk attachment repository. Since this host name is case-sensitive, run the *hostname* command from the CA SDM server and enter exactly the same value that is returned from the command.

  Important! In the advanced availability configuration, if you have used the background server host name for this field and the system administrator performs a scheduled failover, the background server becomes the standby server. You must add the new background server host name to this field after the failover.

- **ACCESS POLICY**
  Specifies the name of the Web Services Access Policy as configured during the CA SDM installation and that is used to generate the authentication certificate. Use the access policy mentioned in the Verify Prerequisites (see page) topic.

4. Click **UPLOAD CERTIFICATE** to upload the authentication certificate that you created in the Verify Prerequisites (see page) topic. The certificate file name must match the name of the **ACCESS POLICY**.

5. Follow these steps to enable live chat:

   a. Select **YES** to enable Live Chat from the Search, Home, and Request pages.

   b. (Optional) Customize the Live Chat link text (Default text: Chat with an IT Analyst now!).

   Important! Users with OOTB Customer access type cannot create tickets (incident or request) or launch live chat from Unified Self-Service. The Customer access type must have Employee as the role in CA SDM to perform these actions. For more information, see Support Automation (see page 2821) .

6. In the **INSTRUCTIONS** field, enter information that should appear at the top of new request forms.

7. In the **SERVICE DESK REST URL FOR MOBILE APP** field, enter the CA SDM server URL (where REST is installed and configured) to allow users to access the ITSM mobile application.
   Format: http://<*CA_SDM_Server_Host_Name*>:<*Rest_Port_Number*>/
   Example: http://<*CA_SDM_Server_Host_Name*>:8050/

8. Click **TEST CONNECTION**. If it fails, review the data that you entered and correct as necessary.

9. When you are ready to enable the data source for your organization, set the **STATUS** to **Enabled**.

10. Click **SAVE**.
    Unified Self-Service is integrated with CA SDM and the data source is available for your users. You can now configure the request form to include the fields and information that your organization requires.

11. Configure Request Form (see page 1691).

Configure Request Form

You can configure the request form that your organization users use to create a CA SDM request. The request form comes prepopulated with some standard fields that cannot be modified. You must add the fields that your implementation of CA SDM requires to create requests. You can also add optional fields to record any other information. The requester can fill these fields, or you can design fields that automatically pass preset information. You can add as many fields as you need to the request form. The number of fields that you can configure is defined in the *portal-ext.properties* file. For more information about configuring the maximum number of default or tenant specific fields, see Configure CA SDM Data Source Property (see page 1688).

Note: This task assumes that you are working with a CA SDM administrator. Unified Self-Service cannot discern what fields your CA SDM installation requires to create a valid request.

Follow these steps:

1. On the Data Sources page for CA SDM, click **CONFIGURE NOW**.
   The field table listing the fields that are currently in use for request forms appears.

2. To add new fields to the request form, do the following steps for each addition:

   a. Click the drop-down arrow and select the required field to add.

   b. Click **ADD FIELD**.

   c. Set values and properties for the new field as follows:

   - **DEFAULT VALUE**
     Sets a default value for the new field.

   - **DISPLAY NAME**
     Defines the field name that displays on the request form.

   - **HINT TEXT**
     Defines the instructional text that appears in the field.

- **DISPLAY**
  Controls whether the field is visible on the request form.
  Limit: Five fields.

- **REQUIRED**
  Indicates the mandatory fields that you must define before you submit the request.

> **Note:** When you select the ticket type as an Incident, the **DISPLAY NAME** and **HINT TEXT** values of the priority (string) field must be changed to an Urgent Incident. As a result, while creating the incident, you can see an Urgent Incident check box instead of an Urgent Request check box.

3. (Optional) Drag and drop the new fields into the required order.

4. Click **SAVE**.
   Your request form changes are saved and all new requests reflect the new configuration.

How to Configure the CA Service Catalog Data Source

Configure the data source for the users to create, review, and search for information from CA Service Catalog in Unified Self-Service. Before you configure this data source, verify that the Unified Self-Service tenant is configured with same CA EEM server that is configured for CA Service Catalog.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.

2. In the menu, click Settings and then click Data Sources.

3. Click the arrow for the CA Service Catalog data source and enter the following fields:

   - **NAME**
     Specifies the name of the data source.

   - **BASE URL**
     Specifies the URL to access CA Service Catalog.
     Format: http://*CA_Service_Catalog_Server_Hostname*:*Port_Number*/usm/

   - **DEFAULT REQUEST OFFERING ID**
     Specifies the ID related to the **Report an Issue** offering from CA Service Catalog. When the Unified Self-Service user clicks REPORT AN ISSUE to create a request, the request form that is displayed corresponds to this ID. You can obtain this ID from CA Service Catalog. For example, log in to CA Service Catalog, navigate to Catalog, Offerings, IT Support Services, Service Management, Report an Issue, and obtain the ID from the Details page. Ensure that the CA Service Catalog server is imported with the Service Management content pack. For more information about the content pack, see the CA Service Catalog documentation.

- **(Optional) COMMON ADMINISTRATION OFFERING ID**
  Specifies the offering ID to display the administrative service offerings of the solution. As an administrator, if you want to access the common administration service offerings quickly from the menu bar, specify the common administration offering ID from CA Service Catalog.

- **Service Desk (Tickets) View**
  Indicates whether you want users to view the CA SDM tickets (incidents or requests) on Unified Self-Service. These tickets were created before configuring the CA Service Catalog data source.

- **(Optional) MY RESOURCE OFFERING ID**
  Specifies the offering ID to display the assets owned by the logged in user. If you want the Unified Self-Service users to view the assets requested from CA Service Catalog, you must enter the **My Resources** offering ID from CA Service Catalog. You can obtain this ID from CA Service Catalog.
  For example, log in to CA Service Catalog , navigate to Catalog, Offerings, IT Support Services, Service Management, My Resources, and obtain the ID from the Details page. Ensure that the CA Service Catalog server is imported with the Service Management content pack. For more information about the content pack, see the CA Service Catalog documentation.

- **(Optional) BUSINESS UNIT**
  Specifies the name of the business unit in CA Service Catalog.

- **(Optional) EEM APPLICATION CONTEXT**
  Specifies the application context name used in CA EEM for CA Service Catalog.

4. Upload the PEM File and Key File to access CA Service Catalog. These files can be obtained from the CA Service Catalog installation directory.

5. Click **TEST CONNECTION** to test the data source connection.

   - If the connection is not successful, review the data that you entered and correct as necessary.

   - If the connection is successful, select the **STATUS** as **ENABLED**.

6. Click **SAVE**.

The CA Service Catalog data source is configured for the Unified Self-Service users to access.

How to Configure the Google Data Source

Unified Self-Service integrates with Google Search to provide search results from Google directly within Unified Self-Service. Google Search is configured for you; no additional setup is necessary. You enable or disable this feature for all users by editing the Google data source. The Google data source includes a global local setting. This setting allows you to specify a country to focus your users search results. This setting is a global setting that affects all users; users cannot set this value individually.

Follow these

1. Log in to Unified Self-Service as an Administrator.
2. In the menu, click Settings and then click Data Sources.
3. Select Data Sources from the Administration page.
4. Click the arrow for the Google data source.
5. Select STATUS as Enabled.
6. Specify the country to focus your search results for the selected geography.
7. Click SAVE.
   Google Search is enabled. When Unified Self-Service users search for information from the Google Data source, the results are provided by Google from the respective geographic region of the user.

Note: If the user is using a proxy server to use the internet, add the following entries in the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory:

```
# Aquila Search
aquila.search.googleProxyUserName=
aquila.search.googleProxyPassword=
aquila.search.googleProxyIP=
aquila.search.googleProxyPort=
aquila.search.useProxyForGoogle=yes
```

How to Configure the Microsoft SharePoint Data Source

This article contains the following topics:

Microsoft SharePoint is widely used as an enterprise business collaboration platform and for storing documents. Unified Self-Service search integrates with Microsoft SharePoint to include search results from your SharePoint server.

Follow these steps:

Enable SharePoint Access from the Internet

Unified Self-Service search integrates with Microsoft SharePoint to include search results from your SharePoint server. If your organization has Microsoft SharePoint (that is implemented within your Intranet), integration with Unified Self-Service requires some additional configuration. This configuration requires a SharePoint server that can be accessed from the Internet. The SharePoint server can either be your primary application server, if it is accessible from the Internet, or a secondary server could be deployed in the DMZ.

Follow these steps:

1. On Microsoft SharePoint 2003/2007, open the SharePoint Central Administration Site.
   Note: The navigation may vary based on the Microsoft SharePoint version you deployed. Microsoft SharePoint 2003/2007 is considered only as an example.

2. Select the Operations tab.

3. Under Global Configuration, click Alternate access mappings.

4. Click Add Internal URL.

5. Select the Alternate access mappings collection for the SharePoint site that you want to connect to Unified Self-Service.

6. Add all Unified Self-Service server hostname URLs.
   Example: http://*Unified_Self_Service_Server_Hostname*/
   Once you add the hostnames to the SharePoint Alternate access mappings, you can integrate Unified Self-Service with your SharePoint instance.

Configure the Microsoft SharePoint Data Source

Configure the Microsoft SharePoint.data source to search information from the SharePoint server in Unified Self-Service.

Follow these steps:

1. Log in to Unified Self-Service as an Administrator.

2. In the menu, click Settings and then click Data Sources.

3. Click the arrow to enter the following configuration information.

   - **NAME**
     Defines the data source name.

   - **URL**
     Defines the URL of your web service that your SharePoint server hosts and is accessible from the Internet.
     Format: http://<hostname>

- **USER NAME**
  Identifies the user name of a user who has access to documents stored in SharePoint. This name is used for authentication for the search API. However, it is the logged in user that determines the document access level.

- **PASSWORD**
  Identifies the password of the user that is listed for User Name. This password is used for authentication.

4. If you enabled the Unified Self-Service Connection, select YES to use it.

5. Click **TEST CONNECTION** to test the data source connection. If the test is not successful, review the data that you entered and correct as necessary.

6. When you are ready to enable the data source for your organization, set the **STATUS** to **ENABLED**.

7. Click **SAVE**.
   Microsoft SharePoint data source is configured in Unified Self-Service.

How to Create and Manage Communities

This article contains the following topics:

As a tenant administrator, you create a community in Unified Self-Service and assign the community owners. Community owners manage the communities in your organization.

Create a Community

A tenant administrator creates a community (apart from the existing General Topics community) in Unified Self-Service to facilitate communication among members on a specific subject. You can create two types of communities using Unified Self-Service:

- **Open**
  Specifies an open community that is accessible to every Unified Self-Service user. All users can view posts in an open community, however only members can reply or post messages. Members can join or leave the community any time.

- **Private**
  Specifies a private community that is restricted and designed for a limited audience to use for private conversations. Members outside the private community cannot see these communities or post messages. Only the community owner and the tenant administrator can add or remove members.

Follow these steps:

1. Log in as the tenant administrator and access the following URL:

   ```
   http://<Company_Host_Name>:<Port_Number>/
   ```

   Note: For a default tenant, log in as an administrator and access http://<*Unified_Self_Service_Server_Name*>:<*Port_Number*> URL.

2. In the Menu bar, click Settings, Communities.

3. Click Add Community.

4. Enter a name for the new community, select the type, and specify a description that explains the purpose and scope of the community.

5. Click Save.
   The community is created.

Assign Community Owners

The tenant administrator assigns owners to a community.

Follow these steps:

1. On the Manage Communities page, find the community to which you want to assign an owner and click the edit icon  .
   The Community details page appears.

2. Select the Owner check box against the user that you want to assign as an Owner.

   Note: You can assign more than one owner for a community.

3. Click Save.
   The community owners are assigned.

Add Community Members

Users can either join a community directly or request to join depending on whether the community is open or private. Community owners are responsible for individual communities.

Note: Only a community owner can add community members.

Follow these steps:

1. On the Manage Communities page, navigate to the community you want to add members and click the icon  .
   The Member Directory page appears.

2. Select the check box next to the names you want to add as members.

3. Click Save, Done.
   The new community members are added.

Note: The tenant administrator creates communities. The community owners can monitor their own communities.

Monitor the Community

Community owners monitor the community content for its accuracy and track activities on the Unified Self-Service console. The community owner takes care of the memberships.

Email notifications are sent for every post on the community. Community owners need to monitor the posts and delete inappropriate posts, if any.

Follow these steps:

1. Open the email notification about the inappropriate post and click the link provided in the email.
   The Unified Self-Service login page opens.

2. Log in to Unified Self-Service.

3. Verify the inappropriate post that the community member has reported.

4. Delete the post by clicking the delete icon or modify the inappropriate post.

After you create and manage the communities, the members of the communities can communicate and collaborate effectively.

Enable or Disable the Community

As a USS administrator, you can enable or disable the community from the USS console for all or specific tenants.

Follow these steps:

1. Log in to Unified Self-Service server as an administrator.
2. Navigate to the *$US4SM/*OSOP folder and edit the file: *portal-ext.properties*

   Note: *$US4SM* is the default Open Space installation directory.

3. Set the *disable.uss.community* property value to *true* to disable the community from the console.
   By default, the community board is enabled.
4. (Optional) Disable the community for a specific tenant by setting the value in the *someCompany.com.disable.uss.community* property.
5. Replace *someCompany.com* with the Web ID of the tenant.
   You can obtain the Web ID from the Portal Instances in the Control Panel: *http(s)://server-name:<port-no>/group/control panel > Portal Instances*
   For example, ca.com.*disable.uss.community=true*
   The value in *disable.uss.community* property is overridden by the tenant specific values.

   Note: By default, the community is enabled for all tenants.

6. Save the file and restart (see page 1704) the services.

Configure Notifications

This article contains the following topics:

Enable Web Notification Feature

By default, the web notification feature in Unified Self-Service is disabled. You must enable it to use the feature.

Important! Enabling this feature may lead to performance degradation.

Follow these steps:

1. Log in to the Unified Self-Service server.
2. Open the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory.
3. Set the value for the following variables:

```
cometd.enable=true
live.users.enabled=true
session.tracker.memory.enabled=true
```

4. Save the file.
5. Restart Unified Self-Service services.
   Web notification is enabled.

Configure Email Notification for Default Tenant

OOTB, the email notification is enabled in Unified Self-Service, but, you are required to configure it for a default tenant.

Note: This action is not required for a newly onboarded tenant.

Follow these steps:

1. Log in to the Unified Self-Service control panel as the administrator.
   Example: http://<*Unified_Self_Service_Server_Name*>:8686/group/control_panel
2. Select Server, Portal Instances, and click on the Web ID of the default tenant (whose virtual host is specified as the localhost).
3. Change the virtual host name to Unified Self-Service server host name and click Save.
   Email notification is configured for the default tenant.

Support Non-English and Multi-Byte Characters in Screen Name

You can enter non-english and multi-byte characters in Screen Name. By default, this feature is disabled.

Follow these steps:

1. Log in to the Unified Self-Service server.
2. Open the portal-ext.properties file located in the OSOP folder of the Unified Self-Service installation directory.

3. Set the value for the following variable:

   ```
   bypass.liferay.screenname.validation=true
   ```

4. Save the file.

5. Restart Unified Self-Service services.
   Non-english and multi-byte characters are supported in Screen Name.

Change the Debug Log Settings

The administrator can change the log level settings in Unified Self Service to debug any error and to know the flow of request in the code.

Example: If you face some error while configuring DataSource, you can increase the log level of com.ca.sfo.portlet.datasource.action.ViewAction class.

com.ca.sfo.portlet.datasource.action.ViewAction is the Struts Action class, which gets the code to fulfill the web request.

Follow these steps:

1. Log in to the Unified Self Service control panel as the administrator.
   Example: http://*Unified_Self_Service_Server_Name*:8686/group/control_panel

2. Click Server Administration from the left pane.

3. To view the present log levels for each package, select the Log Levels tab.

4. To debug any error and to know the flow of request, change the level to Debug.
   You can find the log file (liferay.<date>.log) located in the OSOP folder of the Unified Self Service installation directory.

Add a New Category

Add a new category (package or class) to mention the log levels.

Follow these steps:

1. Click Add Category under the Log Levels tab.
   You can change the default log level from Debug, if necessary.

2. Enter package name and click Save.
   Example: com.ca
   Changes that are made to the log level take effect immediately. You need not re-start the server.

For any issues with DataSource configuration or Request creation, check the related data source logs.

Modify Unified Self-Service

You can change any of the following settings:

- Tomcat Settings
- Database Settings
- Administrator Settings
- Mail Server Settings

Important! Before you modify Unified Self-Service, ensure that you install JRE 1.7.51 or higher and set JAVA_HOME to the JRE path. Ensure to add JAVA_HOME in the Environment PATH variable.

Follow these steps:

1. Depending on your operating system, perform one of the following steps:
   - (Windows) Click Start, All Programs, CA, Unified Self-Service, Change Unified Self-Service Installation for Windows.
   - (LINUX) Navigate to the install directory, run Change Unified Self-Service Installation, select Modify Unified Self-Service Settings.
     The Manage Instances page opens.
2. Select Modify an Existing Instance and click OK.
3. Follow the on-screen instructions to modify the settings.

Configure Organization Name and Logo

You can customize Unified Self-Service to reflect the name and logo of your organization. Use the Unified Self Service Web client, Settings, Customization and set the following options:

- **HEADER LOGO**
  The logo appears in the banner area, next to the product name.

  Note: Use a transparent background for the logo, or match the color of the header background.

- **FAVICON**
  The favicon is the small icon displayed in the browser address bar and in bookmark lists.

Important! For supported IE browsers, use only .ico file, and select an icon that is of equal height and width.

- **COMPANY NAME**
  The company name appears on the browser title bar and tabs, and in bookmark lists.

Apply the Unified Self-Service Theme to the User Interface

Unified Self-Service has a new and improved user interface. If you are installing Unified Self-Service for the first time, the new user interface theme is automatically applied.

If you are upgrading from CA Open Space 2.0, 2.0 SP1, or 3.0, the Unified Self-Service user interface prompts you to apply the theme changes. However, if you do not see a prompt message on the user interface, you can apply the theme manually.

Note: We recommend you to apply the new theme to the user interface to leverage all the features of Unified Self-Service.

Follow these steps:

1. Log in to Unified Self-Service control panel as an administrator.

   `http://<Unified_Self_Service_Server_Name>:<port_number>/group/control_panel`

2. Click General Topics > Site Pages.
   The Site Pages page opens.

3. Click Public Pages and click Import.
   The Import window opens.

4. Under **Import a LAR file to overwrite the selected data**, click Choose Files and select the following location:
   C:\Program Files\CA\Open Space\OSOP\data\aquila\OpenSpace-v4.0.lar

5. Under Applications, uncheck the Archived Setups check box.

6. Under Other, check the Categories check box.

7. Click Import.

8. Log out from Unified Self-Service and log in again.

9. Verify the new theme changes.

Configure Unified Self-Service to Support a New Language

For information on how to configure Unified Self-Service to support a new language, click here (https://communities.ca.com/docs/DOC-231152439).

Managing Unified Self-Service Services

This article explains how to start and stop the Unified Self-Service (USS) services.

Start the USS Services on Windows

Follow these steps:

1. Navigate to *Start*, run and type *services.msc.*
2. Locate the service name: *CA Unified Self Service Server*
3. Right-click on the service and click **Start** to start the USS services.

Start the USS Services on Linux

Follow these steps:

1. Navigate to the *$US4SM* folder.
2. Locate the service name: *Start Unified Self-Service*
3. Execute the following command to start the USS services:

```
./Start\ Unified\ Self-Service
```

Stop the USS Services on Windows

Follow these steps:

1. Navigate to *Start*, run and type *services.msc.*
2. Locate the service name: *CA Unified Self Service Server*
3. Right-click on the service and click **Stop** to stop the USS services.

Stop the USS Services on Linux

Follow these steps:

1. Navigate to the *$US4SM* folder.

2. Locate the service name: *Stop Unified Self-Service*
3. Execute the following command to stop the USS services:

```
./Stop\ Unified\ Self-Service
```

Building CA Service Desk Manager

CA SDM lets you fulfill various IT Service Management functions. The product provides a broad feature set, and various best-practice content to help meet your service management needs.

The default implementation of CA SDM closely matches the processes and terminology that is used in most IT organizations. You can extend CA Service Desk Manager to work with the unique aspects of your organization. The product includes the following spectrum of approaches to build the product to meet your unique needs:

- End-user personalization
- System-wide configuration
- Tool-based adaptation
- Code-level modifications

This section contains the following articles:

Modify Notification Methods

This article contains the following topics:

The CA SDM automatic notification methods notify personnel at key points in the service desk management process. The standard notification methods are shown as follows:

- Email
- Notification (Log)
- Pager_Email

You can define modified notification methods to specify new methods of transmission. For example, voice mail, display boards, or a specific printer. You can also access data from another application and include it in the notification message.

The Notification Process

Ticket notifications (applicable to issues, change orders, and requests) are processed when the ticket is saved:

- If the notification method is other than Notification, such as Email, the notification processor executes the notification method for each contact in the list. This method is typically an executable or shell script, which is launched in a new process. Details about the notification are stored in environment variables for easy access by the executable/script.

- For each notification requested, the notification processor sets the NX_NTF_MESSAGE and NX_NTF_SUMMARY environment variables using the Notification Message Title and Notification Message Body information that is provided on the Message Template notebook page of the Activity Notifications Detail window. If the recipient is a valid contact, other environment variables are created using information in their Contact Detail record.

- If the Write To File option is selected for the notification, a text file is created. The text file indicates that the notification method can use to obtain more detailed information.

- A list of contacts to receive the notification is built from the information that is provided on the Objects, Contacts, Types, and Survey notebook pages of the Activity Notifications Detail window. For those having a notification method matching the Notify Level and the log_all_notify Options Manager option that is installed, a notification is generated first to the notification log.

Notification Method Variables

Two sets of variables are created and made available to the notification method.

Basic Environment Variables

The first set of variables is created for every notification that is sent, independent of whether you select the Write To File option for the notification. They are written to the environment as environment variables that the notification method can access in the standard way.

The following environment variables give you basic information about the notification. They are always defined, even if the corresponding value is empty:

Environment Variable	Description
NX_NTF_MESSAGE	The completed message template text, including full expansion of all variables
NX_NTF_SUMMARY	The completed message template header, including full expansion of all variables
NX_NTF_URGENCY	The notification urgency (1 is low, 4 is emergency)

The following environment variables are created only if the recipient is a valid CA SDM contact. The variables are set using values from the Contact Detail record of the recipient as shown in the following table:

Variable	**Contact Detail Window Fields**
NX_NTF_BEEPER_PHONE	Pager Number
NX_NTF_COMBO_NAME	Last Name, First Name, Middle Name
NX_NTF_CONTACT	Contact ID
NX_NTF_EMAIL_ADDRESS	Email or Pager Email Address (depending on notification type)

Variable	Contact Detail Window Fields
NX_NTF_FAX_PHONE	Fax Number
NX_NTF_PUBLIC_PHONE	Phone Number
NX_NTF_USERID	User ID
NX_NTF_VOICE_PHONE	Alt. Phone #

Note: These variables are not created if the corresponding values are empty (except for NX_NTF_CONTACT, which cannot be empty).

Attribute Variables

The second set of variables is available only if you select the Write To File option when you define the notification method. The following attributes are called attribute variables and are written to the notification file only -- not to the environment. They are of the form:

NX_NTF_attribute[**.**secondary_attribute]=value

- ***attribute***
  The name of the attribute whose value you want to obtain. This value is the attribute name as defined for the object. For a complete list of all attribute names for any object, see CA Service Desk Manager Reference Commands (see page 3496). The most common objects that are associated with notifications are the ticket, which has an object name dependent of the type of ticket (for example, cr for requests), and the contact identifying the recipient, which has an object name of cnt. For example, the environment variable for the description attribute of a ticket can look as follows in the notification file:

  NX_NTF_DESCRIPTION=<sample description>

- ***secondary_attribute***
  If the first *attribute* is an internal identifier for another object, a secondary attribute is attached to give more meaningful information using the dot notation. In database terms, attribute is a foreign key that points to a row in another table, rather than a simple data value. Using this raw key value would probably have little meaning. Many of these types of fields are resolved or de-referenced for you. The secondary_attribute is the value in the referenced table. For example, instead of writing the value for the assignee attribute, which is stored as the unique ID of the contact record for the assignee, the assignee's combined name is the combo_name attribute for the contact object, as shown in the following example:
  NX_NTF_ASSIGNEE.COMBO_NAME=Armstrong, Beth
  If an attribute does not have a value, the corresponding value is usually (NULL) or blank. For example:
  NX_NTF_CALL_BACK_DATE=(NULL)
  NX_NTF_GROUP.COMBO_NAME=

Note: An attribute variable that exists for both the ticket and the recipient is NX_NTF_ID (the id attribute), which is the unique database ID for the object.

The Notification File

If you select the Write To File option when you define a notification method, all the basic environment and attribute variables are written to a text file. This file is closed before executing the notification method script or program. This notification file is updated every time the notification method is invoked for a contact. This method is a handy mechanism for passing relevant information to the notification script that is not otherwise available in the environment.

The full path of the notification file is set in the NX_NTF_FILENAME environment variable, which is available to the notification method . The file name is also added to the end of value you enter in the Notification Method field when defining the notification method. For example, if the Notification Method is 'pdm_perl - w mymethod.pl', then the actual process executes 'pdm_perl - w mymethod.pl *unique_notification_file_name*'.

Important! The administrator can clean up the notification files. This clean-up is especially important for a site using a high volume of notifications. The files are located in the standard temporary directory (TEMP on Windows and TMP on UNIX). One suggestion is to delete the file at the end of the notification method script/program.

The notification file is a standard text file that is divided into sections. Each line contains either an attribute/value pair or a section marker. Each notification file has three sections. All sections begin with "-----" followed by a new line.

- **SECTION=obj**, where obj identifies the object type of the ticket
  - **Iss**
    Provides information about the issue.
  - **Chg**
    Provides information about the change order.
  - **Cr**
    Provides information about the request.
- **SECTION=cnt**
  Provides information about the recipient.
- **SECTION=notification**
  Provides the same information that is available from the basic environment variables.

Note: The section names for the ticket and recipient are actually the object names for the attributes in that section. For a complete list of all attribute names for any object, see the CA Service Desk Manager Reference Commands (see page 3496) section.

Several lines of attribute/value pairs, each of which represents an attribute of the corresponding object, are contained in each section. The Attribute Variables in this section provide the detailed information about how these lines are formatted and what they mean.

Line breaks in an attribute value are reproduced as new lines in the notification file. Your notification method process can only use the attribute or value lines that begin with NX_NTF, and section markers. Generate a sample file and look at its contents before working with a notification file in your notification method process.

Using Perl Scripts

Most notification methods invoke an executable or shell script to read the environment variables and send the message. This action works well on most UNIX servers, but difficulties arise reading the environment variables on a Windows server.

You can use a Perl script to overcome environment problems on Windows. CA SDM includes a ready-to-use installation of the Perl interpreter named pdm_perl. Any Perl script that is invoked with pdm_perl as a notification method can reliably obtain the environment variables. The Perl script can read and format the environment variable values. The script can also carry on with the rest of the notification, such as invoking a pager or sending an email.

For Windows-based servers, consider using the launchit utility. You can invoke your scripts or programs in a shell environment with the proper environment variables set.

For example, suppose that you write a Perl script that is named read_env.pl to read several of the environment variables. You can invoke this script for a notification by entering the following command in the Notification Method field on the Notification Method Detail window:

pdm_perl *script_path*/read_env.pl

This notification method starts the Perl interpreter and executes the instructions in read_env.pl script.

Create a Notification Method

Follow these steps:

1. Create a script to process the message template and transmit it to the recipient. The script can be any executable, depending on the platform. Third-party or public domain interpreters can also be used. Typically, Bourne shell scripts are used on UNIX and .bat files are used on Windows. If your script requires a special template, create it.

2. Add the new notification method to your site using the web interface.

Create a Script

You can create a notification method script.

Follow these steps:

1. Determine how you want the notification to be delivered (for example, printed on a particular printer).

2. Determine the contents of the notification message.
3. Specify what information from the message template to include in the notification.
4. Set up a script to transmit the notification.
5. Place the script in an executable file in the path of the CA SDM server.

Add the Notification Method

After you create a script, define the new notification method to CA SDM. You can use *one* of the following methods to add a notification method:

- Using the web interface
- Using a UNIX shell script

Add a Notification Method Using the Web Interface

Use the web interface to add a notification method (see page 834).

Add a Notification Method Using a UNIX Shell Script

The following steps create a notification method shell script that sends the notification message to the service desk printer, SDPR2. In this example, the notification message consists of the message header and the message text from the message template:

1. Set up the shell script to assemble the notification text and transmit it, as follows:

```
#!/bin/sh
echo "
TO:       $NX_NTF_USERID
SUBJECT:  $NX_NTF_SUMMARY
MESSAGE:
$NX_NTF_MESSAGE" |lp -dSDPR2
```

2. Name the executable file sd_print. Place it in any directory that is used for common scripts at your site, such as /usr/local/netbin.
3. Make the shell script an executable file using chmod.
4. Select Notification Methods from Notifications on the Administration Interface.
5. Select New from the File menu.
6. Enter data in these fields:
   - **Symbol**
     SDPR2
   - **Description**
     Send backup notification to service desk printer SDPR2

- **Notification Method**
  /usr/local/netbin/sd_print

7. Click the Save button to save the new record. Then click Close Window to close the detail window.

Query and Message Modifications

CA SDM provides a number of features that let you narrow the focus of information so you can concentrate on requests, change orders, and issues that apply to your immediate situation. One of these functions stores queries that you can use to see relevant information on the scoreboard of the administrative or web interface. Another lets you modify the messages that notify key personnel of ticket activities.

Stored queries can provide a focus on tickets related to the logged-in user and modify the counter fields in the scoreboard area of the administrative and web interfaces. You can modify activity notification messages to include attributes from the activity log object and information on specific tickets.

Activity Notification Messages Modifications

This article contains the following topics:

Notification messages can be sent automatically when request activities occur.

Note: For information about notification messages and instructions for defining activity notifications, see the Activity Notification Messages Modifications (see page 1713) section.

Two of the fields that must be defined on the Activity Notifications Detail window are Notification Message Title and Notification Message Body. Both of these fields can contain attributes from the activity log object (alg for Requests/Incidents/Problems, chgalg for Change Orders and issalg for Issues. These three activity log objects are almost identical) and can identify the specific request related to the activity.

Formatting Attributes for Activity Notifications

Optional formatting and escaping of individual attributes can be achieved using the properties listed below. This can be useful especially if formatting HTML notification where the data in the attribute may need to be escaped to conform to HTML standards.

To include formatting, use the following syntax:

```
@{property=value property=value:attribute_name}
```

Property values pairs are separated by at least one space and are not case sensitive. A colon separates the formatting properties from the attribute name. If no properties are listed, no formatting or escaping will be done on attribute.

The following table the available formatting properties:

Property	Description
DATE_FMT	Specifies the date format for attribute. Valid values are: MM/DD/YYYY MM-DD-YYYY DD/MM/YYYY DD-MM-YYYY YYYY/MM/DD YYYY-MM-DD Valid only for Date attributes. Dates embedded in strings are not affected.
ESC_STYLE=NONE | HTML | URL	Specifies the escape type of the formatted text. Valid values are: **NONE** Default setting. Specifies that no special treatment be given to any character in the content body. **HTML** Give special treatment to the following characters, which are meaningful in HTML text: & becomes & ”_becomes " < becomes < > becomes %gt; **URL** Translate all characters other than letters, digits, and '@*-_.#' to '%xx', where xx is the hexadecimal coding of the translated character.
JUSTIFY=LEFT | CENTER | RIGHT | TRUNCATE| WRAP | LINE	Specifies the justification of the formatted text. Valid values include: **TRUNCATE** (default if formatting) Truncates text to WIDTH property value if a positive integer. If ESC_STYLE=HTML, eliminates HTML formatting by replacing '<' and '>' with < and > (see KEEPLINKS and KEEPTAGS). **LEFT|CENTER|RIGHT** Produces exactly WIDTH characters, truncated or padded with spaces as necessary, with any embedded new lines replaced by a single space. If ESC_STYLE=HTML, the output text is delimited by [set the pre variable for your book] and </pre> tags. The WIDTH argument must be specified as a positive integer. **WRAP** Same as LEFT, except that text wrapping honors word boundaries (line breaks are not placed within words). **LINE** Same as TRUNCATE, except that it also replaces all embedded line breaks with tags if ESC_STYLE=HTML.
KEEPLINKS=YES|NO	If KEEPLINKS=YES is specified, the action of JUSTIFY=LINE or JUSTIFY=TRUNCATE is modified to preserve HTML anchor tags (Action:) while converting all other '<' and '>' characters. Mutually exclusive with KEEPTAGS. Only valid if ESC_STYLE=HTML.
KEEPNL=YES|NO	The normal action of PDM_FMT is to convert all embedded new lines and any following spaces to a single space. If KEEPNL=YES is specified, embedded new lines are preserved. This argument is ignored for JUSTIFY=LINE.

Property	Description
KEEPTAGS=YES|NO	If KEEPTAGS=YES is specified, the action of JUSTIFY=LINE or JUSTIFY=TRUNCATE is modified to preserve all HTML tags. Mutually exclusive with KEEPLINKS. Only valid if ESC_STYLE=HTML.
PAD=YES|NO	If PAD=NO is specified, PDM_FMT does not convert empty strings to a single space. This is the normal action when WIDTH is non-zero, or JUSTIFY is TRUNCATE or WRAP.
WIDTH=*nn*	When non-zero, specifies that the text should be formatted to exactly WIDTH characters.

For example, to format the Request description for an HTML notification by escaping HTML specific characters, adding
 tags for line breaks and keeping any HTML Links as links, enter the following:

```
@{ESC_STYLE=HTML JUSTIFY=LINE KEEPLINKS=YES:call_req_id.description}
```

To format the open_date of a Request to European format, enter the following:

```
@{DATE_FMT=DD-MM-YYYY:call_req_id.open_date}
```

Attributes from the Activity Log Object

To include an attribute from the activity log object, include this in the Notification Message Title or Notification Message Body field:

```
@{att_name}
```

The name of the object, alg or chgalg or issalg, is the default and need not be specified. For example, to include the type of activity in the message title, enter this in the Notification Message Title field (along with the rest of what you want in the title):

```
@{type}
```

To include the description of the activity in the message body, enter this in the Notification Message Body field (along with the rest of what you want in the body):

```
@{description}
```

Information on Specific Change Orders

For messages to provide information on the specific change order that triggered the notification, the Notification Message Title or Notification Message Body fields must contain an attribute in the activity log object that references the change order object. Enter the reference in this format:

```
@{change_id.chg_att_name}
```

In this reference, the following information applies:

- **@**
  Indicates to replace this expression.
- **change_id**
  The attribute in the activity log object that links it to a specific instantiation of the change order object (chg).

- ***chg_att_name***
  Any attribute in the chg object.

For example, to include the priority of the change order in the message title, enter the following in the Notification Message Title field, along with the rest of what you want in the title:

```
@{change_id.priority.sym}
```

To identify who reported the change order (Affected End User) in the message body, enter the following in the Notification Message Body field, along with the rest of what you want in the body:

```
@{change_id.requestor.combo_name}
```

If you want to reopen a specific change order by number, and want the message to appear as follows, use the following syntax:

```
Reopen Change Order @{change_id.chg_ref_num}
```

Note: For messages to provide information about an issue that triggered a notification, the Notification Message Title or Notification Message Body fields must contain an attribute in the activity log object that references the issue object, iss. For more information about objects and attributes, see the CA Service Desk Manager Reference Commands (see page 3496) section.

For example, to include the priority of the issue in the message title, enter the following in the Notification Message Title field, along with the additional information you want in the title:

```
@{issue_id.priority.sym}
```

Information on Specific Requests

For messages to provide information on the specific request that triggered the notification, the Notification Message Title or Notification Message Body fields must contain an attribute in the activity log object that references the request object. Enter this reference in this format:

```
@{call_req_id.cr_att_name}
```

- **@**
  Indicates to replace this expression.

- **call_req_id**
  The attribute in the activity log object that links it to a specific instantiation of the request object (cr).

- ***cr_att_name***
  Any attribute in the cr object.

For example, to include the impact of the request in the message title, enter this in the Notification Message Title field (along with the rest of what you want in the title):

```
@{call_req_id.impact.sym}
```

To identify the affected resource in the message body, enter this in the Notification Message Body field (along with the rest of what you want in the body):

```
@{call_req_id.affected_resource.name}
```

If you want to reopen a specific request by number, and want the message to appear as follows, use the following syntax:

```
Reopen Request @{call_req_id.ref_num}
```

There are several other mechanisms by which messages can be sent which are in the context of the request itself (or change order or issue). When the context is the request itself, you do not need (and cannot use) the "call_req_id" part of the reference. So, in these cases, you need to use:

```
"@{ref_num}" rather than "@{call_req_id.ref_num}"
```

ITIL-Specific Queries

Problems and Incidents are requests with one of two values in the *type* attribute: “I” for Incidents or “P” for Problems.

The following stored query obtains all Incidents in which the Assignee's Organization or the Group's Organization equals the logged-in Analysts Organization:

```
assignee.organization IN @cnt.organization OR group.organization IN @cnt.
organization) AND active = 1 AND type = \'I\'
```

For Problems, the query is identical except for type = \'P\'

Scoreboard Queries

This article contains the following topics:

One of the tables in the database, Cr_Stored_Queries, defines stored queries. These stored queries, which are similar to SQL queries, can be used to customize the counter fields on nodes in the scoreboard area of the administrative and web interfaces. The counter fields tell how many records match the query. For example, they can tell how many of various types of requests have been assigned to the logged-in user.

Each user can customize the counter fields that appear on his or her scoreboard (this is explained in the online help.) However, the system administrator must first define the various types of requests that can be counted in these counter fields as stored queries.

Note: Scoreboard counts will be incorrect if database query values are equal to NULL. For example, if your Scoreboard query specifies that assignee.organization = xyz, and an assignee field is blank (NULL) for a record, then that record will not be part of the Scoreboard count.

Stored Queries for Logged in User

Two of the fields that must be defined on the Stored Query Detail window are Where Clause and Label. Both of these fields can contain expressions that are customized to the logged-in user. Stored queries refer to objects and attributes, rather than to table names and columns. A stored query that is customized to the logged-in user consists of two parts, as follows:

- **The object (such as cr for a request)**
  This is usually specified on the left of the equal (=) sign. The syntax for this part of the stored query is:

```
att_name[.att_name...].SREL_att_name
```

A stored query always has a Type, which is an object name that the query is executed against and provides context for the query. In the syntax above, the first att_name must be an attribute name of the context object.

- **The logged-in user (the instance of the cnt object for this user)**
  This must be specified on the right of the equal (=) sign if the tickets are to be selected based on an attribute of the logged-in user. The syntax for this part of the stored query is:
  @att_name[.*att_name*...].*SREL_att_name*

Note: For more information about objects and attributes, see the CA Service Desk Manager Reference Commands (see page 3496) section.

Syntax for cr Object

Use this syntax if the reference is to the request (cr) object:

```
att_name[.att_name...].SREL_att_name
```

This example identifies the location of the person assigned to handle a ticket. In this example, the object name is omitted, as the type of the Stored Query implies the cr object:

```
assignee.location=@cnt.location AND active=1
```

- **assignee**
  The attribute in the request object that maps to the assignee field in the corresponding table. For example, the assignee attribute is defined in the cr object with SREL agt, which means it refers to the agt factory. The agt factory is part of the cnt object definition.

- **location**
  The attribute in the cnt object that maps to the c_l_id field in the Contact table. The location attribute is defined in the cnt object with SREL loc, which means it refers to the loc object.

WHERE Clause

The following example demonstrates a value you can code in a WHERE clause:

```
assignee.location=@cnt.location AND active=1
```

Given the Stored Queries type is a Request, this query selects all active requests where the assignee's location is the same as the location of the logged-in user.

Label

Attributes in the cnt object can be included in labels the same way they are included in WHERE clauses. Here is an example of the use of an attribute in the cnt object in a label:

```
@cnt.location.name Calls
```

This label will include the name of a location, for example, Phoenix, where Phoenix is substituted for @cnt.location.name when the label is displayed on a window. The label will be displayed as Phoenix Calls.

The IN Keyword

The IN keyword allows a stored query to reference two (or more) tables without creating a join. This can result in significant efficiency in executing the query. It is coded as follows:

```
SREL_att_name IN ( value1 [, value2 [,...]] )
```

For example, a request query could be coded as:

```
category.sym IN (\'Soft%\', \'Email\')
```

This results in the following SQL WHERE clause:

```
category IN (SELECT persid FROM prob_ctg WHERE sym LIKE 'Soft%' OR sym = 'Email')
```

One use of IN is to avoid Cartesian products. For example, the following query results in a Cartesian product and is very inefficient:

```
assignee.last_name LIKE 'MIS%' OR group.last_name LIKE 'MIS%'
```

By using IN, the query does not create a Cartesian product; in fact, it creates no joins at all, as illustrated by the following example:

```
assignee.last_name IN 'MIS%' OR group.last_name IN 'MIS%'
```

Note: The parentheses that normally enclose the list of values on the right side of IN can be omitted if there is only one value in the list. Similarly, you should avoid joins in data partitions by converting a data partition, illustrated as follows:

```
assignee.last_name LIKE 'Smith'
to:
assignee = U'374683AA82ACE34AB999A042F3A0BA2E'
```

where:

- **U**
  indicates that the value is a uuid.
- **'374683AA82ACE34AB999A042F3A0BA2E'**
  The 32 characters in single quotes indicates the string representation of an actual uuid.

This avoids the join with some loss in clarity. Using IN, the same partition can be written as illustrated in the next example, with the clarity of the first version and almost the same efficiency as the second version:

```
assignee.last_name IN 'Smith'
```

CA SDM supports the IN clause applied to QREL or BREL lists. For example, if you want to find all the Requests with Assets that are parents of another specific Asset (with id 374683AA82ACE34AB999A042F3A0BA2E), the appropriate where clause is as follows:

affected_resource.[parent]child_hier.child IN (U’374683AA82ACE34AB999A042F3A0BA2E’)

The first part of the clause, *affected_resource*, is an SREL (foreign key) of the cr (Request) object, pointing to the Network_Resource table. The *child_hier* portion is a list of hier objects pointing to the hierarchical relationships. The last part, *child*, forms the first part of the where clause for the IN sub query. The *374683AA82ACE34AB999A042F3A0BA2E* portion is the foreign key value to match on *child* . *[parent]*specifies thesub query return. Since the id value is a string representation of a UUID it must be indicated as such and written as U’374683AA82ACE34AB999A042F3A0BA2E’

The following is an example of the actual SQL generated, which provides all the Requests where the Asset is a parent of a specific Asset:

```
SELECT Call_Req.id FROM Call_Req WHERE Call_Req.affected_rc IN (SELECT hier_parent
FROM Asset_Assignment WHERE hier_child = U'374683AA82ACE34AB999A042F3A0BA2E')
```

To query on multiple parents, you can provide a comma-separated list in the () portion of the SQL, as shown by the following example:

```
affected_resource.[parent]child_hier.child IN (U'374683AA82ACE34AB999A042F3A0BA2E',
U'374683AA82ACE34AB999A042F3A0BA2E')
```

The attribute name in brackets ([]) is used to form the SELECT portion of the sub-clause. Bracket notation is not used for the group Stored Queries shipped with CA Service Desk Manager Version 6.0, as illustrated in this example:

```
(assignee = @cnt.id OR group.group_list.member IN (@cnt.id)) AND active = 1
```

Note: If bracket notation is not used, the SQL subsystem assumes that it is the attribute name of the first symbol in the dot-notation portion. It works in this case, more out of luck, that the group_list object has an attribute named ‘group’ in it. If it were named anything else, the where clause would fail to parse! The equivalent clause with brackets illustrated as follows:

```
(assignee = @cnt.id OR group.[group]group_list.member IN (@cnt.id)) AND active = 1
```

Note: You cannot extend the dot notation. For example, the following does not work:

```
affected_resource.[parent]child_hier.child.name IN ('chicago1')
```

Query Based on Priority

In the database, the Priority table has two columns named sym and enum. The value the users see are the sym values. But the application sees the sym based on the enum values. At present, the default sym values 1 to 5 are reversed in their enum value.

Example

Sym	Enum
1	5
2	4
3	3
4	2
5	1

Therefore, when writing the stored query, when you reference a value of 5, you are actually looking for priority 1 unless you use a .sym to specify which attribute to look at.

Important! Do not change the default enum values the product assigns. Instead, when adding new sym values, just continue from the highest enum value and so on.

Time-Based Queries

Time spans can be used to create time-based stored queries. A time span specifies a period of time, which can be relative to the current date. For example, a time span could refer to today, yesterday, last week, or last month. A time span has a name, such as TODAY or YESTERDAY. You refer to a time span in a stored query by using either of two built-in functions, as follows:

- **StartAtTime (*timespan-name*)**
  This refers to the beginning of the period described by the time span.

- **EndAtTime (timespan-name)**
  This refers to the end of the period described by the time span.

The syntax rules for stored queries require that the time span name be enclosed in single quotes, with each single quote preceded by a backslash. For example, to refer to the beginning of last week, you would specify:

```
StartAtTime(\'PAST_WEEK\')
```

The passage of time makes it necessary to periodically refresh a stored query containing a reference to a time span. For example, the interval described by “yesterday” changes at midnight. You specify the Start Time, End Time, and Trigger Time for refreshes in the Timespan Detail window.

Start Time

Start Time specifies the beginning of the time span in absolute or relative terms. The following table describes the fields within the Start Time section of the Timespan Detail window:

- **Year**
  An explicit year, such as 2000, or a relative year, such as +1 (next year) or - 1 (last year)

- **Month**
  An explicit month from 1 (January) to 12 (December), or a relative month, such as +1 (next month) or - 1 (last month)

- **Day**
  An explicit day from 1 to 31, or a relative day, such as +1 (tomorrow) or - 1 (yesterday)

- **Hour**
  An explicit hour from 0 to 24, or a relative hour, such as +1 (next hour) or - 1 (last hour)

- **Minute**
  An explicit minute from 0 to 59, or a relative minute, such as +1 or - 1

End Time

End Time specifies the end of the time span in absolute or relative terms. The End Time fields of the Timespan Detail window are the same as the Start Time (see page 1722) fields of the Timespan Detail window.

Trigger Time

The Trigger Time field specifies when the WHERE clause of a stored query containing a reference to the time span is recreated and the stored query refreshed. Trigger Time must be relative to the current time as described in the following table:

- **Year**
  Must be a relative year from - 1 (last year) to +36 (36 years from now).
- **Month**
  Must be a relative month from - 1 (last month) to +11 (11 months from now).
- **Day**
  Must be a relative day from - 1 (yesterday) to +31 (31 days from now).
- **Hour**
  Must be a relative hour from - 1 (last hour) to +23 (23 hours from now).
- **Minute**
  Must be a relative minutes from +9 (9 minutes from now) to +59 (59 minutes from now).

Web Interface Modifications

Contents

The CA SDM web interface(also referred to as the browser interface) provides you with CA SDM functionality through the Internet. This functionality includes the ability to open, update, or close tickets, display and post announcements, and access supporting data tables. It enables independent browsing of the knowledge base to help reduce the number of calls to the service desk and speeding resolution times. The web interface can be fully customized and can be used with many web browsers.

If you installed and configured the web interface, you can integrate it into your existing web interface and customize it to suit your needs. For customization, be familiar with HTML and the web browser in use at your site.

Note: WSP Design view works for CA SDM controls (PDM_MACROs). When working on forms that do not contain CA SDM controls, you can only work on the Source tab. The Employee and Customer web forms do not contain CA SDM controls and therefore appear on the Source tab rather than the Design tab. Some Analyst forms do not contain CA SDM controls, and therefore would appear on the Source tab too.

Important! CA SDM no longer uses any customized .mac files for pdm_macro in the NX_ROOT\site\mods\www\macro directory. You cannot customize macros.

Important! Technical support cannot provide assistance with design or debugging of customizations (including documentation, such as online help systems). We provide general information for customizing the CA SDM web interface. When doing so, be aware that you are solely responsible for your own customizations. CA SDM technical support can assist you in interpreting and understanding customization.

Support for the customization techniques here extends to helping ensure that the techniques and facilities perform as documented. Be careful not to exploit undocumented features or to extend documented features beyond their documented capabilities. Such exploitation is not supported and can result in system problems or instability that may appear unrelated to the customization. For this reason, support may ask you to remove customizations to reproduce the problems. Sites should prepare for this eventuality by carefully following the guidelines on placing all modifications in the site mods directory tree and maintaining change logs. Sites that make frequent, complex, or extensive changes should consider approaching CA SDM customization as a software engineering project with disciplined source control, testing, and controlled releases to production.

Migrating customizations between releases can present unique challenges, and we have developed the product in ways to preserve the efforts put into customization. In addition, if Level Two support supplies a patch to a system, the patch is written with these same assumptions. Patching or upgrading a system with undisciplined customizations is a risky undertaking that often results in costly system down time. Avoid it by following these guidelines and practising sound software engineering principles.

Modify the Scoreboard

The Scoreboard on this tab allows you to view the requests, change orders, issues, call backs, and tasks assigned to you or your group. You can customize your Scoreboard to display only specific folders and nodes. By default, the Scoreboard displays nodes that itemize the records for the entire application. These records can include requests, issues, change orders, assets, configuration items, callbacks, documents, and tasks.

Follow these steps:

1. Select File, Customize Scoreboard.

   The Customize Scoreboard window opens.

2. Select the Scoreboard you want to customize from the following options:

   UserDisplays the Scoreboard for the username under which you are logged in. RoleAllows you to customize the Scoreboard for all members of one type of user, such as administrators. Select a value from the drop-down list.

3. Navigate the Scoreboard tree and select an item to work with.

To update or delete an item, select the item. To add a new node or folder, select the item after which you want to add the new item.

Note: The Add Node and Add New Folder options are disabled when the system reaches the Scoreboard limit. To add more nodes or folders, you can remove them or ask your administrator to use Options Manager to increase the scoreboard_entry_limit.

4. Complete the entry fields for the task you want to complete. Depending on the task, you can edit the following fields:

   Node LabelDisplays the name of the node that you want to add or update.Node's Stored QueryShows the stored query of the node that you want to add or update. Enter a value directly or select the Node's Stored Query link to search for a stored query.Folder LabelDisplays the name of the folder that you want to add.

5. Click the button for the task you want to complete.

   The Scoreboard tree refreshes to display your changes.

6. (Optional) Click Reset Tree to undo your changes to the Scoreboard tree.

7. Click Finished.

   The Customize Scoreboard window closes and the Scoreboard displays your changes.

Set Preferences

Setting preferences allows you to define the desired default behaviors.

Follow these steps:

1. Choose View, Preferences in CA SDM Web UI.

   The Preferences window appears.

2. Set the appropriate preferences
   For example, select the Using Screen Reader option.

   Note: For more information about using a screen reader with CA SDM, click Help, Screen Reader Usage.

3. Click Save to save the preferences. The new settings take effect immediately.

Preferences Fields

General Settings

- **Avoid Popups**
  Opens new forms in the main browser window whenever possible, reducing the number of popups.Note: If this option is selected, the Back to List button is activated and is used to navigate from detail forms back to the previously displayed list window. The Back to List button appears in the upper right-hand side of the window.

- **Display Score Count**
  Displays the score count as left-justified.Keep Log Reader WindowKeeps the Log Reader window open when you close all popups, and when you log off. This setting has no effect when the Log Reader window is not open.

- **Preserve Popup Size**

  Causes new popup windows to open with the same dimensions as the most recently resized popup window. The popup size that is preserved is dependent on the window size used by that type of popup (Large, Medium, Small, or Xsmall). For example, if you resize a Large popup, such as a Request detail page, the new size is preserved for all Large popups. If you resize a Medium popup, such as an activity log page, the new size is preserved for all Medium popups.Note: If you maximize a popup window, subsequent popup windows may cover any other window you have open. However, new popup windows appear slightly off the screen, to the right and lower. This is because there is a 10 pixel (left and top) offset for popups to prevent them from completely overlaying the currently displayed window. We recommended that you do not maximize popup windows when using this option.

- **Mouseover Menus**

  Causes a menu to display when the mouse pointer is over the menu's link, without clicking the mouse button. You must reload any active forms for this setting to take effect on the page.

- **Using Screen Reader**

  Modifies system behavior for optimal use with a screen reader for blind and limited vision users. You must log off and log back on for this change to take effect. From the Help menu, select Screen Reader Usage for an overview of using CA SDM with a screen reader.Use Default RoleUses the default role assigned to a Contact or a Contact's Access Type as the initial role when the Contact logs in.

- **Disable Mouseover Previews**

  Select this check box if you do not want to see preview forms pop up automatically.Note: Mouse-over previews are disabled automatically when either Using Screen Reader or Mouseover Menus is enabled.

Support Automation Analyst UI Localization

English is the default language.

Knowledge Search Document Settings

- **Search Type**

  Select either Keyword Search or Natural Language Search.

- **Match Type**

  Select the default method to use for text matching during a search. Possible values are Any of the Words (OR), All of the Words (AND), and Exact Phrase.

  Important! Match Type and Match preferences only set the default search criteria when you search in Knowledge Management. For example, you log in as an analyst and click the Knowledge tab of any ticket. Knowledge searches from within a ticket always default to Match Type=Any of the words (OR) and Match=Whole Words, regardless of your preference settings.

- **Match**

  Select the default method by which CA SDM searches documents, either Whole Words or Words Beginning With.

- **Order By**

  Select the default property for sorting retrieved documents.

- **Search In**

  Select the document fields where you want to search for specified keywords. These options only display when Keyword Search is the selected search type.

Knowledge Document List Settings

- **Documents Per Page**
  The number of documents (10, 25, or 50) that the product that display on each page of the Knowledge Document List pane.

- **Show Document List Details**
  If selected, the Knowledge Document List pane on the Knowledge tab includes the following detailed information:
  Title
  Summary
  Document ID
  Modify Date
  If not, only the document title displays.

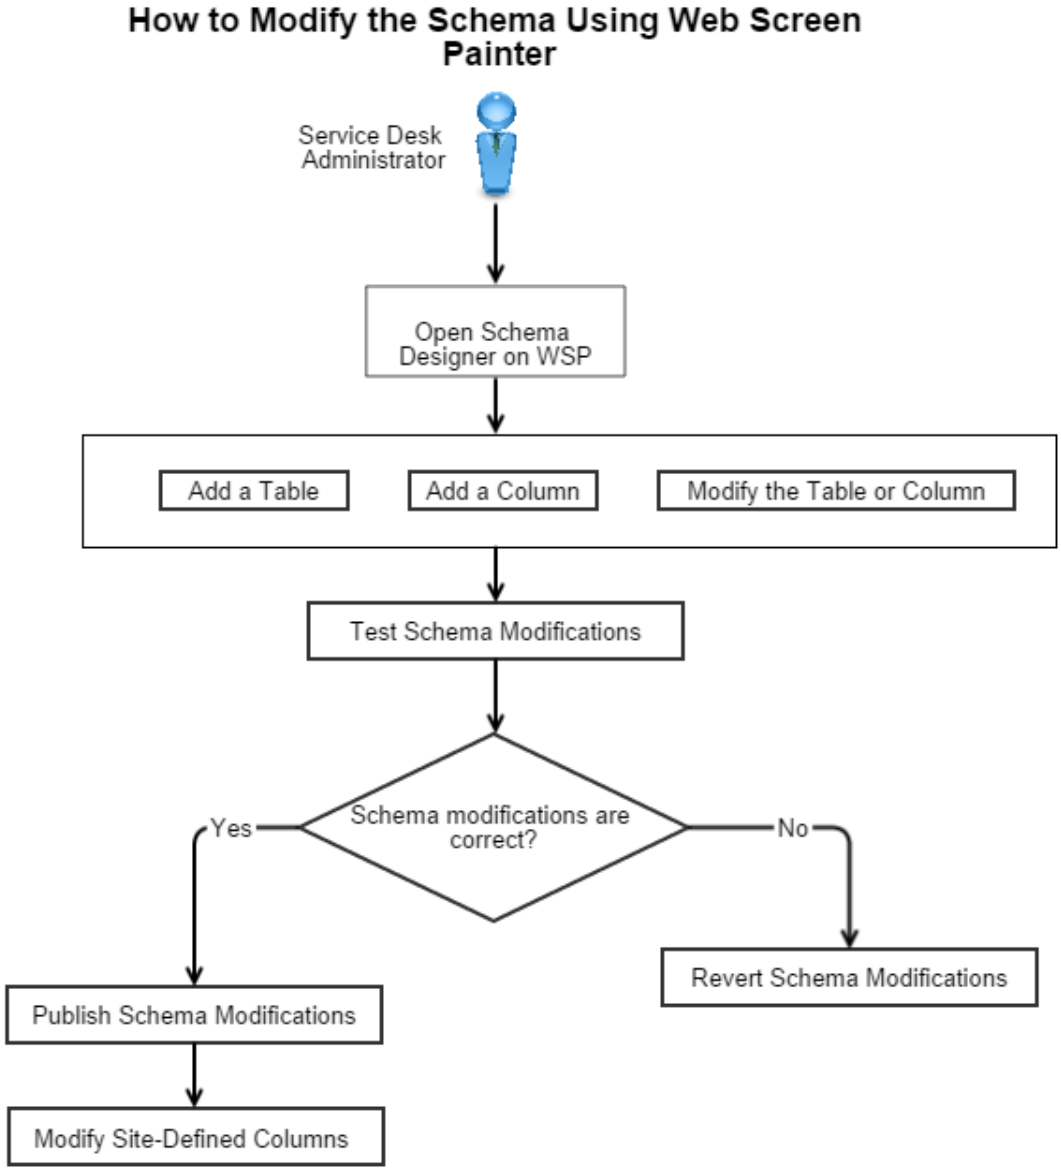
Knowledge Categories Document List Settings

- **Documents Per Page**
  The number of documents (10, 25, or 50) that the product that display on each page of the Knowledge Document List pane.

- **Attributes to be shown in list**
  Select the properties to be listed for each document in the Knowledge Document List pane. Select the desired attributes from the Available list and click the arrows to move them to the Selected list.

How to Modify Schema Using Web Screen Painter

Use the Schema Designer of Web Screen Painter to modify the database schema of CA SDM. Schema Designer provides a graphical user interface to review and modify this schema. The following diagram shows how to modify the schema using Web Screen Painter:



Follow these steps:

1. Verify the Web Screen Painter Considerations (see page).
2. Open Schema Designer on WSP (see page 1729).
3. Add a Table (see page 1730) or Add a Column (see page 1733) or Modify the Table or Column (see page 1738).
4. Test Schema Modifications (see page 1739).
   - If the schema modifications are correct, Publish Schema Modifications (see page 1739).
   - If the schema modifications are incorrect, Revert Schema Modifications (see page 1743).
5. (If necessary) Modify Site-Defined Columns After Publishing (see page 1744).

Verify the Web Screen Painter Considerations

Consider the following information before using Web Screen Painter:

- You cannot use WSP to change the length of an existing column, and we strongly recommend that you *do not* use other tools to do so. Changes to the length of an existing column are not supported, and may cause other applications accessing the CA SDM database to fail.

  Important! Do not shorten a field or delete an existing field, because these actions could cause CA SDM to fail.

- Be careful when adding columns to an existing table, because you can inadvertently exceed the record length capacity of the underlying database. Check the specifications for the database that you are using with CA SDM and make modifications within the limits of that database.
- Publishing changes to the database schema could require limited or considerable downtime, depending on the changes you make and the capabilities of your underlying database.
- If you are a new user of CA SDM, it is easier to make all of your changes during testing instead of waiting until you are in production.
- Review general procedures you must complete before and after changing the database schema.
- Use specific procedures to modify your schema. Most of these procedures are followed by an example of a change you might want to make to the standard database schema.

Open Schema Designer on WSP

To start working on the Schema Designer, ensure that you have WSP installed on the CA SDM server. For more information about the WSP installation, see Install Web Screen Painter (see page 498).

Follow these steps:

1. Log in to the following CA SDM server where WSP is installed, depending on your CA SDM configuration:

- Conventional: Primary server
- Advanced availability: Background server

2. Start WSP using any of the following actions, depending on the operating system that is installed on the CA SDM server:
   - (Windows) From the Start menu, select Program Files, CA, CA SDM, Web Screen Painter.
   - (UNIX) Enter the command pdm_wsp with $NX_ROOT/bin in your path.

   The Web Screen Painter login window opens.
3. Enter your login credentials.
4. Select Tools, Schema Designer.
   The Schema Designer window opens. The left side of the Schema Designer window shows the CA SDM database in a tree format. The tables and columns are displayed by their Object Name. If the Display Name differs from the Object Name of the table or column, the Display Name is displayed in parentheses along with the Object Name.

Add a Table

Use the Schema Designer to add a table in the database.

Follow these steps:

1. Select Edit, Add Table.
   The Add New Table dialog opens.
2. Enter the table name in the New Table Name field and click OK. Ensure that you begin the name of a site-defined table with the letter z to prevent conflict with possible future standard tables.
   WSP adds a z to the beginning of the table name if you do not add.
3. Complete the following fields, as appropriate:
   - **Name**
     (Read-only) Specifies the object name of the table. For example, the object name of the cr table is cr.
   - **Display Name**
     Specifies the user-friendly name of the table. For example, the Display Name of the cr table is Request. You can change the Display Name of a table by entering a new name in this field.
   - **Schema Name**
     (Read-only for standard tables) Specifies the name used to refer to the table in CA SDM utilities, such as pdm_userload. For site-defined tables, Schema Name defaults to the Object Name. You can change the Schema Name by entering a new value in this field.

- **DBMS Name**
  Specifies the name used to refer to the table in the physical DBMS. This field is read-only for all tables. For site-defined tables, it is always the same as Schema Name.

- **Default Display Field (common name)**
  Specifies the column displayed on the UI for a field that references this table. For example, the assignee field of a request is a reference to the Contact table. Because the common name of the Contact table is combo_name (last, first middle), the combo name of the referenced contact displays as assignee. You cannot change the value of common name.

- **Foreign Key Field (rel attr)**
  Specifies the column stored in the database for a field that references this table. For example, the assignee field of a request is a reference to the Contact table. Because the rel attr of the Contact table is id, the assignee column in a Request contains the id of the referenced contact. You cannot change the value of rel attr.

- **Function Group**
  Specifies the name of the group that controls the level of access that users have to records in this table. Each access type of a contact specifies whether they have read, modify, or no access to data in tables in each function group. You can change the value of rel attr by selecting a new value from the drop-down list.

Important! The Schema Designer includes an Advanced tab. Information on this tab is intended for CA Technologies Support and field representatives. You will not need to work with this tab for most uses of the Schema Designer, and it will not be discussed further in this document.

The Advanced tab of the Schema Designer column dialog shows information meaningful only to persons with internals knowledge of CA SDM. Its contents vary with the column type. We recommend that you modify the values in this tab only on direction from a CA Technologies employee. It contains the following fields if a table is selected:

- **Active Triggers**
  Enter the triggers currently active in the Object Engine for the column. A trigger is a small program that runs under the direction of the Object Engine at certain times when a column is modified. The active trigger list includes both standard and site-defined triggers (so that site-defined triggers are listed both in the active list and in the site-defined list).

- **Site-Defined Triggers**
  Enter the triggers that have been installed at your site. For example, these may be triggers that have been activated as a result of installing a CA SDM option, or triggers that have been written for your site by CA Technical Services. The active trigger list includes both standard and site-defined triggers (so that site-defined triggers are listed both in the active list and in the site-defined list).

- **LRel Specification**
  Enter the specification of a many-to-many relationship between two tables, in the form: table1 column1 <> table2 column2
  This shows that the LREL is a many-to-many relationship between table1 and table2, with virtual column column1 containing the relationship in table1, and virtual column column2 containing the relationship in table2.

- **Active xRel Query Information**
  Enter the active specification of the query that defines a BREL or QREL virtual column. The specification is in Object Engine Majic format.

- **Site-Defined xRel Query Information**
  Modify the query associated with a BREL or QREL. It is recommended that you enter data into this field only under the direction of a CA employee.

- **Active Derived Expression**
  Enter the active specification of the expression that the Object Engine uses to construct the value of a DERIVED virtual column.

- **Site-Defined xRel Query Information**
  Modify the expression associated with a DERIVED column. It is recommended that you enter data into this field only under the direction of a CA employee.

The Domsets tab of the Schema Designer Table dialog contains the following:

- **MLIST_DYNAMIC**
  A dynamic domset with no WHERE clause.

- **MLIST_STATIC**
  A static domset with no WHERE clause.

- **RLIST_DYNAMIC**
  A dynamic domset with a WHERE clause defined in the STANDARD_LISTS section of the FACTORY statement.

- **RLIST_STATIC**
  A static domset with a WHERE clause defined in the STANDARD_LISTS section of the FACTORY statement.

If you double-click one of the Domsets, the Properties dialog opens and contains the following fields:

- domset_name
- fetch_columns
- max_fetch
- sort columns **(**This is the only editable field)
- volatility

- where

4. Do one of the following to save the table:

   - If you are working on the test system, select File, Save.

   - If you are working on the production system, select File, Save and set to Test Mode.
     This selection saves your changes in the database, and creates a file (wsptest.mods) on the server defining your changes to the Object Engine. This file is stored in the site/mods /majic subdirectory of your CA SDM installation directory. After creating the wsptest.mods file, WSP causes its Object Engine to recycle so that it will use the new changes. This may take from a few seconds to a couple of minutes, depending on the complexity of your schema.
     A message is prompted. Click Yes to continue. The wsptest.mods file affects only the Object Engine designated by the wsp_domsrvr option. Other Object Engines on the same server do not process this file, and the file is not distributed to other servers. In addition, new tables and columns in Test mode are defined to the Object Engine as local objects. This means that the Object Engine knows about them and you can use them on web forms. However, they do not exist in the database, and do not affect other users. Typical CA SDM users do not use WSP Object Engine, so they are unaffected by the schema modifications you are testing.

   The table is added.

Add a Column

Use the Schema Designer to add a column in the database.

Follow these steps:

1. Select the table for which you want to add a column (or select any of its existing columns).

2. Select Edit, Add Column.
   The Add New Column dialog opens.

3. Enter the column name in the New Column Name field and click OK. Ensure that you begin the names of a column with the letter z to prevent conflict with possible future standard columns. WSP verifies that you added the prefix, but adds a z to the beginning of the column name if necessary.

4. Complete the following fields as appropriate:

   - **Name**
     (Display-only) Specifies the object name of the column. For example, the object name of the Contact alt_phone column is alt_phone.

   - **Display Name**
     Specifies the user-friendly name of the column. You can change the Display Name of a column by entering another name in this field. For example, the display name of the Contact alt_phone column is alternative phone.

- **Schema Name**
  (Read-only for standard tables) Specifies the name used to refer to the column in CA SDM utilities, such as pdm_userload. For site-defined tables, Schema Name defaults to the Object Name. You can change the Schema Name by entering another value in this field.

- **DBMS Name**
  (Read-only for all tables) Specifies the name used to refer to the table in the physical DBMS. For site-defined tables, the DBMS Name equals the same as Schema Name.

- **Description**
  Provides a brief description of the column.

- **Field Type**
  (Read-only for all standard columns in standard tables, and saved site-defined columns) Specifies the data type of the column. You can specify or change the field type of new site-defined columns by selecting a value from the drop-down. The following list describes the available Field Types:

  - **INTEGER**
    Indicates a numeric value.

  - **STRING**
    Indicates a text string. The String Length field indicates the number of characters in a string.

  - **DATE**
    Indicates a date and time. The integer value stored in the database contains the number of seconds since midnight on January 1, 1970.

  - **DURATION**
    Indicates a period of time. The value stored in the database is an integer containing a number of seconds.

  - **DOUBLE**
    Indicates a real (floating point) number.

  - **SREL**
    Indicates a foreign key reference to another table. The SREL Table field specifies the referenced table. The value stored in the database is the rel attr of the referenced table, which can be either an integer or a string. The value displayed in the product is the common name of the referenced table row. For information on setting SREL attributes with foreign key values, see CA Service Desk Manager Reference Commands (see page 3496).

  - **BREL**
    Indicates a virtual column representing the set of all objects with an SREL to this table. It exists only in the Object Engine and is not physically stored in the database. Select this field type only on direction from a CA Technologies employee.

- **QREL**
  Indicates a virtual column representing a set of objects selected by the where clause on the Advanced tab. It exists only in the Object Engine and is not physically stored in the database. Select this field type only on direction from a CA Technologies employee.

- **DERIVED**
  Indicates a virtual column constructed by the Object Engine from the values of other columns, under the direction of a formula specified on the Advanced tab. It exists only in the Object Engine and is not physically stored in the database. Select this field type only on direction from a CA Technologies employee.

- **String Length**
  The length of a string column. This field is blank for non-string columns. It is read-only for all standard columns, and for site-defined columns that have been saved. You can specify or change the length of new site-defined STRING columns by entering an integer between 1 and 32767 in this field.

- **SRel Table**
  The table referenced by an SREL column. This field is blank for non-SREL columns. It is read-only for all standard columns, and for site-defined columns that have been saved. You can specify the table referenced by a new site-defined SREL by selecting it from the drop-down list.

- **On New Default**
  The default value assigned to this column when a new row of the table is defined. It should be a value appropriate to the field type. Some keyword values are available for particular field types:

  - **NOW**
    Specifies the current date and time for a DATE column.

  - **USER**
    Specifies the active user for an SREL to the Contact table.

- **On Save Set**
  The value assigned to this column when a row of the table is updated. It should be a value appropriate to the field type. Some keyword values are available for particular field types:

  - **NOW**
    Specifies the current date and time for a DATE column.

  - **USER**
    Specifies the active user for an SREL to the Contact table.

- **Required**
  When checked, this option indicates that a value must be supplied for the column before a row of the table containing it can be saved. You can set this option for both standard and site-defined columns, and you can disable an option that you have set. However, you cannot turn off the option of a standard column unless it was set by your site.

- **Updatable only for new record**
  When checked, this option indicates that a value for this column can be provided only when a row of its table is initially created, and cannot thereafter be changed. You can set this option for both standard and site-defined columns, and you can disable an option that you have set. However, you cannot turn off the option of a standard column unless it was set by your site.

- **Key for pdm_userload**
  When checked, this option indicates that this column is one of the columns tested by pdm_userload to determine whether or not its input is an update to an existing row. This option is available only for STRING columns. It is read only for all columns in standard tables.

- **DBMS Index Options**
  These options specify characteristics of a column that is an index of the physical DBMS. They are available only for columns in site-defined tables.

  - **Unique**
    Specifies that the column is unique within the table and that no two rows have the same value for the column.

  - **Ascending**
    Specifies that the DBMS index is listed in ascending sequence by this column. Mutually exclusive with Descending.

  - **Descending**
    Specifies that the DBMS index is listed in descending sequence by this column. Mutually exclusive with Ascending.

Important! The Schema Designer includes an Advanced tab. Information on this tab is intended for CA Technologies Support and field representatives. You will not need to work with this tab for most uses of the Schema Designer, and it will not be discussed further in this document.

The Advanced tab of the Schema Designer column dialog shows information meaningful only to persons with internals knowledge of CA SDM. Its contents vary with the column type. We recommend that you modify the values in this tab only on direction from a CA Technologies employee. It contains the following fields if a table is selected:

- **Active Triggers**
  Enter the triggers currently active in the Object Engine for the column. A trigger is a small program that runs under the direction of the Object Engine at certain times when a column is modified. The active trigger list includes both standard and site-defined triggers (so that site-defined triggers are listed both in the active list and in the site-defined list).

- **Site-Defined Triggers**
  Enter the triggers that have been installed at your site. For example, these may be triggers that have been activated as a result of installing a CA SDM option, or triggers that have been written for your site by CA Technical Services. The active trigger list includes both standard and site-defined triggers (so that site-defined triggers are listed both in the active list and in the site-defined list).

- **LRel Specification**
  Enter the specification of a many-to-many relationship between two tables, in the form:
  table1 column1 <> table2 column2
  This shows that the LREL is a many-to-many relationship between table1 and table2, with virtual column column1 containing the relationship in table1, and virtual column column2 containing the relationship in table2.

- **Active xRel Query Information**
  Enter the active specification of the query that defines a BREL or QREL virtual column. The specification is in Object Engine Majic format.

- **Site-Defined xRel Query Information**
  Modify the query associated with a BREL or QREL. It is recommended that you enter data into this field only under the direction of a CA employee.

- **Active Derived Expression**
  Enter the active specification of the expression that the Object Engine uses to construct the value of a DERIVED virtual column.

- **Site-Defined xRel Query Information**
  Modify the expression associated with a DERIVED column. It is recommended that you enter data into this field only under the direction of a CA employee.

The Domsets tab of the Schema Designer Table dialog contains the following:

- **MLIST_DYNAMIC**
  A dynamic domset with no WHERE clause.

- **MLIST_STATIC**
  A static domset with no WHERE clause.

- **RLIST_DYNAMIC**
  A dynamic domset with a WHERE clause defined in the STANDARD_LISTS section of the FACTORY statement.

- **RLIST_STATIC**
  A static domset with a WHERE clause defined in the STANDARD_LISTS section of the FACTORY statement.

If you double-click one of the Domsets, the Properties dialog opens and contains the following fields:

- domset_name

- fetch_columns

- max_fetch
- sort columns (This is the only editable field)
- volatility
- where

5. Do one of the following to save the column:
   - If you are working on the test system, select File, Save.
   - If you are working on the production system, select File, Save and set to Test Mode.
     This selection saves your changes in the database, and creates a file (wsptest.mods) on the server defining your changes to the Object Engine. This file is stored in the site/mods /majic subdirectory of your CA SDM installation directory. After creating the wsptest.mods file, WSP causes its Object Engine to recycle so that it will use the new changes. This may take from a few seconds to a couple of minutes, depending on the complexity of your schema.
     A message is prompted. Click Yes to continue. The wsptest.mods file affects only the Object Engine designated by the wsp_domsrvr option. Other Object Engines on the same server do not process this file, and the file is not distributed to other servers. In addition, new tables and columns in Test mode are defined to the Object Engine as local objects. This means that the Object Engine knows about them and you can use them on web forms. However, they do not exist in the database, and do not affect other users. Typical CA SDM users do not use WSP Object Engine, so they are unaffected by the schema modifications you are testing.

   The column is added to the table.

Modify the Table or Column

To modify information about a table or column, click table or column on the Schema Designer, and enter the new information in the appropriate fields. The information you can modify depends on the status of the table or column:

- **Standard Tables**
  Lets you modify the Display Name, Description, and Function Group fields.
- **Standard Columns**
  Lets you modify Display Name, Description fields, the On New Default Value, and the On Save Set value. In addition, if the check boxes for Required or Updatable only for new record are not selected, you can select them. You cannot remove these options if they are set by default. However, you can reverse your own changes.
- **Site-Defined Table**
  If the table is not published, you can modify all fields, except Name, which cannot be changed after the new table has been saved. After a site-defined table has been published, you can modify only the Display Name, Description, and Function Group fields.

- **Site-Defined Column**
  If the column is published, you can modify all fields, except Name, which cannot be changed after the new column has been saved. After a site-defined column has been published, you can modify only the Display Name and Description fields, the On New Default Value, the On Save Set value, and the check box for Required, Updateable only for new record, Key for pdm_userload, and the DBMS index options.

Test Schema Modifications

You can test your schema modifications and create, update, and view web forms using them before making any changes to the physical database. Putting schema changes in Test mode defines them to the Object Engine, but does not physically store their data in the database. Because putting schema modifications in Test mode has the potential of impacting other users, this option is available only if your installation has installed the wsp_domsrvr and wsp_webengine options to dedicate an Object Engine to WSP.

To put schema changes in Test mode, select Save and set to Test Mode from the File menu. This selection saves your changes in the database, and creates a file on the server (where you are logged in) defining your changes to the Object Engine. This file is called wsptest.mods, and is stored in the site/mods/majic subdirectory of your CA SDM installation directory.

After creating the wsptest.mods file, WSP causes the Object Engine to recycle so that it will use the new changes. This may take from a few seconds to a couple of minutes, depending on the complexity of your schema.

Once the Object Engine has completed recycling, your schema modifications are available, and can be used and test on web forms created with WSP. Data in table and columns in test mode is saved only in internal storage in the WSP Object Engine. It cannot be seen by, and does not affect, other users of the system.

Publish Schema Modifications

After you are satisfied with your schema modifications, you can make them available to all users by publishing them. WSP stores your new or updated tables and columns in the wsptbl and wspcol tables of the database, respectively.

Follow these steps:

1. Create or update files describing the modified schema to the Object Engine and to CA SDM utility programs. WSP creates the following files on the web engine designated by the wsp_webengine option (which defaults to web:local):

   - **wsp.mods**
     Describes all Web Screen Painter-maintained schema changes to the Object Engine.

   - **wsp_schema.sch**
     Describes all Web Screen Painter-maintained tables and columns.

   - **wsp_index.sch**
     Describes DBMS indexes for Web Screen Painter-maintained tables.

- **wsp.altercol**
  Names new columns created by WSP but not yet defined to the DBMS.

- **wsp.altertbl**
  Names new tables created by WSP but not yet defined to the DBMS. In addition, WSP distributes the wsp.mods file to all CA SDM servers with an Object Engine.

2. Select File, Save and Publish.
   The necessary files are created on the CA SDM servers, but does not recycle any of them. Thus, the new files have no immediate impact. However, after the files are created, they will be used the next time CA SDM services are recycled.

3. If you are using the *conventional configuration*, complete the following steps:

   - Shut down the CA SDM services on the primary server and run the following command:

     ```
     pdm_publish
     ```

     This command modifies the physical DBMS to contain information about the new schema.

     Important! Running pdm_publish process has a significant impact on other users. Ensure that you carefully plan the publishing of the schema changes. We recommend you use CA SDM Change Orders to schedule and obtain approval for your planned schema publication.

4. If you are using the *advanced availability configuration,* complete the following steps:

   a. Execute the following command on the background server to notify all active users using Support Automation to save their work:

      ```
      sa_server_notifier [-h] | [-q seconds] | [-c]
      ```

      - **-h**
        Displays the help page.

      - **-q seconds**
        This option notifies a local server (background) to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. This option cannot be used for a standby server or application server.

      - **-c**
        This option cancels a previously sent quiesce request.

      A pop-up message is displayed to all the active users using Support Automation on the background server. This message notifies the users about the server shutdown and the scheduled time left for the shutdown. The users must save their work and logout within that scheduled time.

   b. Shut down the CA SDM services on the background server.

Important! Do not restart the CA SDM services on standby or application servers after "save and publish" is performed from WSP. This action corrupts the advanced availability configuration. If the CA SDM services on standby or application servers are stopped and you want to start the services, run the pdm_server_control -v command on the servers to suppress the version control before starting the CA SDM services.

Important! If the background server fails during the publishing activity, ensure that you recover the WSP changes. For more information, see the Recover WSP Changes During Background Server Failure (see page 1742) topic.

c. Execute the following command on the standby server that you wish to promote as the new background server:

```
pdm_server_control  -b
```

- **-b**
  Notifies a local standby server to become the background server. The standby server must already be running. If the server is not running, it is started but no failover is performed; to start a failover, run the command again.

The background server shuts down automatically and the standby server is promoted as the new background server. This change does not affect the end-user sessions. The in-progress updates (if any) are stored and delayed, until the new background server comes online.

d. Run the following command on the original background server (now the standby server) to update the DBMS with the schema changes:

```
pdm_publish
```

The pdm_publish command creates a control file that causes the next CA SDM startup to suppress synchronizing the standby server with the background server. This action is necessary to preserve the schema file changes made by pdm_publish. This command optionally performs the second fail-over after successful publishing of the schema changes. The following message is prompted to the user at the end of successful publishing:

```
Do you want pdm_publish to start CA Service Desk Manager in this standby
server and perform fail-over(Y/N)?
```

- If you enter Y, pdm_publish starts the CA SDM services on the standby server and performs fail-over automatically. Skip to step g to apply the schema changes on all the application servers.

- If you enter N, go to Step e.

e. Start CA SDM services on the standby server (original background server).
The startup detects the control file that is created by pdm_publish, but does not synchronize the standby server with the background server. This lack of synchronization preserves the changes made by pdm_publish for this startup.

> **Important!** Ensure that you follow these directions exactly, as the failure to failover to the original background server after a pdm_publish results in corrupted services.

f. Run the following command on the standby server (original background server) to make it the background server again:

```
pdm_server_control  -b
```

This command also deletes the control file, so that version control works normally when this server again becomes a standby server.

g. Execute the following command on the application servers:

```
pdm_server_control -q interval -s server_name
```

- **-q interval -s server_name**
  Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

A pop-up message is displayed to all the active users on the specified application server. This message notifies the users about the server shutdown and the scheduled time left for the shutdown. The users must save their work and logout within that scheduled time. The users log on to the updated application server to resume their work.

h. Restart all standby servers.

Recover WSP Changes During Background Server Failure

You can recover the MDB schema changes when the background server fails during the publishing activity.

> **Important!** We recommend you not to perform the recovery steps directly on the production environment. Ensure that you first validate them on the test or development environment.

Follow these steps:

- If the background server has crashed before publishing, the last saved schema changes are preserved in MDB. You log in to the new background server and resume your publishing tasks.
- If the background server crashed after publishing, perform the following actions:

  1. Stop CA SDM services on the crashed background server.
  2. Choose a standby server that you want to promote as the new background server.
  3. Copy the following files from crashed background server to the same location on the standby server:
     - "NX_ROOT/site/mods/majic/wsp.mods"
     - "NX_ROOT/site/mods/wsp.altertbl"
     - "NX_ROOT/site/mods/wsp.altercol"
     - "NX_ROOT/site/mods/wsp_index.sch"
     - "NX_ROOT/site/mods/wsp_schema.sch
  4. Run the following command on the standby server to publish the schema changes and to perform the automatic fail-over:

     ```
     pdm_publish
     ```

  5. Select Y on the message prompt that appears after successful publishing of schema changes. The CA SDM services are started on the standby server.

     Note: If automatic fail-over does not occur, run the pdm_server_control -b command from the standby server to promote it as the new background server.

  6. Quiesce and recycle each application server. Restart all standby servers. For more information, see the Publish Schema Modifications topic.

Revert Schema Modifications

If you change your mind about your schema modifications after putting them in test mode, you can revert back to the published, version of the schema. Reverting schema modifications has the potential of impacting other users. For this reason, this option is available only if your installation has installed both the wsp_domsrvr and wsp_webengine options to dedicate an Object Engine and a Web Engine to WSP.

Follow these steps:

Select File, Revert Test Mode.
WSP deletes the wsptest.mods file, causing WSP Object Engine to revert its schema back to the published version.

After deleting the wsptest.mods file, WSP causes its Object Engine to recycle so that it can rebuild its internal schema. This may take from a few seconds to a couple of minutes, depending on the complexity of your schema.
After the Object Engine has completed recycling, the active schema is back to its published version.

Note: Web forms modified to work with the new schema are not automatically reverted, and may not work correctly when used with the published schema.

Modify Site-Defined Columns after Publishing

After site-defined schema modifications are published, WSP treats them similarly to the standard schema and restricts further changes. You can delete a site-defined column or can change the length of a site-defined string column by manually updating the DBMS and schema external to WSP. Then you run the pdm_wspupd script to update the database wspcol table to synchronize WSP with the external changes.

Follow these steps:

1. Log in to the following server, depending upon your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server
2. Find the site/mods subdirectory in your CA SDM installation directory.

   Tip: Create a backup of the wsp_schema.sch file, at a location other than the site /mods subdirectory, to avoid processing the duplicate files.
3. Edit the wsp_schema.sch file to delete unwanted site-defined columns or change the length of site-defined STRING columns. These updates are the only changes supported by this procedure. You can use any standard text editor to edit the wsp_schema.sch file.

   Important! If any of the index options (such as, UNIQUE) were specified for deleting a column, edit the wsp_index.sch file and remove references to the column. If the column was the only indexed column in the table, remove all references to the table from wsp_index.sch.
4. Edit majic/wsp.mods file with the same changes made to wsp_schema.sch:
   - Delete unwanted site-defined columns.
   - Change the length of site-defined STRING columns.

5. Enter the following command using the command prompt:

   ```
   pdm_wspupd
   ```

   The pdm_wspupd script reads wsp_schema.sch and compares it with the wspcol table in the database, writing a line to the console for any differences. For example, see the following output:

   ```
   PDM_WSPUPD - Update wspcol table from wsp_schema.sch
   Reading wsp_schema.sch to for current DBMS information...
   Reading wspcol table for WSP schema information...
   String column zSalesOrg.description length changed from 350 to 400
   Column zSalesOrg.sym not found in wsp_schema.sch - deleting wspcol row
   pdm_wspupd found 1 WSP-maintained column(s) to update and 1 to delete. Please
   verify that your DBMS has been manually updated to correspond to wsp_schema.
   sch, then reply Y to update wspcol or anything else to cancel.
   ```

6. Verify that the changes found by pdm_wspupd correspond exactly to the changes you made to wsp_schema.sch. If they match, type **Y** to confirm the changes.
   After you confirm the update, the script uses standard CA SDM utilities to update the wspcol table. Then, Schema Designer shows your changes.

7. Stop the CA SDM servers.

8. Using the appropriate utility for your DBMS, alter the DBMS definition of the columns you changed:

   - Delete any columns from the database that you deleted from wsp_schema.sch.
   - Change the database length of any string columns you changed in wsp_schema.sch.

   Take care that the changes you make to the DBMS correspond exactly to the changes you made to wsp_schema.sch.

9. Publish Schema Modifications (see page 1739).

10. Start the CA SDM servers.

How to Modify the Web Interface using Web Screen Painter

Web Screen Painter (WSP) lets you modify web forms to the requirements of your site without programming.

Some of the Knowledge Management forms cannot be modified in the design view of WSP. For these forms, there are alternate approaches to providing the customization, such as:

- Document view -- the document template that is used when creating the document determines the contents of this page. These templates can be modified on the administration tab under documents, document templates.

- Knowledge categories document list -- you can modify this page by using WSP, but it is also managed by user preferences. The “preferences” screen provides personalization per user for defining which document properties displays in the document list and how many documents display per page.

Follow these steps:

1. Verify the Prerequisites (see page 1747)

2. Start WSP (see page)

3. Choose the Form to Modify (see page)

    - Create a Form (see page 1747).

    - Open an Existing Form (see page 1749).

4. Modify a Form (see page)
   WSP always saves changes on the server where WSP is installed. When you save a file, it becomes accessible to other WSP users in a preview session, but is invisible to typical CA SDM users. This is because WSP saves all files in the site/mods/wsp directory, and this directory is not used by a typical CA SDM session.

5. If you are making web form changes in the test system, Migrate from Test to Production System (see page 1762).

6. Publish Form Changes (see page 1763).

7. (If necessary) Delete Forms After Publishing.

Verify the Prerequisites

Verify the following prerequisites before you begin the customization:

- Modified the schema that you want to add in the web forms.
- (For advanced availability configuration only) Verified that the following prerequisites to publish the web forms successfully:
  - (Recommended) CA SDM services are up and running on all the CA SDM servers. Otherwise WSP publishes only on the CA SDM servers that are up and running.
  - (Required) At least one webengine instance running on every CA SDM server.

Start WSP

Start WSP to modify web forms.

Follow these steps:

1. Log in to the computer where you have WSP installed.
2. Start WSP.
   - (Windows) Click Start, Programs, CA, Service Desk, WSP.
   - (UNIX) Enter the command *pdm_wsp* with $NX_ROOT/bin in your path.

     Important! When you use UNIX, ensure that you have Firefox installed to use WSP.

   The WSP login window opens.
3. Enter your credentials.
   WSP displays the main form.

Choose the Form to Modify

You can create a form or can open an existing form to modify. Choose from the following possibilities:

- Create a Form (see page 1747).
- Open an Existing Form (see page 1749).

Create a Form

Create a form in WSP.

Follow these steps:

1. Click File, New.
   The New Form dialog opens.

2. Complete the following fields, as appropriate:

   - **Interface or File Type**
     Indicates the file type of the form. For example, to create an HTMPL form select an interface (Analyst, Customer, Employee, Default, or PDA). To create a form of other file type by select the type directly (CSS Stylesheet, HTML, or JavaScript). When you select an interface or file type, WSP displays a list of all available templates for the selected file type in the File Name field.

   - **Form Group**
     Indicates the form group (as defined for your CA SDM installation) where you want to create your new form or file. If you have not defined any form groups, only the DEFAULT form group is listed.

   - **File Name**
     Indicates the template for the selected interface or file type. A template contains the basic requirements for a new form or file of the desired type.

   - **Select table for new list or detail form**
     Indicates the CA SDM tables for which you can create a new list or detail form. This field is populated according to your selection of an interface (Analyst, Customer, Employee, Default, or PDA).

     Note: Only one detail or list form can exist for each table in a forms group, so edit an existing form (rather than create one) for tables that already have an existing form. If you want to have multiple versions of a form, create one or more form groups to hold the additional versions.

3. Click New.

4. The form is displayed for your customizations. The following two tabs are displayed:

   a. **Design**
      Available for detail forms, list forms, and menu bar forms, and shows the controls on the form laid out more or less as a user would see them. It is not an image of how the form looks to an end user. To see this, select **Tools**, **Preview**.

   b. **Source**
      A Notepad-style editor allowing you to review and edit the source code for a form. Some forms are editable only in the Source tab. For those forms, the edit window opens up on the Source tab, and the Design tab is disabled.

   The form is ready for customization.

Important! When you create or edit a detail or list form, use the list_ and detail_ prefixes to name the HTMPL file. For example, use list_test.htmp" and detail_test.htmpl. This prefix lets you correctly preview a form. When you save a detail template with a custom name, you must also manually edit the <PDM_WSP> tag. For example, <PDM_WSP mode=edit preview="test.htmpl+OP=CREATE_NEW" factory=cr>.

Open an Existing Form

Open an existing form in WSP to modify it.

Follow these steps:

1. Select File, Open.
   The Open Form dialog opens.

2. Select the Interface (Analyst, Customer, Employee, Default) or File Type (CSS Stylesheet, JavaScript, or HTML) and the forms group that contains the form you want to edit.

3. Select either the form you want from the list, or enter its name in the textbox.
   When you enter a name in the textbox, WSP automatically scrolls the list to the first name matching the characters entered. You can use the Files of Status drop-down list to restrict the list of files displayed:

   - **Site Modified with Unpublished Changes (+)**
     Restricts the list to files that have been modified with WSP, but not yet published. These files are identified with a plus sign (+) after the file name.

   - **Site Modified (*)**
     Restricts the list to forms modified at your site, both published and unpublished. The unpublished files are identified with a plus sign (+) after the file name. The published site modifications are identified with an asterisk (*) after the file name.

   - **All**
     Displays the list with no restrictions. The unpublished files are identified with a plus sign (+) after the file name. The published site modifications are identified with an asterisk (*) after the file name.

4. Click Open.
   The form is displayed and ready for your customization.

Modify a Form

After you open the form you want to edit in WSP, you can use the toolbar, menu commands, and shortcuts to customize it. You can perform the following customization:

- Insert a Control
- Edit Control Properties
- Modify Menu Bars

- Modify Stylesheets
- Modify Mouse-Over Preview Form
- Modify Data Grid List on List Form
- Modify Notebooks on Detail Form
- Modify HTML and JavaScript Files

Insert a Control

Add a control on the form. For example, add a textbox in the form.

The controls that can be inserted on both list and detail forms are the following:

Control	Icon	Description
Insert Row	 BSVC_r12.1--Inserting a Control	Causes the selected control to be the last in its current row (moves following controls to the next row).
Delete Row	N/A	Deletes all controls on the same row as the currently selected control.
Textbox	 BSVC_r12.1--Inserting a Control (2)	Inserts a single or multi-line textbox for editing a string or text field.
Dropdown	 BSVC_r12.1--Inserting a Control (3)	Inserts a drop-down list for editing a field validated against a table.
Lookup	 BSVC_r12.1--Inserting a Control (4)	Inserts a lookup control for editing a field validated against a table. The control consists of a textbox with a hyperlink in the label that pops up a select form.
Button	 BSVC_r12.1--Inserting a Control (12)	Inserts a button.

Control	Icon	Description
Hierarchical Lookup	 BSVC_r12.1--Inserting a Control (5)	Similar to a Lookup control, except that it is used for a field with a hierarchical selector (such as request category).
Date	 BSVC_r12.1--Inserting a Control (6)	Inserts a date field. The control consists of a textbox with a hyperlink in the label that pops up a date selector.

The following additional controls are available for detail forms only:

Control	Icon	Description
Checkbox	 BSVC_r12.1--Inserting a Control (7)	Inserts a check box.
HTML Editor	 BSVC_r12.1--Inserting a Control (8)	Inserts an HTML editor for a text field that contains HTML.
Read Only Textbox	 BSVC_r12.1--Inserting a Control (9)	Inserts a non-editable text field.
Read Only Lookup	 BSVC_r12.1--Inserting a Control (10)	Inserts a non-editable lookup field. The field is displayed as a hyperlink to pop up the detail form defining it.
Read Only	 BSVC_r12.1--Inserting a Control (11)	Inserts a non-editable date field.

Control	Icon	Description
Notebook	 BSVC_r12.1--Inserting a Control (13)	Inserts a notebook. There can only be one notebook on a detail form, so this control can be inserted only on forms that do not already contain a notebook.

The following additional control is available for list forms only:

Control	Icon	Description
List	 BSVC_r12.1--Inserting a Control (14)	Inserts a list. There can only be one list on a list form, so this control can only be inserted on new list forms.

Follow these steps:

1. Right-click the form at the location where you wish to add the control and select Insert Control.
   A dropdown list is displayed.

2. Select the insert control dialog options (see page 1752).
   The control is placed on the form.

3. Select Tools, Preview to check how the form is displayed to the end user. Although it resembles a standard CA SDM window, and most buttons and menus are functional, it is not a standard session, and you should not attempt to use it that way.

4. Click File, Save.
   The controls are added on a form.

Insert Control Dialog Options

Open the Insert Control dialog from the File menu. The dialog lists all of the appropriate UI controls for the section of the form you select to edit.

The dialog contains the following options:

- **Insert Before**
  Inserts the selected control from the list before the currently selected control on the base form, and makes it the currently selected control.

- **Insert After**
  Inserts the selected control from the list after the currently selected control on the base form, and makes it the currently selected control.

- **Prev**
  Moves the currently selected control to the control that precedes it on the form.

- **Next**
  Moves the currently selected control to the control that follows it on the form.

- **Properties**
  Opens the Properties dialog for the currently selected control.

- **Close**
  Closes the Insert Control form.

- **Close Form After Insert**
  (Enabled) Inserts the selected control and closes the Insert Control dialog when you click Insert Before or Insert After.
  (Disabled) Inserts the selected control when you click Insert Before or Insert After. The Insert Control dialog remains open to insert additional controls or request properties for the currently selected control. After you clear the check box, the Close Form After Insert check box remains unchecked until you either select it again or end your WSP session.
  Default: Enabled

Edit Controls Properties

Edit the properties of a control.

Follow these steps:

1. Select the control and press F4.
   The Properties dialog opens.

2. Change properties as appropriate. For example, the Caption property specifies the header label that is displayed above a control. To specify this property, enter the desired value in the cell to the right of the Caption property.

3. Close the Properties dialog.

4. Select Tools, Preview to check how the form is displayed to the end user. Although it resembles a standard CA SDM window, and most buttons and menus are functional, it is not a standard session, and you should not attempt to use it that way.

5. Click File, Save.
   The properties of the control is modified and the form is saved.

Modify Menu Bars

Forms with names beginning *menubar_* define a menu bar. The Design view for a menu bar displays the menu at the top. You can click a menu item to lower the menu, but cannot otherwise edit the menu bar directly in Design view. To edit a menu bar, double-click the menu item to display the Menu Designer.

Note: Menus (and menubar forms) are used only in the analyst interface. The customer and employee interfaces use a "launch bar" containing actual links, not drop-down lists. To modify the customer or employee launch bar, edit form std_body_site.htmpl from the appropriate interface.

Follow these steps:

1. Select Tools, Menu Designer or double-click the menu shown in the Design tab of a menubar form.
   The Menu Designer dialog is displayed.

2. Complete the fields in the Menu Designer dialog (see page) to add or edit menu items.
   For more information about adding menu items, see the Functions Useful in Menu Items (see page 1755) topic.

3. Click OK to close the dialog.

4. Select Tools, Preview to check how the form is displayed to the end user. Although it resembles a standard CA SDM window, and most buttons and menus are functional, it is not a standard session, and you should not attempt to use it that way.

5. Click File, Save.
   The menu bar is modified in the form.

Menu Design Dialog

The Menu Designer dialog appears when you select Menu Designer from the Tools menu, or double-click the menu shown in the Design tab of a menubar form. Use the Menu Designer dialog to add a menu bar, menus, submenus, and menu commands to the open form.

Note: You can access the Menu Designer only while editing HTMPL forms with a name beginning with “menubar_”, such as menubar_admin.htmpl.

The Menu Editor dialog contains the following controls:

- **Menu List**
  From the menu list, select the menu item you want to change. To change the menu label, for example, select a menu label from the list, type a new name in the Caption text box, and click Apply. You can add, insert, delete, and move the menu items using the controls in the Menu Designer.

  Note: Only one level of indentation is possible.

- **Caption**
  Enter the name for the selected menu item. See the property for more information.

- **Function**
  Enter the JavaScript function to execute when the user clicks the menu. See the description of the Function property for more details, including some pre-defined functions that may be useful in menus.

- **ID**
  Enter the HTML/JavaScript id to be assigned to the menu item.

- **Hot Key**
  Enter a list of characters directing CA SDM's selection of the hotkey for this menu item. The hotkey is underlined in the menu caption when it is displayed. CA SDM typically selects the first key in the menu caption not already in use as a hotkey. You can specify one or more characters here to restrict the selection to those characters, or specify one or more characters preceded by an explanation point to prevent selection of those characters.

- **Image**
  Enter the location of the image that you want to appear next to the menu item.

- **Internal**
  Select this option to specify that the JavaScript invoked by the function should be executed in the context of the current window (which could be a pop-up detail window). Leave this option unchecked to specify that the function should be executed in the context of the main form.

- **Variable**
  Enter the JavaScript variable to be assigned to the menu item.

- **Tool Bar**
  Adds a tool bar icon and tooltip that corresponds to a non-top-level menu item.

- **Icon File**
  Identifies the location of the Tool Bar icon.

- **Tip**
  Specifies the tooltip text.

Functions Useful in Menu Items

CA SDM provides a menu bar on almost every form to control its functions. The menu bar is generated by an HTMPL form with a name of the form menubar_*xx*.htmpl. We recommend that you use WSP to modify existing menu bars and define new ones.

The following predefined functions may be useful for scripts invoked by menu items:

- **upd_frame(form)**
  Loads a new form into the main window content frame.

- **create_new(factory, use_template, width, height [,args])**
  Pops up a form to define a new record.
  Popup_window(name, form[, width, height [,features [,args]]])
  Pops up a new window.

- **showDetailWithPersid(persid)**
  Pops up a detail record.

The following terms and definitions apply to the previous functions:

- **Form**
  This is either an HTMPL file name of the form xxx.htmpl or an operation code (for example CREATE_NEW).

- **factory**
  This is the name of a database object.
- **use_template**
  This is either true or false.
- **width**
  This represents the desired form width or zero for default.
- **height**
  This represents the desired form height or zero for default.
- **features**
  This is a list of window features, in the same format used with the standard window.open function.
- **args**
  This is one or more args of the form "keyword=value" for the operation specified for form.
- **persid**
  This is a persistent ID in the form factory:ID.

Modify Stylesheets

You can use WSP to edit or create CSS (cascading stylesheet) files.

Note: For performance reasons, CA SDM stylesheets are delivered in two forms: Individual files (such as search_filter.css) and combination files grouping a number of individual files with comments and excess white space removed (such as analyst_styles.css). WSP always edits the individual files; you cannot edit a combination file directly. When you publish stylesheet changes, WSP automatically builds the associated combination file if necessary.

Follow these steps:

1. Create or open CCS stylesheet file.
   WSP displays the Source view of the stylesheet.
2. You can edit directly in Source view, or display the Style Designer by selecting Tools, Style Designer.
3. Complete the fields in the Style Designer dialog (see page 1757), as appropriate. There are a number of style attributes, such as margin and border that can neither be seen nor edited in the Style Designer. These must be edited in Source view.
4. Click OK in the Style Designer.
   WSP reformats the stylesheet and updates the Source view.
5. Click File, Save.
   The stylesheet is modified.

Style Designer Dialog

The Style Designer lets you modify or customize style sheets. By default the Style Designer dialog opens in the Font and Color tab and contains the following controls:

- **Style Classes**
  From the drop down list, select a style element you want to modify.

- **Add**
  Click to add a new style class.

- **Rename**
  Click to rename the style class selected in the Style Classes dropdown list.

- **Delete**
  Click to delete the style class selected in the Style Classes dropdown list.

- **Installed Fonts**
  This property lists the fonts that are installed on the system. Click the left and right arrows to move the selected fonts between the Installed Fonts list and the Selected Fonts list.

- **Selected Fonts**
  This property specifies a hierarchical list of preferred fonts that a browser uses to draw the style class element. A browser uses the first font in the list that is installed on the system it is running on.
  Click the up and down arrows to move the selected fonts up or down the hierarchy.

- **Font Size**
  Select the font size from the dropdown list.

- **Bold**
  Select a font style from the dropdown list.

- **Italics**
  Select a font style from the dropdown list.

- **No Effect**
  Select this option if you do not want any text decoration or special effects.

- **Underline**
  Select this option if you want the text to be underlined.

- **Strikethrough**
  Select this option if you want the text to appear with a line through it.

- **Overline**
  Select this option if you want the text to appear with a line above it.

- **Foreground Color**
  Select the foreground color for the text element by clicking the Browse button to the right of the Foreground Color property. Then select the color you want from the Color palette, and click OK.

- **Background Color**
  Select the background color for the text element by clicking the Browse button to the right of the Background Color property. Then select the color you want from the Color palette, and click OK.

- **Transparent**
  Select this option if you want the background of the style element to be transparent.

A sample of the style element is displayed in the preview area at the bottom of the dialog.

To set the position of the style element, click the Position tab. The Position tab contains the following controls:

- **Position**
  From the dropdown list, select one of the positions for the element. The position property places an element in a static, absolute or relative position. Selecting a Static value will place the element in accordance with the normal flow. Selecting an Absolute value will place the element anywhere on a page. Selecting a Relative value moves the element relative to its normal position.

- **Left**
  Enter a value for the left margin in the text box for the element. Select a size from the dropdown list. This property is disabled when the selected position is Static.

- **Top**
  Enter a value for the top margin in the text box for the element. Select a size from the dropdown list. This property is disabled when the selected position is Static.

- **Width**
  Enter a value for the width in the text box for the element. Select a size from the dropdown list.

- **Height**
  Enter a value for the height in the text box for the element. Select a size from the dropdown list.

- **Z-Index**
  Enter a value for the stack order in the text box for the element. An element with greater stack order is always in front of an element with lower stack order. Z-index only works only on elements that have Absolute position

Note: Elements can have negative stack orders.

Click the Other tab to set some of the specific properties for the element. The Other tab contains the following controls:

- **Visibility**
  Select the type of the visibility for the element from the dropdown list. The Visibility property sets how the content of an element is displayed if it overflows its area.

- **Overflow**
  Select the type of overflow for the element from the dropdown list. The Overflow property sets what happens if the content of an element overflow its set area.

- **Display**
  Select the type of the display for the element from the dropdown list. The Display sets how an element is displayed.

- **Cursor**
  Select the type of cursor for the element from the dropdown list. The cursor property specifies the type of cursor to be displayed when pointing on an element.

- **OK**
  Click to close this dialog and save your changes.

- **Cancel**
  Click to close the Style Designer dialog.

Modify Mouse-Over Preview Form

The Mouse-over previews let you view key details within the current form without the need to click a link or open a new web page. The mouse-over preview appears when you place a cursor over an object link on a list or detail form for a certain amount of time. If you move the mouse away from the link before the delay time expires, the preview does not appear. Mouse-over previews appear by default on all list and detail forms in read-only mode.

You can create mouse-over previews for forms that do not have preview_ forms by default. You can also create mouse-over previews for custom forms you created in your CA SDM environment.

The following predefined mouse-over preview forms are available:

- preview_chg.htmpl (Change Order)
- preview_cnt.htmpl (Contact)
- preview_cr.htmpl (Request)
- preview_in.htmpl (Incident)
- preview_iss.htmpl (Issue)
- preview_KD.htmpl (Knowledge Document)
- preview_nr.htmpl (Configuration Item)
- preview_pr.htmpl (Problem)

Follow these steps:

1. Open one of the following forms for the customization:
   - Open an existing form that does not have a preview_ form by default.For example, detail_loc.htmpl
   - Open an existing mouse-over preview form. For example, preview_chg.htmpl.
2. Modify the form. For example, add or remove custom controls from the form.

3. Click File, Save As, specify a file name using the preview_ prefix, and click Save. For example, enter preview_loc.htmpl.
   The mouse-over preview form is created and modified.

Modify Data Grid List on List Form

Data grid lists let you view the contents of a product page on a list form without opening a new page. This data-bound control lists items from the data source in a table so you can select items, sort items, and fetch data. For example, the expand and collapse options on the Incident List form.

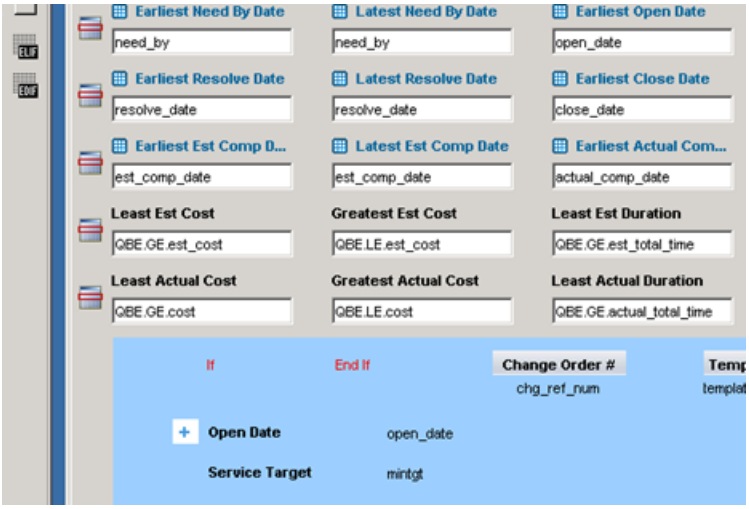
Follow these steps:

1. Open a list form.

2. Locate the blue area after the labeled fields near the end of the form in the Design view. If you prefer Source view, the data grid appears between the following lines of code:

   ```
   <PDM_MACRO name=lsStart>
   <PDM_MACRO name=lsEnd>
   ```

   The following example shows this data grid area in Design view:



The plus sign in the data grid area represents the beginning of the expansion section of the row (the fields that are displayed only when a user clicks plus on the row in the list form grid). The following code generates the plus sign in the Source view:

```
<PDM_MACRO name=lsCol attr=open_date label="Open Date" sort="DESC" startrow=yes>
```

The *startrow=yes* parameter specifies to start a row, and it starts the expansion section of the row.

- Drag-and-drop columns to move them in a list. You can move columns between the main part of the row and the expansion section. You cannot move an existing control after the grid area.

- To insert a list column, right-click a control or anywhere within the blue background, and select either Insert Column or Insert Control.

- If you select Insert Column, WSP inserts a column to the left of the currently selected control.
- If you select Insert Control, WSP displays the Insert Control dialog that lets you add the desired control to the form.

- Select Tools, Preview to check how the form is displayed to the end user. Although it resembles a standard CA SDM window, and most buttons and menus are functional, it is not a standard session, and you should not attempt to use it that way.
- Click File, Save.
  The data grid list is modified on the list form.

Modify Notebooks on Detail Form

The Nested tabs (notebook) control lets you expand or collapse key details within the current form. For example, use the control to customize how you organize tabs on the Incident Detail Form. From the Design View, you can use the Notebook control to add nested tabs to a detail form that does not already contain one. Double-click the Notebook control to modify it. Use drag-and-drop to add, insert, and delete notebook tabs, and to change their captions. You can also use the up and down arrow buttons to rearrange tabs by changing the position of the currently selected tab. The New Row check box specifies whether or not the selected tab begins a new row in the notebook header.

Follow these steps:

1. Open a detail form.
2. Locate the blue area of the form in the Design view that contains the first numbered label. If you prefer Source view, the notebook area appears between the following line of code:

```
<PDM_MACRO name=startNotebook hdr=cng_nb><PDM_MACRO
name=endNotebook>
```

Note: In CA SDM r12.6, a notebook can contain nested tabs. In WSP, a high-level tab (a tab containing other tabs) is named a tab group. WSP displays a tab group as a dark blue solid bar that spans the entire blue notebook area, with a numbered label in its center. A low-level tab (a tab that does not contain other tabs) is named a tab. WSP displays low-level tabs as rectangles with rounded corners.

3. Click a tab to select it. Selecting a tab highlights and displays a link to the contents of the tab at the bottom of the notebook.
   You can move tabs and tab groups within a notebook using drag-and-drop. Moving a tab group moves all the tabs within the group with it.
4. To insert a tab or tab group, right-click a control or anywhere on the blue notebook background and select Insert Tab, Insert Tab Group, or Insert Control.
   If you select Insert Tab or Insert Tab Group, WSP inserts a new tab or tab group to the left of the currently selected control. If you select Insert Control, WSP displays the Insert Control dialog that lets you add the desired control to the form.

5. Select Tools, Preview to check how the form is displayed to the end user. Although it resembles a standard CA SDM window, and most buttons and menus are functional, it is not a standard session, and you should not attempt to use it that way.
   Click File, Save.

Modify HTML and JavaScript Files

You can use WSP Source view to edit HTML and JavaScript forms.Open an HTML or JavaScript file and make the necessary changes.

Note: For performance reasons, some CA SDM JavaScript files are delivered in two forms: Individual files (such as window_manager.js) and combination files grouping a number of individual files with comments and excess white space removed (such as std_head.js). WSP always edits the individual files; you cannot edit a combination file directly. When you publish script changes, WSP automatically builds the associated combination file if necessary.

Migrate from Test to Production System

One of the design goals for WSP was to make it safe to develop and test forms modifications on a production database. Such features as a WSP-only directory tree on the server, dedicated WSP server processes, and read-only preview sessions support this goal. However, many users prefer to develop their forms modifications in an independent test system and then migrate the forms to a separate production system after they are complete as follows:

1. Copy any HTMPL forms to be migrated from the appropriate subdirectory of site/mods/www /htmpl on the test system to the same subdirectory of site/mods/wsp/project on the production system.

2. Copy any CSS, JavaScript, and HTML files to be migrated from the appropriate subdirectory of site/mods/www/wwwroot on the test system to the same subdirectory of site/mods/www /wwwroot/wsp/project on the production system.

   Note: Ensure that you copy the files and forms on the following servers of the production system, depending on your CA SDM configuration:

   - **Conventional:** Primary server
   - **Advanced availability:** Background server

Note: You can use any file copying method supported by your operating system to perform the copying described in steps 1 and 2 above. Windows users should substitute backslash (\) for slash (/) in the directory paths shown.

Publish Form Changes

When you are satisfied with the changes, you can make them available to all CA SDM users by publishing them. Publishing updates all CA SDM servers with new or revised forms.

Follow these steps:

1. Select File, Publish.
   If you have any unsaved changes, WSP prompts you to save them, and then displays a confirmation dialog showing all pending Web Screen Painter changes (including those saved in previous sessions, or saved by other Web Screen Painter users). By default, all changes are selected for publication. You can change the selection of changes to be published by clicking them.

2. Click OK when you are satisfied with the selection.

3. (Advanced availability configuration only) If the webengine is not running on any of the CA SDM servers, an error message is displayed with the list of CA SDM servers on which WSP failed to publish. Complete the following steps:

   a. Configure the CA SDM server (the server specified in the error message) to make the corrections.

   b. Edit the file in WSP to add a white space character in the <PDM_IF 0> macro and save it.

   c. Go back to step 1 to republish the web form.

   Note: If you do not want to make any configuration changes, you have to manually copy the nx_root/site/mods/www folder from the background server to all the other servers.

4. (Advanced availability configuration only) If the background server crashes while publishing, recover the HTMPL changes.

5. (For mouse-over preview forms) Execute the following command after publishing the changes:

   ```
   pdm_webcache  - H
   ```

   The web cache is refreshed. WSP makes the selected changes available to all users active on all the servers.

Note: Only site-modified forms can be deleted. Requests to delete a previously published form take effect when you publish changes. To cancel a pending delete request, select File, Undelete Form. You undo changes to a form after publication.

Recover the HTMPL Changes

You recover the HTMPL changes when the background server fails during the publishing activity.

Important! We recommend you not to perform the recovery steps directly on the production environment. Ensure that you first validate them on the test or development environment.

Follow these steps:

1. Go to the following directory on the crashed background server:

   ```
   $NX_ROOT$/site/mods/www/wwwroot/wsp/project/web
   ```

2. Copy all the content from the web folder.

3. Log in to the new background server and paste all the copied content in the NX_ROOT/site /mods/www/wwwroot/wsp/project/web folder.

4. Resume publishing the changes on the new background server.

HTML Templates (HTMPL Form)

This article contains the following topics:

Forms in the CA SDM web interface are delivered as HTML templates, in files with a suffix of .htmpl. These are called HTMPL forms in the remainder of this document.

An HTMPL form contains standard HTML (including JavaScript) plus language extensions that are interpreted by a CA SDM server daemon (or service) called the web engine that delivers standard HTML to the browser. These extensions are:

- References to server variables. These are indicated by a name beginning with a dollar sign. They can be the values of columns in the CA SDM database, references to web engine configuration properties, or other server information.

- Special tags directing the web engine to perform tasks on the server, such as read information from the CA SDM database. These tags have names of the form <PDM_...> or <pdm_...>.

Note: You do not need to understand the HTMPL extensions or even HTML itself to be able to customize CA SDM forms with WSP.

Template Naming Conventions

The following naming conventions are used to identify the four basic types of HTMPL files, where *xxx* is the object:

Template Type	Name
List (search filter and results)	list_*xxx*.htmpl
Combined read-only and edit detail form (analyst interface)	detail_*xxx*.htmpl
Read-only detail form	detail_*xxx*_ro.htmpl
Edit detail form	detail_*xxx*_edit.htmpl

You can find the definitions of the objects and their properties in the following locations:

- (UNIX) $NX_ROOT/bopcfg/majic/*.maj
- (Windows) *installation-directory*\bopcfg\majic*.maj

For information about the objects and attributes that define CA SDM, see CA Service Desk Manager Reference Commands (see page 3496).

HTMPL Directories

There are different sets of HTMPL files supplied to implement these interfaces, as shown in the following table:

Operating System	Directory Containing HTMPL Files
Windows	*Installation-directory*\bopcfg\www\htmpl\web*interface*
UNIX	$NX_ROOT/bopcfg/www/htmpl/web/*interface*

In this table, *interface* is the name of the interface (analyst, customer, or employee).

Note: There is no separate directory for guest interface files; by default, this interface uses the employee interface files. You can change the guest user interface by changing the access type associated with user System_Anonymous. Both the customer and employee files dynamically modify themselves depending on whether the current user is a known user or a guest, using the <PDM_IF> template command described in this document.

There are three additional interface subdirectories under the htmpl directory:

- **default:**
  Contains HTMPL files common to all interfaces. When searching for a file, the web engine looks first in the directory corresponding to the current user's interface, and then in the default directory.
- **pda/analyst: (UNIX)**

- **pda\analyst: (Windows)**
  Contains HTMPL files used by the mobile device interface. In CA Service Desk Manager r11.0, the mobile device interface is provided only for analysts.

- **web/*interface*/legacy: (UNIX)**

- **web*interface*\legacy: (Windows)**
  Contains HTMPL files from your previous release of CA SDM that are no longer used. This directory is automatically created if you upgrade from a previous release when you install CA SDM. You can delete the legacy directory when none of its files are referenced by your customized files.

We strongly recommend that you do not directly modify the supplied HTMPL files. Instead, either use WSP, or manually copy the file you want to modify to the site mods directory, and modify it there. The CA SDM web server looks for a new form in the appropriate site mods directory before checking the distribution directory. The standard site mods directories for each of the interfaces are as follows:

Operating System	Directory For Site-Modified HTMPL Files
Windows	***installation-directory**site**mods**www**htmpl**interface**interface***
UNIX	$NX_ROOT/site/mods/www/htmpl/*interface/interface*

Note: If you change the form and save it into the *install directory**site**mods**www**htmpl**interface* directory, the form will be seen by everyone, regardless of the form group to which they belong. If you save it into the *install directory* \site\mods\www\htmpl\interface*interface* directory, only those Contacts that are defined as belonging to that form group will see the changed forms.

In the previous table, *interface* is the name of the interface (analyst, customer, or employee). There is no separate directory for guest interface files; this interface uses the employee interface files. The advantage of storing your modified HTMPL files in the site mods directory is that this directory is preserved when you install CA SDM maintenance or a new release. In addition, keeping your modified files in site mods while preserving the originals ensures that you always have a correct copy of the originally distributed HTMPL file.

Each web interface page has a primary function, as indicated in the following table that lists the major HTML templates. However, you can add <PDM_FORM> blocks to any template to directly access any web interface supported operation. For example, you can modify the main menu to include fields for submitting an issue without using the intermediate page, or you can add search criteria fields and a search button to a list form:

Web Page	HTML Template
Main form	menu_frames.htmpl
Display/create/update a change order	detail_chg.htmpl
Display a list of change orders	list_chg.htmpl
Display/create/update and issue	detail_iss.htmpl

Web Page	HTML Template
Display a list of issues	list_iss.htmpl
Display/create/update a request	detail_cr.htmpl
Display a list of requests	list_cr.htmpl
Display announcement detail information	detail_cnote_html
Display a list of announcements	list_cnote.html
Login	login.htmpl

Note: For a complete list of templates, view the contents of the directories in the table at the beginning of this section.

Web Form Groups

You can collect customized web pages into one or more form groups. Form group directories are in the following directories:

- **Windows**
  install-directory\site\mods\www\htmpl\web*interface*
  install-directory\site\mods\www\wwwroot\subdirectory

- **UNIX**
  $NX_ROOT/site/mods/www/htmpl/web/*interface*
  $NX_ROOT/site/mods/www/wwwroot/subdirectory

Each form group is a subdirectory under these directories. You specify the customized form directory in the Customization Form Group field of the access type.

When a user requests a form, the web engine looks first in the appropriate customized form group directory, then in the standard directory for the user's web interface, and finally in the default directory. You can define more than one access type for the same web interface, each with a different customized form group. This lets you define a few specialized forms for different types of users, and still take the majority of the forms from the standard interface.

A similar process occurs when a web page requests a file from one of the subdirectories of wwwroot (css, html, img, or scripts). The webengine examines an HTMPL reference of the form CAisd/img/xxx.gif and converts it to one of the following GIF files, selecting the first one where it finds xxx.gif:

- /CAisd/sitemods/img/formgroup/xxx.gif
- /CAisd/sitemods/img/xxx.gif
- /CAisd/img/xxx.gif

How to Create a Web Form Group

You can create a web form group.

Follow these steps:

1. If you want a form group besides the predefined Analyst, Customer, or Employee form groups, create a form group by selecting Save As from the File menu in WSP and clicking the Add Form Group button on the Save Form As dialog. For example, if you want to provide two separate customized versions of the Analyst interface, you might create form groups called Analyst1 and Analyst2 to handle these. You might also define a new form group if the interface you are defining does not logically fit into one of the predefined form groups.

2. On the web interface (not a Web Screen Painter preview session), select Security, Access Types from the Administration menu. Then click an access type (or create one) and use the Customization Form Group drop-down list on the Access Type Detail window to assign a form group to an access type. CA SDM determines the access type when a contact logs in and uses customization form group to determine where to look in the site mods directory structure for customized forms. If the web engine does not find a form in the form group directory, it looks first in the standard directory for the user's access type, and then in the default directory.

3. In WSP, select Save from the File menu, or manually copy the customized HTMPL files to the following directory:
   In Windows: *installation-directory*\site\mods\www\htmpl\web*form_group_name* directory
   In UNIX: $NX_ROOT/site/mods/www/htmpl/web/*form_group_name*

After you set up a new web form group and copied any supporting files to the appropriate subdirectories, you must restart the web service before the changes take effect.

PDM_MACRO Insert Text from a Macro File

The <PDM_MACRO> tag is used to insert a macro file into an HTMPL file. Its functionality is similar to PDM_INCLUDE, with two important differences:

- A file included by PDM_MACRO has a formal argument list, with required arguments and arguments with default values.

- A file included by PDM_MACRO always comes from the directory specified for the configuration property MacroPath, regardless of the current user's access type.

- **NAME=*macroname***
  (Required) Specifies the macro to include. The web engine affixes the suffix ".mac" and searches for the file in the path specified by configuration file property MacroPath.

Other properties may be required, depending on the macro included. A macro file has the general layout:

```
comments
#args
name1 [= value1]
name2 [= value2]
...
#data
data to insert
```

The following descriptions explains the file layout, line by line:

- **comments** -- The only valid statements in a macro prior to the #args statement are comments. Comments are indicated by either a # sign or a // as their first non-blank character or characters.

- **#args** -- Must be coded exactly as shown, with the # sign in column one and no other information on the line. This statement begins the args section, which can contain argument definitions and comments.

- **name [= value]** -- Defines an argument for the macro. Only arguments explicitly mentioned in the args section are valid for the macro. A value specified for an argument in the args section is that argument's default value. Arguments without a default value are required, and must be supplied by the caller on the <PDM_MACRO> statement itself.

- **#data** -- Must be coded exactly as shown, with the # sign in column one and no other information on the line. This statement begins the data section, which is the part of the macro inserted into the file using PDM_MACRO. Everything in the data section is inserted into the calling file, including lines that would be comments prior to the data section.

- **data to insert** -- The data to insert into the calling file. This data can contain references to arguments in the form:

- **&{arg_name}** -- These references are replaced with the value of the argument supplied by the caller, or with the default value if the caller did not supply a value.

The web engine normally reads a macro file only once, the first time it is used, and then stores the parsed macro in its own memory. This improves performance, but can be inconvenient if you are developing a macro. Use the configuration file property SuppressMacroCache to prevent this behavior and cause the web engine to discard all macros in its memory each time it begins processing a new form.

To Comment Out PDM_MACRO Tags

To comment out <PDM_MACRO> tags, enter an exclamation point in front of the P as follows: <! PDM_MACRO>. To prevent the browser from processing the commented out portion of the form, place <PDM_IF 0> before the <!PDM_MACRO> tag, and </PDM_IF> after the line you commented out.Example:

```
<PDM_IF 0>

<!PDM_MACRO NAME=dtlDropdown hdr="Status" attr=status lookup=no
evt="onBlur=\\\"detailSyncEditForms(this)\\\"">
<!PDM_MACRO NAME=dtlDropdown hdr="Priority" attr=priority lookup=no
evt="onBlur=\\\"detailSyncEditForms(this)\\\"">

</PDM_IF>
```

Predefined Macros Used by WSP

This article contains the following topics:

- Menubar Macros (see page 1773)

CA SDM includes a number of predefined macros. Most of these macros insert JavaScript text to create an element on a web form. Use Web Screen Painter to create and modify forms using these macros.

Detail Form Macros

The following list describes the Detail Form macros:

- **button**
  Inserts a graphic button.
- **dtlCheckbox**
  Inserts a check box on a detail form.
- **dtlDate**
  Inserts a date field on a detail form.
- **dtlDateReadonly**
  Inserts a read-only date field on a detail form.
- **dtlDropdown**
  Inserts a drop-down list on a detail form.
- **dtlEnd**
  Ends a detail form.
- **dtlEndTable**
  Ends a table within a detail form.
- **dtlForm**
  Begins a detail form.
- **dtlHTMLEditBox**
  Inserts a detail form field that is a text box containing an HTML editor.
- **dtlHier**
  Inserts a detail form field that is a text box validated against an external table with a hierarchical lookup.

  Important! We recommend that you do not change the dtlHier macro to dtlLookup in the HTMPL file. Use the Options Manager suppress_web_hier_search option instead so that autocomplete works correctly.

- **dtlLookup**
  Inserts a detail form field that is a text box validated against an external table.
- **dtlLookupReadonly**
  Inserts a detail form field that is a read-only hyperlink to an external table.

- **dtlReadonly**
  Inserts a read-only text field on a detail form.

- **dtlStart**
  Begins the first table in a detail form.

- **dtlStartExpRow**
  Begins an expandable row on a detail form.

- **dtlStartRow**
  Begins a normal row on a detail form.

- **dtlTextbox**
  Inserts a text box on a detail form.

contactLookup

The contactLookup macro creates a contact lookup. This macro has the following arguments:

```
contactLookup("&{header}","&{frameName}","&{factory}","&{lookupName}");
```

- **header**
  Identifies the lookup header.

- **frameName**
  (Required) Identifies the form name.

- **factory**
  Specifies the factory.
  Default: agt

- **lookupName**
  (Required) Identifies the lookup name.

You can also enable and disable this element by using the following:

```
contactLookupDisable( Name, bDisable )
```

- **bDisable=**

- true
  Disables the element.

- false
  Enables the element.

dtlCheckboxReadonly

The dtlCheckboxReadonly macro specifies a readonly checkbox field on an HTMPL detail form. The macro has the following arguments:

```
detailCheckboxReadonly("&{hdr}","&{attr}",&{colspan},"$args.&{attr}", "&{on}", "&
{off}");
```

- **hdr**
  Specifies the text of the header.
  Default: "$args.&{attr}.DISPLAY_NAME"

- **attr**
  (Required) Specifies the name of the attribute.

- **on = "X"**
  Specifies the value shown on readonly form when field is checked.

- **off = ""**
  Specifies the value shown on readonly form when field not checked.

- **colspan = 1**
  Specifies the number of columns on the form.

On both the readonly and edit forms, the field is displayed as specified in "on" and "off" arguments.

Note: This macro is similar to dtlCheckbox.mac, except that it is always read-only, even in Edit mode.

List Form Macros

- **lsCol**
  Specifies a column in a list form.

- **lsEnd**
  Ends the list portion of a list form.

- **lsStart**
  Begins the list portion of a list form.

- **lsWrite**
  Inserts text into the repeating section of a list form.

- **sfDate**
  Inserts a date field in a search filter.

- **sfDropdown**
  Inserts a drop-down list on a search filter.

- **sfEnd**
  Ends a search filter.

- **sfHier**
  Inserts a search filter field that is a text box validated against an external table with a hierarchical lookup.

- **sfLookup**
  Inserts a search filter field that is a text box validated against an external table.

- **sfStart**
  Begins a search filter.

- **sfStartRow**
  Begins a row within a search filter.

- **sfTextbox**
  Inserts a textbox into a search filter.

Menubar Macros

The following list describes the Menubar macros:

- **endMenu**
  Ends a menu within a menu bar.

- **menuItem**
  Defines a global item on a menu.

- **endMenubar**
  Ends a menu bar.

- **menuItemLocal**
  Defines an item on a menu invoked in the context of the current window.

- **menubarItem**
  Defines a menu within a menu bar.

- **startMenu**
  Begins a menu within a menu bar.

- **startMenubar**
  Starts a menu bar.

HTMPL Tags

This article contains the following topics:

This section outlines PDM commands to add HTMPL tags.

PDM_EVAL Insert the Value of a Pre-Processor Variable

The pdm_eval tag is used to insert the value of a pre-processor variable into the input of the webengine parser. If used inside a macro, its effect is deferred until the macro completes.

The pdm_eval tag works similarly to pdm_include or pdm_macro. It inserts the text into the parser at the point of the tag, exactly as if the value of its variable had been coded in place of the tag.

pdm_eval has the following syntax:

```
<PDM_EVAL TEXT=PRE.name>
```

- **name**
  (Required) The name of the pre-processor variable whose value is to be inserted into the webengine's input.

PDM_FORM Start an HTML Form with a Session ID

<PDM_FORM> and </PDM_FORM> can be added to any web interface HTML template to create an HTML form including two hidden fields for the server variables SID (session ID) and FID (form ID). The optional OP operand creates an additional hidden field for one of the supported operations, as with the PDM_LINK tag. Except for the automatically-generated hidden fields, <PDM_FORM> and </PDM_FORM> are used in the same way as the standard HTML <form> and </form> tags (and generate these tags as part of their expansion).

PDM_FMT Format Text from a Server Variable

The <PDM_FMT> and </PDM_FMT> tags are used to format blocks of text inserted by server variables ($args.xxx) as directed by its arguments.

Note: <PDM_FMT> is ignored for literals, including $prop.xxx variables.

The following table describes these tags:

Property	Description
ESC_STYLE=**NONE** | **E** | C |	Specifies the escape type of the formatted text. Valid values are: **NONE** Default setting. Specifies that no special treatment be given to any character in the content body. **C** Give special treatment to the characters ', ", \, \r, `, and \n, which are meaningful in C

Property	Description
HTML | JS | JS2 | URL	programs. These characters will be escaped. **HTML**Give special treatment to the following characters, which are meaningful in HTML text: & becomes & ' becomes ' " becomes " < becomes < > becomes %gt; **JS**Give special treatment to the following characters, which are meaningful in JavaScript text: ' becomes %27 " becomes %22 / becomes %2F \ becomes %5C \r becomes %0D \n becomes %0A **JS2** Same as JS, but give no special treatment to the character, /, and give special treatment to two additional characters: - % becomes %25 - Line breaks are suffixed with %0A **URL** Translate all characters other than letters, digits, and '@*-_.#' to '%xx', where xx is the hexadecimal coding of the translated character.
JUSTIFY=LEFT | CENTER | RIGHT | **TRUNCATE**| WRAP | LIN	Specifies the justification of the formatted text. Valid values include: **TRUNCATE** Default setting. Eliminates HTML formatting by replacing '<' and '>' with < and > **Note:** For more information, see the following information about KEEPLINKS and KEEPTAGS. **LEFT|CENTER|RIGHT** Produces exactly WIDTH characters, truncated or padded with spaces as necessary, with any embedded new lines replaced by a single space, and the output text delimited by [set the pre variable for your book] and </pre> tags. The WIDTH argument must be specified as a positive integer. **WRAP** Same as LEFT, except that text wrapping honors word boundaries (line breaks are not placed within words). **LINE** Same as TRUNCATE, except that it also replaces all embedded line breaks with tags.
KEEPLINKS=YES| **NO**	If KEEPLINKS=YES is specified, the action of JUSTIFY=LINE or JUSTIFY=TRUNCATE is modified to preserve HTML anchor tags (Action:) while converting all other '<' and '>' characters. Mutually exclusive with KEEPTAGS.
KEEPNL=YES|**NO**	The normal action of PDM_FMT is to convert all embedded new lines and any following spaces to a single space. If KEEPNL=YES is specified, embedded new lines are preserved. This argument is ignored for JUSTIFY=LINE.
KEEPTAGS=YES| **NO**	If KEEPTAGS=YES is specified, the action of JUSTIFY=LINE or JUSTIFY=TRUNCATE is modified to preserve all HTML tags. Mutually exclusive with KEEPLINKS.
PAD=**YES**|NO	If PAD=NO is specified, PDM_FMT does not convert empty strings to a single space. This is the normal action when WIDTH is non-zero, or JUSTIFY is TRUNCATE or WRAP.

Property	Description
WIDTH= *nn*	When non-zero, specifies that the text should be formatted to exactly WIDTH characters.

<PDM_FMT> without WIDTH or JUSTIFY does no formatting on the enclosed text, but surrounds the text with [set the pre variable for your book]and </pre>.

For example, to produce a multi-line description, enter the following:

```
<PDM_FMT WIDTH=50 JUSTIFY=WRAP>$args.description</PDM_FMT>
```

To produce multi-column output, enter the following:

```
<PDM_FMT><PDM_FMT WIDTH=20 JUSTIFY=LEFT>$cst.last_name</PDM_FMT>
 <PDM_FMT WIDTH=20 JUSTIFY=LEFT>$cst.first_name</PDM_FMT>
  <PDM_FMT WIDTH=20 JUSTIFY=TRUNCATE>$cst.middle_name</PDM_FMT>
</PDM_FMT>
```

PDM_IF Conditional Processing

These tags are used to conditionally include text. <PDM_IF> blocks can be placed anywhere in an HTMPL file - in HTML, in JavaScript, and even within HTML tags. <PDM_IF> and <PDM_ELIF> (else if) both take a simple conditional clause as their properties rather than name-value pairs. If the clause is true, the text after the tag to the closing tag is included in the file; if the clause is false, the server discards the text between the tag and the closing tag. The closing tag can be <PDM_ELIF>, <PDM_ELSE>, or </PDM_IF>.

The <PDM_ELSE> and <PDM_ELIF> tags are optional. If both are specified, all <PDM_ELIF> tags must precede <PDM_ELSE>. There can be any number of <PDM_ELIF> tags between <PDM_IF> and <PDM_ELSE> (or </PDM_IF> if <PDM_ELSE> is omitted).

The syntax of the conditional in <PDM_IF> and <PDM_ELIF> is as follows:

- 0 is false; any other number is true
- "" is false; "*any-string*" is true
- "*value op value*" evaluates the left and right values against each other according to *op*. If both values consist of digits (optionally preceded by - or +), the comparisons are done numerically. Otherwise, they are done lexically (ASCII collation). Valid *op* values include:

op Value	Description
==	Equal to
!=	Not equal to
>=	Equal to or greater than (must be written as \>= or >=)
<	Less than (must be written as \< or <)
>	Greater than (must be written as \> or >)
<=	Equal to or less than (must be written as \<= or <=)

op Value	Description
&	Performs a bit-and of the left and right values. True if any bits are set; false if none are set.
%	Returns true if the left value is an even multiple of the right value, and false otherwise (useful for building two-dimensional tables).
:	Performs a byte-oriented pattern match like the UNIX grep command. It returns true if the left value contains the regular expression defined by the right value.

Example:

```
<PDM_IF $count \>= 10> . . .
<PDM_ELIF $count &lt; 5>  . . .
<PDM_ELSE> . . .
</PDM_IF>
```

There can be more than one conditional in a PDM_IF statement. Conditionals are separated by connectors, either && (and) or || (or). There is no precedence for either connector. The web engine examines a conditional from left to right until it reaches a connector. If the initial condition is true and the connector is ||, it considers the entire condition to be true without further evaluation. If the initial condition is false and the connector is &&, it considers the entire condition to be false without further evaluation. Otherwise, it considers the condition undetermined, and evaluates the conditional from after the connector.

PDM_INCLUDE Inserting from a Different File

The <PDM_INCLUDE> tag is used to insert text from a second file into an HTMPL file. The server replaces the <PDM_INCLUDE> tag with the contents of the second file.

Included files can contain <PDM_INCLUDE> tags. There is no limit to the depth of nesting.

The <PDM_INCLUDE> tag supports the following properties:

Property	Description
FILE=filename	(Required) Specifies the file to include. The web engine searches the directories used for HTMPL files, as defined in the current user's access type.
FIXUP=[**YES**|NO]	(Optional) Indicates whether the file should be interpreted by the web interface like a normal HTML template file, such as expanding variables beginning with dollar signs ($) and interpreting other CA SDM tags, such as PDM_LIST, and PDM_FORMAT. The value YES, indicates that the file should be treated as a regular HTML template file, and the value NO means that the included file should be treated as literal text. The default is YES. **Note:** For compatibility with previous releases, the values TRUE or 1 can be substituted for YES, and the values FALSE or 0 can be substituted for NO. These values are deprecated, and should not be used in new pages.
propname=value	Specifies that property propname should have the specified value. The property's value can be accessed within the included file by prefixing propname with $prop. For example, the following specification would allow the included file to reference $prop.menubar: <PDM_INCLUDE … menubar=no> Global properties can also be specified in the web.cfg configuration file. For information

Property	Description
	about web.cfg, see How to Configure the Web Interface (see page 884). **Note:** For compatibility with previous releases, property values specified on <PDM_INCLUDE> can be referenced without the preceding 'prop.', in the form $propname. This usage is deprecated and should not be used in new pages.

PDM_JSCRIPT Conditionally Include a JavaScript File

The <PDM_JSCRIPT> tag is used to conditionally include a JavaScript file on a form. This tag has two forms:

```
<PDM_JSCRIPT file=xxxx.js [include=yes|no]>
```

Pdm_jscript with file=xxx.js specifies that JavaScript file xxx.js is required by this form. The webengine adds the file to a list of JavaScript files required by the form. Processing of the tag occurs while the form is being parsed, and is not affected by pdm_if. That is, a pdm_jscript tag referencing a file adds that file to the list of JavaScript files if it occurs anywhere in the file or in an included file, or in a macro.

The optional argument *include=no* can be specified to instruct the webengine to ignore the tag. This argument provides conditional processing for the tag, and is primarily useful when the tag is invoked in a macro. For example, the dtlTextbox macro specifies the following:

```
<PDM_JSCRIPT file=spellcheck.js include=&{spellchk}>
```

This indicates that any form containing a dtlTextbox macro that specifies spellchk=yes requires the JavaScript file spellcheck.js.

The second form of the pdm_jscript tag is the following:

```
<PDM_JSCRIPT insert=here>
```

Pdm_jscript with insert=here requests the webengine to insert standard HTML <script> tags for all required JavaScript files. The webengine processes this form of the tag during the HTML generation phase, so that it is affected by pdm_if. A pdm_jscript tag with insert=here is part of std_head_include.htmpl, so it is present on virtually every form.

Note: The webengine inserts script tags only the first time it encounters pdm_jscript insert=here.

PDM_LINK Create a Hyperlink Invoking an HTMPL Operation

<PDM_LINK> and </PDM_LINK> can be added to any web interface HTML template to create links a link that invokes an HTMPL operation. The <PDM_LINK> tag generates the standard HTML <a href=... > tag and has similar arguments, except that it allows specification of a CA SDM operation in place of a URL.

The format is as follows, where *operation* is one of the supported operations (see page 1789):

```
<PDM_LINK OP=operation> ... </PDM_LINK>
```

Example:

```
<PDM_LINK OP=MENU> Menu </PDM_LINK>
<PDM_LINK OP=CREATE_NEW FACTORY=iss> Submit Issue </PDM_LINK>
<PDM_LINK OP=LOGOUT> Logout </PDM_LINK>
```

PDM_LIST Format a List of Database Rows

The <PDM_LIST> and </PDM_LIST> tags are used to delimit repeating sections of HTML for multi-record output. Everything between <PDM_LIST> and </PDM_LIST> is repeated once for each record to be output. There are two types of PDM_LISTs:

- Lists taken from an object attribute that implies a list. For example, the properties attribute of the request object is the list of properties associated with that request. This type of PDM_LIST always has a SOURCE property.
- Lists with an explicit where clause. This type of PDM_LIST always has a WHERE property.

An object attribute <PDM_LIST> takes the following properties:

Property	Description
ESC_STYLE=**NONE** | C | HTML | JS | JS2 | URL	Specifies the escape type of the formatted text. Valid values are: **NONE**Default setting. Specifies that no special treatment be given to any character in the content body. **C**Give special treatment to the characters ', “, \, \r, ', and \n, which are meaningful in C programs. These characters will be escaped. **HTML**Give special treatment to the following characters, which are meaningful in HTML text: & becomes &' becomes '" becomes "< becomes <> becomes %gt; **JS**Give special treatment to the following characters, which are meaningful in JavaScript text: ' becomes %27" becomes %22/ becomes %2F\ becomes %5C\r becomes %0D\n becomes %0A **JS2** Same as JS, but give no special treatment to the character, /, and give special treatment to two additional characters: - % becomes %25 - Line breaks are suffixed with %0A **URL** Translate all characters other than letters, digits, and '@*-_.#' to '%xx', where xx is the hexadecimal coding of the translated character.
LENGTH=*nn*	Specifies the number of rows of output (defaults to all).
PREFIX=*prefix*	Specifies the prefix on references to attributes from records in the list. These are referenced in the form *$prefix.attr_name* in the text between <PDM_LIST> and </PDM_LIST>. The PREFIX property is optional in an object variable list. If PREFIX is omitted, the value of SOURCE is also used for the prefix.

Property	Description
SEARCH_TYPE=DISPLAY|**GET_DOB**	Specifies the method the server should use to build the list form: DISPLAY specifies the server should issue a single query for the entire form GET_DOB specifies the server should issue separate queries for each row of the form The choice affects list performance, and depends on the complexity of the list (the number of joins required to display it) and the characteristics of your DBMS. GET_DOB has more predictable performance than DISPLAY, and is the default.
SORT=*index-name*	Specifies the index name to use for sorting. The default value of this argument is DEFAULT (which means the first sort index for the underlying factory).
SOURCE=*source*	Specifies the object variable defining this list. This field is required. Do not put a dollar sign ($) in front of *source* on the PDM_LIST statement itself. If the PREFIX property is not specified, *source* is also used as the prefix for references to attributes from records on the list, in references of the form *$source.attr_name*. When used in a reference, *source* does require a preceding dollar sign.
START=*n*	Specifies the first output row (defaults to zero).

Example:

```
<table border>
<tr>
<th>Child Change Order Number</th>
<th>Summary</th>
</tr>
<PDM_LIST SOURCE=args.children>
<tr>
[assign the value for TD in your book]$args.children.chg_ref_num</td>
[assign the value for TD in your book]$args.children.summary</td>
</tr>
</PDM_LIST>
</table>
```

Because no prefix was specified, references to attributes of the listed records are prefixed by $args.children, the source value.

A where clause PDM_LIST takes the following properties:

Property	Description
FACTORY=*name*	Specifies a class of object to be searched. This property is required.
LENGTH=*nn*	Specifies the number of rows of output (defaults to all).
ORDER_BY=*attr-name*	Specify the attribute name to sort by. It can contain the DESC (descending) or ASC (ascending) modifiers.
PREFIX=*prefix*	Specifies the prefix on references to attributes from records in the list. These are referenced in the form *$prefix.attr_name* in the text between <PDM_LIST> and </PDM_LIST>. The PREFIX property is required in a where clause list.

START=*n* *n*	Specifies the first output row (defaults to zero).
WHERE=*where-clause*	Specify the where clause for the search. It can contain (dotted) attributes. This property is required.

For example:

```
<table>
<tr>
<th>Child Change Order Number</th>
<th>Summary</th>
</tr>
<PDM_LIST PREFIX=list FACTORY=chg WHERE="status = 'OP'">
<tr>
[assign the value for TD in your book]$list.chg_ref_num</td>
[assign the value for TD in your book]$list.summary</td>
</tr>
</PDM_LIST>
</table>
```

PDM_NOTEBOOK Create a Notebook

Several of the forms in the CA SDM analyst interface use nested tabs (notebooks). Nested tabs display several sets of fields in the same physical area of the screen, with only one set visible at a time. The user selects the set of fields that is visible by clicking a named tab at the top of the notebook, or by pressing the access key combination Alt+*n*, where *n* is the number of the tab. An example of a form using a notebook is the Issue Detail (detail_iss.htmpl). We recommend that you use WSP to modify the contents of notebooks, or insert a notebook into a form that does not already contain one.

The following tag marks the end of a notebook:

```
<PDM_MACRO name=endNotebook>
```

PDM_PRAGMA Specify Server Information

The <PDM_PRAGMA> tag is used to specify information used by the web engine, such as form release and version. It does not generate any HTML code, and can be placed anywhere in a form. Possible arguments are:

Argument	Description
RELEASE=value	Specifies the CA SDM release number corresponding to this form. This value is “110” on all CA Service Desk Manager r11.0 forms. It is accessible within the form in the $prop.release variable.
SITEMOD=value	Specifies a site-defined string identifying the modifications applied to this form. It is accessible within the form in the $prop.sitemod variable.
VERSION=value	Specifies a CA Technologies-defined string identifying the version number of this form. It is accessible within the form in the $prop.version variable.

Argument	Description
OVERIDE=YES|**NO**	Specifies whether or not values in this PDM_PRAGMA statement override values in previous PDM_PRAGMA statements.

CA Technologies uses PDM_PRAGMA statements to document form versions. All CA Service Desk Manager r11.0 forms include the following PDM_PRAGMA statement:

```
<PDM_PRAGMA RELEASE=110>
```

In addition, the std_head.htmpl form includes the following JavaScript statement:

```
cfgFormRelease = "$prop.release" - 0;
```

The PDM_PRAGMA statement and the cfgFormRelease variable allows the CA SDM web interface to distinguish CA Service Desk Manager r11.0 forms from previous release forms. Releases prior to CA Service Desk Manager r6.0 did not support the PDM_PRAGMA statement.

Normally, only PDM_PRAGMA statements in the highest-level file of a form (that is, a file not brought in by PDM_INCLUDE) are used to set $prop.release, $prop.sitemod, and $prop.version. In addition, a PDM_PRAGMA statement will not override a non-empty value set by a previous PDM_PRAGMA statement. You can specify OVERRIDE=YES to specify that a PDM_PRAGMA statement can override previous PDM_PRAGMA statements, or that a PDM_PRAGMA statement in an included file can be used.

PDM_SCOREBOARD Build a Scoreboard Tree

The <PDM_SCOREBOARD> tag is used to generate the scoreboard shown on the left side of the main form. It takes the following property:

- **TARGET=*value***
  Specifies the name of the target frame for lists requested by clicking a node on the scoreboard. Lists are loaded into the target specified, which can be any value supported for the target attribute of a link. The default value is *_self* (the window containing the PDM_SCOREBOARD tag).

Any HTMPL form including a <PDM_SCOREBOARD> tag must also include the fldrtree.js JavaScript file. This file can be included with the following statement in <HEAD> section of the form:

```
<SCRIPT LANGUAGE="JavaScript" SRC="$CAisd/CAisd/fldrtree.js"></SCRIPT>
```

In addition, it is desirable to include a link with the name scoreboard_asof_data to display the effective date of the numbers in the tree. See the distributed file scoreboard.htmpl for an example of the use of this tag.

The queries included on the scoreboard are defined by the contents of the User_Query table (object name usq) for the current user. A record in this table defines each line on the tree (folder or node).

Initially, users have no entries in their User_Query table. A user with no User_Query entries receives the default set of scoreboard queries associated with their access type. A user with administrative authority can also customize the default scoreboard for an access type.

PDM_SET Set the Value of a Server Variable

The <PDM_SET> tag is used to assign a value to a server variable. It has the following syntax:

```
<PDM_SET arg.name[+]=value>
```

- **arg**
  (Required) Specifies the variable type, and must be arg for normal use.

  > **Note:** There is no $ character.

- **Name**
  (Required) Specifies the name of the variable.

- **+**
  (Optional) Specifies that the value should be appended to the existing value of the variable. There cannot be any spaces before or after.

- **=**
  (Required) Must be specified exactly as shown, with no spaces before or after.

- **value**
  (Required) Specifies the text to be assigned or appended to the variable.

The PDM_SET tag can also be used in the preprocessor phase to create or update a preprocessor variable.

PDM_TAB Create a Tab within a Notebook

The <PDM_MACRO name=startNotebook hdr=cng_nb> tag is used to define a notebook tab. We recommend that you use WSP to modify the contents of notebooks, or insert a notebook into a form that does not already contain one.

PDM_WSP Control WSP Preview

The <PDM_WSP> tag is used to control the WSP preview feature. It does not generate any HTML code, and can be placed anywhere in a form.

By default, WSP determines how to preview a form by examining the form name:

- For detail forms (names of the form detail_*factory*.htmpl), WSP displays the form in edit view, with data from the most recently created row of the appropriate table. If there is no data you are allowed to view in the table, WSP displays the form set up to create a row. WSP preview sessions are typically prohibited from updating the database. WSP displays forms in edit view to allow you to preview all features. However, CA SDM ignores a Save request from a read-only preview session. The web engine changes the text on the Save button to noSave as a visual reminder of this.

- For list forms (names of the form list_*factory*htmpl), WSP displays the form in list view, with the list displaying data from the most recently created row of the appropriate table. If there is no data you are allowed to view in the table, WSP displays the form in search view, with the filter open.

- For other forms, WSP displays the form with no database context.

You can change this default behavior by placing a PDM_WSP tag anywhere on the form. For example, you can display a notebook tab form on its associated detail form, or provide prerequisite arguments for forms normally invoked with an environment provided by another form. Possible arguments are the following:

Property	Description
FACTORY=*value*	Specifies the Object Engine factory used by this form.
PREVIEW=*name*.htmpl | *value* | no	Specifies the preview URL. This can be an HTMPL file name, in the form xxxx.htmpl; a CA SDM URL (used unaltered if it begins with “OP=”); or the keyword “no”, indicating the form cannot be previewed. A value not beginning OP= is modified by replacing a reference of the form {*factory*} or {*factory*:} with an ID or persistent ID (respectively) of the most-recently created row from the referenced factory that the current user is authorized to view.
WHERE=*value*	Specifies a where clause used to search for a representative row or rows to show on the previewed form.
MODE=*value*	Specifies the mode of the constructed URL. Can be the following: GENERAL. General format. Determine the mode by examining the preview argument: detail_xxxx.htmpl - READONLY list_xxxx.htmpl - LIST any other - GRONK READONLY. Detail file in read-only view. EDIT. Detail file in edit view. LIST. List file. GRONK. Unspecified file. In this situation, gronk the file.

Server Variables

This article contains the following topics:

CA SDM information is included in the HTML template using variables beginning with a dollar sign ($). Each page is created with some variables that are documented in the template file. These variables can be put on the page or used in conditional statements:

- Simple Variables

- Property Variables
- Environment Variables
- Business Object Variables
- List Variables

Simple Variables

Simple variables specify flags that are passed to the web page. To access a simple variable, use the variable name preceded by a dollar sign ($). This makes the value of the variable available. For example, two such variables are $CAisd and $cgi. Putting $CAisd in a template results in the substitution of the main CA SDM web server installation directory, whereas $cgi refers to the URL of the pdmweb.exe program. Simple variables are documented in the upper section of the HTMPL file that uses them.

The following shows a list of variables that can be used in all the HTMPL files:

- **$ACCESS.*group***
  The user access privilege object contains the privilege settings on the function group *group* for the current login user. For example, $ACCESS.admin holds the privilege value for the admin functional group. Valid privilege values are:
  - 0-NO ACCESS
  - 1-VIEW
  - 2-MODIFY

  This variable is not available in the login form.
- **$cgi**
  The URL of the pdmweb.exe program.
- **$cst**
  The data object of the current login user. This variable is not available in the login form. You can reference individual attributes of this object with the form $cst.*attrname*; for example, $cst. first_name.
- **$CAisd**
  The URL of main CA SDM web server installation directory.
- **$MachineName**
  The MachineName defined in the web.cfg file.
- **$ProductName**
  The product name defined in the NX.env file.
- **$SESSION**
  The session object saves all session variables including session ID ($SESSION.SID) and all variables defined in the web.cfg file.

- **$USER_STATE**
  User-defined state information.

Property Variables

Property variablesrepresent a property of the configuration file, web.cfg. You can access any entry in the web.cfg file (including user-defined entries) within an HTML template file by prefixing it with "$prop."

For example, one of the lines in web.cfg, which specifies the number of entries displayed in a single page on a list form is as follows:

```
ListPageLength 10
```

You can refer to this variable in an HTML template with the specification:

```
$prop.ListPageLength
```

If you use the <PDM_INCLUDE> special tag to incorporate another file into a template file, you can specify additional properties as attributes of the <PDM_INCLUDE> tag. You can reference these properties in the included file in the same way as web.cfg properties. A property specified as a <PDM_INCLUDE> attribute that has the same name as a web.cfg property overrides the web.cfg property within the included file.

For example, the following <PDM_INCLUDE> tag creates a property called $prop.menubar that can be referenced within the std_body.htmpl file:

```
<PDM_INCLUDE FILE=std_body.htmpl menubar=no>
```

Note: You can refer to configuration file property *xxx* in two ways: $prop.*xxx* or *$SESSION.xxx*. Both return the same value. However, the $prop.*xxx* syntax is preferred because it involves less server overhead.

In addition to properties from web.cfg, there are several predefined properties that can be accessed with $prop. These are:

- **$prop.browser**
  A string identifying the browser in use. This will be "IE" for Internet Explorer.

- **$prop.combo_name**
  A string containing the current user's name, in the form "last_name, first_name middle_name."

- **$prop.factory**
  A string containing the factory associated with the current form, such as "cr" for requests or "iss" for issues.

- **$prop.FID**
  A string containing the numeric form ID of the current form.

- **$prop.form_name**
  A string containing the name of the current HTML template, in the form *xxx*.htmpl.

- **$prop.form_name_1**
  A string containing the substring of the form name before the first underscore. For example, for the form detail_chg_edit.htmpl, form_name_1 would be “detail.”

- **$prop.form_name_2**
  A string containing the substring of the form name after the first underscore and before the last underscore (or dot). For example, for the form detail_chg_edit.htmpl, form_name_2 would be “chg.”

- **$prop.form_name_3**
  A string containing the substring of the form name after the last underscore and before the dot. For example, for the form detail_chg_edit.htmpl, form_name_3 would be “edit.” For the combination detail form, which has a file name of the form detail_*xxx*.htmpl, $prop. form_name_3 is set to the current view, either “ro” or “edit”.

- **$prop.release**
  A string containing the release level of the form. The PDM_PRAGMA statement contains more details on this property.

- **$prop.SID**
  A string containing the numeric session ID of the current session.

- **$prop.sitemod**
  A string containing the site-defined modification name of the form. The PDM_PRAGMA statement contains more details on this property.

- **$prop.user_type**
  A string containing “analyst,” “customer,” “employee,” or “guest.”

- **$prop.version**
  A string containing the version of the form. The PDM_PRAGMA statement contains more details on this property.

Environment Variables

Environment variablesrepresent an entry within the NX.env configuration file. You can reference any entry in NX.env within an HTMPL template file by prefixing it with “$env.”

For example, one of the lines in NX.env, which specifies the host name of the CA SDM server is as follows:

```
@NX_SERVER=hostname
```

You can refer to this variable within an HTMPL template file with the specification:

```
$env.NX_SERVER
```

Business Object Variables

Businessobject variablesrepresent a CA SDM object, such as an issue or a request. To access an object, you need to start with the variable name, followed by a period (.), followed by whatever attribute names you want to display. For example, on an issue where, by convention, the object is represented by the variable args, you can display the description, the open date, the assignee's phone number, the number of activities on the issue, and the description of the first activity, as shown by the following:

```
$args.description
$args.open_date
$args.assignee.phone_number
$args.act_log.length
$args.act_log.0.description
```

You can use braces to delimit the variable name if it is not surrounded by white space. For example, $foo bar and ${foo}bar are both valid. You can also use the variable args to access non-attribute values (for example, $args.KEEP.*name* as described in Supported Operations (see page 1789)).

It is possible that a non-attribute variable may not be defined. For example, it may be possible to get to a form from two different places, only one of which provides a value for $args.KEEP.foo. You can provide a default value for a $args reference with the following syntax, where the string after the colon is substituted for the reference if *variable* is undefined:

```
${args.variable:default}
```

- **Time Zone Date Variables**
  Time zone date variables are a special case of business object variables. They provide a means to convert universal dates (UTC) represented as integers to string dates adjusted for the time zone of the user's browser. The variable for representing integer dates is:

  ```
  $args.attr_name_INT_DATE
  ```

  Example: $args.open_date_INT_DATE

- **Factory Data Variables**
  Factory data variables are a special case of business object variables. A factory data variable is replaced by information about a referenced object. There are seven such variables available:

  - **$args.*attr_name*.COMMON_NAME**
    The common name (externally readable string) of the table referenced by the attribute. For example, on the Request Detail form, the value of $args.assignee.COMMON_NAME is the assignee's combo name (“last, first, middle”).

  - **$args.attr_name.COMMON_NAME_ATTR**
    The attribute name of the common name in the table referenced by the attribute. For example, on the Request Detail form, the value of $args.assignee.COMMON_NAME_ATTR is “combo_name”.

  - **$args.FACTORY_*attr_name***
    The name of the factory associated with the specified attribute. For example, on the Request Detail form, the value of $args.FACTORY_assignee is “agt”.

- **$args.LENGTH_*attr_name***
  The maximum length of the attribute. For example, on the Request Detail form, the value of $args.LENGTH_summary is 240.

- **$args.*attr_name*.REL_ATTR**
  The rel attr (foreign key) of the attribute. For example, on the Request Detail form, the value of $args.assignee.REL_ATTR is the value of the assignee's ID field.

- **$args.*attr_name*.REL_ATTR_ATTR**
  The attribute name of the rel_attr in the table referenced by the attribute. For example, on the Request Detail form, the value of $args.assignee.REL_ATTR_ATTR is “id”.

- **$args.REQUIRED_*attr_name***
  A string, either “0” or “1” indicating whether the referenced attribute is required.

- **$args.*attr_name*.SELECTIONS**
  A list of valid selections for *attr_name*. This value is an empty string if *attr_name* is not a reference to another table, or if the size of table referenced by *attr_name* exceeds the value of the configuration file property SelListCacheMax. Otherwise, the SELECTIONS variable is a string containing the common name and rel attr of all the entries in the referenced table. Successive values are separated by the string “@,@”, so the variable's value has the form: "cname1@,@rel_attr1@,@cname2@,@rel_attr2"

- **$args.*factory*_SEL_UNDER_LIMIT**
  A string, either “0” or “1”, indicating whether the current number of rows in the table corresponding to *factory* is less than the value of the configuration file property SelListCacheMax. This variable is deprecated in favor of the SELECTIONS variable, which should be used in all new forms.

Factory data variables containing a dotted reference (COMMON_NAME, REL_ATTR, and SELECTIONS) can be used with a dotted reference of any length. For example, on a Request Detail form $args.assignee.organization.COMMON_NAME is replaced by the external name of the assignee's organization.

List Variables

List variables are used to iterate through data. They are accessed using list tags as described in PDM_LIST: Format a List of Database Rows (see page 1779).

Supported Server Operations

This article contains the following topics:

The following operations are supported to let you integrate the CA SDM web pages with your web pages:

- **CREATE_NEW**
  Provides a generic interface to let the user create a row in a specified table. The object name must be specified, and by default a template named *detail_xxx*_edit.htmpl is used for object *xxx*. You can override the .htmpl file by specifying the HTMPL property.

  - **Required specifiers:**
    FACTORY=*object-name*

  - **Optional specifiers:**
    ALG_PRESET=*preset_expressionALG_PRESET_REL=preset_expression*CREATE_ALG=*activity_log_type*HTMPL=zdetailxxx*_factory*.htmplKEEP.*attr_name=value*PRESET=*preset_expression*PRESET_REL=*preset expression*SET.*attr_name=value*use_template=1 | 0 (0 is the default)

  Note: To use the HTMPL specifier with CREATE_NEW, the referenced form must have a name conforming to the naming convention zdetailxxx*_factory*.htmpl. The name must begin with the string zdetail, followed by any alphanumeric characters (including a null string), followed by an underscore and the factory name.

- **ENDSESSION or LOGOUT**
  Ends the current logged-in session. ENDSESSION is the preferred operation.

- **GENERIC_LIST**
  Provides a generic interface to allow the user to display a list from any table in the database. The object name must be specified, and by default a template named list*_xxx*.htmpl is used for object *xxx*. You can override the .htmpl file by specifying the HTMPL property.

  - **Required specifiers:**
    FACTORY=*object-name*KEEP.*attr_name=value*

- **DISPLAY_FORM**
  Provides a generic interface to let the user display any customized form.

  - **Required specifiers:**
    HTMPL=*htmpl_file*

  Note: DISPLAY_FORM replaces JUST_GRONK_IT. Existing implementations can continue to use JUST_GRONK_IT, which functions exactly like DISPLAY_FORM. DISPLAY_FORM is the preferred operation.

- **MENU**
  Displays the main menu page, which is defined in the web.cfg file in the Menu property.

  - **Optional specifiers:**
    HTMPL=*menufile*
    menufile is the name of an alternate main menu file.

- **PAGE_EXTENSION**
  Allows the webmaster to specify additional extensions to the interface.

  - **Required specifiers:**
    NAME=*html_file*
    html_file is one of the file names listed in the configuration file UserPageExtensions directive.

  - **Optional specifiers:**
    REQUIRES_LOGIN=1
    If present, a login page appears first if the user is not currently logged in. If omitted or set to zero, the file is shown without checking if the user is currently logged in.

- **RELOG**
  Displays the login page.

- **SEARCH**
  Provides a generic interface to allow the searching of any table in the database. This operation assumes that an appropriate search_*xxx*.htmpl has been created, where *xxx* is the *object-name*, as defined in the .maj files in the majic directory in bopcfg.

  Note: For more information, see CA Service Desk Manager Reference Commands (see page 3496). By default, the results of this search are displayed in list_*xxx*.htmpl, but this can be overridden by specifying the HTMPL property.

  - **Required specifiers:**
    FACTORY=*object-name*QBE.*op.attr_name=value*

  - **Optional specifiers:**
    ALG_PRESET=*preset_expression*ALG_PRESET_REL=*preset_expression*CREATE_ALG=*activity_log_type*HTMPL=*list_htmpl_file*KEEP.*attr_name=value*

- **SEC_REFRESH**
  Refreshes the user access information from the security subsystem. A hyperlink for this operation is provided to users who have MODIFY privileges (for the admin functional group) on the menu screen. After updating user access privileges with the security program, this operation provides a means to refresh access information. (This operation refreshes the security information for all users.)

  Note: Security refresh is an asynchronous process. When the security refresh is done, a message shows in the standard log file (stdlog).

- **SET_MENU**
  The behavior of this operation is the same as MENU when MENU is used with the HTMPL variable. The only difference is that this operation also sets the default menu form to the menu form specified with the HTMPL property.

  - **Required specifiers:**
    HTMPL=*htmpl_file*

Note: This operation overrides the MENU set in the web.cfg until the web service is restarted.

- **SHOW_DETAIL**
  Provides a generic interface to allow the user to display a read-only detail of a row in a specified table. The persistent ID name must be specified (from which the object name is inferred). By default, a template named detail_*xxx*_ro.htmpl is used for object *xxx*. The .htmpl file can be overridden by specifying the HTMPL property.

  - **Required specifiers:**
    PERSID=*persistent-id*

  - **Optional specifiers:**
    ALG_PRESET=*preset_expression*ALG_PRESET_REL=*preset_expression*CREATE_ALG=*activity_log_type*HTMPL=*readonly_detail_htmpl_file*

- **UPDATE**
  Provides a generic interface to editing any table. The ID and object name must be passed in and a detail form that the user can edit is displayed to the user. By default, the user has exclusive access to the record for two minutes, and is guaranteed to get changes into the database if they are submitted in this time.

  - **Required specifiers:**
    PERSID=*persistent-id* orSET.id=*id-of-row-to-update* FACTORY=*object-name*

  - **Optional specifiers:**
    NEXT_PERSID=*persistent-id* (of record to display after successful update)KEEP.*attr_name=value*KEY.*attr_name=value*HTMPL=zdetailxxx_*factory*.htmpl

Note: To use the HTMPL specifier with UPDATE, the referenced form must have a name conforming to the naming convention zdetailxxx_*factory*.htmpl. The name must begin with the string “zdetail”, followed by any alphanumeric characters (including a null string), followed by an underscore and the factory name.

Note: For information about web.cfg, see How to Configure the Web Interface (see page 884).

Operation Variables

This table lists the variables that can be set for each of the operations in the supported operations:

Variables	Description	Operations
ALG_PRESET ALG_PRESET_REL	Specifies values for one or more of the attributes of the activity log created as a result of the CREATE_ALG variable. If CREATE_ALG is not specified, ALG_PRESET and ALG_PRESET_REL are ignored.	CREATE_NEWSEARCHSHOW_DETAIL
CREATE_ALG	Specifies the activity log type of an activity log to be created as a side effect of the operation. Use the ALG_PRESET or ALG_PRESET variables to specify values for the attributes of the new activity log. The timing of creation of the activity log depends on the operation, as follows: **CREATE_NEW**The activity log is created when the new record is saved. If the new record is not saved, no activity log is created. **SEARCH**The activity log is created when a record is selected from the list form. If the record is viewed instead of selected (that is, the user explicitly selects the View command from the list form's mouse-over menu), no activity log is created. **SHOW_DETAIL**The activity log is created before the record is displayed.	CREATE_NEWSEARCHSHOW_DETAIL
FACTORY	Specifies the class of object to be searched, created, or updated. You can use any name specified as an OBJECT in the *.maj files in $NX_ROOT /bopcfg as listed in CA Service Desk Manager Reference Commands (see page 3496).	CREATE_NEWGENERIC_LISTSEARCHUPDATE
HTMPL	Allows the HTMPL author to override the default template naming convention and explicitly specify the HTMPL file to display, instead of the default template. **Note:** When the HTMPL specifier is used with CREATE_NEW or UPDATE, the name of the referenced form must conform to the naming convention zdetailxxx_factory.htmpl, where xxx are any characters, and *factory* is the factory name.	CREATE_NEWDISPLAY_FORMJUST_GRONK_ITMENUSEARCHSET_MENUSHOW_DETAIL UPDATE
KEEP.*name*	Specifies the value that can be saved and passed between pages.	CREATE_NEWGENERIC_LISTSEARCHUPDATE
KEY.*attr_name*	Similar to the SET.*attr_name*, except that this specifies a lookup on *attr_name*, which must be a reference to another table or object.	UPDATE
NEXT_PERSID	Specifies the persistent ID of the record to be displayed next.	UPDATE
PERSID	Specifies the persistent ID of a record to be displayed. You can specify this in either of the following ways: Directly, with a persistent ID consisting of a factory name, a colon (:), and a unique integer database ID. For example, PERSID=chg:1234, specifies the change order with database ID 1234. Indirectly, with a persistent ID consisting of a factory name, a colon (:), an attribute name, a second colon (:), and a value. This form of PERSID specifies the record of the specified factory that has an attribute of the specified value. For example, PERSID=chg:chg_ref_num:demo:3 specifies the change order with reference number demo:3.	SHOW_DETAILUPDATE
PRESET PRESET_REL	Specifies values for one or more of the attributes of the record created as a result of the CREATE_NEW variable. If CREATE_NEW is not specified, PRESET is ignored.	CREATE_NEW
		SEARCH

Variables	Description	Operations
QBE.*op*.*attr_name*	Specifies the values to use when performing a search. These values are identified using a QBE keyword, where *attr_name* identifies any attribute name on a ticket that can be set and *op* indicates to search where the attribute: EQ is equal to the value NE is not equal to the value GT is greater than the value LT is less than the value GE is greater than or equal to the value LE is less than or equal to the value NU is null NN is not null IN matches the SQL LIKE expression KY contains the text entered If you do not define any QBE variables, the standard search window is displayed.	
SET.*attr_name*	Specifies an attribute name to use when a ticket is created, where *attr_name* identifies any attribute in a ticket that can be set. The attribute names will vary depending on the underlying object. All objects and their attributes can be found in the *.maj files in the majic directory in bopcfg as listed in CA Service Desk Manager Reference Commands (see page 3496).	CREATE_NEWUPDATE
SET.*id*	Specifies the database ID of the row to be updated.	UPDATE
SKIPLIST	When set to 1, searches that result in 1 hit do not display the search result list. Instead, the read-only detail is displayed directly.	SEARCH
use_template	When set to 1, the SEARCH operation will return a list of templates. The returned template selected will be used in the CREATE_NEW operation to populate a new record. This variable is valid for change orders, issues, and requests.	CREATE_NEWSEARCH

Syntax of PRESET, PRESET_REL, ALG_PRESET, and ALG_PRESET_REL

The PRESET, PRESET_REL, ALG_PRESET and ALG_PRESET_REL keywords in the URL specify initial values for attributes of the ticket and its activity log, respectively. There are two possible formats:

- **[ALG_]PRESET=*attr*:*value***
  Indicates that the specified attribute of the ticket or activity log should be set to the specified value. For example, the following specification sets the description of the new ticket to “Hello:”

```
PRESET=description:Hello
```

- **[ALG_]PRESET_REL=attr:obj.relattr:testattr:value**
  Indicates that the specified attribute of the ticket or activity log should be set to a value copied from another database table. The value is copied from the *relattr* attribute of the *obj* whose *testattr* has the specified *value*. For example, the following specification sets the analyst attribute

of the new ticket to the ID of the contact with user ID xyz123:
PRESET_REL=analyst:cnt.id:userid:xyz123
When this format is used, the implied query must retrieve a unique record. If more than one contact has a user ID of xyz123 (or none), the example PRESET specification has no effect.

The PRESET, PRESET_REL, ALG_PRESET and ALG_PRESET_REL keywords can occur as many times as desired in a URL, allowing the setting of multiple attributes. Alternatively, a single keyword operand can specify multiple values separated by @@. If the '@@' separator is used, you cannot mix value formats for [ALG_]PRESET and [ALG_]PRESET_REL keywords. For example, the following example shows two different ways of specifying values for ticket description, summary and analyst:

```
PRESET=description:Hello+PRESET=summary:HelloThere+PRESET_REL=analyst:cnt.id:userid:
xyz123
PRESET=description:Hello@@summary:HelloThere+PRESET_REL=analyst:cnt.id:userid:xyz123
```

For requests, issues, incidents, problems, and change orders, both PRESET and PRESET_REL support a keyword attribute ASSET to link an object to an asset. The ASSET attribute updates the affected_resource attribute of a request, incident, or problem, or the asset LREL of an issue or change order.

Link Examples

The following link examples do not include the path to CA SDM. All CA SDM URLs begin with coding of the following form:

http://*hostname*[:*port*]/CAisd/pdmweb.exe

In this example, *hostname* is the name of your server and *port* (optional) is the port number if you are using Tomcat. This coding is shown as an ellipsis (...) in the following URL examples:

- To create a request with an affected end user with the userid tooda01, use the following example URL:

  ```
  ...?OP=CREATE_NEW+FACTORY=cr+PRESET_REL=customer:cnt.id:userid:tooda01
  ```

- To display a list of all requests assigned to userid tooda01, use the following example URL:

  ```
  ...?OP=SEARCH+FACTORY=cr+QBE.EQ.assignee.userid=tooda01
  ```

- To display the detail form for request 1234, use the following example URLs:

  ```
  ...?OP=SHOW_DETAIL+FACTORY=cr+PERSID=cr:ref_num:1234 (read-only view)

  ...?OP=UPDATE+FACTORY=cr+PERSID=cr:ref_num:1234 (update view)
  ```

Note: You can bypass the logon challenge by using Web Services for authentication. For information about the getBopsid() method, see CA Service Desk Manager Reference Commands (see page 3496).

Advanced Modifications

This article contains the following topics:

You must be aware of various aspects of modifying web pages if you elect to use tools other than Web Screen Painter to modify HTMPL, or if you have unusually complex customization requirements. However, we strongly recommend that you work with WSP to modify CA SDM web pages before trying any other approach. WSP is capable of doing almost any modification you need, and it automatically handles housekeeping issues, such as placing updates in the site mods directory, and distributing published files to all servers.

The Web Engine and Its Cache If you decide to create version any

When modifying web pages, it is helpful to understand the structure of the CA SDM web server. The web interface uses either a J2EE servlet container, such as Tomcat, or a standard HTTP server, such as Apache or Microsoft Internet Information Server (IIS). When a user requests a CA SDM web page, the HTTP server invokes the supplied program pdmweb.exe.

After it starts, pdmweb.exe sets up a connection with a CA SDM daemon (or Windows service) called the web engine. The web engine interprets the user's request. Most requests require the web engine to look up a template (HTMPL) file and translate it into standard HTML. Usually, the translation process requires the web engine to communicate with a CA SDM server to read or update the database, and include database information in the generated HTML. After the HTML is complete, the web engine sends it to pdmweb.exe, which in turn sends it back to the user's browser.

To maximize performance, the web engine typically reads each HTMPL file only once. After parsing the file and determining how to translate it to HTML, the web engine stores the parsed file in its cache, significantly reducing the processing time the next time the file is requested. While the cache is beneficial in a production environment, it can be inconvenient in development, as it means that changes to HTMPL files do not take effect until either the web engine is recycled or the pdm_webcache utility is used. In a development environment, you can avoid this behavior by specifying the configuration file property SuppressHtmplCache. However, we recommend that you do not suppress the HTMPL cache in a production environment because it severely impacts overall performance of the web engine.

The web pages served up by pdmweb.exe are generated by reading HTMPL files and using them to generate HTML. HTML template files are identified by a file suffix of .htmpl. You can modify these template files, and thereby modify the CA SDM web pages.

The pdm_webcache Utility

Use the pdm_webcache utility to remove one or more HTMPL forms from the web engine cache. This forces the web engine to fetch these forms from the disk the next time they are used, allowing changes to forms to take effect.

```
pdm_webcache [-f form-name] [-g form-group] [-i interface] [-p process] [-v]
```

- **-f *form-name***
  Specifies the name of the form to be removed from the cache, such as detail_cr.htmpl. You can use '%' (or '*') as a wildcard character to select more than one form. For example, the specification:
  -f detail%
  selects all detail forms.
  This argument is optional. If it is omitted, all forms in the cache are selected.

- **-g *form-group***
  Specifies the name of the form group to be removed from the cache, such as Analyst. You can use '%' (or '*') as a wildcard character to select more than one form group**.** For example, the specification:
  -g Anal%
  selects all form groups beginning with "Anal".
  This argument is optional. If it is omitted, all form groups in the cache are selected.

- **-i *interface***
  Specifies the name of the web interface to be removed from the cache, such as analyst, customer, or employee. You can use '%' (or '*') as a wildcard character. For example, the specification:
  -i a%
  selects the analyst interface.
  This argument is optional. If it is omitted, all interfaces in the cache are selected.

- **-p *process***
  Specifies the name of the web engine process whose cache is to be modified, such as web:local.
  This argument is optional. If it is omitted, all web engines are selected.

- **-v**
  Specifies verbose output. When this argument is specified, pdm_webcache lists the full name of every form removed from the cache, in the form:
  interface:*form-group*:*form-name*
  This argument is optional. If it is omitted, pdm_webcache reports only a count of forms removed from each web engine's the cache.

How to Modify HTML Templates

Typically, you can make two types of changes to the HTML templates:

- You can make modifications that will be visible to the user but will not be altered by the web interface prior to display. For example, you could add a GIF file for your company logo to the web interface pages (a “pass through”) by adding the reference to the appropriate template file or you could add JavaScript to your page to validate input. Any changes you make to the HTMPL file that are not contained within a PDM tag, as defined in the following, are passed unchanged in the HTML returned to the user.

- You can modify the replaceable sections of the templates. For example, you can add new application data to the request detail page.

Several kinds of template entries let you do the following:

- Display information from CA SDM to the user.

- Set up a query page.

- Create links to other CA SDM pages using link tags.

Files That Should Not be Modified

Certain HTMPL templates and JavaScript files contain information required by many CA SDM web forms. The information in these templates is both release dependent and critical to the successful operation of the CA SDM web interface. Therefore, these files are always replaced when a new version of CA SDM is released; changes made to them are not upgraded.

The templates affected by this restriction are as follows:

- **ahdtop.htmpl**
  Contains styles, scripts, and JavaScript variables used throughout the CA SDM web interface. This file is part of the main frameset of the web interface, and is always present during a session. All CA SDM forms have access to the JavaScript variable ahdtop that references the window containing ahdtop.htmpl.

- **menu_frames.htmpl**
  Defines the HTML frameset used by the CA SDM main form.

- **msg_cat.js**
  Contains the text of all messages used in CA SDM JavaScript files.

- **reports.htmpl**
  Contains data required for web reports.

- **std_body.htmpl**
  Contains standard information used at the beginning of the BODY section of most HTMPL templates.

- **std_footer.htmpl**
  Contains standard information used at the end of the BODY section of most HTMPL templates.

- **std_head.htmpl**
  Contains standard information used at the beginning of the HEAD section of almost all HTMPL templates.

- **styles.htmpl**
  Contains CSS styles used throughout the CA SDM web interface.

Although you cannot modify these files directly, you can add additional information to them. Each restricted file xxx.htmpl (except for menu_frames.htmpl and reports.htmpl) has a corresponding xxx_site.htmpl file that you can modify. For example, you can add additional information to ahdtop.htmpl by modifying ahdtop_site.htmpl, or add new messages by modifying msg_cat_site.js.

The xxx_site.htmpl file corresponding to each restricted file is loaded after the main file so you can override or change JavaScript in the main file. Use caution when adding information, as badly designed changes to these files can cause unexpected problems throughout the CA SDM web interface.

Guidelines for New HTMPL Files

You can add your own HTMPL files to the CA SDM web interface. Follow these guidelines to help ensure your HTMPL file works well with the rest of the CA SDM interface:

1. Include the following statement somewhere in the <HEAD> section of the file. This statement should follow the <TITLE> statement (if any). It defines several JavaScript global variables required by CA SDM web interface, and also registers your page with the CA SDM window manager:

   ```
   <PDM_INCLUDE FILE=std_head.htmpl>
   ```

2. Include the following attribute as part of the <BODY> tag of the file. This attribute helps the CA SDM window manager keep track of your page:

   ```
   onUnload="deregister_window()"
   ```

3. Include the following statement at the beginning of the <BODY> section of your file. The “menubar=no” argument is optional; if specified, it suppresses the CA SDM menu bar:

   ```
   <PDM_INCLUDE FILE=std_body.htmpl [menubar=no]>
   ```

4. Include the following statement at the end of the <BODY> section of your file.

   ```
   <PDM_INCLUDE FILE=std_footer.htmpl>
   ```

How to Add User Defined State Information

Many customers want to be able to embed their own state information in the CA SDM web pages, and have CA SDM pass the state information to all subsequent pages it serves up to the user's session. This information can be interrogated with conditional statements in the HTMPL files.

State information for a user's session is accomplished by setting the special attribute USER_STATE in your links or forms. After it is submitted into the CA SDM web engine, every page that is presented to the user will have the HTMPL variable USER_STATE available and set to the value last submitted for USER_STATE.

The following examples show how you might set up an entry into CA SDM from some other part of your site, such as from pages that are oriented to your sales force:

- Using a hyperlink

```
<a href="/CAisd/pdmweb.exe?USER_STATE=Sales">Service Desk</a>
```

- Using a form with a hidden field

```
<form action="http://yourhost.com/CAisd/pdmweb.exe">
<input type=hidden name=USER_STATE value=Sales>
```

Click the button for the Service Desk

```
<input type=submit>
</form>
```

Then you can modify your HTMPL forms based on the state information:

```
<PDM_IF "$USER_STATE" == "Sales">
```

custom information for sales audience

```
<PDM_ELIF "$USER_STATE" == "Engineering">
```

custom information for engineers

```
<PDM_ELSE>
```

information for everyone else

```
</PDM_IF>
```

How to Directly Create a Request from a Template

It is possible to create a Request directly from a Template using an URL.

Example

```
http://machinename/CAisd/pdmweb.exe?FACTORY=cr+OP=CREATE NEW+PERSID=cr:
3106+use_template=1
```

where cr:3106 is the persid of the template.

Directories Used by Your HTTP Server

The default installation of CA SDM defines two virtual directories to your HTTP server:

- The CAisd virtual directory points to the following directory in your CA SDM installation:
  1. In Windows: *installation-directory*\bopcfg\www\wwwroot
  2. In UNIX: $NX_ROOT/bopcfg/www/wwwroot
- The CAisd/sitemods virtual directory points to the following directory in your CA SDM installation:

1. In Windows: *installation-directory*\site\mods\www\wwwroot
2. In UNIX: $NX_ROOT/site/mods/www/wwwroot

Subdirectories under these virtual directories are:

Subdirectory	Stores
css	Style sheets
help	Web interface help
html	HTML files
img	Graphic files
scripts	JavaScript
sitemods	Site-defined modifications

If you decide to create versions of any of the files in the css, html, img, or scripts directories, we strongly recommend that you do not update the file in /CAisd. Instead, store the file in the appropriate subdirectory of /CAisd/sitemods. For example, if you decide to modify a style sheet in /CAisd/css, store your modified version in /CAisd/sitemods/css. When the web engine parses an HTMPL file, it automatically modifies file names beginning with $CAisd to point to sitemods if the file exists in a subdirectory of sitemods.

Using the /CAisd/sitemods directory has these advantages:

- It allows you to keep a record of the distributed files you have changed.
- It gives you easy access to the original version in case there is a question or a problem.
- It makes the process of installing maintenance or a new release easier, since CA SDM installation never places anything in the /CAisd/sitemods directory.

Note: There is no /CAisd/sitemods/help subdirectory. Because the help data is in standard HTML files (not HTMPL templates), the web engine cannot dynamically change file references. If you need to modify help, you must make your changes in /CAisd/help.

The HTML subdirectory contains a few heavily used files that do not need to be processed by the web engine and can improve performance when cached on the browser. If you create version of any of these files, carefully check the file for references to other modified files. Because there is no web engine processing, you must manually insert a reference to sitemods where appropriate.

Download PDF Attachments

When you download and try to view a PDF attachment in CA SDM, the PDF file may not display correctly, or a blank window may appear after you upgrade to Adobe Acrobat release 7.0 or 8.0. With CA SDM, you can display the PDF file correctly by completing the following steps:

1. Set the *forceDecompressOnDownload* parameter to YES in $NX_ROOT\bopcfg\www\CATALINA_BASE\webapps\CAisd\WEB-INF\web.xml.

   Note: On Linux, $NX_ROOT is /opt/CAisd

2. Restart the CA SDM services.

Edit in List Modification

This article contains the following topics:

Several list forms, such as the Request and Issue lists, include an Edit in List button. When this button is available and a result set is displayed, the user can click Edit in List to replace the search filter with a small edit form. The edit form allows the user to update records directly on the list form. The user can even update everything selected in the list by placing the desired new data in the edit form and clicking Change All.

Editing list data involves no communication with the server until the user clicks Save. When the user clicks Save, all the updates (marked by yellow highlights on the form) are sent to the server, which applies all the changes in a single operation, returning a status message and redisplaying the list.

You can modify this feature by controlling whether the Edit in List button is available on a particular list form, and by controlling the fields that appear in the edit form displayed when the user clicks Edit in List.

To place an Edit in List button on a list form, including the following statement somewhere in the <HEAD> section of the form:

```
<SCRIPT LANGUAGE="JavaScript" SRC=$CAisd/CAisd/list_edit.js></SCRIPT>
```

Simply adding this statement puts the button on the form. However, the button is disabled unless JavaScript statements specifying the contents of the edit form are also included in the form. These statements must be placed immediately prior to the results set specification, and have the following format:

Statements	Comments
startListEdit(_search_filter);	Specify exactly as shown
listEditStartRow();	Specify exactly as shown
listEditField("attr"[, "hdr"]);	Specify zero or more
listEditReadonly("attr[", "hdr"]);	Specify zero or more

Statements	Comments
endListEdit();	Specify exactly as shown

The endListEdit() statement must be followed by the ResultSet() statement that begins the results set. You specify the fields in the edit form and their sequence on the form by coding one or more listEditReadonly() or listEditField() statements.

startListEdit(_search_filter)

This statement begins the list edit form. It must be coded exactly as *startListEdit(_search_filter);*.

listEditStartRow()

This statement begins a new row of fields on the list edit form. It must be coded exactly as *listEditStartRow();*. You must place a listEditStartRow() statement immediately after the startListEdit() statement. You can optionally include additional listEditStartRow() statements among the listEditField() and listEditReadonly() statements that specify the fields on the form.

listEditField(attr_name ,hdr)

This statement specifies an attribute to be included on the list edit form.

- **attr_name**
  Specifies the name of the attribute to be included in the edit form (including dots, if appropriate). All attributes specified for a list edit form must also be in the results set. The *attr_name* specified must be identical to that specified in the rs.showData() or rs.showDataWithLink() that adds the attribute to the results set.
  The attribute appears on the edit form in the same format that it appears in the search filter. If the attribute is not in the search filter, it is edited in a 20-character text box.
  attr_name is a required argument.

- **hdr**
  Specifies the text of the header on the field in the edit form. This argument is optional; if omitted, the header text is taken from the search filter. If hdr is omitted and the attribute is not in the search filter entry for attr_name, the header text defaults to the attribute name surrounded by question marks.

listEditReadonly(attr_name ,hdr)

This statement specifies a non-editable attribute to be included on the list edit form. Its arguments have the same significance as those for listEditField().

endListEdit()

This statement ends the list edit form. It must be coded exactly as *endListEdit();*.

Integrating with Your Own Web Pages

This article contains the following topics:

You can integrate the CA SDM web interface functionality with your web pages to present a seamless interface for your users.

Note: The web engine, which is the executable that acts as the gateway between the web server and the CA SDM server, allows multiple simultaneous connections from a given user. More than one frame at a time can have an open connection to the CA SDM web engine process.

You can integrate the web interfaces in the following ways:

- By creating links from any of your web pages to the appropriate CA SDM web page without having to go through the web interface menu page.
- By adding HTML forms to your web pages that collect input and perform supported operations directly, without displaying any CA SDM web data entry pages.
- By creating web form groups that can be used to associate HTML web-based forms to users through their access type. Similar to the form groups used by the administrative interface, web form groups can be used to customize your HTML pages.

Linking to CA SDM Functions

You can link directly to major CA SDM functions without displaying the main page. You typically do this by accessing the pop-up window for the new window containing the CA SDM information. You can also replace your web page with the CA SDM page.

In both cases, the product displays the requested page in the same way that the user sees it in a typical session, but without the main page and scoreboard. If you are an analyst, display the main page and scoreboard by selecting File, Restore Scoreboard, which is available only on pages displayed by bypassing the main page.

To create a link that bypasses the main page, specify a URL of the following form:

```
http://hostname[:port]/CAisd/pdmweb.exe?OP=operation+var=value+...
```

In this example URL, *hostname* is the web server host computer; *port* is the port number (typically 8080) required only if you are using Tomcat as your http server; *operation* is one of the supported operations, and *var=value* is one or more of the variables allowed with the operation.

For example, a link that loads the form for creating a request can be specified as the following:

```
<A HREF=http://hostname/CAisd/pdmweb.exe?OP=CREATE_NEW+FACTORY=cr>Define Request</A>
```

Posting Forms to CA SDM

You can also access CA SDM functionality by adding HTML forms to your web pages that refer to supported operations (see page 1789). If the form is submitted with sufficient information to perform the operation, such as creating a request, the operation is performed without displaying a form to collect additional input.

When you add an HTML form to your web page:

- The ACTION for the form is the URL for pdmweb.exe.
- The METHOD is POST.
- Either the name of the SUBMIT button should be one of the supported operations, or you should have a hidden field named OP whose value is one of the supported operations (see page 1789).

For example, to create an HTML form that loads the page for creating a request, specify the following code:

```
<FORM ACTION=/CAisdCAisd/pdmweb.exe METHOD=POST>
<INPUT type=HIDDEN NAME=FACTORY VALUE=iss>
.
.
.
<INPUT type=SUBMIT NAME=CREATE_NEW VALUE=" OK ">
</FORM>
```

JavaScript Modification

This article contains the following topics:

The CA SDM web interface makes extensive use of JavaScript and includes a number of JavaScript files in the /CAisd/scripts directory. If you decide to modify any of these script files, place the modified version in /CAisd/sitemods/scripts, as described in Directories Used by Your HTTP Server (see page 1800).

For performance reasons, the JavaScript files delivered in the /CAisd/scripts directory are compressed, with comments and unnecessary white space removed. This compression can make them difficult to read. You can find uncompressed versions of all JavaScript files in one of the following directories:

- (UNIX) $NX_ROOT/sdk/scripts
- (Windows) $NX_ROOT/sdk/scripts

If possible, avoid creating modified versions of entire JavaScript files, because each file contains a number of functions and you may only want to modify one function. In most cases, you can override individual functions by placing a modified version in the JavaScript file sitemods.js. We strongly recommend that you take this approach when modifying JavaScript.

sitemods.js

A skeleton *sitemods.js* file is distributed with CA SDM. All distributed HTMPL files include this file at the end of their <head> section, making it the last JavaScript file loaded. Because it is the last file, any functions defined in it override functions with the same name included earlier. This lets you provide your own version of a distributed JavaScript function without directly modifying distributed code.

This approach is not effective for functions invoked at load time in the <head> section, such as those in menubar.js and ahdmenus.js.

However, you can modify most JavaScript functions by completing the following steps:

1. Place a modified version of the function in sitemods.js.
2. Store the updated copy of sitemods.js in CAisd/site/mods/www/wwwroot/scripts.

Modifying Context Menus

A number of forms within CA SDM use context menus, accessed by right-clicking an object. Using the Web Screen Painter, you can modify context menus to add, remove, or modify their items.

Note: For more information about adding menu items, see the *Web Screen Painter Help*.

Updating and Creating Change Orders as Employee User

By default, a user can only view change orders from the Employee web interface. You can enable creating and updating change orders by employees:

Follow these steps:

1. Sign on to the web as the Administrator, and select the Administration tab.
2. Select Access Type from the Security menu.
   The Access Type List appears.
3. Select the Employee link to display the Employee Access Type Detail window.
4. Set the Change Orders to "modify" under the Function Access tab and save.
5. Click the Back button to return to the Administration tab, and then select Data Partitions, Data Partition List.
6. Click Employee to display the Data Partition Detail window. On the Constraints List portion of the window, review the Type column for following Change_Request Tables:
   - Pre-Update
   - Create

7. For each Table that you want to edit, click the Table name to display that table's Data Partition Constraint Detail window.

8. Click the Edit button.

9. Edit the constraint as follows:
   change "id = 1" to "affected_contact = @root.id".

10. Click Save.

Now when you login to the web interface as an employee user, the *Create Change Order* link appears.

Add a "Closed Change Orders" link to the Employee Scoreboard

You can use the product to add a Closed Changes node option to the Employee web interface scoreboard.

Follow these steps:

1. Log in to the product as an Administrator.

2. Click the Service Desk tab.

3. Select File, Customize Scoreboard.
   The Customize Scoreboard dialog appears.

4. Click the Role option and select Employee in the drop-down list.

5. Under Add New Node, click the Node's Stored Query link.
   The Stored Query List dialog appears.

6. Search and select Closed Changes from the Stored Query list. This is typically displayed as code CHGUBIN7.

7. Specify a location for the new node by selecting an item in the scoreboard tree on the left.

8. Click Add New Node.
   The new node named Closed Changes is added to the scoreboard tree.

9. Click Finished.

Download Attachments

When you download an attachment in CA SDM, it automatically displays the attachment in the browser window without prompting for a response from you. This action can be dangerous if a virus is associated with the attachment.

With CA SDM, you can force a save-as dialog that prompts you to respond if you want to save the attachment on the disk or open it. Saving an attachment can be a secure method because you can save the attachment on the disk and scan it before you can actually open it. You also have the option to force the save-as dialog only on certain attachment types.

You can force the save-as dialog to appear through the web.xml servlet configuration file. The web.xml file is located at the following paths:

Windows: $NX_ROOT\bopcfg\www\CATALINA_BASE\webapps\CAisd\WEB-INF\web.xml

Linux: $NX_ROOT is "/opt/CAisd"

Free-Form Modification of Detail Forms

This article contains the following topics:

The topics in this section describe how to perform free-form modification of Detail Forms.

Using JavaScript on Detail Forms

Use WSP to add your own fields to a detail form, or rearrange or change edit characteristics of fields provided on the form by default. However, sometimes you want to modify a form beyond simply adding new fields to a grid. There are a number of a JavaScript functions provided with CA SDM to make it easy to merge your own modifications into a combination detail form and give it any appearance you want. These functions are summarized as follows:

- You can place any HTML whatsoever prior to the DetailForm() statement or after the endDetail() statement without affecting the operation of the detail form at all.

- You can use the detailEndTable() function to close the table that lays out detail form elements in a grid. After you have done this task, you can lay out your own HTML in any desired format. In this case, your HTML is inside the detail form, and any form fields within it are submitted to the web engine when the user clicks Save. You can use the detailNextID() function to generate ID fields for your HTML elements that allow them to participate in mouse-less navigation of the detail form. You can see several examples of this technique in the notebook tabs, such as xx_alg_tab.htmpl.

- You can follow your own HTML with a dtlStartRow macro to restart standard detail form formatting. This starts a second grid, whose fields will not necessarily be aligned with the first. This technique is used in every notebook tab.

- If you want to insert a custom element at the end of a row, you can use the detailWriteRow() function to write out the contents of a row without closing it. You can see an example of this technique in the code that generates the "24 Hour" button in detail_cr.htmpl and detail_iss.htmpl.

- If you want to explicitly specify the contents of an element in a row without closing out the table that lays out the grid, you can use the detailRowHdr() function to specify the header text and the detailSetRowData() function to specify the data text. You can see an example of this technique in the code that generates the timer field in detail_cr.htmpl and detail_iss.htmpl.

- If you provide a function to validate a field's value (normally in an event handler), and want its results reported during browser-side validation (so that an erroneous field is redrawn with a thick red border, and an error message appears in a yellow band at the top of the form), use the function detailReportValidation(). You can see an example of this in the validate_duration() function used to validate the duration fields in xx_candp_tab.htmpl. The validate_duration() function is in the file val_type.js.

- If you want review the HTML generated for a detail form, you can use functions docWrite() and docWriteln() in place of the standard functions document.write() and document.writeln(). Then if you invoke the function holdHTMLText() anywhere in the <HEAD> section of your form, CA SDM will pop up a debugging form containing a TEXTAREA with all of the HTML generated for the form, which you can review or copy and paste into a validation tool.

While you are composing your modifications, remember that the combination detail form is displayed in both a read-only and an edit view. If your modifications apply specifically to one view or the other, you can test the current view in one of two ways:

- In JavaScript, the expression _dtl.edit is true in the edit view and false in the read-only view.

- In either JavaScript or open HTML, the statements:

```
<PDM_IF "$prop.form_name_3" == "edit">

</PDM_IF>
```

(Used only in the edit view)

or

```
<PDM_IF "$prop.form_name_3" == "ro">
```

(Used only in the read-only view)

```
</PDM_IF>
```

Used to bracket code intended only for the edit or read-only view, respectively.

detailEndTable()

This function closes the HTML table that lays out the detail form elements in a grid. It has no arguments.

You can start a new grid with the dtlStartRow() macro. However, elements in a new grid are not necessarily aligned with elements in a previous grid.

detailNextID(colspan, lastelement)

This function returns a string of the form:

```
" ID=df_nn_nn TABINDEX=n onFocus=func onBlur=func"
```

Inserting this string into an HTML element causes the element to follow the conventions of CA SDM mouse-less navigation, including accessibility with the arrow keys and turning pale yellow when focused. The returned string begins with a space and ends with no space.

- **colspan**
  Specifies the number of columns in the grid occupied by the element. This argument is optional; it defaults to one if not provided. If omitted, the element is assumed to occupy one column of the grid. This affects arrow key behavior. The *colspan* argument can be omitted even if the *lastelement* argument is provided.

- **lastelement**
  A Boolean value specifying whether the element for which the ID being generated is the last one in its row. If omitted, the element is assumed to be followed by other elements. This affects arrow key behavior.

detailNextLinkID()

This function returns a string of the form:

```
" ID=dflnk_nn_nn TABINDEX=0 onFocus=func onBlur=func"
```

Inserting this string into an HTML element defining a link element causes the element to follow the conventions of CA SDM mouse-less navigation, including accessibility with the up arrow key from the base element and turning pale yellow when focused. The returned string begins with a space and ends with no space.

This function takes no arguments.

detailReportValidation(field, has_error, emsg)

This function reports the result of external field validation. If validation is reported to have failed, the field is redrawn with a thick red border and the error message provided is shown in a yellow band at the top of the form. The user is not permitted to save the record until a subsequent call to detailReportValidation() reports the field as error-free.

The detailReportValidation() function is functional only for fields registered for browser-side validation. All fields created with detail form macros are automatically registered for validation. You can register other fields with the detailSetValidateFunction().

- **field**
  (Required) Specifies the form element object containing the field. The easiest way to obtain this is to pass this argument to the event handler performing the validation. Another way is to use the standard JavaScript function document.getElementById().

- **has_error**
  (Required) A Boolean or integer value specifying whether the field is in error. Setting a field in error prevents the user from saving the record, causes the field to be highlighted with a thick red border, and places the error message supplied as the third argument in a yellow band at the top of the form. Setting a field as not in error reverses these changes.

- **emsg**
  A text string specifying the message to display in the yellow band at the top of the detail form when the *has_error* flag is set. This argument is required if *has_error* is set.

detailSetValidate(hdrtext, is_required, maxsize)

This function specifies that the most recent field created with an ID supplied by detailNextID() is subject to browser-side validation. Validation for required fields and for fields with a maximum size is automatic. Other forms of validation may be provided through JavaScript functions or event handlers calling detailReportValidation().

You should call detailSetValidate() only for form fields you have defined yourself whose ID was created by detailNextID(). The detailSetValidate() function must be called immediately after creating a field that you want validated. It is unnecessary (and will caused unexpected results) to call detailSetValidate() for fields created by detail form macros.

- **hdrtext**
  (Required) Specifies a string used to identify the field in error messages.

- **is_required**
  (Required) A Boolean or integer value specifying whether the field is required. CA SDM automatically verifies that all required fields are provided whenever the user attempts to save a record.

- **maxsize**
  An integer specifying the maximum length of data allowed for the field. CA SDM automatically verifies that all fields with a *maxsize* value have a length within limits whenever the user attempts to save a record. This argument is required. To suppress *maxsize* validation, specify a value of 0.

detailRowHdr(hdrtext, colspan, is_required)

This function stores text for the header (TH) element of an item in the grid. The text is not actually written to the form until a detailWriteRow() function or dtlStartRow macro is invoked.

- **hdrtext**
  Specifies the text in the header element. This argument is required.

- **colspan**
  Specifies the number of columns in the grid occupied by the element. This argument is optional; it defaults to one if not provided. If omitted, the element is assumed to occupy one column of the grid. This affects arrow key behavior. The *colspan* argument must be provided if the *is_required* argument is provided.

- **is_required**
  Specifies whether the *hdrtext* should be displayed in the style corresponding to a required field. The argument can be a Boolean, a number, or a string. A number or a string is interpreted as false if zero and true otherwise. This argument is optional; if omitted, the *hdrtext* is styled as a non-required field.

detailSetRowData(text)

This function stores HTML text for the data (TD) element of an item in the grid. The text is not actually written to the form until a detailWriteRow() function or dtlStartRow macro is invoked. The single argument is the HTML text of the element to be stored.

detailWriteRow()

This function writes the HTML stored for the current row. This creates two HTML table rows, one for the header (TH) elements and one for the data (TD) elements. The function also writes the [assign the value for TD in your book] tag that begins a new data element. The TD tag is automatically closed by the dtlStartRow macro, so it is unnecessary (and incorrect) to provide the [assign the value for TD in your book] tags in HTML text that follows detailWriteRow(). This function has no arguments.

Create a Quick Close Ticket With Preset Options

In the Quick Profile View, you can create a Quick Close ticket, for example, a Quick Close Incident. Add a preset string to the URL when you create a Quick Close ticket to add a description, a summary, or other field information automatically.

Follow these steps:

1. Copy the ahdtop_site.htmpl file from NX_ROOT/bopcfg/www/htmpl/default to NX_ROOT/site /mods/htmpl/www/default.

2. Edit the ahdtop_site.htmpl file to add the appropriate variable (depending on the type of Quick Close ticket) with the preset string.

   - Quick Close Incident -- var quick_close_preset_in
   - Quick Close Problem -- var quick_close_preset_pr
   - Quick Close Request -- var quick_close_preset_cr
   - Quick Close Issue -- var quick_close_preset_iss

   For example, the following string sets the description to HelloIncident and summary to HelloIncidentSummary for a Quick Close Incident.

   ```
   var quick_close_preset_in = "PRESET=description:HelloIncident@@summary:
   HelloIncidentSummary";
   ```

3. Log in to CA SDM.

4. Select View, Quick Profile in the Service Desk tab.
   The Quick Profile Contact Search page appears.

5. Complete one or more of the search fields for the contact, and click Search.
   The Quick Profile Contact List populates with those contacts that match your search criteria.

6. Select a contact.
   The right pane displays the information for that contact.

7. Click Quick Close.
   The ticket is created with the preset information.

Looking Up Information in Reference Tables

Input fields on a detail form editing a database record are namedSET.attr_name. When the record is saved, data from SET fields are copied directly to the underlying record. Thus, an input field for an attribute that references another table should contain the REL_ATTR (foreign key) of that table. This is normally the id, persistent_id, or code of the reference record.

Users do not directly provide REL_ATTR values, and the SET fields for attributes referencing another table are hidden. The visible field on the form is named KEY.*attr_name*, and it contains the common name of the referenced record. A common name must be converted into a REL_ATTR to update the record. There are several times when this might be done:

- For fields with a drop-down list, the SET value is provided directly by the drop-down.
- For fields with a lookup when the user clicks the lookup and selects an item, the SET value is copied from the selected item.
- For fields with a lookup where the user provides a partial key that uniquely identifies the record and then clicks the label, the browser requests the SET value from the server and copies both it and the full key back to the form.
- If the Autofill configuration file property is provided or defaulted, and the user both provides a partial key that uniquely identifies the record and clicks Notebook to exit the field, the browser requests the SET value from the server and copies both it and the full key back to the form.

Otherwise, when the record is saved with a KEY value and no SET value, the web engine resolves the value during the save. If any KEY values cannot be resolved to a unique SET value, the save is prevented, and the edit form is redisplayed.

If a form has been redisplayed as a result of a save that failed due to a lookup resolution failure, the following variables are available in the HTMPL for each attribute field for which a lookup was performed:

- **LIST_*attr***
  Contains all the matches found. Typically this is specified as the right-hand side of the SOURCE= field in a <PDM_SELECT> statement.
- **FLAGS_*attr***
  This is set to one of the following values:
  - **0**
    Display initial search field.
  - **1**
    More than one and fewer than MaxSelectList were found (typically a <PDM_SELECT> list would be displayed in this case).
  - **2**
    No matches were found.

- **3**
  Too many matches were found (more than MaxSelectList).

- **SEARCH_STATUS_*attrstring***
  Contains the TooManyMatches text string from the web.cfg file.

Specifying Lookups on Contacts

When specifying a contact (last name, first name, middle name) in an editable form, you can delimit the contact name with commas (,) or blank spaces, but not both. Commas are preferable because names often have embedded spaces, which cause problems.

Since a combination of commas and blank spaces is not allowed, the presence of commas implies that all parts of the name are comma-separated; if no commas are present, names are delimited by spaces.

Since the information is eventually passed to an SQL query, the percent symbol (%) serves as a wildcard character. For example, 'P%, J%' would match 'Public, John', 'Penxa, Jane', and any other names whose last name begins with P and first name begins with J. (Case-sensitivity depends on the underlying database.) Similarly, 'P% J%' would bring up the same names.

However, 'P%, Jon D' would not bring up all contacts with a first name of Jon, a middle initial of D, and a last name beginning with P, because the presence of one comma means all delimiters are commas. Therefore, the last name would be looked up as 'P%' and the first name would be looked up as 'Jon D'. To avoid this error, specify 'P%, Jon, D' instead.

Understanding List Forms

The following information provides background information about the internals of CA SDM list forms. We recommend that you use the Web Screen Painter Design View to modify these forms.

CA SDM list forms are defined with the following macros (invoked with the PDM_MACRO tag):

- **lsStart**
  Begins a list

- **lsCol**
  Defines a column in a list

- **lsWrite**
  Inserts text into the pdm_list part of a list

- **lsEnd**
  Ends a list

The general form of a list using these macros is the following:

```
<pdm_macro name=lsStart>
<pdm_macro name=lsCol hdr=hdr1 attr=attr1>
<pdm_macro name=lsCol hdr=hdr1 attr=attr1>
<pdm_macro name=lsEnd>
```

This results in text similar to the following example in the output HTML:

```
var rs = new Resultset();    From lsStart
rs.startList(); From lsStart
rs.header("hdr1"); From lsCol
rs.setData("attr1","options"); From lsCol
rs.header("hdr2"); From lsCol
rs.setData("attr2","options"); From lsCol
<PDM_LIST SOURCE=list> From lsEnd
rs.data(attr1) From lsCol/lsEnd
rs.data(attr2) From lsCol/lsEnd
</PDM_LIST> From lsEnd
```

Note: There are two distinct sections to the output list: the setup section before the <PDM_LIST> tag, and the actual list between the <PDM_LIST> and </PDM_LIST> tags. The lsCol macro makes use of preprocessor variables and the <PDM_SET> tag to output data to both sections of the list. The entire list section of the list is created by a <PDM_EVAL> tag generated by the lsEnd macro.

To insert your own JavaScript in the setup section of the list, simply include it where needed. Use the lsWrite macro to insert your own code into the list section of the list.

The lsWrite Macro

The lsWrite macro specifies text for the list section of a list (the portion between the <pdm_list> and the </pdm_list> tags). Text specified for the text argument of this macro is deferred, and not written to the output HTML until the lsEnd macro.

lsWrite [both=no|yes]

text=”xxx”

- **both**
  Specifies that the text operand is to be written both immediately to the output HTML and to the deferred text buffer. This can be useful to output JavaScript to conditionally bypass both the setup and the list information output by a subsequent lsCol macro. Optional; defaults to no.

- **text**
  Specifies the text generated by this macro. Text specified is deferred until the lsEnd macro.

It is often desirable to include pdm tags and references to form variables in the text output by an lsWrite macro. To prevent these from being interpreted by the web engine during parsing of the lsWrite macro itself, follow these syntax rules:

- If the lsWrite macro generates a pdm_tag, omit the surrounding “<” and “>” delimiters of the tag. For example, to insert a <pdm_else> statement into the list section of the list, code:

  ```
  <PDM_MACRO NAME=lsWrite text="pdm_else">
  ```

  The web engine automatically inserts the “<” and “>” before producing the text when it detects that the first four characters are “pdm_” (or “PDM_”).

- If the lsWrite macro generates a reference to a form variable, code an @ character in place of the $ character that designates the variable. For example, to generate a reference to the list variable $list.persistent_id, code:

```
<PDM_MACRO NAME=lsWrite text="@list.persistent_id">
```

  The web engine automatically converts the "@" to "$" before producing the text. To produce a literal @ sign, precede it with a backslash.

Web Engine PreProcessing

This article contains the following topics:

The web engine goes through two phases when processing an HTMPL file:

- The preprocessing phase, when it reads the HTMPL file and any referenced files (including files referenced by PDM_INCLUDE and PDM_MACRO tags). The output from preprocessing is an entry in the web engine's internal cache.

- The generation phase, where it reads the form from its cache and generates HTML. The output from generation is HTML delivered to the browser.

The pre-processing phase is typically done once for each form in the lifetime of the web engine. The generation phase is done each time a form is requested.

You can use the PDM_SET and PDM_EVAL tags during the preprocessor phase to generate and store information, such as HTML text, that the web engine can use in the generation phase.

Preprocessor Variables

Preprocessor variables begin with the string "$PRE.". They are created and updated with the PDM_SET (see page 1783) tag. This tag has the following syntax when used with a preprocessor variable:

```
<PDM_SET PRE.name[+]=value>
```

This tag assigns or updates a preprocessor variable, creating it if necessary. It is processed when the web engine encounters it while reading a form. Only the invariant PDM_IF statements affect PDM_SET of a preprocessor variable; others are ignored.

Invariant PDM_IF Detection

When parsing a form, the web engine detects invariant PDM_IF statements. An invariant PDM_IF is one whose argument consists entirely of literals, environment variables, constant properties, and preprocessor variables. When the web engine detects an invariant PDM_IF, it evaluates its condition immediately. This has the following effects:

- PDM_SET and PDM_EVAL tags that are bypassed by an invariant PDM_IF are ignored. All other pdm_eval tags and PDM_SET tags referencing preprocessor variables are executed when processed, even if they are within a non-invariant PDM_IF.

- Form variable references bypassed by an invariant PDM_IF are ignored, and their value is not fetched when the form is used. You can use this technique to improve the performance of a form. For example, if a form contains the following, the web engine fetches the value of $args.def before it displays the form:

```
<PDM_IF "$env.NX_OTB_MARKET == "itil" && "$args.a" == 1>

<h1>This is form $args.def</h1>

</PDM_IF>
```

  However, if the following segment has been written, the web engine determines that the first PDM_IF is invariant, and retrieves the value of $args.def only if $NX_OTB_MARKET is “itil”.

```
<PDM_IF "$env.NX_OTB_MARKET == "itil">

<PDM_IF "$args.a" == 1>

<h1>This is form $args.def</h1>

</PDM_IF>

</PDM_IF>
```

PDM_EVAL Insert Text from a Preprocessor Variable

The PDM_EVAL tag inserts the value of a preprocessor variable into the input to the web engine parser. If used inside a macro, its effect is deferred until the macro completes.

The PDM_EVAL tag works similarly to PDM_INCLUDE or PDM_MACRO. It inserts the text into the parser at the point of the tag, exactly as if the value of its variable had been coded in place of the tag.

PDM_EVAL has the following syntax:

```
<PDM_EVAL text=PRE.name>
```

where PRE.name specifies the name of the preprocessor variable whose value is to be inserted into the web engine's input

Execution of the PDM_EVAL tag can be controlled by invariant PDM_IF statements.

Important! On UNIX, the LIBPATH needs to be set before running the utility. Use pdm_task to perform this task. For example, before running the utility, input "pdm_task pdm_eval".

Event Log Data Storage Modification

The system environment variable *@NX_EVENT_LOG_EXCLUDE*, which is set in the *NX.env* file and requires a restart of the CA SDM services, lets you control the amount of data that is stored in the event log (event_log table). This variable lets you store only the events you want to track, report on, and use as part of the Recent Activity that can be launched as a button from the Quick Profile page.

In this variable, commas separate list items (for example, *@NX_EVENT_LOG_EXCLUDE = FAQ, KD_OPEN*). For example, if you use the LOGIN,LOGOUT events from the following table (@NX_EVENT_LOG_EXCLUDE value of LOGIN,LOGOUT), the product does not record login and logout events.

Refer to the following information when modifying data to store in the event log using this variable:

Event	Enum	By	Sets	Comments
LOGIN	1	CA SDM		Specifies that the User logs in to the system.
LOGOUT	2	CA SDM	numdata1	Specifies that the User logs out, where numdata1=logout reason:**0** -- normal**1** -- timeout**2** -- abnormal
CR_CREATE	3	CA SDM	sd_ob_type, sd_obj_id, kd, numdata1	Indicates that the User creates a request, where numdata1=id of affected end user.
ISS_CREATE	4	CA SDM	sd_ob_type, sd_obj_id, kd, numdata1	Indicates that the User creates a change order, where numdata1=id of the affected end user.
CHG_CREATE	5	CA SDM	sd_ob_type, sd_obj_id, kd, numdata1	Indicates that the User creates an issue, where numdata1=id of the affected end user.
EMAIL	6	Knowledge Management	kd	Specifies that the Analyst emails a document.
LINK	7	Knowledge Management	kd, sd_obj_type, sd_obj_id	Indicates that the User accepts a solution, and links it to a ticket.
UNLINK	8	CA SDM	sd_id, sd_obj_type, sd_obj_id	Specifies that the User unlinks a solution from a ticket.
SEARCH	9	Knowledge Management	numdata1,	Indicates that the User searches knowledge, where numdata1=CI_ASKED_QUES id.
FAQ	10		numdata1	Indicates a FAQ search, where numdata1=O_INDEXES id (category).

Event	Enum	By	Sets	Comments
		Knowledge Management		
DT_NAVIGATE	11	Knowledge Management	kd,numdata1, textdata1	Indicates that the User navigates a decision tree, where numdata1=ES_NODES ID textdata1=path.
KD_BOOKMARK	12	Knowledge Management	kd	Indicates that the User bookmarks a KD.
KD_COMMENT	13	Knowledge Management	kd, numdata1	Indicates that the User adds a comment to a KD, where numdata1=O_COMMENTS id.
KD_CREATE	14	Knowledge Management	sd_ob_type, sd_obj_id, kd	Specifies that a User creates a document. CA SDM IDs are used when a KD is created using submit knowledge from a request or an issue.
KD_OPEN	15	Knowledge Management	kd, numdata1	Indicates that a User opens a KD, where numdata1=BU_TRANS ID.
KD_RATE	16	Knowledge Management		Indicates that a User rates a KD, where numdata1=BU_TRANS ID.
KD_NEW	17	Knowledge Management	numdata1	Specifies that a User clicks on the New Documents folder in the Knowledge tab.
NX_ATTACH_AUDIT_TO_NEW_TICKET	18	CA SDM		When a User opens a new ticket, all events for the current session appear by default on the Event Log tab of the ticket. **0** -- Only events relevant to the ticket appear on the Event Log tab. **1** -- All events for the current session appear on the Event Log tab of the ticket.
TICK_OPEN	19	CA SDM		Indicates that the ticket was viewed.
TICK_SEARCH	20	CA SDM		Indicates the user who searched for tickets and links the number of searches.
KD_PRNT	21	Knowledge Management	kd	Indicates the knowledge document was printed.

Print CA SDM Web Pages

CA SDM uses background graphics to format its buttons and notebook tabs. The default setting for many browsers is *not* to print these background images. Therefore, if you select File, Print on either the browser menu or the CA SDM menu, the printed page shows only the corners of the buttons or tabs.

You can print CA SDM web pages on Internet Explorer.

Follow these steps:

1. Select Tools, Internet options.
   The Internet Options dialog appears.

2. Select the Advanced tab.

3. Scroll down to the Printing heading, and select the Print Background Colors and Images option.
   The printed CA SDM web pages include background graphics.

You can print CA SDM web pages on Firefox.

Follow these steps:

1. Select File, Page Setup.

2. Select the Format & Options tab.

3. Select the Print Background (color & images) check box.
   The printed CA SDM web pages include background graphics.

Modify CA Business Intelligence Reports

This article contains the following topics:

The following reports are shipped with CA Service Management Release 14.1:

- (For CA SDM) Crystal Reports and Web intelligence reports

- (For CA Service Catalog and CA Asset Portfolio Management) Web Intelligence reports

Before you modify the reports, ensure that you have followed these prerequisites:

- Installed Crystal Reports 2013 Designer on the machine where CA Business Intelligence Release 4.1 SP3 Client Tools are installed.

- Completed CA Business Intelligence Configuration for CA SDM using the CA Service Management Installer.

Important! Please do not modify OOTB Universe and Reports. Always make a copy, modify the copy and save it outside the CA Reports folder.

Modify Crystal Reports

Follow these steps:

1. Open the Crystal Reports 2013 Designer on the machine where it is installed.
2. Log in to the BusinessObjects Repository.
3. Navigate to the Folder structure in the Repository Explorer and open the Target Report that you want to modify.
4. Click Database Menu, Database Expert Edit Query.
5. Make the necessary modifications.
6. Create or update formulas, if required.
7. Click File, Save As. Provide a New Report Name and save it outside of the CA Reports folder.

Modifying Web Intelligence Reports

Follow these steps:

1. Open the Web Intelligence Rich Client on the machine where CA Business Intelligence Client Tools are installed.
2. Log in to the BusinessObjects Repository.
3. Navigate to the Folder structure in the Repository Explorer and open the Target Report that you want to modify
4. Click Design, Structure.
5. Click Data Access, Edit.
6. Make the necessary modifications.
7. Create or update variables, if required.
8. Click File, Save As. Provide a New Report Name and save it outside of the CA Reports folder.

At the end of this topic, you have successfully modified the reports.

CA Business Intelligence Infrastructure

CA Business Intelligence (CA BI) is an enterprise reporting infrastructure that enables you to create, maintain, store, schedule, and distribute reports for CA SDM users and roles. BusinessObjects Enterprise XI, Release 2 and its associated tools, coupled with BusinessObjects Crystal Reports 2013 are the backbone of the architecture. BusinessObjects Enterprise tools are contained in a CA SDM created package, merging CA SDM reporting essentials into an industry leading business intelligence framework.

Note: Although Crystal reports are delivered as the primary component of CA BI, the report creation and maintenance tool, Crystal Reports 2013, is not delivered. Crystal Reports 2013 is a separately licensed product that can be purchased from BusinessObjects and used in conjunction with CA BI.

Reporting Components

Following are the primary components included in the CA Business Intelligence infrastructure:

- **CA SDM** Database/ Domsrvr / ODBC Driver -- Report data is stored in a SQL Server or Oracle CA SDM database. BusinessObjects reporting applications (Crystal Reports and Web Intelligence) access the database using an ODBC driver that connects directly with the CA SDM object engine (domsrvr). All CA SDM security, including data partition and tenancy restrictions, is automatically applied to reports.
- **Central Management Server** -- The Central Management Server (CMS) is the central repository that stores all objects used in every reporting process.
- **Central Management Console** -- The Central Management Console (CMC) is the main administrative facility for BusinessObjects. It provides access to all BusinessObjects administration functions. Using the CMC, you can deploy reports and assign user access and folder permissions for Business Intelligence Launch Pad.
- **BusinessObjects Universe** -- The universe provides a business representation of a data warehouse or transactional database. It describes the classes (tables) and objects (columns) which are used in reports. The CA SDM universe is installed and configured during the installation. At the completion of the installation, the universe connection is assigned to various groups and users in CA SDM.
  - **Universe Design Tool** -- It is a tool in BusinessObjects Enterprise that lets you modify the CA SDM Universe, which is a metalayer between CA SDM schema, and BusinessObjects reporting tools. The Import/Export Wizard facilitates object population or extraction within the CMS.
- **Default Predefined Reports** -- Predefined reports are web-based CA SDM and Knowledge Management reports developed with either BusinessObjects Web Intelligence (WebI) or Crystal Reports. The reports can be used as models for defining site-specific reports.

- **Business Intelligence Launch Pad** -- Business Intelligence Launch Pad is a web interface that allows authorized CA SDM users to interact with web-based predefined reports by viewing, running, and scheduling report types including, but not limited to, WebI and Crystal Reports. Reports are contained in folders in the public section in Business Intelligence Launch Pad.

- **Ad Hoc Reports** -- Ad hoc reports are created and administered from Business Intelligence Launch Pad using a WebI plugin-based interface. This tool is intended for users who want to create basic reports easily without writing queries.

Development Environment

This article contains the following topics:

Updating the CA Business Intelligence infrastructure with CA SDM schema changes is an administrative function. An administrator who is promoting modified schema into the reports must set up the environment, apart from their production environment.

Some of the tools used by CA Business Intelligence require a Windows-based architecture. This means that installations of Linux/UNIX must configure CA Business Intelligence on a Windows computer to interact with the Linux/UNIX production environment CA Business Intelligence installation. If you are using Windows servers in production, you should configure an additional Windows computer for your development environment.

Tools

Updating the CA Business Intelligence infrastructure with CA SDM schema changes is an administrative function. To promote modified schema changes into the reports, you must include the following tools in your development environment:

- **Universe Design Tool**
  This full client Windows tool is installed on the CA Business Intelligence production server as part of the base CA Business Intelligence installation for windows. When the CA Business Intelligence server is a non-Windows architecture, or when login access to the production CA Business Intelligence application server is undesirable, you must create a separate CA Business Intelligence installation on a Windows (development) server. A development CA Business Intelligence server installation allows you to access the production CA Business Intelligence objects remotely, no matter the architecture of the CA Business Intelligence production server installation.

- **BusinessObjects Web Intelligence**
  This web-based report creation tool is used for modifying and creating Web Intelligence (WebI) reports. You can access the WebI tool through the Business Intelligence Launch Pad interface. Administrative permissions for the WebI and Business Intelligence Launch Pad tools are available within CA Business Intelligence, specifically using the BusinessObjects Central Management Console (CMC) tool.

- **CA SDM ODBC Driver**
  Provided with the CA Business Intelligence installation is the CA SDM ODBC Driver. This component enables WebI and Crystal Reports to access CA SDM data while enforcing data

partition security. The ODBC Driver is installed as part of the base CA Business Intelligence installation on the CA Business Intelligence application server. It is also available as a client installation so that it can be used on a computer not running CA Business Intelligence along with the Crystal Reports XI client.

Note: For information on defining data partitions security for your reporting environment, see the Set Up Data Partitions Security for Reporting (see page 3212) section.

How to Create a Development Environment

To create a development environment, do the following:

1. Secure a server with a supported Windows operating system.
2. Install and configure CA SDM.
3. Install and configure CA Business Intelligence.
4. Change the default ODBC DSN Name from casd_xxxxx to casd_yyyyy where yyyyy is exactly the same as the DSN on the production implementation.

   Important! Regardless of the actual connection properties, the DSN name must be identical on the development and production implementations.

5. (Optional) Install and configure Crystal Reports XI.

   Note: It is not required to install Crystal Reports on the same computer as CA Business Intelligence. Crystal Reports can be installed on a different computer, as long as the CA SDM ODBC Driver is also installed on the Crystal Reports computer , and the DSN Name is modified to be identical to the production implementation, regardless of the actual connection properties. For more information about installing an individual copy of the CA SDM ODBC driver, separate from the CA Business Intelligence installation, see your ODBC Driver documentation.

6. Create the Framework (see page).

Framework

After the tools are available in your development environment, the next step is to create a framework that will allow schema changes to be preserved through product upgrades.

Important! Do not modify the default development CA SDM universe installed with CA Business Intelligence. Otherwise, your schema changes may be overwritten during patch and upgrade processes. Modifying the CA SDM universe will eventually result in lost schema changes within the CA Business Intelligence infrastructure.

The BusinessObjects universe is the metalayer that describes the schema within the CA Business Intelligence infrastructure. Instead of changing the CA supplied universe, you can create a customer-specific universe linked to the CA SDM universe. Using this approach, you can maintain local schema changes with minimal effort during the upgrade process, and CA SDM will be able to provide upgrades to the base universe.

CA SDM customers familiar with BusinessObjects universe documentation will be aware of other documented procedures available from BusinessObjects that allow tying universes together. The process discussed here, however, is the only process that is supported by CA for maintaining customer modifications.

The default universe is named "CA SDM" and it is stored in the "CA Universes" folder within the Central Management Console (CMC). This default universe is the "kernel" universe in a structure where universes are linked.

The CA SDM universe can be named anything you choose. The name will be displayed to report writers when they are building reports, so make sure the name is meaningful. The customer universe is the "derived" universe in a structure where universes are linked.

Within this framework, any number of derived universes can be maintained, but only one is required for maintaining schema changes. Multiple derived universes may be used for ease of maintenance or security requirements, but such decisions are solely at the discretion of your production support needs.

In any multiple derived universe environment, ensure that you do the following:

- Maintain the z_ naming convention for the universe file name on all universes.
- Use the CA SDM connection, then store the universe in the CA Customer Universe folder.
- Do not delete the link to the kernel universe.

Create a Framework for Promoting Schema Changes to CA Business Intelligence

Use the Universe Design Tool to create a framework for promoting schema changes to CA Business Intelligence.

Follow these steps:

1. Open the Universe Design Tool.
   Select File, New from the Universe Design Tool menu.
   The Universe Parameters window appears.

2. Click the Definition tab and enter a meaningful name for this universe in the Name field.

3. (Optional) Enter a description in the Description field.

4. Select CA SDM from the Connection drop-down list.

5. Click the Add Link button on the Links tab.
   The Universe to Link dialog appears.

6. Expand the CA Universes folder and complete these tasks:

   a. Open the CA Service Desk.unv file. The Universe to Link dialog closes and the CA SDM universe appears on the Links tab.

   b. Click OK to close the Universe Parameters dialog.

   Universe Design Tool may take a few minutes to process the link and create the derived universe.

7. After the derived universe is created, perform these tasks:

   a. Modify the following parameter(s) as appropriate.

      - Select Parameters from the File menu.
      - Click the Parameter Tab.
      - Specify ANSI92 = YES.

   b. Click the Controls tab and set the following fields to a value appropriate to your implementation, then click OK to save the values and close the parameter dialog:

      - Limit size of result set
      - Limit execution time
      - Limit size of long text objects (minimum of 4000).

   c. Define hierarchies. Note that customer hierarchies are not imported.

      - Select Tools, Hierarchies.
      - Multi-select all custom hierarchies, then click the Add arrow button. All hierarchies are moved to the right side.

8. From the Universe Design Tool menu, click File, Save.
   The Save As dialog appears.

9. In the File Name field, select any descriptive file name, and proceed the file name with "z_". For example, a universe named "ACME Anvil Co" might default to: "ACME_Anvil_Co.unv." Change this file name to "z_ACME_Anvil_Co.unv" before saving.

10. Export the derived universe to the CMS as follows:

    a. Select File, Export from the Universe Design Tool menu.

b. From Domain field drop-down list, select <Browse>, then locate and select CA Customer Universes.

c. Click OK to export the universe to the local CMS
The Universe Successfully Exported dialog appears.

The framework now exists to promote custom schema changes throughout CA Business Intelligence.

11. Log into Business Intelligence Launch Pad as an administrative user and do the following:

a. Select Public Folders.

b. From the Business Intelligence Launch Pad toolbar, click New, Folder.

c. In the Folder Name field, provide a description meaningful to report users, such as "Organization Name Reports."

d. Click OK to see the folder created under Public Folders.

This creates the minimum framework to use and store reports by your organization. Any number of subfolders and objects can be added to this folder structure.

Reports and Folder Structures

This article contains the following topics:

Included with the CA BI installation are several Crystal Report XI and WebI report objects. The reports are contained in the following CA SDM folder: CA Reports\CA SDM.

Important! Do not modify the CA SDM universe and report objects contained in the CA SDM folder structure.

Consider the following information about reports and the folder structures:

- The steps for creating a framework explain how to add a folder in the Business Intelligence Launch Pad public section, which is specific to the end user. Within this folder, a user can create additional subfolders and report objects.

- In an implementation where each user is authorized access to CA BI by their unique CA SDM login ID, users can save reports for personal use within the My Folders section. BusinessObjects enforces security on this folder by showing these objects only to the logged in user.

- In an implementation where all users have a single reporting user ID for accessing CA BI, the My Folders section is available to all users.

Create a Web Intelligence Report

Use CA Business Intelligence to create a Web Intelligence report.

Follow these steps:

1. From the CA SDM Reports tab, click the Business Intelligence Launch Pad button.
   The Business Intelligence Launch Pad home page appears.
2. Click New, Web Intelligence Document from the menu bar.
3. Select the derived universe that you created when you defined your development framework.
   The Web Intelligence report creation tool appears.

   Note: Save your document at regular intervals. If the connection session times out, your report modifications will be lost. For information on how to increase the Web Intelligence connection session time-out value, see Change the Web Intelligence Session Time-Out (see page 3263).

4. From the Web Intelligence toolbar, select Save, Save as.
   The Save Document dialog appears.
5. In the General section, specify a meaningful name for this report in the Title field.
6. In the Location section, select the appropriate folder.
7. (Optional) modify the properties as desired.
8. Click OK to save the report.
   The report appears in the specified folder and is available to all report users.

Modify a Web Intelligence Report

Use CA Business Intelligence to modify a report that was delivered in the CA Reports\CA Service Desk folder structure.

Follow these steps:

1. From the CA SDM Reports tab, click the Business Intelligence Launch Pad button.
   The Business Intelligence Launch Pad home page appears.
2. In the left pane, navigate the CA Reports folder structure, and open the desired Web Intelligence report.
3. Click the name of the report so that the report runs and displays a result.

4. From the Web Intelligence toolbar, select Document, Save as.
   The Save Document window appears.

5. In the Location section, select the appropriate folder.

6. Click OK to save the report in the new location.

7. Select Document, Edit.

8. Click Edit Query (the name of the universe CA SDM appears on the Data tab).

9. Click the Properties tab. If necessary, click the down-facing arrows next to the Universe, so that the CA SDM text is displayed with an ellipse (…).

10. Click the ellipse (...) button to display the Universe dialog.
    The Other Available Universes window appears.

11. Select the name of your universe and click OK.
    Web Intelligence will automatically map all known fields from the CA SDM universe to your universe and display the Change Source dialog. Green check boxes appear next to each mapped field. If all fields are mapped correctly, click OK to confirm the change. If any fields are displayed with a red "X", click the ellipse (...) button next to the field name, and select the appropriate field.

12. From the Web Intelligence toobar, click Edit Report, and select the Properties tab.

13. Expand the General node.

14. Click the ellipse (...) button next to the Document Properties value.
    The Document Properties dialog appears.

15. In the Document Options section, select the Refresh on Open check box.

16. Click Save and then close Web Intelligence.
    The report is associated with the appropriate universe and can be modified as needed.

Create a Crystal Report

Use Crystal Reports to save a report in the CA Business Intelligence Universe.

Follow these steps:

1. Launch Crystal Reports XI.

2. Select File, New, Blank Report.
   The Database Expert dialog appears.

3. Expand the Create new Connection node and click Universes.
   The Business Objects Enterprise dialog appears.

4. Log on to BusinessObjects Enterprise using your administrator credentials.

5. Navigate to the folder containing the derived universe.

6. Select the derived universe and click Open.
   The Business Objects Query Panel dialog appears.

7. In the Universe tree structure, drag and drop the appropriate attributes into the Select and Filter sections of the Query panel.

8. When the query building process is complete, the standard Crystal Reports designer tool is presented.

9. Build and run the report.

   Note: For more information about building and running reports, see Crystal Reports documentation.

10. Save the report in the Business Objects Enterprise repository as follows:

    a. Select File, Save as.

    b. In the Save As dialog, select Enterprise.

    c. Navigate to the folder created when you defined your development framework, and save the new report in BusinessObjects Enterprise.

    The new report is now available in the enterprise, and can be modified as needed.

Modify a Crystal Report

Use Crystal Reports to modify a report in the CA Business Intelligence Universe.

Follow these steps:

1. Open Crystal Reports XI.

2. Select File, New, Blank Report.
   The database expert dialog displays.

3. Click to expand Create new Connection.
   Click Universes.
   The Business Objects Enterprise dialog displays.

4. Log on to Business Objects Enterprise as administrator.

5. Click to navigate the folder housing the derived universe and click to select the derived universe.
   Click Open.
   The Business Objects Query Panel dialog displays.

6. Navigate the universe tree structure to find, drag, and drop attributes to the select and filter portions of the query panel.
   When the query building process is complete, the report writer is presented with the standard Crystal Reports designer tool.

7. Build and run the report as per Crystal Reports instructions.

8. When ready, save the report to the Business Objects Enterprise repository.

   a. Choose File, Save as
      The Save as dialog displays.

   b. On the left side of the save as dialog, click the Enterprise icon.

   c. Navigate the folder structure starting with the customer-specific folder created earlier in this document and click Save to save this report in Business Objects Enterprise.

9. The new report is now available in the enterprise, and can be modified as needed.

Schema Changes to the Infrastructure

This article contains the following topics:

After the CA BI development environment is established and schema changes have been published to CA SDM using the documented process for customizing schema data, the schema changes are ready to be promoted through the CA BI infrastructure. You can make the new schema available for report creation and modification.

Add Schema Changes to Derived Universe

Promoting schema changes into the CA BI infrastructure is as straight-forward as adding the new schema object to the derived universe.

Note: Before you begin, verify that the appropriate steps have already been completed, and the new schema objects have been added to the CA SDM flexible schema.

Follow these steps:

1. Open the BusinessObjects Designer, and import the derived universe to a local file system as follows:

   a. Select File, Import from the Designer menu.
      The Universe Successfully Imported dialog appears.

   b. Click OK.

2. Refresh the structure of the derived universe as follows:

   - Select View, Refresh Structure from the Designer menu.
     The following questions appear:

     - "Do you want to refresh the out of date columns in selected tables?" Click OK.

     > **Note**: If the message "No update needed" appears, it means the CA SDM object layer has not been appropriately updated with the new schema. Review the steps for publishing schema changes to CA SDM.

   - "Refresh structure: The structure has been successfully modified." Click OK.

   New columns appear in the universe structure on the right side of the window, making new object(s) available for use within the derived universe.
   The objects are available to the CA BI tools after they are moved from the right pane to the left pane. When you add objects to the left pane, make sure that you follow the common schema modifications (see page 1833) standards.

3. Drag and drop the new object(s) to the desired location in the left pane.

4. Click Save.

5. Select File, Export from the Designer menu.
   The Universe Successfully Exported dialog appears.

6. Click OK.
   Changes added to the derived universe schema are exported to the local CMS.

7. From the Designer menu, select Tools, Check Integrity.

   a. In the dialog that appears, select the Parse Objects check box. (Do not change other settings.)

   b. Click OK. The integrity check is started.

   > **Note**: No parse errors should be reported. If errors are found, modify your objects in the left pane so that they do not produce parse errors.

8. Click OK to close the dialog.

9. Export the derived universe to the CMS as follows:

   a. Select File, Export from the Designer menu.

   b. From Domain field drop-down list, select <Browse>, and then locate and select CA Customer Universes.

c. Click OK to export the universe to the local CMS.

The Universe Successfully Exported dialog appears.

10. Save your changes and export the CA SDM universe.
The changes are now available in your CA BI reporting environment, including Web Intelligence and Crystal Reports.

Common Schema Modifications

You can implement schema modifications in the Universe. To familiarize you with the process, the following table lists the common schema modifications that you might encounter.

When a field type is defined in Web Screen Painter as...	Follow these rules when using the field in the Universe: Right click the attribute and select...
INTEGER	Object Properties, Definition Tab, Type = Number
STRING	Object Properties, Definition Tab, Type = Character
DATE	Object Properties, Definition Tab, Type = Date Object Format, Number Tab: Choose category "Date/Time"; Choose Format mm/dd/yyyy hh:mm:ss AM/PM
DURATION	Object Properties, Definition Tab, Type = Number; Object Properties, Definition Tab, Select = PdmSeconds(object.attr)
SREL	Create a CA SDM attribute alias.
BREL	Not Applicable
QREL	Not Applicable
DERIVED	Use an appropriate data type and object format for the value stored in the derived field, if desired. The Derived field can produce any result, so there is not a specific standard to follow.
Special Case: Local This is not a data type defined within Web Screen Painter, but instead a data type used by the universe sometimes to indicate an unsupported data type.	The Local field is displayed in the right pane of the universe with type "L". These fields can be dragged, but not dropped into a class on the right universe pane. Most often, fields data types such as binary, are not supported by the Universe. However, they can be added to the left pane of the universe by creating an object and placing the PdmString (object. attribute) in the "SELECT" window of the Edit Properties dialog.

Legacy Reports Modification

CA SDM lets you modify legacy reports or design your own reports. You can:

- Modify legacy Summary, Detail, and Analysis reports to contain exactly the information you need, such as additional fields.

- Produce a new report with any information available from the database in a format that is useful to you.
- Pass arguments of variable information into the report by including command line arguments. Arguments can be values or expressions, such as the current value of a field or an SQL WHERE clause expression.
- Generate reports at the command line, from a script file, or from a menu option.

Follow these steps:

1. Design the report:
   - Decide what data you want to include in the report.
   - Create a report template that contains SQL-like queries, expressions, and functions to manipulate data, and statements to format the data for the printed page.
2. Generate the report from:
   - The command line
   - A CA SDM menu option
   - A script file

Note: If you have a third-party database system you can use its report generating tools to create reports with data from the CA SDM database. CA SDM provides several database views that simplify the process of creating modified reports using third-party database systems. See the documentation for your database system for information about reporting on databases. For more information about database views, see the *Reporting (see page 3180)* section.

Modify Crystal Reports

Before you can display any of these reports, the following conditions apply:

- You must make the Crystal reports available to the Crystal Report Selector by copying them to the Crystal directory: $NX_ROOT/bopcfg/rpt.
- Your database client must be up and running, with connectivity established to the database server running on the same or another computer. If you are using a CA SDM Client to run your Crystal or Access reports you need to have installed a database client for the specific database and have established connectivity with the database server in order to run these reports.

After creating any custom Crystal reports, perform the following:

1. Copy custom Crystal reports to the following crystal directory:

```
$NX_ROOT/bopcfg/rpt
```

2. Add the file names of custom Crystal reports to the following configuration file:

```
crystal.cfg
```

You can then access the Crystal reports by clicking Start on the taskbar, and then choosing Reporting, Service Desk Reporting (Crystal Reports) from the CA SDM menu (accessible from the Programs menu). The Service Desk Reporting (Crystal) window appears.

Important! CA SDM clients cannot be upgraded. Therefore, if you create and use Crystal reports on the CA SDM Server and you plan to upgrade your version of CA SDM, you need to copy all custom reports to a different location so you will not lose them. Following the upgrade, copy the reports back to the $NX_ROOT/bopcfg/rpt Crystal directory and modify the crystal.config file to make them accessible from the Report Selector.

Custom Report Design

This article contains the following topics:

To design a custom report, you must have a basic understanding of the following concepts:

- Writing SQL queries.
- Programming, especially in C.
- Creating special programs or script files that you may need to execute before you execute the report template program. For example, you may want to create a program that prompts the user to enter an argument, such as the conditions for a WHERE clause.

Note: Before you create a custom report, be sure to check if the report you need is already provided. CA SDM provides a wide variety of Crystal and Microsoft Access reports, and runtime versions of these products to let you run the reports. For more information about reports, see the Reporting Using CA Service Desk Manager (see page 3180) section.

Selecting Information for the Report

To help you select data from the CA SDM database for customized reports, see CA Service Desk Manager Reference Commands (see page 3496). It lists database tables, fields, descriptions, and other database information.

How to Create a Report Template

A report template is a file that, when executed by a CA SDM report program, generates a report of a particular design. A report template contains variable expressions, functions, and statements that define how the data is fetched, calculated, and printed.

To create a report template, create a file containing the following types of report statements:

- **Block statements**
  Defines the CA SDM database tables from which data will be fetched and the actions that are to be performed on the fetched data.

- **Layout statements**
  Defines how the data variables and literal text display on the report output.

Note: Store all your .rpt files in a new directory, $NX_ROOT/site/mods/rpt (UNIX) or *installation-directory*\site\mods\rpt (Windows). This directory preserves them when you upgrade to a new release of CA SDM.

Block Statements

Block statements provide the report template with its framework. They define the data to be manipulated and control the execution of the report. Block statements begin with a name that must be unique throughout the report template. They then have the following two sections:

- **Data query section**
  Contains SQL SELECT, WHERE, and SORT clauses to define which data is fetched from the database.

- **Output program section**
  Defines the actions that are to be performed on the fetched data. It contains variable declarations, functions, and other block statements, including nested statements, which can be used to create conditional reports. It can also contain layout statements, which format and print the data as ASCII text.

A simplified version of the syntax of a block statement that shows the relationship between the two sections follows:

```
BLOCK blockname ("SELECT clause", "WHERE clause")
   SORT clause {output program statements}
```

The BLOCK (see page 1847) in the Reference section discusses the detailed version of the syntax, along with a description of each clause and parameter.

Layout Statements in Report Templates

Layout statements define how variables and literal text will appear on the report output:

- You can use the PAGE HEADER and PAGE FOOTER statements to place information at the top and bottom of each report page.
- You can nest HEADER, HEADER2, FOOTER, and PRINT statements within the braces section of the parent BLOCK statement to create titles and summary totals for the various *reporting sections* (parts of the report output).

  Note: When nesting, be careful not to confuse the braces used in layout statements with the braces that encompass the nested statements within a parent BLOCK statement.

- You can include literal text to create labels and line drawing characters to enhance the appearance of the report.

The layout statements are as follows:

- **PAGE HEADER**
  Places information at the top of each report page. It is placed outside the BLOCK statement.
- **PAGE FOOTER**
  Places information at the bottom of each report page. It is placed outside the BLOCK statement.
- **HEADER**
  Places information at the top of each reporting section. It is placed inside the BLOCK statement.
- **HEADER2**
  Places continuation header information at the top of each succeeding page of a reporting section, if that reporting section extends over multiple pages. It is placed inside the BLOCK statement.
- **FOOTER**
  Places information at the bottom of each reporting section. It is placed inside the BLOCK statement.
- **PRINT**
  Places the data in a reporting section. It is placed inside the BLOCK statement.

You can also use the following predefined variables in layout statements:

- CT prints the current time
- CD prints the current date
- PG prints the page number
- **Data Fields**
  Specifies any variable in a layout statement that results in a piece of data when you generate the report. Use the following guidelines when placing fields in your report template:

- Enclose data fields in square brackets ([ ]).
- The field's square brackets define its print space on each line of output. This space is the number of characters delimited by the square brackets, including the brackets. If the output of a variable is longer than the print space, the output is truncated. To ensure that the field has enough print space, you can add trailing spaces between the variable name and the closing bracket. For example, these trailing spaces allow for contacts with long names:

```
[contact          ]
```

- For output that is less than one line, the field can be closed with a greater than right angle bracket (>). This extends the print space to the right margin. For example, the right angle bracket used in a HEADER statement allows the current date to print without being truncated:

```
[CD               >
```

Note: When the field is more than one line and the variable is flagged as MULTILINE, the right angle bracket (>) acts exactly the same as the right square bracket (]). If the print statement for a MULTILINE variable is closed with the right angle bracket (>), characters wrap on white space to stay within the field defined by the left bracket ([) and the right angle bracket (>). Also, if the variable is not MULTILINE, the right angle bracket (>) causes all the data to be displayed on the current line regardless of its length.

- A field in a layout statement can refer to a previously defined variable or a column name.
- To reference a variable or column name in another block statement, use the following syntax:

```
blockname::column | variable-name
```

- **Literal Text**
  Literal text allows you to include supplementary information in your report. It will appear on the report output exactly as specified in the template. To include literal text in a layout statement, place it on any line after the opening brace ({) and before the closing brace (}). Do not enclose it in quotes or square brackets.
  In this example, "ACME Company" and "Page: " are interpreted as literal text by the CA SDM report program:

```
PAGE HEADER {

               ACME Company          Page: [PG]

}
```

Variable Expressions in Report Templates

Every value that you want to appear on the report output can be assigned to a variable. Variable expressions let you:

- Manipulate CA SDM data

- Use functions to perform calculations on fetched values

The following example creates a variable named *desc* to reference the contents of the chg_desc field in the Change Order window. The MULTILINE flag allows the variable to print in its entirety over multiple lines:

```
desc = description MULTILINE;
```

The following example prints the description. The output will be as long as the length defined in the brackets. If you want a longer description to appear, increase the number of spaces in the brackets.

```
PRINT { [desc  ]                                  }
```

Example Report Template

The following Affected Contact Report template shows how to create a report template. It produces a report that lists open change orders with the same affected contact:

```
PAGE HEADER {
                                                        As Of: [CD>
                                                               [CT>
}
PAGE FOOTER {
                          Page: [PG>
}
BLOCK chg ("SELECT \
        chg_ref_num, description, priority, \
        status, category, assignee \
      FROM Change_Request",
    "WHERE #Change_Request.status = 'OP' \
AND #Change_Request.requestor = #ca_contact.id \
AND #ca_contact.last_name = ? \
AND #ca_contact.first_name = ? \
AND #ca_contact.middle_name = ? " , $1, $2, $3)
{
    BLOCK st ("SELECT sym FROM Change_Status",
            "WHERE code = ? ", chg::status) {}
    BLOCK (strlen(category)) cat ("SELECT sym FROM Change_Category",
                    "WHERE code = ? ", chg::category) {}
HEADER {
        OPEN CHANGE ORDERS WITH SAME REQUESTOR/FROM CONTACT
CHANGE ORDER Summary          Pri   Status    Category          Assignee
}
HEADER2 {
CHANGE ORDER Summary          Pri   Status    Category          Assignee
-------------------------------------------------------------------------
}
    num = chg_ref_num;
    desc = description MULTILINE;
    pr = deref (priority);
    stat = st::sym;
    catgry = cat::sym;
    asgn = deref (assignee);
```

```
PRINT {
[num      ] [desc            ][pr ] [stat    ] [catgry          ] [asgn ]
}
}
```

- **Page Header**
  Specifies what to print on the top of each page of the report. CD and CT are predefined variables that give the current date and time. They will appear in the header on the top of each page. Each of these fields ends with an angle bracket, which allows the field to expand towards the right margin. Because “As Of:” is outside of a field and because it is on a line after the opening brace, it will appear as literal text on the report output.

```
PAGE HEADER {                              As Of:  [CD>

                                                   [CT>

}
```

- **Page Footer**
  Includes the page number with “Page: ” as literal text.

```
PAGE FOOTER {

                                Page: [PG>

}
```

> **Note:** Since PAGE HEADER and PAGE FOOTER statements produce global headers and footers, they are not included in a BLOCK statement.

- **Reporting Section**
  Creates a reporting section for the main BLOCK statement, along with its nested statements. A reporting section is usually only part of the data in the report, but this report has only one reporting section. The unique name of this block is chg.
  The SELECT clause selects the columns to be included in the data for the report FROM three tables, but only where conditions specified by the WHERE clause are met.
  The last three AND expressions in the WHERE clause contain question marks, which act as argument placeholders that take the values of the $1, $2, and $3 arguments, in order. Thus $1 is for ca_contact.last_name, $2 is for ca_contact.first_name, and $3 is for ca_contact.middle_name. The $1, $2, and $3 arguments obtain the values of command line arguments.

```
BLOCK chg ("SELECT \

...",

"WHERE \

...\

AND #ca_contact.last_name = ? \

AND #ca_contact.first_name = ? \

AND #ca_contact.middle_name = ? ", $1, $2, $3)
```

- **Reporting Section Headers**
  Specifies that the opening brace starts the output program part of the BLOCK statement: its statements tell what to do with the data fetched by the SELECT and WHERE clauses. This example has nested HEADER and HEADER2 statements that will apply to this reporting section only. HEADER2 prints only if the report output is on multiple pages.

```
{

   ...

   HEADER {

            OPEN CHANGE ORDERS WITH SAME REQUESTOR/FROM CONTACT

CHANGE ORDER Summary           Pri    Status  Category  Assignee

}

   HEADER2 {

CHANGE ORDER Summary           Pri    Status  Category  Assignee

------------------------------------------------------------------

}
```

- **Variable Assignments**
  Specifies variable expressions that act on the data specified by the SELECT clauses. They assign variables to the values of columns and to the results of expressions. These variables match the fields in the PRINT statement that follows.
  The MULTILINE flag on the *desc* variable causes them to print or display on multiple lines rather than being truncated. The deref function is used to return the string expression contained in the referenced columns.

```
num = chg_ref_num;

desc = description MULTILINE;

pr = deref (priority);

stat = st::sym;

catgry = cat::sym;

asgn = deref (assignee);
```

- **Printing**
  Contains the fields to be printed. This statement could have also included literal text of lines that could enhance the appearance of the report. The final ending brace matches the opening brace of the output program section of the BLOCK statement.

```
PRINT {

[num ] [desc         ] [pr]  [stat] [catgry] [asgn         ]

}

}
```

Report Template Reference

You can use variable expressions, functions, and statements in a report template.

This section contains the following articles:

Variable Expressions

This article contains the following topics:

Variable expressions define the data to be printed or displayed in a report template. They are placed in a layout or block statement.

Variable Expression Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string is as follows:

```
variable-name = expression [flags]
```

Variable Expression Flags

Flags format the result of a variable expression. Use these flags to format text fields:

- **MULTILINE**
  Displays on multiple lines rather than truncating.

- **RIGHT**
  Right justifies.

Use these flags to format numeric fields:

- **BLANKZERO**
  Functions as null-value fields, which do not print a zero.

- **BOOL**
  Converts zero to no or non-zero to yes.

- **REAL**
  Displays as floating point (default is integer).

- **ZEROFILL**
  Shows leading or trailing zeros

Use these flags to format date and time fields:

- **DATE**
  Shows only date portion of date/time.

- **DAYS**
  Displays durations with days.

- **HOURS**
  Displays durations with hours.

- **MINUTES**
  Displays durations with minutes.

- **SECONDS**
  Displays durations with seconds.

- **TIME**
  Shows only time portion of date/time.

Variable Expression Example

The following line displays a Variable Expression example:

```
desc = description MULTILINE
```

Variable Expression Remarks

Variable names must be unique within a BLOCK statement and must not duplicate any column in the SELECT clause for the block. The same variable name can be used in different BLOCK statements but it cannot be repeated within a BLOCK statement.

Follow these syntax rules when including expressions in your report template:

- Use any valid C expression.

- Do not enclose variable or column names in quotes.

- Enclose string constants in single or double quotes.

- You can refer to a nested block, but only if it contains exactly one row.

- To include a column name that is the same as a keyword, precede the column name with a backslash (\). For example, ALIAS is a keyword and \alias is a column name.
- Use the dollar sign ($) to reference environment variables, such as $name, and to reference command line arguments, such as $*n*, where *n* is the position of the argument on the command line.
- To specify the number of command line arguments, use $#. For example, the following expression means that if the number of command line arguments is greater than one, use the additional argument as an argument; otherwise, set the value of the argument to an empty string. The report template itself is considered a command line argument. Therefore, the number of arguments is at least one.

```
$# > 1 ? $1 : "
```

- Use ## to concatenate two strings, for example:

```
title = "This is the " ## "first line. "

long_name = fn

irst_name ## last_name
```

- The following casts are supported:
  - (number)
  - (string)
  - (date_time)
  - (duration)
- To reference a variable or column name in another block, precede the name with its block name and two colons. For example:

```
blockname::column | variable-name
```

Report Template Functions

The following functions can be used in your report template:

- **is_null (*expr*)**
  This function returns true if the expression is null.

```
false = 0

true = is_null (false)
```

- **sqrt (*expr*)**
  This function calculates the square root of the expression.

```
nine = 9

three = sqrt (nine)
```

- **pow (*expr1, expr2*)**
  This function raises *expr1* to the power *expr2.*

```
two = 2

three = 3

eight = pow (two,three)
```

- **log (*expr, expr*)**
  This function calculates the natural log of the expression.

```
ten = 10

result = log (ten)
```

- **catname (*expr*, *expr*, *expr*)**
  This concatenates three strings representing a contact name into a string with commas, according to rules in the field format file.

```
last = "Murphy"

first = "Fred"

middle = "P"

contact_name=catname (last, first, middle)
```

- **strlen (*string*)**
  This function returns the length of the string.

```
buffer = "A thirty character long string"

thirty = strlen(buffer)
```

- **strindex *(string, pattern [, start_index]*)**
  This function returns the index of the first pattern match, or the next pattern match after the start_index, in the string. Returns -1 if there is no match.

```
buffer = "A thirty character long string"

zero = strindex(buffer, " [A-Z] ")

two = strindex(buffer, " [a-z] ")
```

- **substr (*string, pattern [, length]*)**
  This function returns the portion of the string after the first pattern match. It length is defined, it limits the length of the output string. Returns a string of zero length, if there is no match.

```
buffer = "A thirty character long string"

last_word = substr(buffer, " [a-z]*$ ")

first_capital_letter = substr(buffer, " [A-Z] ",

    1)
```

- **substr *(string, index [, length]*)**
  This function returns the portion of the string after the index. Its length is defined and limits the length of the output string. Returns a string of zero length, if there is no match.

```
buffer = "Summary: The network card displays a

    code of ... "

summary = substr(buffer, 9)

30_char_summary = strindex(buffer, 9, 30)
```

The remaining functions (pseudofunctions) perform on a block of data rather than on variable expressions. These functions are usually placed in a BLOCK statement to get information about a nested BLOCK statement's data.

- **count (*block-name*)**
  Returns the number of rows in the block specified in the BLOCK statement. The block-name must be a simple string.

```
BLOCK sample ("SELECT id  FROM Contact") {

entries = count (sample)

}
```

- **sum (*block-name, expr*)**
  Executes the expression for each row of the specified block and sums the result.

```
BLOCK sample ("SELECT actual_cost, est_cost FROM Change_Request") {

difference = sum (sample, est_cost-actual_cost)

}
```

- **average (*block-name*, *expr*)**
  Executes the expression for each row of the block and returns the average of the result.

```
BLOCK sample ("SELECT actual_cost, est_cost FROM Change_Request"){

avg_difference = average (sample, est_cost-actual_cost)

}
```

- **prev (*expr*)**
  Returns the previous value of the expression. This function should be used with caution so its value does not overwrite the latest value by accident.

- **downtime *(sla_schedule, expr1, expr2 [, delay-block, expr, expr]*)**
  Invokes an SLA downtime calculation. The first argument must be a string that identifies a workshift. The other arguments are start and end times:
  expr1 is the start date/time of the event
  expr2 is the end date/time of the event
  In this example, the wrkshft BLOCK fetches the work shift schedule, the evt_dly BLOCK statement fetches the delays and the downtime function uses these records to calculate the downtime.
  BLOCK attevt ("SELECT start_time, fire_time, event_tmpl, obj_id FROM Attached_Events")

```
{
BLOCK evt ("SELECT persid, sym, work_shift FROM Events ", "WHERE persid = ?", attevt::event_tmpl) {}
BLOCK wrkshft ("SELECT sched FROM Bop_Workshift", "WHERE persid = ?", evt::work_shift) {}

BLOCK evt_dly ("SELECT start_time, stop_time FROM Event_Delay", "WHERE obj_id = ?", attevt::obj_id) {}
total_downtime = downtime(wrkshft::sched,
attevt::start_time,  attevt::fire_time,
evt_dly,
evt_dly::start_time, evt_dly::stop_time);
}
```

- **deref (*column-name*)**
  Returns the string representation of the pointer by performing an automatic lookup in the appropriate table.

```
BLOCK chg ("SELECT organization FROM Change_Request") {
org = deref (organization)
}
```

Because this pseudofunction involves lookups, it is valid only if it is the only thing in the expression. For example, this is valid:

```
model = deref (nr_model)
This is not valid:
model = "model"  ## deref (nr_model)
```

Note: Forward references to variables or blocks are not allowed.

Report Template BLOCK Statements

This article contains the following topics:

Block statements define the database tables from which data will be fetched, and can include actions to perform on the fetched data.

Block Statement Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string for BLOCK is as follows:

```
BLOCK blockname (
       "SELECT [ALIAS,] field_name[, field_name ...]
       FROM table_name[, table_name ...] "
       [,"WHERE where_clause"][, arguments,] )
       [SORT "sort clause"]
{
output program statements
}
```

Block Statement Parameters

- ***blockname***
  Identifies the block. Each *blockname* must be unique.

- **SELECT clause**
  Follows the *blockname* and is delimited by double quotes. Lists the columns to be fetched, followed by the keyword FROM, followed by the tables from which the columns are to be fetched. It is required. Here is an example with three tables specified:

  ```
  "SELECT open_date, chg_ref_num \

  last_name, first_name \

  FROM Change_Request, \

  ca_contact"
  ```

  You cannot include an SQL alias, such as:

  ```
  "SELECT open_date As OpenDate"
  ```

- **WHERE clause**
  (Optional) Follows the SELECT clause and further qualifies the information selected. It may be a string constant or an expression evaluating to a string. If the WHERE clause is an empty string, all records are returned. WHERE clauses can contain replacement arguments (which refer to variables or command line arguments) using the syntax of a question mark (?). The following WHERE clause could follow the previous SELECT clause:

  ```
  "WHERE #Change_Request.open_date >= ? \

  AND #Change_Request.active_flag = 1 \

  AND #ca_contact.last_name = ? ", $1
  ```

  Note: The WHERE clause must be separate from the SELECT clause because the WHERE clause can be an expression evaluating to a string, whereas the SELECT clause is exclusively a string constant. This gives you more flexibility and data manipulation capabilities in producing your report.

- **SORT clause**
  (Optional) Follows the SELECT and WHERE clauses and sorts the fetched rows of data. The SORT clause is formatted like the SQL ORDER BY clause. Here is an example:

```
SORT "open_date"
```

- **Output program statements**
  Controls execution of the report. Before the data query, the HEADER statement, if included, prints the heater test for the block. The data query then runs. If data is returned, each statement executes in the order written, with one exception. Block functions, like sum and average, behave as thought they were at the end of the output program. In fact, their values are not stable until execution begins on the next data record.

Important! The output program depends on the success of the data query. If no data is returned from the query, then, except for the HEADER statement, the output program will not execute.

Block Statement Example

This BLOCK statement assumes that an argument will be passed that holds an integer equal to the change order priority. The WHERE clause first checks the number of arguments passed ($#). If one is present, it is used to evaluate the expression to produce the WHERE clause; otherwise a null WHERE clause is substituted (" ").

```
BLOCK chg ("SELECT priority FROM Change_Request",
$# > 1 ? "WHERE priority =" ## $1 :  "") {}
```

Footer Statement Example

The following lines display a Footer Statement example:

```
FOOTER {
     Summary Information:
             Total Failures:  [Fail_count >
             Total Downtime:  [Downtime >
}
```

Block Statement Remarks

HEADER, HEADER2, FOOTER, PRINT and variable expressions can be placed in the braces. Any statement will be executed for each row selected.

Note: PAGE HEADER and PAGE FOOTER statements cannot be placed in a BLOCK statement.

Report Template FOOTER Statements

This article contains the following topics:

This layout statement places information at the bottom of a reporting section.

Footer Statement Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string for FOOTER is as follows:

```
FOOTER {parameters}
```

Footer Statement Parameters

The parameters are as follows:

- **CD**
  A predefined variable used to display the current date.
- **CT**
  A predefined variable used to display the current time.
- **PG**
  A predefined variable used to display the current page number.
- **column | variable-name**
  This field can be a variable from an earlier variable expression or a reference to a column in the SQL clause of a BLOCK statement.
- **literal-text**
  Any text that is not a predefined variable or a column or variable name is interpreted as literal text. Literal text that you include in the FOOTER statement appears in the exact horizontal location where you enter it.

Footer Statement Remarks

FOOTER statements are printed at the bottom of a reporting section. A typical use might be to present summary information or statistics. You can include a FOOTER statement in a BLOCK statement.

A field's content occupies the exact space delineated by the square brackets. Any excess characters are truncated. However, you can close a field with an angle bracket (>) to permit its content to expand in its entirety towards the right margin.

To reference a variable or column name in another BLOCK statement, use the following syntax:

```
blockname::column | variable-name
```

HEADER

This article contains the following topics:

This layout statement places information at the top of a reporting section.

Header Statement Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string for HEADER is as follows:

```
HEADER {parameters}
```

Header Statement Parameters

For a list and explanation of the valid parameters for this statement, see Report Template PAGE HEADER Statements (see page 1853).

Header Statement Example

The following lines display a Header Statement example:

```
HEADER {
                 Contact Summary Report
     Contact Name   Contact Alias   Organization
}
```

Header Statement Remarks

HEADERS are printed at the beginning of a reporting section and can be included in a BLOCK statement. HEADERS are typically used to present section and/or column headings.

A field's content occupies the exact space delineated by the square brackets. Any excess characters are truncated. However, you can close a field with an angle bracket (>) to permit its content to expand in its entirety towards the right margin.

Note: If the print statement for a MULTILINE variable is closed with the right angle bracket (>), characters wrap on white space to stay within the field defined by the left bracket ([) and the right angle bracket (>). Also, if the variable is not MULTILINE, the right angle bracket (>) causes all the data to be displayed on the current line regardless of its length.

To reference a variable or column name in another BLOCK statement, use the following syntax:

```
blockname::column | variable-name
```

Report Template HEADER2 Statements

This article contains the following topics:

This layout statement places continuation HEADER information at the top of each succeeding page of a reporting section, if that reporting section extends over multiple pages.

Header2 Statement Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string for HEADER2 is as follows:

```
HEADER2{parameters}
```

Header2 Statement Parameters

For a list and explanation of the valid parameters for this statement, see Report Template HEADER2 Statements (see page 1851).

Header2 Statement Example

```
HEADER2 {
   Contact Summary Report (continued)
   Contact Name   Contact Alias   Organization
}
```

Header2 Statement Remarks

A HEADER2 statement can be included in a BLOCK statement.

A field's content occupies the exact space delineated by the square brackets. Any excess characters are truncated. However, you can close a field with an angle bracket (>) to permit its content to expand in its entirety towards the right margin.

To reference a variable or column name in another BLOCK statement, use the following syntax:

```
blockname::column | variable-name
```

Report Template PAGE FOOTER Statements

This article contains the following topics:

This layout statement places information at the bottom of each report page.

Page Footer Statement Syntax

```
PAGE FOOTER {parameters}
```

Page Footer Statement Parameters

With the exception that you cannot use column and variable names, the parameters for this statement are the same as those for FOOTER. For a list and explanation of the valid parameters for this statement, see Report Template PAGE FOOTER Statements (see page 1852).

Parameters for a Page Footer Statement Example

```
PAGE FOOTER {
                Page Number: [PG>
}
```

Parameters for a Page Footer Statement Remarks

A field's content occupies the exact space delineated by the square brackets. Any excess characters are truncated. However, you can close a field with an angle bracket (>) to permit its content to expand in its entirety towards the right margin.

To reference a variable or column name in another BLOCK statement, use the following syntax:

```
blockname::column | variable-name
```

Report Template PAGE HEADER Statements

This article contains the following topics:

This layout statement places information at the top of each report page.

Page Header Statement Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string for PAGE HEADER is as follows:

```
PAGE HEADER {parameters}
```

Page Header Statement Parameters

With the exception that you cannot use column and variable names, the parameters for this statement are the same as those for FOOTER. For a list and explanation of the valid parameters for this statement, see Report Template PAGE FOOTER Statements (see page 1852).

Page Header Statement Example

```
PAGE HEADER {
   Date of Report:  [CD>
   Time of Report:  [CT>
}
```

Page Header Statement Remarks

PAGE HEADERS are printed at the top of every report page. They can be defined at any point within the report template file, but they cannot be included within a BLOCK statement.

A field's content occupies the exact space delineated by the square brackets. Any excess characters are truncated. However, you can close a field with an angle bracket (>) to permit its content to expand in its entirety towards the right margin.

To reference a variable or column name in another BLOCK statement, use the following syntax:

```
blockname::column | variable-name
```

Report Template PRINT Statements

This article contains the following topics:

This layout statement places data in a reporting section.

Print Statement Syntax

Syntax refers to the rules governing the formation of statements in a programming language. The structure of this string for PRINT is as follows:

```
PRINT {parameters}
```

Print Statement Parameters

Refer FOOTER (see page 1849) for a list and explanation of the valid parameters for this statement.

Print Statement Example

```
PRINT {
[num ] [desc          ] [pr]  [stat] [catgry] [asgn              ]
}
```

Print Statement Remarks

Place PRINT where you want the data for a reporting section to appear in the report. You can include a PRINT statement in a BLOCK statement.

A field's content occupies the exact space delineated by the square brackets. Any excess characters are truncated. However, you can close a field with an angle bracket (>) to permit its content to expand in its entirety towards the right margin.

> **Note:** If the print statement for a MULTILINE variable is closed with the right angle bracket (>), characters wrap on white space to stay within the field defined by the left bracket ([) and the right angle bracket (>). Also, if the variable is not MULTILINE, the right angle bracket (>) causes all the data to be displayed on the current line regardless of its length.

To reference a variable or column name in another BLOCK statement, use the following syntax:

```
blockname::column | variable-name
```

Web Services Management

This article contains the following topics:

Web Services are a set of data exchange standards that enable communication between products, even if they are on different operating environments. This ability is analogous to browsing the Web on a personal computer -- all remote websites are accessible regardless of whether they are hosted on Solaris, AIX, Windows, and so on. In the same manner, Web Services allow products to communicate over HTTP to various servers regardless of operating environment. For example, a Microsoft Office product can communicate with a program on a UNIX server, and a Java Server Page can access a server hosted on a Windows server. This platform-neutral communication allows for powerful integrations.

The Web Services take advantage of this technology, allowing almost any product to access CA SDM and Knowledge Management. Web Services clients can create tickets, update assets, search the knowledge base, and so forth.

> **Important!** For additional information on web services, see the CA SDM Reference (see page 3496).

CA SDM Components

CA SDM provides the installation files for this version of the J2EE Web Services in the following directory:

```
<NX_ROOT>/sdk/websvc/R11
```

Note: <NX_ROOT> specifies the root installation path for CA SDM.

Web Service Options

These options control the web service session:

- **rest_webservice_access_duration**
  Specifies the number of hours that the REST Web Service Access Key remains active before expiration. The Access Key timeout is not based on inactivity time, but it is based on duration time since the Access Key creation. After the Access Key meets the specified duration, the Access Key ends regardless of whether it is being used.
  Optionally, the REST client can also provide the Access Key duration time for the specific Access Key during the Access Key request. To provide the duration value, set it directly on the expiration_date attribute of the rest_access resource, as part of the POST request payload.
  Valid Range: 1-8760 hours
  Defaut: 168

- **rest_webservice_disable_basic_auth**
  Disables Basic Authentication in REST Web Services.
  Default: No

- **rest_webservice_list_max_length**
  Specifies the maximum number of rows that a REST Web Service query returns.
  Default: 500

- **rest_webservice_list_page_length**
  Specifies the default number of rows that a REST Web Service query returns per page.
  Valid Range: 1-500
  Default: 25

- **rest_webservice_resources_to_expose**
  Specifies the list of Majic factories (resources) that CA SDM exposes through REST Web Services. This option overrides the default behavior. By default, CA SDM exposes all factories through REST Web Services.
  If you do not enter values in this option, the default behavior exposes any Majic factory that does not have the REST_OPERATIONS property set to NONE. By default, no Majic fatory has this property set to NONE.
  Use the REST_OPERATIONS property to set the specific HTTP CRUD (CREATE, READ, UPDATE, DELETE) methods for CA SDM to expose on a given Majic factory.
  Default: rest_access
  Example: rest_access, cnt, grp, cr, crs, pri, alg, urg, imp, pcat, org

- **hmac_algorithm**
  Specifies the algorithm that you use to compute the signature for Custom/Secret Key Auhentication in REST Web Services.
  Default: HmacSHA1

- **string_to_sign_fields**
  Specifies the fields that you use to compute the signature for Custom/Secret Key Authentication in REST Web Services, in addition to the default REQUEST_METHOD, REQUEST_URI, and QUERY_STRING fields.
  Default: blank

- **webservice_domsrvr**
  Specifies the name of the object engine that SOAP web services use. If not installed, SOAP web services use "domsrvr".
  The value of the option must be a string beginning with the characters "domsrvr:"

- **webservice_session_timeout**
  Sets the timeout value (in minutes) for SOAP Web Service sessions. When the time between successive web method calls is greater than the value specified, the session ID is marked expired. The session is then no longer valid.
  To prevent sessions from expiring due to activity, set the value for this option to 0. Other methods, such as logoff routines, can still invalid sessions.

Note: These options require restarting the CA SDM server.

Web Services Installation

Depending on your configuration type, CA SDM installs web services for the following servers:

- Conventional: Both primary and secondary servers. For web service clients to use a URL on a secondary server, you add a web engine to the secondary server

- Advanced Availability: Application server

Web services use the default object manager that is installed on the CA SDM server. To use any other object manager, install and set the *webservice_domsrvr* option in Options Manager.

Note: For information about adding and configuring object managers, web directors, and web engines, see the *Configuring (see page 819)*. For information about installing and setting the *webservice_domsrvr* option, see the Options Manager (see page 1303) section.

How to Activate Design-Time

The CA SDM Web Services includes a method stub configuration feature for developers in the Java version. When activated, the Web Services ignores the CA SDM server and returns simulated data for method calls so that Web Services calls can be made without running a CA SDM server.

Follow these steps:

1. Edit deploy.wsdd to uncomment the sections for “design_mode_stubs”.
2. Reverse the deployment and redeploy the server.
3. Restart the application server.
   The design-time feature is activated.

Note: The design-time feature applies to CA SDM Web Services methods only.

Web Services Security

When you deploy web services, understand the important security considerations. The default configuration when using HTTP is insecure, as it is for all information in web service calls sent between the client and the server in plain text over the network using the HTTP protocol. This includes not only application data, such as ticket descriptions and contact names, but also web service session identifiers (SID). Depending upon the web service application login methods used, it can include passwords.

We recommand that Administrators deploying web services review this information carefully, and to take additional configuration steps at the application and network levels to secure their web service environment.

Important! The default web service configuration used with HTTP is insecure and vulnerable to security threats, which can include password discovery, session fixation, and data spying, among others.

There are three interrelated key security considerations in deploying Web Services:

- What (application level) access authentication schemes should this deployment support?
- What additional networking level security features does this deployment require?
- How will these requirements be enforced through web service configuration options?

The following describes each security feature:

- **Web Service Application Level Authentication Schemes** -- To access Web Services, a web service client application must be authenticated with the web service application. Web Services provides two schemes of access authentication. The first is by username/password, and the other is by Public Key Infrastructure (PKI) technology. Both work with the Access Control and Management component in Web Services, using access policy. Access authentication and access management are the most important security features of Web Services.
  Authentication with username/password methods may be disabled using the following security configuration command:

`disable_user_logon`

Before enabling this option, the administrator needs to determine if each web service client for which an enterprise is requesting Web Services access, can actually provide support for the alternative authentication method, which is the PKI-based login method. The key advantage to the PKI technology is that Web Services client applications do not require *maintained* system user accounts, that is; the maintenance, storage, and transmission of their passwords.

- **Networking Level Security Configuration** -- In both authentication schemes, username/password and Public Key Infrastructure (PKI), notice that the session identifier returned from the specific login method (as well as all subsequent information), are transmitted in plain text when using HTTP. Furthermore, if the username/password authentication scheme is used, the password is sent unprotected (in plain text) from the web service client application to the Web Services. During product development, the W3C did not have recommended standards for web services security. Subsequently, WS-Security is not used by these Web Services implementations to provide a security context. Instead, point-to-point transport layer security (SSL/TLS) and other network level security mechanisms (for example, IPSec), are recommended to protect the otherwise plain text transmission of the application-level authentication exchange(s), and subsequent session identification and data.

  Important! We recommend using SSL (or https) when deploying Web Services to protect the application-level authentication exchanges and subsequent transmissions of session identification and data.

- **Web Service Configuration** -- To allow administrators to enforce communications protocol-level security at the level of the Web Services application, the following two security configuration commands are supported:

  `require_secure_logon`

  This security feature requires you to use SSL (or https) for calling the Login() and LoginService() methods. This feature also provides a handy method for protecting the username and password, while avoiding the overhead of SSL for the rest of the web services.

  Important! If you use the require_secure_logon command, the Web Services application will not confirm that communications protocol-level security is enforced for methods other than Login() and LoginService(). Unless other precautions are taken, the other Web Services methods may be invoked insecurely, causing greater vulnerability to security threats.

  `require_secure_connection`

  This security feature requires you to use SSL to access any part of the web service. If https is required but not used, then a SOAP Fault with code UDS_SECURE_CHANNEL_REQUIRED is returned.

Note: For information about how to configure SSL, see your J2EE Servlet Container documentation.

Use the Web Services

The information in this section provides you with the fundamentals for using the CA SDM Web Services. Example code using the Web Services exists in the following CA SDM installation directory:

```
<NX_ROOT>/samples/sdk/websvc/java
```

The sample code is written in Java using Apache Axis for SOAP messaging.

Logins

Before any Web Services method can be used, a SID (session ID) must be obtained from one of these methods: login(), loginService(), and loginServiceManaged(). The first two methods require a username and password that are validated exactly the same as the CA SDM web interface; the contact's Access Type specifies the validation method. The third method requires a public/private key pair, where login request encrypted with the private key can only be decrypted through the public key, and vice versa.

How to Perform Common Tasks

The Web Services provides a flexible and powerful API into CA SDM, but it requires some knowledge of the object structure used by the product as follows:

1. Familiarize yourself with the information about objects and attributes in CA Service Desk Manager Reference Commands (see page 3496).
   This guide lists the attributes of each object in the system, which is essential because many of the Web Services methods require attribute names.

2. Review the Web Services methods, especially generic ones. For example, if your application must display all the activity logs for a request, first identify how the activity logs relate to the request.
   The CA Service Desk Manager Reference Commands (see page 3496) section shows that the request object has two lists of Activity Logs: The act_log (which shows only noninternal logs), and act_log_all (which lists all activity logs).

3. Identify which Web Services methods you require. To get lists attached to an object, use getRelatedList() or getRelatedListValues().

Default Handles

Some default data provided by the product is frequently used. Instead of looking up handles for these objects, some of the commonly used ones are listed in the following tables.

Note: While the handles do not change the legible symbols may be edited.

Contact Type (Object name: ctp)

Handle	Note
ctp:2307	The “Analyst” type
ctp:2310	The “Customer” type
ctp:2305	The “Employee” type
ctp:2308	The “Group” type

Impact (Object name: imp)

Handle	Note
imp:1605	Impact ‘None’
imp:1600	Low impact ‘5’
imp:1601	Medium-low impact ‘4’
imp:1602	Medium impact ‘3’
imp 1603	Medium-high impact ‘2’
imp:1604	High impact ‘1’

Priority (object name: pri)

Handle	Note
pri:505	Unassigned priority ‘None’
pri:500	Low priority ‘5’
pri:501	Medium-low priority ‘4’
pri:502	Medium priority ‘3’
pri:503	Medium-high priority ‘2’
pri:504	High priority ‘1’

Severity (object name: sev)

Handle	Note
sev:800	Low severity ‘1’
sev:801	Medium-low severity ‘2’
sev:802	Medium severity ‘3’
sev:803	Medium-high severity ‘4’`
sev:804	High severity ‘5’

Call Request Type (object name: crt)

Handle	Note
crt:180	Request
crt:181	Problem

Handle	Note
crt:182	Incident

Query for Requests, Issues, or Change Orders Assigned to a Contact

One of the most common operations is retrieving the active requests assigned to an analyst (assignee). You can use one of several methods, such as doQuery() (to get a list reference), or doSelect() (to get the values immediately). Assuming the assignee's handle is already known, the where clause to use is as follows:

```
assignee.id = U'<assigneeID>' AND active = 1
```

In this where clause, <assigneeID> is the id portion of a contact handle, value, such as "555A043EDDB36D4F97524F2496B35E75".

This where clause works for requests, change orders and issues because they all have the 'assignee' and 'active' attributes, and they mean the same thing for all three object types. The 'active = 1' portion of the where clause restricts the search to active requests.

The Active Flag

Most CA SDM objects have a field called 'active' or 'delete_flag'. This is actually an SREL pointer to the Active_Boolean_Table object or Boolean_Table object. Consider adding these fields to your queries to filter objects marked as Inactive by the system administrator. For querying purposes, search for 'delete_flag = 0' to find active records and 'delete_flag = 1' for inactive records. For example, the following pseudo-code demonstrates using doSelect() to retrieve values for all active Request Status objects:

```
doSelect(SID, "crs", "delete_flag = 0", -1, new String[0]);
```

To set an object to active or inactive, you need to pass the handle of the Boolean object representing either true or false. These handles do not change, so you can safely hard-code them. These are listed as follows:

Active_Boolean_Table	Boolean_Table
actbool:4551 = 'Active'	bool:200 = 'False'
actbool:4552 = 'Inactive'	bool:201 = 'True'

Retrieve Related List Length

When requesting attribute values from an object, such as with getObjectValues(), you can get the length of a related list by requesting the following attribute:

```
 "<listName>.length"
```

For example, to get the number of Activity Logs for a certain request, pass the following to getObjectValues():

```
"act_log_all.length"
```

Note: This is the only way you can use list names in these types of methods.

Access Control and Management

This article contains the following topics:

To minimize the potential problem of web services ticket flooding and to maintain the stability of the CA SDM server, this version of CA SDM Web Services uses an Access Control and Management system. It works primarily to handle the excessive service activities initiated by trusted user applications that can result from programming errors or exceptions. It also works as a barrier for controlling access to CA SDM Web Services from malicious attackers. An administrator of a web service application is able to create and define an access policy in CA SDM that controls access to CA SDM Web Services from a web service application.

Note: A default access policy with a code of DEFAULT is provided. The default access policy contains no access restrictions and is only applied to sessions authenticated through username and password.

Define an Access Policy

To create any SOAP web services access policy, an administrator defines an access policy.

Follow these steps:

1. Click the Administration tab.
2. In the tree on the left, click SOAP Web Services Policy, Policies.
   The SOAP Web Services Access Policy List page appears.
3. Click Create New.
   The Create New SOAP Web Services Access Policy dialog appears.
4. Enter the information for the new access policy:

Note: The defaultvalue of -1 in any operation counter indicates that no restrictions apply to the corresponding operation. A value of 0 (zero) indicates that the corresponding operation is not allowed.

- **Symbol**
  (Required) Identifies a symbolic name of the access policy.
- **Code**
  (Required) Indicates the unique text that identifies this access policy.
- **Status**
  (Required) Identifies the status of an access policy. An inactive policy is not used.
- **Proxy Contact**
  Identifies the contact to use for all web services operations and CA SDM security.
- **Default**
  Identifies the default policy. Set this policy as the default policy. Only one active default policy is allowed to exist. Creating a default policy automatically sets the current default policy to a nondefault status.
- **Has Key**
  (Read-Only) indicates whether a public key has been associated with this policy. This field is updated when a public key is associated with a policy through the pdm_pki utility.
- **Allow Impersonate**
  Identifies the allow impersonate permission. When you set this field, the policyholder can invoke the impersonate() web services method and create a web services session in the name of the user to be impersonated. Additional access authentication is not performed when creating the session. However, only when the access_level of the new access type for the user is less than or equal to the grant_level of the proxy access type for the user can this method be successfully called.
- **Description**
  Indicates the detailed description of this access policy.
- **Ticket Creation**
  Indicates the number of ticket (call request, change order, and issue) insertion operations allowed per hour.
- **Object Creation**
  Indicates the number of CA SDM object (other than ticket object) insertion operations allowed per hour.
- **Object Updates**
  Indicates the number of CA SDM object update operations allowed per hour.
- **Attachments**
  Indicates the number of attachment-related operations allowed per hour.

- **Data Queries**
  Indicates the number of data query operations allowed per hour.

- **Knowledge**
  Indicates the number of knowledge-related operations allowed per hour.

5. Click Save.
   The SOAP web services policy is defined.

Web Services Methods by Category

Each CA SDM Web Services method belongs to a specific category. The following lists each category and their corresponding methods:

- Ticket Creation
- Object Creation
- Object Updates
- Attachments
- Data Queries
- Knowledge

When an access policy is updated by CA SDM, Web Services dynamically updates the corresponding policy information. Active Web Services sessions controlled under this policy remain controlled with configurations in the policy. New Web Services sessions for this policy to manage and control, take the latest configurations in effect.

Note: For information about each method, see the CA Service Desk Manager Reference Commands (see page 3496) section.

Define an Error Type

Error types are assigned when creating tickets and an access policy defines one set of these error types. A CA SDM Web Services user application may use low-level web methods to create a ticket (request, change order or issue), specifying one of these types to categorize the error addressed in the ticket. Error types can be used only with the high-level createTicket() method. Low-level methods, such as createRequest(), do not use error types.

Web Services Error Types

CA SDM Web Services also provides a defined set of default error types, which are created for *every* policy. These default types, designated as *internal* error types, can be deactivated, but cannot be deleted. In the product, you can use the Web Services Access Policy Detail page to see the default error types provided when a new policy is created.

The following information describes each internal error type:

- **ACCESS_ERROR**
  Indicates that the system failed to connect to or find a resource, such as a file, website, and so on.
- **EXCEPTION_FATAL**
  Indicates that the application is shutting down unexpectedly.
- **EXCEPTION_RUNTIME**
  Indicates that the application code encountered an exception.
- **LOGIN_ERROR**
  Indicates that the operator failed to gain access to the application.

Additional Error Types

The administrator of an access policy can add additional error types as described in the following information:

Error Type	Description
Ticket Template	Identifies a template of a Incident or Error, issue, or change order that you use to create a ticket when this error type is reported. **Note:** The owning policy's contact is used as the end user. The Ticket Type and Ticket Template Name define the ticket template.
Default	Indicates if this error type is the default for the policy. Only one default is allowed per policy. **Note:** A new default error type overwrites the existing default error type associated with the policy.
Active	Represents an active error type. **Note:** An inactive type does not create tickets.
Internal	Identifies the field as read-only, which indicates whether this error type is an internal, default error type.
Symbol	Indicates the symbolic name of the error type.
Code	Identifies the unique text identifier of the error type.
Description	Describes the detailed description of the error type.
Duplicate Handling	Defines the action to take when the product detects that an identical ticket already exists.
Return Data	Identifies the user-defined return message you can specify for the web method "createTicket()" to return to client applications. Return data might be used for indicating an action the application should take (Application Data Return), or a message (User Data Return) to display to the end user.

Duplicate Ticket Handling

The Web Service Access Policy can detect and handle duplicate tickets, which is helpful for preventing ticket flooding. A ticket created with the potential of being a duplicate applies if all of the following conditions are true:

- At least one ticket of the same type (cr, iss, or chg) already exists and is ACTIVE.
- The existing ticket was created by the web service.
- The existing ticket was created with the same Policy and Error Type as the ticket being created.
- The “create date” of the existing ticket is within a specified threshold (for example, it was opened less than 2 days ago).

  Note: The create date field is configured using the Maximum time interval for searching duplicates.

- The duplicate ID matches the one provided by users when invoking the createTicket() method.

Users can also assist in preventing duplicates by classifying tickets as being unique or different, based on criteria known to the user. To do this, add an optional string parameter to the createTicket Web Services call. If duplicate handling is on, the string parameter is inspected after other duplicate handling criteria match to determine whether this is a unique or duplicate call to this method.

Duplicate Ticket Results

If the create ticket action results in a duplicate, the existing Error Type may be configured to do one of the following:

Reconfigured Error Type	Results
Create the New Ticket and Ignore Duplicates	A new ticket handle and number are returned (default).
Do Not Create a New Ticket; Add an Activity Log to the Existing Duplicate Instead	The ticket handle and existing ticket number are returned.
Do Not Create a New ticket; Add an Entry to the CA SDM Standard Log Instead	A ticket handle and existing ticket number are returned.
Create a New Ticket and Attach it as a Child to the Duplicate	A new ticket handle and number are returned.

Simplified Web Services Access

CA SDM Web Services provides an abbreviated set of high-level web services methods that are simplified versions of existing web services methods. The majority of users applications do not have to completely rely on a large set of web services methods before requesting service desk services

through CA SDM Web Services. Working closely with user-defined access policies and using default parameters defined in the policies, this set of high-level web services methods can function with little knowledge of the CA SDM object schema. Also, the high-level methods cover a common set of CA SDM functionalities that most service-aware applications need.

The following describes the use of these high-level web services methods:

- **createTicket (SID, Description, Error_Type, Userid, Asset, DuplicationID)**
  You must specify an error type for the reported error if you use this method. The error type should contain the ticket template appropriate for the ticket you want to create. It should define the action to take in the case of a duplicate ticket, specify the data outputs, and finally, it must be associated to the access policy that is defined for the user application.
  When this method is invoked, CA SDM Web Services locates the current access policy and the error type required for the ticket creation. The following shows the sequence that CA SDM Web Services uses for locating the proper error type:

  - If a specific error type code is provided as input and it matches a error type that is associated to the policy, this error type is used, regardless of whether it is internal.
  - If an error type is not specified or the previous step fails to locate an error type, the default error type is used if there is one defined for the policy.
  - If a default error type is not defined for the policy or the previous step fails, the default error type defined for internal error types is used.

  After an error type is defined, CA SDM Web Services uses it to create a ticket. The proxy user defined in the access policy is used for the ticket creation if the userid is empty, and asset information is added to the ticket (if the input is not empty). After the ticket is created, CA SDM Web Services returns both user data and application data, as specified by the error type.

- **closeTicket (SID, Description, TicketHandle)**
  Users can call this function to close an open ticket. It simply sets the status of an open ticket to ‘close’ and adds the input description to the activity log.

- **logComment (SID, TicketHandle, Comment, Internal_Flag)**
  Adds an entry with the input comment to the activity log for the open ticket.

- **getPolicyInfo (SID)**
  Lets users obtain the policy information that controls the current web services session. You can use this information as an indicator of server capacity for this user application. Users may want to adjust their web services calls to fit into the capacity.

By having this set of simplified Web Services APIs, a majority of users are spared the tremendous effort of understanding the complete set of web services API and CA SDM schema. Using them simplifies and accelerates the process of creating service-aware enabled applications for these users.

CA SDM Objects

This article contains the following topics:

CA SDM treats each entity, such as a contact or an issue, as an *object*. These high-level objects are defined in majic (.maj) and mod (.mod) files on the CA SDM server in the following directory:

```
/bopcfg/majic
```

Customized objects are defined in the following directory:

```
/site/mods/majic
```

Objects are essentially high-level wrappers around a database table.

An object's type (sometimes referred to as *factory*) defines the object. For example, request objects belong to the 'cr' type. Each object's type is defined by the "OBJECT" declaration in a majic file.

Note: All objects shipped with CA SDM are enumerated in the CA Service Desk Manager Reference Commands (see page 3496) section.

An object has *attributes*, which are essentially columns in a database table (do not confuse these with XML attributes). Web Services offers many methods to retrieve values for attributes. Many methods require you to name attributes for setting or retrieving values. You must use the attribute name assigned in the majic or mod file that defines the object, which can be different from the actual database name. Client sites can add additional attributes as a customization.

Note: For a list of all the attributes for each object, see the CA Service Desk Manager Reference Commands (see page 3496) section.

Web Services uniquely identifies an object by its *handle,* which is a string value of the form *objectType:ID*, where *objectType* is the object's type (factory) name, and ID is a unique value. The ID value matches that of the 'id' attribute found in every CA SDM object. Because the 'id' attribute is almost always indexed in the DBMS, using the ID portion of the object handle is especially valuable for forming efficient queries. Each object, regardless of its type, stores this value in an object attribute named "persistent_id".

Note: In prior releases, the ID portion of the handle was always a string of integers. In CA Service Desk r11.0 and later, the ID portion may also be the string representation of a UUID, typically 32 characters.

The following information lists the object and factory names of the entities that use UUIDs:

Object Name	Factory Name
Contact	cnt

Object Name	Factory Name
Asset	nr
Organization	org
Location	loc
Company/Vendor	ca_cmpny
Model	mfrmod

Handles are *persistent;* a handle representing a particular object is always unique for its lifetime, even across database migrations. Clients may want to take advantage of this persistence when working with fairly static objects, for example, Status or Contact Types.

Object handles are the key to using CA SDM Web Services. Many methods, especially those that update data, require handles. Most methods that return object data also include the object's handle.

System Updates and Caching

Web Services caches information for object types. Type information is not cached until the type is referenced for the first time, and will cause a small delay.

To avoid any server or caching delays, you may want to run a primer client to activate the Web Services and cache the most popular object type information. The easiest way to cache the object type information is to perform repeated calls to GetObjectTypeInformation(). The object types to consider for this technique could be one of the following:

Object Type	Definition
cr	Request
chg	Change Order
iss	Issue
cnt	Contact
nr	Asset
prp	Property (for Change and Issue)
prptpl	Property Template (for Change and Issue)
cr_prp	Request Property
cr_prptpl	Request Property Template
cr_wf	Classic Workflow (Request/Incident/Problem)

Add any additional object types your client code references.

Categories and Properties

The request, change order and issue objects all have a category field, which is used to classify the nature of the ticket. A category may have property objects, which are attached to the ticket when the category is assigned. Some of these may be marked *required*, which means a value must be supplied before the ticket can be saved (applies to both insert and update operations).

CA SDM Web Services automatically supplies default values for any ticket created with the Web Services. The default value (currently, “-“) is obtained from the CA SDM localized message catalog.

If you need to set property values at creation time, there are three ticket creation methods: createChangeOrder, createIssue, and createRequest. Each has a parameter with which you can pass in values for any properties. To discover which properties will be attached, you must find out the properties associated with the category you intend to assign to the ticket. The easiest method to use is getPropertyInfoForCategory().

Note: For more information about the getPropertyInfoForCategory(), see the CA Service Desk Manager Reference Commands (see page 3496) section.

To identify the valid values for a property, first find the property validation rule for the appropriate property template. To do this, request the validation_rule attribute when calling the getPropertyInfoForCategory method. Then, retrieve the associated validation_type for that rule. If the type is dropdown, you can then use the getRelatedList method to retrieve the values associated with the rule, using the "values" BREL attribute in the prpval_rule object.

Note: For more information, see the CA Service Desk Manager Reference Commands (see page 3496) section.

To set property values after an update operation with updateObject(), you must query the property list after the update. getRelatedList() can help with this task.

Validation of property values through Web Service methods is not currently supported. For example, to assign property values to a validation rule with a validation type of drop-down option, you would have to write additional code to create property values while creating the drop-down option validation rule. Do not attach a property value to a check box validation rule.

Note: For more information about property validation rules, see the Define a Category or Area (see page 1054). For information about creating property validation rules through the CA SDM interface, see Create Property Validation Rules in Setting Up Category or Area (see page 1050) section.

XML Object Returns

Many of the Web Services methods return an XML representation of CA SDM objects. The Web Services uses a standard XML structure beginning with the following root element:

```
<UDSObject>
```

The format of the XML representation is described in the following table:

XML Element	Type	Description
<UDSObject>	N/A	Identifies the root node.
<Handle>	String	Identifies the object's handle.
<Attributes>	Sequence	Identifies the attribute values. This holds zero or more elements for the object's attribute values.
<*attrName0* DataType = *"typeEnum"*>	String	Identifies the *AttrName0,* which is an object attribute name as defined in the CA SDM majic (.maj) or mod (.mod) file. This name may use dot-notation depending on the web method used. The element's value is the attribute's value. An empty element indicates a null/empty value for this object's attribute. The DataType attribute is an integer indicating the attribute's data type in the CA SDM environment.

For example, a call to getObjectValues() can return information illustrated by the following:

```
<UDSObject>
    <Handle>cnt:555A043EDDB36D4F97524F2496B35E75</Handle>
    <Attributes>
        <Attribute DataType="2003">
            <AttrName>first_name</AttrName>
            <AttrValue>first name</AttrValue>
            <DisplayValue>Yaakov</DisplayValue>
        </Attribute>
        <Attribute DataType="2005">
            <AttrName>organization</AttrName>
                <AttrValue>342</AttrValue>
        <DisplayValue>Accounting Crew</DisplayValue>
    </Attribute>
</Attributes>
    <Lists>        <List name="mylist1">
            <UDSObject>...</UDSObject>
            <UDSObject>...</UDSObject>
        </List>
    </Lists>
</UDSObject>
```

Some methods, such as doSelect(), return a sequence of <UDSObject> elements contained inside a <UDSObjectList> element.

The <Lists> section holds zero or more <List> nodes. A <List> node holds zero or more <UDSObject> nodes. <List> elements are generally returned only when a specific request for list values is made.

When you want to return a list of values related to a specific object, you should use the *getRelatedListValues* method.

If a request is made just for a list with no attribute name, such as actlog, then the entire <UDSObject> is returned in the <List> section.

Specialized methods, like getDocument(), can of course be different. When a request is made for an attribute, the database value is returned. For SREL attributes, this may not be so useful. Requesting the assignee attribute of a Request returns an integer because the Contact REL_ATTR (foreign key) is its ID. For CA Service Desk r11.0, the return data for attributes includes elements for the DBMS and common name value of SREL references.

ITIL Methodology

This article contains the following topics:

By default, the Web Services fully support the ITIL methodology. CA SDM ITIL features let you take advantage of the ITIL methodology.

Incident or Problem Creation

CA SDM supports ITIL methodology so that incidents and problems can be created using the CA SDM Web Services. Both incidents and problems are held in the cr (Call_Req) object. Its *type* attribute distinguishes the record as an incident, problem, or request. To create an incident, problem, or request, call createRequest and specify the appropriate value for the type attribute.

The type attribute is a pointer (SREL) to the crt (Call_Req_Type) object, so you must pass a handle as the value.

The following code examples illustrate how to create an incident or problem by passing the correct crt object handle to the createRequest method. Setting the *type* attribute in the name-value pair that is passed as a parameter to createRequest, creates the tickets:

Example: Syntax for a Problem

```
attrVals = {"summary", "A new problem", "description", "new problem", "type", "crt:
181", "catagory", "pcat:40002"}
USPSD.createRequest(SID, creatorHandle, attrVals, template, new String[0], new String
[0])
```

Note: All the workflow tasks that are attached to a category are available for a problem. The workflow task is selected on the configuration of CA Process Automation or Classic workflow.

Example: Syntax for an Incident

```
attrVals = {"summary", "A new incident", "description", "new incident", "type", "crt:
182", "catagory", "pcat:40002"}
USPSD.createRequest(SID, creatorHandle, attrVals, template, new String[0], new String
[0])
```

Note: All the workflow tasks that are attached to a category are available for an incident. The workflow task is selected on the configuration of CA Process Automation or Classic workflow.

Query for Incidents or Problems

To retrieve incidents or problems, include the *type* attribute of the cr object in the where clause. The following example illustrates a where clause for retrieving all active Incidents. This where clause could be used with methods that perform queries for 'cr' objects, such as doSelect and doQuery:

```
type.id = 182 AND active = 1
```

The '182' is the ID portion of the handle representing Incident types.

Note: For more information, see the crt (Call_Req_Type) objects table illustrated in Default Handles (see page 1860). For more information about forming proper queries, see WHERE Clause (see page 1719).

Attach an Incident to a Problem

You can associate one or more incidents to a problem. The problem attribute of an incident relates the incident to a problem.

Example: Associate an Incident to a Problem

This example demonstrates how to relate a newly created incident to an existing problem.

To associate the incident to the problem, use UpdateObject to set the problem attribute of the incident. The following example code sets the problem attribute to the handle of an existing problem ticket:

```
attributeValues = {"problem", "cr:12346"}
USPSD.UpdateObject(SID, incidentHandle, attributeValues, new String [0])
```

Attach a Problem to a Change Order

Incidents and problems can be linked to change orders with the attachChangeToRequest method. The following example code uses this method to simultaneously create a change order and attach it to a problem. In the example, "cr:12347" is the object handle of the problem -- it passes a blank handle for the fourth parameter, which causes the method to create a change:

```
UPSPSD.attachChangeToRequest(SID, creatorHandle, "cr:12347", "", new String[0],
"activity description")
```

Change Order Creation

CA SDM supports ITIL methodology so that a Change Order can be created using the CA SDM Web Services. Change Order are held in the chg (Change_Request) object. To create an change order, call createRequest and specify the appropriate value for the type attribute. The following code examples illustrate how to create a change order:

Example: Syntax for a Change Order

```
attrVals = {"summary", "A new change order", "description", "new change order","
catagory", "chgcat:400002"}
USPSD.createChangeOrder(SID,creatorHandle,attrVals,template,new String[0], new String
[0])
```

Issue Creation

CA SDM supports ITIL methodology so that an Issue can be created using the CA SDM Web Services. Issue are held in the iss (Issue) object. To create an Issue, call createRequest and specify the appropriate value for the type attribute. The following code examples illustrate how to create an change order:

Example: Syntax for Issue

```
attrVals = {"summary", "A new Issue", "description", "new Issue", "catagory", "isscat:
400002"}
USPSD. createIssue(SID,creatorHandle,attrVals,template,new String[0], new String[0])
```

Configuration Items

ITIL methodology uses the term *configuration item* (CI) to refer to hardware, software, and other IT resources. This term refers to the “nr” object stored in the CA Technologies-owned resource database table. All methods that use *asset* objects also work with CIs. This is only a difference in terminology.

Public Key Infrastructure (PKI) Authentication

This article contains the following topics:

If you plan to use the PKI authentication, realize that the content of the login request is encrypted with a private key that can only be decrypted by its matching public key. The response of the login request is returned as plain text.

Generally, each application accessing CA SDM Web Services is assigned with a policy. CA SDM Web Services stores detailed information about a policy, along with the public key of a digital certificate. An application, as the policy holder, uses the private key of the digital certificate and the policy code (as policy identifier) to assemble a login request.

loginServiceManaged (Policy, Encrypted_Policy)

CA SDM Web Services performs the user authentication by locating the policy through the plain text policy code, retrieving the policy holder's public key associated with the policy, decrypting the encrypted policy code, matching the decrypted content with the policy code, and finally, opening a session with a back-end server. The plain text session ID (SID) is returned and can be used for subsequent method invocations. Only the policyholder holds the private key that matches the policy' s associated public key stored in CA SDM.

All subsequent web services calls must include the returned session ID (SID). The Proxy contact specified in the policy is responsible for all web services activities initiated in this session. All function group security and data partition is enforced for the proxy contact.

Important! The Encrypted_Policy parameter should be in the BASE64 text format. The user application must perform proper conversion from the binary format.

Policy is a required field. When you define it, use plain text policy code as defined in a policy. Encrypted_Policy (the digital signature of the policy code encrypted with the policy holder's private key) is required. When you define Encrypted_Policy, use the algorithm SHA1 with RSA to obtain the digital signature.

Implement loginServiceManaged in Java

The following shows how to generate Certificates and then use these generated Certificates to access the CA SDM web services.

In the following example, the login process completes using the CA SDM Certificate and then performs two common web services calls. The getBopsid() web services method call allows you to obtain a token that is linked to a specific user. This token can be used to login to the CA SDM web interface as the linked user without being prompted for a password. This allows seamless integration to be enabled between different applications.

Important! The generated BOPSID token expires after 30 seconds, so it must be used promptly.

Important! There is a known issue when using the 1.4 version of the AXIS tool. For more information, see the *Release Notes*.

Follow these steps:

1. Generate the stub classes with AIXS Tool WSDL2Java. For more information, see the Generating Stub Classes with AXIS Tool WSDL2Java section from the PKI_loginServiceManaged_JAVA_steps file. Find the file in the following location:

```
$NX_ROOT/samples/sdk/websvc/java/test1_pki
```

2. Start the CA SDM service.

3. Run pdm_pki -p DEFAULT.
   DEFAULT.p12 is created in the current directory. This policy will have the password equal to the policy name (in this case DEFAULT).

   Note: This command will also add the Certificate's public key to the field pub_key field (public_key attribute) in the sapolicy table/object.

4. Log in to CA SDM.

5. Select SOAP Web Services Policy, Policies on the Administration tab.
   The SOAP Web Services Access Policy List page opens.

6. Click DEFAULT.
   The SOAP Web Services Access Policy Detail page opens.

7. Complete the Proxy Contact field (in this example, ServiceDesk) and confirm that the DEFAULT policy record Has Key field displays "Yes."

8. Copy DEFAULT.p12 (from the directory where command pdm_pki is executed), the JSP file called *pkilogin.jsp* and the HTML file called *pkilogin.htm* (from the $NX_ROOT/samples/sdk /websvc/java/test1_pki directory) to the following directory:

   ```
   $NX_ROOT/bopcfg/www/CATALINA_BASE/webapps/axis
   ```

9. Open the HTML form (from the axis directory). For example, http://localhost:8080/axis /pkilogin.htm
   Complete the appropriate fields.

   Note: The Directory field identifies the location of the Certificate file. Modify the path to the correct location.

10. Click Log me in!
    The results page opens.

11. Click the BOPSID URL.

    Important! Click this immediately! The BOPSID has a limited life token of about 30 seconds.

The format of a URL using a BOPSID is as follows:
http://<server name>:CA Portal/CAisd/pdmweb.exe?BOPSID=<BOPSID value>

Note: In order to use the loginServiceManaged method for a Java client program running on AIX, you may need to replace a pair of security policy files within your JAVA_HOME. Go to http://www.ibm.com (http://www.ibm.com) and search for "developerworks java technology security information AIX". In the "developerWorks : Java technology : Security" document, follow the link to "IBM SDK Policy files". Download the unrestricted policy files, local_policy.jar and US_export_policy.jar. Use these files to replace the original files in your JAVA_HOME/lib/security directory."

Configuration for the PKI Authentication Type

To configure for PKI authentication, you must first create an access policy. The process flow is as follows:

- **Create an Access Policy**
  The administrator performs this task using the product (Web Interface only), and as part of the process, needs to assign a unique text code to each access policy.

- **Obtain a Digital Certificate with a Public/Private Key Pair and Associate it with the Access Policy**
  For PKI access authentication, a user application needs to obtain a digital certificate that contains both a public key and private key pair. An administrator can obtain the digital certificate through third-party Certificate Authority (CA) or security products that support digital certificates. CA SDM also provides a server-side utility that can generate a digital certificate. It is located in <NX_ROOT> /bin directory as follows:

```
pdm_pki  - p policy_code [ - l certificate file] [ - f] [-h]
```

  - **-p**
    Identifies a unique policy code.

  - **-f**
    Allows the utility to replace the existing public key with a new public key.

  - **-l**
    Loads the public key stored in a X509 V3 certificate.

  - **-h**
    Displays help on the command line window.

  If you obtain a digital certificate through a third-party, CA Technologies, or security products, import it to where the CA SDM server is located, and then associate it to an access policy. The administrator of the user application should obtain a digital certificate file that includes the content of an X509 V3 certificate in DER/ASN.1 format.
  In addition, the certificate should contain only the public key of the public/private key pair. Using the - l option, the administrator should invoke the pdm_pki utility to load the certificate. The utility then loads the certificate, extracts the public key, converts the public key to BASE64 text format, and saves it with the access policy specified by the policy code.

When a digital certificate is generated by the pdm_pki utility, the administrator invokes the command in CA SDM without the - l option. The utility then generates a public and private key pair (keys are RSA1024 bit keys). The public key is converted to BASE64 text format where it is stored along with the access policy specified by the policy code. An X509 V3 certificate is also created to hold the public key along with other information (the default pass phase is set as the policy code). Finally, the X509 V3 certificate is packaged with the private key to a standard portable certificate format of PKCS12. It is then saved in a file with a file name of *policy_code*.p12, depending on the policy code supplied. This file can then be exported to clients.

Note: If an access policy has already been associated with a public key of a certificate, users need to specify the - f option when calling the pdm_pki command in order to overwrite the existing public key with a new public key.

Login to Web Services

The following describes the process flow for logging in to Web Services configured with PKI authentication:

Process	Description
Load the Digital Certificate and Extract the Private Key	The digital certificate must be stored in secure storage on the user side, where it can be retrieved and used for logging in to Web Services. Example of secure storages include the following: Windows Certificate Store Java Certificate Store (managed by java_keytool utility) Certificate store (created by other CA Technologies security products). A user application should be able to load the digital certificate and extract the private key using appropriate APIs, depending on user environments.
Create a Digital Signature of the Plain Text Policy Code with the Private Key	After the private key is extracted from the digital certificate, it can be used to generate a digital signature of policy code. Creating a digital signature encrypts a digest of a text with a private key. The digest algorithm must be standard SHA1, and the encryption algorithm should be RSA. Also, the binary digital signature should be converted to BASE64 text format before it can be used for logging in to Web Services. Depending on user environments, appropriate API calls should be used to archive this information.
Invoke the Web Service Call	A user application should invoke the Web Services method loginServiceManaged(), along with the plain text policy code and the BASE64 text formatted digital signature of the policy code.
Obtain the Returned SID	If the access request is authenticated, a plain text SID is automatically returned.

After a SID is generated, it establishes a successful binding between a Web Service session and an access policy. The user application can invoke other web services methods with this SID, and all of its access to Web Services becomes controlled and managed by this access policy.

Session and Authorization

A successful validation returns a SID that is associated with the validated username, whether it is the user name supplied for login or the proxy contact specified in a policy. Because of this process, each CA SDM user is assigned security rights that you may want enforced in your web service application.

For example, a specific user may have a Data Partition restricting which Requests the user can view. When using a SID for the user to get Request information, the CA SDM system ensures the data partition is enforced.

Function Group security is also applied. For example, a user may not have access to the Call Manager function group. Invoking any web services methods, such as viewing or creating Requests, is denied because access is denied to the Call Manager function group.

When your application is finished doing work for a user, call the Logout() method to invalidate the SID.

Each SID expires after a period of inactivity. That is, a SID expires if the interval between method calls is greater than a certain timeout value. The timeout interval is set in Options Manager and is specified by the following CA SDM option:

```
'webservice_session_timeout'
```

If this value is set to zero (0), a SID never times out. If this option is missing or not set, the default is one hour. If a Web Service method is called with an expired SID, a Fault is returned with an error code of UDS_SESSION_TIMEOUT the first time it is referenced, and UDS_BAD_SESSION each time thereafter.

To keep a SID active, call any web service method before the time out is reached. To keep the SID active without working the server, call serverStatus().

Tips for SOAP Web Services Clients

This article contains the following topics:

The samples directory of the CA SDM installation provides a sample Java client application for Web Services. This sample assists developers with web services client application development.

Many of the Web Services methods require arrays as input parameters. For example, the method createIssue() permits an empty array for propertyValues. Sometimes these arrays are optional, but the service requires an empty array for a successful pass. When you use Visual Studio .NET to access Web Services, specify an empty array with one of the following arrays:

- **C# language**

```
String[] emptyArray = new string[0];
```

- **Visual Basic .NET**

```
Dim emptyArray As String() = {}
```

- **Java**

```
ArrayOfString attr = new ArrayOfString();
attr.setString(new String[0]);
ArrayOfString is a proprietary class.
```

You can then pass emptyArray to array parameters that accept empty arrays.

Note: The CA SDM Web Services use the Apache implementation of standards established by the World Wide Web Consortium (W3C). Ideally, a client on any type of operating environment can access the services, but vendor implementations vary. Many programming environments provide a tool to generate proxy classes from a Web Services Description Language (WSDL) description.

Java Clients

The TableOfContents.doc in $NX_ROOT/samples/sdk/websvc lists several Java sample programs.

Each sample program contains notes on how it can be compiled and run using the script files run_java_test_bat.txt (Windows) and run_java_test_sh.txt (UNIX). These scripts demonstrate how to use org.apache.axis.wsdl.WSDL2Java to generate the CA SDM web services client-side stub files.

The - w parameter is required to properly generate the stub files when using Axis 1.4. Running WSDL2Java as shown will generate the stub files in subdirectory com/ca/www/UnicenterServicePlus /ServiceDesk. The following files are generated:

- ArrayOfInt.java
- ArrayOfString.java
- ListResult.java
- USD_WebService.java
- USD_WebServiceLocator.java
- USD_WebServiceSoap.java
- USD_WebServiceSoapSoapBindingStub.java.

Import these classes with the following statement:

```
import com.ca.www.UnicenterServicePlus.ServiceDesk.*;
```

Many Web Service methods have parameters of type ArrayOfString, a proprietary class. For example, the createRequest() method's attrVals, propertyValues and attributes parameters are all ArrayOfString parameters.

To set the values in an ArrayOfString variable, instantiate the variable and then use setString() as follows:

```
ArrayOfString attrVals = new ArrayOfString();
attrVals.setString(new String[]{"customer", customerHandle, "description",
"description text"});
```

To set it to empty

```
attrVals.setString(new String[0]);
```

Use a variable of type ListResult, another proprietary class, as the return value from the List methods: doQuery(), getRelatedList(), getNotificationsForContact(), getPendingChangeTaskListForContact() and getPendingIssueTaskListForContact(). A ListResult contains listHandle and listLength elements, which can be retrieved using getListHandle() and getListLength() as shown in this example:

```
ListResult doQueryResult = new ListResult();
doQueryResult = USPSD.doQuery(sid, "iss", "active = 1");
int listHandle = doQueryResult.getListHandle();
int listLength = doQueryResult.getListLength();
```

The getListValues() method uses the listHandle, retrieving the values from a subset of the list.

The Handles parameter of the freeListHandles() method is an ArrayOfInt, another proprietary class. Call freeListHandles() using the listHandle taken from a ListResult:

```
ArrayOfInt handleList = new ArrayOfInt();
handleList.setInteger(new java.lang.Integer []{ new java.lang.Integer(listHandle) });
USPSD.freeListHandles(sid, handleList);
```

Some methods have pass by reference parameters of type javax.xml.rpc.holders.StringHolder. For example, createRequest() has two parameters of this type, NewRequestHandle and NewRequestNumber.

```
StringHolder NewRequestNumber = new StringHolder();
StringHolder NewRequestHandle = new StringHolder();
String result;
result = USPSD.createRequest(sid, creatorHandle, attrVals, propertyValues, template,
attributes, NewRequestHandle, NewRequestNumber);
```

The Request's handle and reference number (ref_num) can then be obtained from NewRequestHandle.value and NewRequestNumber.value respectively.

SOAP Web Services Configuration

You can configure the CA SDM SOAP Web Services with entries in special web configuration files. The following table summarizes the names and descriptions of the configuration options:

Option Name	Description
design_mode_stubs	Sets the Web Service *to design mode* (CA SDM only).
require_secure_logon	Requires the login() and loginService() web methods to be called with a secure protocol, such as https.
require_secure_connection	Requires that every web method be called with a secure protocol.
disable_user_logon	Disables both login() and loginService() web methods, so only loginServiceManaged() can be used to log in.

CA SDM adds protection to the integrity of the running Tomcat server by verifying the length of the attribute values that pass to Web Service methods. By default, web service calls return an Axis Fault if the length of an attribute exceeds 900,000 bytes.

You set the following parameters in the deploy.wsdd file:

- **fatal_max_string_length**
  Sets the length of the largest attribute value that a web service method accepts.
  Default: 900,000 bytes

- **validate_parameters**
  Sets whether the attribute value length checking is performed. Set the parameter to 0 to turn off the validation.
  Default: 1 (on)

- **exception_methods**
  Displays a comma-delimited list of Web Service methods that are exempt from the attribute value length validation.

Redeploy the Web Services

New configuration settings take effect when you redeploy CA SDM Web Services. Complete the following steps to redeploy the Web Services:

1. Open a command prompt and set the CLASSPATH environment variable to include the required Axis jar files, which are supplied in <NX_ROOT>/java/lib.
   For example, to set it on Windows, execute the following command:

   ```
   set AXISHOME=%NX_ROOT%\java\lib
   set classpath= %AXISHOME%\axis.jar;%AXISHOME%\jaxrpc.jar;%AXISHOME%\saaj.jar;%
   AXISHOME%\commons-logging.jar;%AXISHOME%\commons-discovery.jar;%AXISHOME%
   \wsdl4j.jar;%AXISHOME%\log4j-1.2.8.jar;%classpath%;
   ```

2. Modify the directory to <NX_ROOT>/sdk/websvc/R11 and execute the following commands:

   ```
   java org.apache.axis.client.AdminClient undeploy.wsdd
   ```

```
java org.apache.axis.client.AdminClient deploy.wsdd
```

3. Recycle Tomcat by recycling the CA SDM service. You can avoid shutting down the entire CA SDM system by recycling Tomcat by simply using the following commands:

   ```
   pdm_tomcat_nxd  - c stop
   pdm_tomcat_nxd  - c start
   ```

   The Web Service is redeployed.

4. Verify that the service deployed by viewing the Axis services listing page at the following default URL:

   ```
   http://<servername>:< port>/axis/services
   ```

   Note: The exact URL depends upon your installation settings.

SOAP Error Handling

If an error occurs with a Web Services method, a SOAP Fault is returned. The SOAP Fault is the standard means of returning exception information for Web Services.

The Fault message contains standardized <Message> and <Code> elements, but the most informative is the <Detail> element. The <Detail> element contains <ErrorCode> and <ErrorMessage> elements. The <ErrorCode> element returns an enumerated error code specific to either the CA SDM or Knowledge Management product. The <ErrorMessage> element contains an English string describing the errors. The <ErrorMessage> elements are more suitable for aiding the developer and more appropriate messages should display to users.

For example, the following illustrates a SOAP Fault when a bad parameter is supplied to the CA SDM getObjectValues() method:

```
<soap:Fault>
   <faultcode>soap:Client</faultcode>
   <faultstring>Error on fetch with attribute list:persistent_id,first_name,
last_nameParamErrorHere<faultstring>
   <detail>
<ErrorCode>1001</ErrorCode>
<ErrorMessage>Error on fetch with attribute list: persistent_id,first_name,
last_nameParamErrorHere </ErrorMessage>
   </detail>
   </soap:Fault>
```

If you are using a client built with Microsoft .NET managed code, a failed Web Services method call raises a "SOAPException" exception. All errors cancel the operation invoked.

In some cases, the servlet container may write errors and therefore, display in the servlet container logs. In other cases, error information may be written to CA SDM logs. These logs are located in the following subdirectories:

- In the /bopcfg/www/CATALINA_BASE/logs subdirectory of CA SDM installation
- In the /log subdirectory of the CA SDM installation and to all logs that have the prefix “stdlog”.

Note: We recommend that you constantly monitor these logs, as the server may log its own errors without reporting them to the CA SDM Web Services.

Lock Errors

CA SDM objects are locked during updates. Methods that update objects (such as, updateObject() or transfer()) may return the following lock error code:

```
UDS_LOCK_ERR
```

This code indicates that another user is updating the record. Often the locking user’s handle is returned in the ErrorMessage element.

Time Outs

If the CA SDM server is heavily loaded, a method may take a long time to process. In rare cases, a method may never return because a separate process failed to reply or some other error occurred. To guard against excessive blocking, every Web Services method times out after a number of seconds. Web Services method time-out is a CA SDM server time-out, *not* a Web server time-out, network time-out, and so on.

Note: The Web Services delay a few seconds the first time accessed after the J2EE application server is recycled. This happens because the application is initializing, loading DLLs, libraries, and so on, and occurs only with the first Web Services method call. All subsequent calls return much faster.

If a method times out, it returns the following error code:

```
UDS_TIMEOUT_ERR
```

The operation is not aborted! The server may have received the request and processes it successfully, although slowly. This type of problem may occur when using the *doSelect( )* method to retrieve several 1000 records.

Note: For information about the *doSelect* method, see the CA Service Desk Manager Reference Commands (see page 3496) section.

Error Codes

The following table lists the possible values for the <ErrorCode> value in a SOAP Fault returned from a Web Services call:

Error Name	Value	Description
UDS_OK	0	Successful.
UDS_FAILURE	1	General failure, check system logs.
UDS_BAD_PARAM	1000	A bad parameter was passed to a method. This error occurs if a required parameter is missing, the wrong type was passed, or an invalid value was used.
UDS_INTERNAL_ERR	1001	Signals that an internal error occurred. A description is found in the return array and the system logs.
UDS_LOCK_ERR	1002	An attempt was made to update an object locked by another user or process. Usually the ID of the contact responsible for locking the object is returned in the return data.
UDS_UPDATE_ERR	1003	An error occurred updating an object. Make sure all required attributes were set and check the system log.
UDS_CREATION_ERR	1004	An error occurred creating an object. Make sure all required attributes were set and check the system logs.
UDS_NOT_FOUND	1005	A search method failed to find any matches or failed to find an object specified. This can happen if a bad or invalid handle is passed to any method.
UDS_SESSION_TIMEOUT	1006	The current method timed out, the CA SDM server may be heavily loaded or the method itself was bad.
UDS_SERVER_GONE	1007	The CA SDM server connection is lost, UDS methods will no longer function and all list references are lost.
UDS_FETCH_ERR	1008	An error occurred while retrieving list data.
UDS_BAD_SESSION	1010	An invalid SID was used.
UDS_CNTXT_TIMEOUT	1011	The SID timed out.
UDS_SECURE_CHANNEL_REQUIRED	1012	The Web Services (or a web service method) requires a secure channel (for example: SSL) for access, but an unsecured channel is being used.
UDS_SECURITY_VIOLATION	1013	The attempted operation violates CA SDM security and was aborted.
UDS_OVER_POLICY_LIMIT	3002	The attempted request is refused because it exceeds the limit defined in the policy.

User Authentication and Authorization

CA SDM lets you specify user access authentication and the features available by access control and management.

User Access Authentication

CA SDM Web Services provides two access authentication schemes. They are associated with the new access control and management feature, which uses an access policy.

- **User Name/Password**
  Verifies the User Name/Password, as described in previous releases of the product.

- **Public Key Infrastructure (PKI) Technology**
  Verifies that the person requesting the access has ownership of a certain private key.

Important! If you plan to use an application that accesses this version of CA SDM Web Services, we recommend strongly that you first define a Web Service Access Policy, complete with its code value, in CA SDM. A default access policy with a policy code of DEFAULT is available when CA SDM is installed and configured.

Credential Authentication

This article contains the following topics:

If you plan to use the User Name/Password type of access authentication, the user application needs to invoke one of following two web services methods to gain access to CA SDM Web Services.

Note: The login user that you specify in the username parameter (not the proxy contact specified in the policy) is responsible for activities initiated in a session. All function group security and data partition is enforced for this login user.

login (Username, Password)

This method is provided for backward compatibility, where access authentication is performed on the username and password supplied. A SID (session ID) is returned only if the access is authenticated. All subsequent web services calls need to include this SID. Default access policy is then applied to all subsequent web services accesses labeled with the SID.

Username and password are required fields that require plain text when you define them.

loginService (Username, Password, Policy)

This method is similar to the previous login function in that access authentication is performed on the username and password supplied. A SID is returned only if the access is authenticated. However, a specific access policy, as identified in the third parameter, is applied to control and manage all subsequent Web Services accesses. Empty content in the policy parameter automatically applies the default policy.

Username and password are required fields that require plain text when you define them. Policy is required, but can be empty, and you must use plain text. Use the policy code defined in a policy.

How a login is validated depends on the contact's assigned *access type*. The access type object is hosted by CA SDM and sets the validation type. You can use the product to view the access type record, and you can also use the getAccessTypeForContact() web method to retrieve any access type object information.

Note: For more information about access types, see the Security and Role Management (see page 1986) section.

CA SDM REST API

This article contains the following topics:

Representational State Transfer (REST) is a style of software architecture for distributed hypermedia systems such as the World Wide Web. The CA SDM REST API lets application, integration, and web developers build UIs and applications for devices such as tablet computers and smartphones. Users such as analysts, employees, and customers can then use the UI or application on these devices. For example, application developers can develop a CA SDM UI that lets analysts use devices to update tickets.

The REST API accesses resources by using a Uniform Resource Identifier (URI) -- a character string that identifies a name or resource on the Internet. In CA SDM, resources can be objects such as tickets, assets, contacts, and so on. An application using the REST API makes an HTTP request to a URI and parses the response. Such identification enables interaction with representations of the resource over a network. Each client to server request contains all the information necessary to understand the request, and does not use any stored context on the server.

Developers use the REST API directly to send HTTP requests to the server for the resource they want to manipulate. Developers only need an HTTP client library, which is available with most programming languages. Because the REST API is based on open standards, you can use any Java programming language to access it.

Note: For information about REST HTTP methods, see the REST HTTP Methods (see page 3981).

REST and SOAP

CA SDM provides REST and SOAP web services APIs. The audience for the REST API is a UI client whereas the audience for the SOAP API is a program. REST services are about resources (manipulating objects, changing object states, exchanging representations, and using nouns rather than verbs). SOAP services are about services (calling methods, using verbs, and doing actions).

REST provides the following advantages over SOAP:

- REST is lightweight, HTTP-based, and stateless (for scalability).
- REST supports client bookmarking and caching.
- REST maintains data contract loosely.
- REST is easily consumed by front-end technologies such as WEB 2.0 and AJAX.
- REST supports XML and JSON data formats.
- REST improves performance.

REST Security

Security uses multiple authentication mechanisms including a custom approach that uses shared secret keys.

The product supports the following security authentication schemes:

- REST web services secret key authentication (uses SSL and HMAC for login)
- REST basic authentication (clear text encoded username/password)
- REST BOPSID authentication (validates CA SDM BOPSIDs)
- External (CA EEM) artifact authentication (CA EEM artifact token)

How Secret Key Authentication Works

The CA SDM Secret Key authentication is a process that verifies the following:

- The identity of the request sender.
- That the sender is a registered user.

Secret Key authentication requires that each request includes information about the identity of the request sender. The request must also include additional information that CA SDM can use to verify the authenticity of the user. When the request passes this verification test, the request is determined to be authentic. During authentication for an Access Key request, CA SDM secret authentication does the following:

1. Assigns an access key to a client. The access key identifies the client responsible for a request and uses the CA SDM session ID as the key value. Because an access key is sent as a request parameter, it is not secret. Anyone sending a request to CA SDM can use the request parameter, therefore, a secret key is needed.

2. Assigns a secret key. A secret key is a 40-character alphanumeric sequence dynamically generated by CA SDM during login. The product encrypts this secret key before storing it in the database.

3. Uses client-provided information (a request signature using the secret key) to identify the client and verify that the request is legitimate. This additional information protects users from impersonation and demonstrates possession of a shared secret known only to CA SDM and the sender of the request.

How to Version System Customizations Across CA SDM Servers

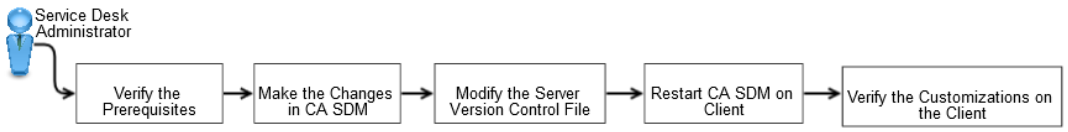
CA SDM version control helps you to manage the system customizations across all CA SDM servers (client and servers). Depending upon the CA SDM configuration, the following client and servers are used:

- Conventional configuration,
  - Client: Secondary server
  - Server: Primary server
- Advanced availability configuration,
  - Client: Application and Standby servers
  - Server: Background server

Example: As a system administrator, you added a field in the detail_usp_server.htmpl page of CA SDM. Now, you want to synchronize this change across the client and the servers. This example is used throughout the scenario to explain how the customization is synchronized.

The following diagram shows how to version the system customizations across the CA SDM servers:

How to Version System Customizations Across CA SDM Servers



Follow these steps:

1. Verify the Prerequisites (see page 1891).

2. Make changes in CA SDM. In this example, add the new field in the CA SDM HTMPL page.
3. Modify the Server Version Control File (see page 1891).
4. Restart CA SDM on Client (see page 1896).
5. Verify the Customizations on the Client (see page 1897).

Verify the Prerequisites

Verify the following prerequisites:

- Ensure that the ver_ctl option set to the **upgrade** value. When a version discrepancy is detected, an upgrade of the affected components is attempted on the client. If the upgrade is successful, the client connection with the server continues; otherwise, the connection terminates. For more information about the ver_ctl option, see the *Online Help*.
- Ensure that the server_secondary_custom.ver file is created at $NX_ROOT\site\mods directory of the primary server or background server (depending upon the CA SDM configuration). All customizations to a version control component must be done in this file. If the file does not exist, ensure that you create it at the same location.

Modify the Server Version Control File

After you complete the customization, (for example, added a field in the HTMPL page) add or update the version control components on the server version control file. A version control component can represent a file, directory, or the client_nx.env environment variable file.

Follow these steps:

1. Log in to the following server depending on your CA SDM configuration:
   - Conventional: Primary server
   - Advanced availability: Background server
2. Go to the following directory:

   ```
   $NX_ROOT\site\mods
   ```

3. Open the server_secondary_custom.ver file.
4. Add the following components:

   ```
   [ MY_USP_SERVERS_HTMPL ]
   directory="$NX_ROOT/site/mods/www/htmpl/web/analyst/Analyst"
   filename="detail_usp_servers.htmpl"
   version="2.0 , 20121119"
   o_mode="RW"
   g_mode="RW"
   w_mode="RW"
   file_ctl
   ```

Note: For more information about adding or updating version control components, see the Version Control Component (see page 1892) topic.

5. Save the server_secondary_custom.ver file.
   The version control component is added in the version control file.

Version Control Components

To define a new component,

- Use the following syntax. Items in *italics* represent data that you supply. The *component-name* and version parameters are always required. Other parameters are required, depending on the value of *control-type*. All other items represent keywords that you must enter exactly as shown in the following example:

```
[ component-name ]

version = "x.x, yyyymmdd"

control-type

filename = "filename"

directory = "directory"

link = "link-directory"

source = "source-directory"

effectivity = "effect-spec"

checksum

min_release = "release"

max_release = "release"

component_type = "file-type"

o_mode = "owner-mode"

g_mode = "group-mode"

w_mode = "world-mode"
```

Note: For more information about the parameters, see Version Control Parameters (see page 1893). For more information about the structure and syntax of version control files, see the .ver files that are installed in the $NX_ROOT\site directory. These files have useful comments and example settings that can help you.

To update an existing component entry,

- Change the parameter. For example, you change the version number.

To remove control from a component,

- Edit the component as follows:

```
! uncontrol component-name
```

Version Control Parameters

The following parameters apply to version control:

- **[component-name]**
  Specifies the name of an item under version control. The name must be unique and enclosed in square brackets. *component-name* is not case-sensitive. This parameter is required to begin a component definition.

- **version="x.x. yyymmd"**
  Specifies a version number (*x.x*) and a date (*yyyymmdd*) that define the version of the component. This parameter is required, and must be enclosed in double quotes. Version control verifies the version of a component by comparing the version number and date on the server with the version number and date on the client. Both version number and date must match for the component to be considered in sync between the client and server. Optionally, if the checksum property is enabled, the file is verified by checksum verification before being updated.

- **control-type**
  Specifies the type of version control for this component. The following settings are valid for control-type:

Setting	Description
dir_ctl	Specifies that the component represents a directory. You must provide the directory parameter to specify the path to the directory. You can also provide the filename parameter to specify the filename parameter to filter a set of files in the directory. Subdirectories are not upgraded on either UNIX or Windows.
file_ctl	Specifies that the component represents a file. You must provide the directory and filename parameters to specify the path to the file.
Nxenv _ctl	Specifies that this component represents the client_nx.env file, which is used to store internal CA SDM environment variables. CA SDM version control and the Options Manager automatically maintain this file. There is one nxenv_ctl component, and its component name must be CLIENT_NXENV.
ver_ctl	This is the default control type. It specifies that the component is generic; that is, not associated with any specific external object. You can use a generic component to provide version control for the client as a whole, or for a file or directory too large for an automatic upgrade. Components with a control type of ver_ctl cannot be upgraded; a version mismatch on a ver_ctl component when the server is in UPGRADE mode causes the client connection to fail.

- **filename="filename"**
  Specifies the name of a file under version control. It does not contain directory specifications. This parameter is required for file_ctl components, but is optional for directory (dir_ctl) control components. When used with directory components, the filename parameter acts as a file mask to restrict the files associated with the dir_ctl component. For example, if the filename for a dir_ctl component is *.README, then an upgrade from that directory includes only files ending with ".README.".

- **directory="directory"**
  Specifies the path to the directory for dir_ctl components, or to the directory containing the file for file_ctl components. This parameter is ignored for ver_ctl and nxenv_ctl components. The directory path must be enclosed in quotes, and can contain references to environment variables preceded with a $.

  Note: Always use forward slashes (not backslashes) to separate subdirectories in the path name, even on a Windows server.

- **link="link-directory"**
  Specifies a link directory on the client in the same format described previously for directory parameter. This parameter is optional for file_ctl and dir_ctl components, and ignored for ver_ctl and nxenv_ctl components. If it is specified, an upgrade to a Linux client causes a symbolic link to be placed in the link directory, pointing to the actual file copied to the location specified by the directory parameter. An upgrade to a Windows client causes the actual file to be copied to both the link and directory locations.

- **source="source-directory"**
  (Optional) Specifies a different directory on the server where the server can retrieve files for delivery. This parameter has the same format described previously for the directory parameter. It is useful if the files that are to be delivered to the client are different from the same files in the directory location on the server. This parameter is used to tell the server to retrieve the file from *source-directory* and deliver it to the location on the client specified by the directory parameter. The directory parameter is required if you specify the source parameter.

- **effectivity="effect-spec"**
  (Optional) Specifies whether the client should get this component. It lets you exclude download to some clients. If a client is not included in the effectivity specification, it does not get the component. If this parameter is omitted, all clients receive the component. The effectivity specification uses the following symbols:

  - **+ (plus sign)**
    Indicates to add a client group.

  - **- (minus sign)**
    Indicates to exclude a client group.

The following client groups are valid:

- SUN4SOL
- AIX
- LINUX
- LINUX390
- HP
- WINDOWS_CLIENTS

- UNIX_CLIENTS

For example, the following specification indicates that only UNIX clients get the files:

```
effectivity = "+ UNIX_CLIENTS"
```

- **checksum**
  Directs the component to upgrade if the checksum of the component on the client does not match the corresponding checksum on the server. If it is applied to a directory, then checksum is applied to each file.

- **min_release="release" and max_release="release"**
  Specifies the oldest and latest client to which this component should be distributed. Statements in the server_default.ver file define releases. These parameters are in the following form, where G*axx* indicates the release, and the values following are genlevels associated with the release.

  ```
  ! Release GA50 50MVV000900 50W7T000900

  ! Release GA45 45MW000900 50WTT000900
  ```

  The order indicates that GA50 is newer than GA45.

- **component_type**
  Specifies the type of component used. Following types of components are used:

Setting	Description
file	This is the default component type. It specifies that files copied to the client be obtained directly from the location on the server indicated by the directory parameter.
exe_file	Specifies that files copied to the client be obtained from a location on the server that is dependent on the client's operating system, as shown by the following: windows (Windows) sun4Sol (Solaris) hp (HP-UX) aix -- AIX) linux (Linux) linux390 (Linux390) Locations for these subdirectories are dependent on the directory parameter setting. If this parameter is set, then subdirectories are located under the indicated *directory*. Otherwise, they are located under the bin directory of the main CA SDM installation directory.

- **o_mode="owner-mode"**
  Specifies file access permissions for the owner of the file.

- **g_mode="group-mode"**
  Specifies file access permissions for users in the file owner group (used for UNIX clients only).

- **w_mode="world-mode"**
  Specifies file access permissions for users not in the file owner group (used for UNIX clients only).
  The three mode parameters allow different versions of the same executable to be maintained on the server. They specify access controls on the file when copied to the client. These parameters are used only during an upgrade operation. They consist of one to three characters, with the following significance:

Setting	Description
R	Read
W	Write
X	Execute

PC clients ignore Write and Execute permissions.

You can specify any combination of one or more file access modes. On UNIX clients, the file is given the access mode of specified. On PC clients, the file is made writable or read-only, depending on whether w_mode has been specified.

Restart CA SDM on Client

You restart CA SDM on the client servers to update the client version control files with the customizations.

Note: Select **Start**, **Settings**, **Control Panel**, **Administrative Tools**, **Services**. Right-click the **CA SDM Server** and choose **Start** to restart or start a server.

Follow these steps:

1. For the conventional configuration, restart the secondary server.
2. For the advanced availability configuration, complete the following steps:
    a. Restart all standby servers.
    b. Choose the less active application server (see page 1896).
    c. Restart the less active application server.
    d. Stop the other application server (see page 1897).
    e. Start the application server.
    f. Performs steps d and e for more application servers.

    The client connects to the server to send a list of its controlled components. The server compares the list to its own master list. The affected components on the client are upgraded.

Choose the Less Active Application Server

You choose an application server with the least user activity. Run the following command on each application server to choose the one with no or minimal active sessions.

```
pdm_webstat
```

Note: This command does not capture the SOAP or REST Web Service sessions.

Stop the Other Application Server

You inform all the active users on an application server to move to the less active application server before you stop it. Ensure that you have restarted the less active application server before moving all the users to it.

Follow these steps:

1. (Recommended) Inform all active Support Automation analysts on the application server which you want to stop, to create a ticket in CA SDM with their session information. This process ensures that the session information is not lost. For example, the Support Automation analyst is in a session with a customer to resolve a hardware issue. In such a case, the Support Automation analyst can create an issue in CA SDM with the session information before the application server shuts down.

2. Send a notification (for example, an email notification) to all the active users on the application server to move to the less active application server that you just restarted. This notification can include the details of the updated application server.

3. Execute the following command on the application server:

   ```
   pdm_server_control [-h] -q interval -s server_name
   ```

   - **-h**
     Displays the help page.

   - **-q interval -s server_name**
     Notifies a local or remote application server to quiesce in a specified time interval. This interval is the number of seconds before the server goes offline. When using this option without a server_name, the local server is notified to quiesce. This option cannot be used for a background or a standby server.

   A pop-up message is displayed to all the active users on the application server to notify them about the server shutdown and the time left for the shutdown. The users must save their work and logout within that time. The application server stops after the specified time. The users log on to the other application server to resume their work. The Support Automation analyst can refer to the ticket and resume their work.
   The application server is stopped successfully.

Verify the Customizations on the Client

You verify the version control file on the client to check if all customizations have been synchronized.

Follow these steps:

1. Log in to the following client depending on your CA SDM configuration:

   - Conventional: Secondary server

- Advanced availability: Standby server and Application server

2. Open the stdlog file from the following location:

   ```
   $NX_ROOT\log
   ```

3. Find out if all the customizations made on the server are applied on the client.

Using the Web Screen Painter (WSP)

Web Screen Painter (WSP) is a component of the CA SDM that provides tools for designing and customizing CA SDM forms. You can modify the existing forms to suit your needs, and you can create forms from scratch. WSP helps you reduce the time and effort it takes to modify and test HTMPL forms. With customized forms, your service desk analysts and customers can quickly find and enter the information that is important to your organization.

With WSP, it is also very easy to modify the database schema, such as adding new tables or columns to the database. It provides a user-friendly interface and automates the complex process of updating a schema. Using WSP, you can build and test forms using custom schema before making any changes to the database.

Readonly Preview Session

In order to allow you to preview how an updated form looks with real data, Web Screen Painter (WSP) previews forms with data from your CA SDM database. Forms you preview in WSP appear in this browser window. Since this is a readonly session, all update operations are ignored. As a reminder of this, the caption of all "Save" buttons is changed to "noSave". Please use WSP itself to logout from this session.

For detail forms, WSP shows the edit version of a form (you can display the readonly version by pressing the noSave button). When you preview a tab, WSP shows the entire detail form containing the tab, with the notebook opened to the previewed tab.

To prevent inadvertent damage to production data from a previewed form in edit mode, WSP normally suppresses updates from a preview session, so that you cannot modify the database from a preview session. To indicate this, WSP automatically changes the text on a "Save" button to "noSave", and displays a small red WSP palette in the upper left corner of the form. You can still press the noSave button (or take other actions that would normally modify the database), but CA SDM will discard your changes.

Optionally, your CA SDM system administrator may choose to enable updates from preview. When this is done, "Save" buttons are displayed normally, and the WSP palette is yellow. You should be cautious when updating the database from a preview session, as WSP preview sometimes bypasses the normal procedure for reaching a form, and the form's environment may not be completely set up. To ensure updates work correctly, return to the CA SDM main form and navigate to your form as you normally would in a standard (non-preview) CA SDM session. For more information about enabling updates from the preview session, see Assign Web Screen Painter Permissions to an Access Type (see page 1986).

Open the CA Standard Version of a Form

The CA standard version of a form is the same form with no site modifications (although it may contain CA-supplied patches). The edit window for the CA standard version of a form includes the words CA STANDARD VERSION in its title.

Follow these steps:

1. Open the form in Web Screen Painter.
2. Click File, Open CA Standard Version.

Insert Controls to a Form

The Insert menu on WSP inserts a field on the form. The insert menus follow:

- **Insert Row**
  Inserts a new row in the form on which you can place controls. If a control is selected, it causes the selected control to be the last in its row, and moves following controls to the new row.
- **Delete Row**
  Deletes a complete row. If there are controls on the row, WSP prompts you before deleting the row along with the controls.
- **Insert Textbox**
  Inserts a simple text field on the form. A text field is displayed as a box where the user can enter unedited text.
- **Insert Dropdown**
  Inserts a dropdown (select) field on the form. A dropdown box is displayed as a list of selections for a field. The user can click the dropdown arrow to choose a response from the list.
- **Insert Lookup**
  Inserts a lookup field on the form. A lookup field is displayed as a text box with a header consisting of a small magnifying glass icon followed by a link that the user can click to display a selection list.
  Lookup fields have an autofill feature. If a user clicks the hyperlink and the text specified is sufficient to identify a value in the underlying table, the pop-up search form is suppressed and CA SDM fills in the value. In addition, if the Autofill configuration property is set and the user presses the Tab key to leave a field after supplying a value, the effect is the same as clicking the hyperlink; either the value is filled in or a pop-up search form appears.
- **Insert Hierarchical Lookup**
  Inserts a hierarchical lookup field on the form. A hierarchical lookup field is displayed as a text box with a header consisting of a small plus sign icon followed by a link that the user can click to pop-up a hierarchical selection list.
  Hierarchical search fields have an autofill feature. If a user clicks the hyperlink and the text specified is sufficient to identify a value in the underlying table, the pop-up list form is suppressed and CA SDM fills in the value. In addition, if the Autofill configuration property is set and the user presses the Tab key to leave a field after supplying a value, the effect is the same as clicking the hyperlink; either the value is filled in, or a pop-up search appears.

- **Insert Date**
  Inserts a date field on the form. A date field is displayed as a text box with a header consisting of a small calendar icon followed by a link that the user could click to pop-up a date helper to allow specification of the date.

- **Insert HTML Editor**
  Inserts an HTML editor on the form for a text field that contains HTML. An HTML editor field is displayed as a multi-line text box with a header containing icons that a user can click to insert HTML tags into the text.

- **Insert Checkbox**
  Inserts a checkbox field on the form. Use checkboxes when an option may be toggled on and off.

- **Insert Read Only Textbox**
  Inserts a read-only version of the textbox field. A read-only textbox field is displayed as simple text.

- **Insert Read Only Lookup**
  Inserts a read-only version of the of the lookup field. A read-only lookup field is displayed as a hyperlink that the user can click to display the detail form for the field's value.

- **Insert Read Only Date**
  Inserts a read-only version of the date field. A read-only date is displayed as simple text, formatted as a date.

- **Insert Button**
  Inserts a rectangular button on the form. The button invokes the JavaScript string associated with it.

- **Insert Notebook**
  Inserts a Notebook with three tabs. You can use the Notebook Designer to delete tabs or insert additional tabs. A notebook allows several sets of fields to be displayed in the same physical area of the screen, with only one set visible at a time. The user can select the set of fields that is visible by clicking a named tab at the top of the notebook.

- **Insert If/Else If/Else/End If**
  Inserts conditional logic that allows a form's layout and contents to be controlled at the time the form is displayed.

- **Insert Object**
  Inserts an Object tool to place an object control on the form. Place an object control on the form when you want to introduce specific code. You can place the object control on the form in Design mode and edit the code in the Object Designer.
  If WSP cannot recognize something on a page, it converts it into an Object control. For example, an Object tag could represent straight JavaScript or Java between PDM_MACRO tags.

Add Controls to Detail Forms

This article contains the following topics:

- Add a Hierarchical Lookup Box (see page 1903)
- Add a HTML Editor (see page 1904)
- Add a Notebook (see page 1904)
- Add a Lookup Box (see page 1906)
- Add a Read Only Date (see page 1907)
- Add a Read Only Lookup Box (see page 1907)
- Add a Read Only Text Box (see page 1907)
- Add a Text Box (see page 1908)
- Add Conditional If (see page 1908)
- Add Conditional Else If (see page 1909)
- Add Conditional Else (see page 1909)
- Add Conditional End If (see page 1909)
- Add Object Button (see page 1909)
- Add a Row (see page 1910)

The Controls available in the ToolBox vary depending on the type of form that is open currently. When a Detail type form is open, the following controls are available in the ToolBox.

- Checkbox
- Command Button
- Date
- Dropdown Box
- Hierarchical Lookup Box
- Tab
- Lookup Box
- Read Only Date
- Read Only Lookup Box
- Read Only Text Box
- Text Box
- Conditional If
- Conditional Else If
- Conditional Else
- Conditional End If
- Object Button

- Row

Add a Checkbox

You can add a Checkbox control to a form.

Follow these steps:

1. Click the CheckBox button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Checkbox control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.

   The Properties dialog lists the following properties for a checkbox control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Event (see page 1915)
- On (see page 1915)
- Off (see page 1915)

Add a Date

You can add a Date control to a form.

Follow these steps:

1. Click the Date button  on the Control Palette and then, click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Date control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a date control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Size (see page 1915)
- Time (see page 1915)

Add a Dropdown Box

You can add a Dropdown box control to a form.

Follow these steps:

1. Click the Dropdown button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Dropdown Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a dropdown control:

- Attribute (see page 1915)
- Autofill (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Default (see page 1915)
- Event (see page 1915)
- Factory (see page 1915)
- Initial (see page 1915)
- Link (see page 1915)
- Lookup (see page 1915)
- Size (see page 1915)
- Where Clause (see page 1915)

Add a Hierarchical Lookup Box

You can add a Hierarchical Lookup Box control to a form.

Follow these steps:

1. Click the Hierarchical Lookup button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Hierarchical Lookup control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a hierarchical lookup control:

- Attribute (see page 1915)

- Autofill (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Event (see page 1915)
- Factory (see page 1915)
- Size (see page 1915)

Add a HTML Editor

You can add a HTML Editor to a form.

Follow these steps:

1. Click the HTML Editor button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The HTML Editor is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a HTML editor control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Event (see page 1915)
- Max Length (see page 1915)
- Option ID (see page 1915)
- Preview (see page 1915)
- Read Only (see page 1915)
- Rows (see page 1915)
- Size (see page 1915)
- Spell Check (see page 1915)
- Toolbar

Add a Notebook

Add a notebook to modify how HTMPL forms appear.

Follow these steps:

1. Create a form in WSP, such as a form based on detail.template.
   The HTMPL file opens.

2. Click the Source view and add the following lines of code:

   ```
   <PDM_MACRO name=startNotebook hdr=cng_nb>
   <PDM_MACRO name=endNotebook>
   ```

3. Click the Design view.
   The notebook area appears after the text box, such as shown in the following example:

   
   BSVC--WSP Notebook Design--SCR

4. Click the Source view and add the following example code after the <PDM_MACRO name=startNotebook hdr=cng_nb> line:

   ```
   <PDM_MACRO name=startTabGroup title="Additional Information">
   ```

   The following example shows the updated notebook area in Design view:

   BSVC--Additional Information Label--SCR

5. Click the Source view and add the following example code after the previous addition:

   ```
   <PDM_IF "$args.id" == "0">
   <PDM_MACRO name=tab title="Attachments" height=300 id=attmnt src="
   OP=SHOW_DETAIL+HTMPL=xx_attmnt_tab.htmpl+FACTORY=cr+PERSID=$args.
   persistent_id+NO_DP=yes">
   <PDM_ELSE
   ```

   The following example shows the updated notebook area in Design view:

   BSVC--Attachments Tab--SCR

6. Continue adding tab groups and end the notebook with the following code:

```
<PDM_MACRO name=endNotebook>
```

Note: Open default forms in WSP to view how notebooks and nested tab groups appear. For example, open the detail_in.htmpl form. You can also move tabs and tab groups within a notebook using drag-and-drop in Design view. Moving a tab group moves all the tabs within the group with it.

7. To insert a tab or tab group, right-click a control or within the notebook background and select Insert Tab, Insert Tab Group, or Insert Control (see page 1899).
   If you select Insert Tab or Insert Tab Group, WSP inserts a new tab or tab group to the left of the currently selected control. If you select Insert Control, WSP displays the Insert Control dialog that lets you add the desired control to the form.

8. Click Preview.
   Your unpublished changes appear in the web browser.

9. Save the form.
   The notebook is added.

Add a Lookup Box

You can add a Lookup Box control to a form.

Follow these steps:

1. Click the Lookup button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Lookup Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a lookup control:

- Attribute (see page 1915)
- Autofill (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Event (see page 1915)
- Factory (see page 1915)
- Link (see page 1915)
- Size (see page 1915)

Add a Read Only Date

You can add a Read Only Date control to a form.

Follow these steps:

1. Click the Read Only Date button  on the Control Palette and then, click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Read Only Date control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a read-only date control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Time (see page 1915)

Add a Read Only Lookup Box

You can add a Read Only lookup box control to a form.

Follow these steps:

1. Click the Read Only Lookup button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Read Only Lookup control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a read-only lookup control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Link (see page 1915)

Add a Read Only Text Box

You can add a Read Only text box control to a form.

Follow these steps:

1. Click the Read Only Text Box button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Read Only Text Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a read-only text box control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- ID (see page 1915)

Add a Text Box

You can add a text box control to a form.

Follow these steps:

1. Click the Text Box button  on the toolbar, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Text Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a text box control:

- Attribute (see page 1915)
- Caption (see page 1915)
- Column Span (see page 1915)
- Event (see page 1915)
- Keep Links (see page 1915)
- Keep Tags (see page 1915)
- Max Length (see page 1915)
- Rows (see page 1915)
- Size (see page 1915)
- Spell Check (see page 1915)

Add Conditional If

You can add a conditional if control to a form.

Follow these steps:

1. Click the If button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Conditional If control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for an if condition:
   Condition (see page 1915)

Add Conditional Else If

You can add a conditional else if control to a form.

Follow these steps:

1. Click the Elif button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Conditional Else If control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for an else if condition:
   Condition (see page 1915)

Add Conditional Else

To add a conditional else control to a form:

1. Click the Else button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Conditional Else control is placed on the form.

Add Conditional End If

To add a conditional end if control to a form:

1. Click the Endif button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Conditional End If control is placed on the form.

Add Object Button

You can add an Object Button control to a form.

Follow these steps:

1. Click the Object button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   The Object Button control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Object Code dialog appears so you can define the source associated with the Object control.

Add a Row

To add a Row control to a form:

1. Click the ROW button  on the Control Palette and then, click the left mouse button and hold it down as you drag-and-drop it on the desired location.
   A blank Row is placed on the form. You can place the controls on the row.

Add Controls to List Forms

This article contains the following topics:

The controls available for a List form are different from the controls available for a Detail form. Some of the controls in the List form have a different set of properties compared to the controls in the Detail forms. When a List form is open, the following controls are available in the ToolBox in addition to the conditional logic controls like IF, Else, and so on, which are exactly the same the controls in the Detail form.

- Date
- Drop down Box
- Hierarchical Lookup Box
- Lookup Box
- Results List
- Text Box

Add a Command Button

To add a Command Button control to a form

1. Click the Command Button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and- drop it on the desired location.
   The Command Button control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the drop down list.
   The Properties dialog lists the following properties for a command button control:
   Caption (see page 1915)
   Disabled (see page 1915)
   Function (see page 1915)
   ID (see page 1915)
   Tooltip (see page 1915)
   Width (see page 1915)

Add a Date

To add a Date control to a form

1. Click the Date button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location of the form.
   The Date control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the drop down list.
   The Properties dialog lists the following properties for a date control:
   Attribute (see page 1915)
   Caption (see page 1915)
   Column Span (see page 1915)
   QBE Condition (see page 1915)

Add a Dropdown Box

To add a Dropdown Box control to a form

1. Click the Drop down button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location of the form.
   The Drop down Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the drop down list.
   The Properties dialog lists the following properties for a drop down box control:
   Attribute (see page 1915)
   Caption (see page 1915)
   Column Span (see page 1915)
   Default (see page 1915)
   OP Code (see page 1915)

Add a Hierarchical Lookup Box

To add a Hierarchical Lookup Box control to a form

1. Click the Hierarchical Lookup button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location of the form.
   The Hierarchical Lookup Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the drop down list.
   The Properties dialog lists the following properties for a hierarchical lookup control:
   Attribute (see page 1915)
   Caption (see page 1915)
   Column Span (see page 1915)
   Factory (see page 1915)

Add a Lookup Box

To add a Lookup Box control to a form

1. Click the Lookup button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location of the form.
   The Lookup control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog appears so you can define properties for the control. The Properties dialog lists the following properties for a lookup control:
   Attribute (see page 1915)
   Caption (see page 1915)
   Column Span (see page 1915)
   Factory (see page 1915)

Add Results List

To add a Results List control to a form

1. Click the List button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location of the form.
   The Results List control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a lookup control:
   Custom

Add Text Box

To add a Text Box control to a form

1. Click the Text Box button  on the Control Palette, and then click the left mouse button and hold it down as you drag-and-drop it on the desired location of the form.
   The Text Box control is placed on the form.

2. Click the control, click the right mouse button, and select Properties from the dropdown list.
   The Properties dialog lists the following properties for a text box control:
   Attribute (see page 1915)
   Caption (see page 1915)
   Column Span (see page 1915)
   Disabled (see page 1915)
   QBE Condition (see page 1915)
   QBE Display (see page 1915)
   QBE Value (see page 1915)
   Size (see page 1915)
   Spell Check (see page 1915)

Customize a Form

This article contains the following topics:

After you open the form you want to edit in WSP, you can use the toolbar, menu commands, and shortcuts to customize it. You can perform the following customization:

- Insert a Control
- Edit Control Properties
- Modify Menu Bars
- Modify Stylesheets
- Modify Mouse-Over Preview Form
- Modify Data Grid List on List Form
- Modify Notebooks on Detail Form
- Modify HTML and JavaScript Files

Add Controls

There are four ways to add a new control to the screen. To add any type of control to a form, follow one of these examples:

Example 1: Drag-and-Drop

1. Click on the button in the Control Palette for the control that you want to add by holding down the left mouse button as you drag the control to the desired location on the form. Release the mouse button to place the control.
   The control is placed on the form.

2. Save the form when you finish adding controls.

Example 2: Double-Click and Reposition

1. Double-click the control you want to add in the Control Palette.
   The control appears on the form.

2. Place the mouse pointer over the control, then click the left mouse button and hold it down as you reposition the control on the form.
   The control is placed in the desired location on the form.

3. Save the form when you finish adding controls.

Example 3: Right-Click and Select

1. Right-click the form at the location where you wish to add the control.
   A dropdown list appears.

2. Select the control that you want to add from the dropdown menu.
   The control is placed on the form.

3. Save the form when you finish adding controls.

Example 4: Controls Menu

1. Click the Controls menu.
   Select the control you want to add from the dropdown menu..
   The control appears on the form.

2. Place the mouse pointer over the control, then click the left mouse button and hold it down as you reposition the control on the form.
   The control is placed on the form.

3. Save the form when you finish adding controls.

Arrange Controls on a Form

You can reposition a control on a form by selecting and dragging it. This changes the control's positioning properties, which set the relative placement of a control on a form.

To move controls:

1. On the form, select the control you want to move by left-clicking on it and holding down the mouse button.
   Handles appear around the selection as the following example shows:

BSVC_r12.1--Handle Bar

2. Drag the selected control to a new position on the form and release the mouse button.

Note: If necessary, choose Undo once from the Edit menu to reverse the most recent editing action, or choose Undo repeatedly to undo a series of actions.

Move a Control

To move a control by dragging, place the mouse pointer over the control, then click the left mouse button and hold it down as you reposition the control on the form.

To resize a control by dragging it:

1. Click to select the control.
2. Place the mouse pointer over a resizing handle so that the pointer changes to ↘, ⤢, ↕, or ↔ .
3. Click the left mouse button and hold it down as you drag the control to the appropriate size.

Note: Some controls, for example, conditionals, have a white border instead of black and cannot be resized. Also, you can change the height of only certain controls, for example, text boxes.

Control Properties

This article contains the following topics:

Attribute

The Attribute property specifies the field in a CA SDM table that is associated with the control. To set this value in the Properties dialog, click the Browse button that displayed at the right side of the selection box when you click on the cell to the right of the Attribute property. Then select the attribute you want from the Select Attribute tree, and click Select.

Autofill

The Autofill feature verifies and completes a lookup field before the form is submitted. If a user clicks the hyperlink and the text specified is sufficient to identify a value in the underlying table, the pop-up search form is suppressed and CA SDM fills in the value. Autofill is also activated when a user types a new value into a lookup field and presses Tab. This causes CA SDM to query the server for a list of all records eligible for the lookup field whose first few characters match the value specified. If it finds a match, it copies the full value into the field. If it finds more than one match, it pops-up a selection form.

The Autofill property is provided for dropdown fields because CA SDM can automatically convert a dropdown field to a lookup when the number of items exceeds a configurable threshold (see the Lookup property).

You can set the Autofill property for a dropdown box, hierarchical lookup box, or a lookup box control in the Properties dialog. To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Autofill property in the Properties dialog. No means that the control will not be filled in automatically when you tab out of it. True is the default Autofill value.

Caption

The Caption property specifies the header label that is displayed above a control. To specify this property, enter the desired value in the cell to the right of the Caption property in the Properties dialog.

Notebook tabs and list columns also have captions. Specify them on the Notebook (see page 1745) or List Designer (see page 1926) that replaces the Properties dialog for these controls.

You can set the caption for a menu item from the Menu Designer (see page 1745) dialog. To do so, select the appropriate item from the list and enter text in the Caption text box.

Column Span

CA SDM lays out controls on a detail form or a search filter in a HTML table, with controls in rows and columns of the table. The Column Span property specifies the number of columns occupied within the table by a control. To specify this property, enter the desired numeric value in the cell to the right of the Column Span property in the Properties dialog.

You can set the column span for a control from the Properties dialog. To do so, enter an integer in the cell to the right of the Column Span property.

Condition

The Condition property sets the conditional logic for the Conditional If and Conditional Else If controls. To specify this property, enter the desired logical condition in the cell to the right of the Condition property in the Properties dialog.

The syntax of the Condition property is as follows:

- 0 is false; any other number is true
- "" is false; “any-string” is true
- “value op value” evaluates the left and right values against each other according to op. If both values consist of digits (optionally preceded by - or +), the comparisons are done numerically. Otherwise, they are done lexically (ASCII collation). Valid op values include:

op values	What it means
==	Equal to
!=	Not equal to
>=	Equal to or greater than (must be written as \>= or >=)
<	Less than (must be written as \< or <)
>	Greater than (must be written as \> or >)
<=	Equal to or less than (must be written as \<= or <=)
&	Performs a bit-and of the left and right values. True if any bits are set; false if none are set
%	Returns true if the left value is an even multiple of the right value, and false otherwise (useful for building two-dimensional tables).

:	Performs a byte-oriented pattern match like the UNIX grep command. It returns true if the left value contains the regular expression defined by the right value

For example:

```
<PDM_IF $count \>= 10> . . .
<PDM_ELIF $count &lt; 5>  . . .
<PDM_ELSE> . . .
</PDM_IF>
```

A condition can include connectors, either && (and) or || (or). There is no precedence for either connector. The web engine examines a conditional from left to right until it reaches a connector. If the initial condition is true and the connector is ||, it considers the entire condition to be true without further evaluation. If the initial condition is false and the connector is &&, it considers the entire condition to be false without further evaluation. Otherwise, it considers the condition undermined, and evaluates the conditional from after the connector.

Default

The Default property specifies a default value for a dropdown field when the associated attribute is empty. To specify this property, enter the desired value in the cell to the right of the Default property in the Properties dialog.

When this property is specified and the underlying attribute has an empty value (normally only when a new record is created), the select box has the specified value automatically selected. This property has no effect if the specified value does not correspond to one of the selections in the dropdown, or if the field is displayed as a lookup. This property is optional; if omitted, the default for an empty attribute is to leave it empty.

Disabled

The Disabled property specifies whether the control is disabled on initial display. A disabled control is displayed in gray text, and the user can neither select it nor enter text into it.

To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Disabled property in the Properties dialog. To specify that a control should be disabled by default, select Yes for this property. A disabled control can be enabled only by JavaScript executed after the form is displayed.

If you specify Yes for the Disabled property in a textbox in the search filter part of a list form, you must also specify values for the QBE Condition, QBE Display, and QBE Value properties.

Event

The Event property specifies one or more event handlers to be associated with the attribute.

To specify this property, enter the desired value in the cell to the right of the Event property in the Properties dialog. Specify the value in the same format, as it would appear on an HTML statement, except that any double quotes in the handler string must be prefixed by three backslashes. For example, the Event property for the Request Area control on form detail_cr.htmpl is:

```
onChange=\\\"change_category_func('cr')\\\"
```

This specifies that the JavaScript function change_category_func('cr') should be invoked whenever the value of the field changes.

You can specify multiple event handlers in the same Event property by separating them with spaces. Consult HTML or JavaScript documentation for a list of available event handlers and their usage.

Factory

The Factory property specifies the CA SDM table referenced by a field in a lookup or dropdown control. This property is normally left blank, meaning that the factory defaults to the one associated with the attribute in the CA SDM object definition. It is seldom necessary or useful to override this value.

To specify this property, select the desired value from the dropdown displayed when you click in the cell to the right of the Factory property in the Properties dialog.

Function

The Function property of a menu item specifies the JavaScript invoked when the user selects the item. To specify this property, enter the desired value in the cell to the right of the Function property in the Menu Designer dialog. Any valid JavaScript can be specified for Function, except that double quotes must be preceded by a backslash.

The following predefined JavaScript functions may be useful:

- **upd_frame(form)**
  Loads a new form into the main window content frame.
- **create_new(factory, use_template, width, height [,args])**
  Pops-up a form to define a new record.
- **popup_window(name, form[, width, height [,features [,args]]])**
  Pops-up a new window.
- **showDetailWithPersid(persid)**
  Pops-up a detail record.

In the above functions:

- **form**
  Is either an HTMPL file name of the form xxx.htmpl or an operation code (example: CREATE_NEW).
- **factory**
  Is the name of a database object.
- **use_template**
  Specifies whether or not the new object should be created with a template that the user must select from a list. It can either be true or false.

- **width**
  Is the desired form width in pixels or zero for default.

- **height**
  Is the desired form height in pixels or zero for default.

- **features**
  Is a list of window features, in the same format as used with the JavaScript window.open() function.

- **args**
  Is one or more arguments of the form "keyword=value" for the operation specified for form.

- **persid**
  Is a persistent ID in the form factory:id.

ID

The ID property sets the HTML or JavaScript id of the command button, tab, or read-only text box controls for use in JavaScript that references the control. To specify this property, enter the desired value in the cell to the right of the ID property in the Properties dialog.

Initial

The Initial property specifies the initial value of a dropdown field. When this property is specified, the database value of the attribute associated with the control is ignored and the select box has the specified initial value selected.

To specify this property, enter the desired value in the cell to the right of the Initial property in the Properties dialog. The specified value should correspond to one of the selections in the dropdown; if it does not, the initial value for the dropdown is empty. This argument is optional; if not specified, the dropdown displays the database value of its associated attribute.

Keep Links

The Keep Links property specifies whether or not HTML Action: tags within a text box on the read-only view of a detail form are displayed as hyperlinks or as simple (non-clickable) text.

To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Keep Links property in the Properties dialog. Specify Yes for this property to specify that Action: tags should be displayed as hyperlinks. Specify the default value of No to specify that Action: tags should be displayed as literal text. HTML tags other than Action: tags are always displayed as literal text (unless the Keep Tags property is specified).

The Keep Links property is ignored if the Keep Tags property is specified as Yes. Note that this property affects only the read-only view of a detail form. HTML is always displayed as literal text in Edit view.

Keep Tags

The Keep Tags property specifies whether or not HTML tags within a text box on the read-only view of a detail form are formatted as HTML or as simple (non-clickable) text.

To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Keep Tags property in the Properties dialog. Specify Yes for this property to specify that HTML tags should have their normal effect. Specify the default value of No to specify that HTML tags should be displayed as literal text.

A value of Yes for Keep Tags overrides the Keep Links property. Note that this property affects only the read-only view of a detail form. HTML is always displayed as literal text in Edit view.

Link

The Link property specifies whether or not a Dropdown, Lookup, or Read Only Lookup field should be displayed as a clickable hyperlink in the read-only view of a detail form. A user can click on a field displayed as a hyperlink to show the detail of the record referenced by the field.

To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Autofill property in the Properties dialog. Select the default value of Yes to specify that the field should be displayed as a link on the read-only view; specify No to specify that the field should be displayed as simple non-clickable text on the read-only view.

Lookup

The Lookup property specifies whether or not a Dropdown control is converted into a Lookup control if the number of entries for the Dropdown control is exceeds an installation-specified threshold (normally ten).

To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Lookup property in the Properties dialog. Select the default value of Yes to specify that the Dropdown control should become a lookup control if the number of entries in the dropdown exceeds the threshold. Select No to specify that the control should always remain a dropdown, regardless of how many entries it contains.

Max Length

The Max Length property specifies the maximum number of characters that can be typed in the Textbox control. This property is normally left blank, meaning that the maximum defaults to the actual length of the database column associated with the textbox.

To specify this property, enter the desired numeric value in the cell to the right of the Max Length property in the Properties dialog.

Off

The Off property sets the value that is displayed on read-only screens when a checkbox value is false. To set this value, enter text in the cell to the right of the Off property.

On

The On property sets the value that is displayed on read-only screens when a checkbox value is true. To set this value, enter text in the cell to the right of the On property.

OP Code

The Op Code property specifies the SQL select operator used with the value of a dropdown on a search filter. The value must be a character string beginning with “QBE.” followed by an operator chosen from:

Operator	Description
EQ	equals
NE	not equals
LT	less than
GT	greater than
LE	less than or equals
GE	greater than or equals
IN	LIKE

The default value of QBE.EQ specifies that the search filter should select rows where the attribute associated with the control exactly matches the value selected from the dropdown.

To specify this property, enter the desired value in the cell to the right of the OP Code property in the Properties dialog.

Option ID

The Options ID sets the HTML or JavaScript id of the option buttons for use in JavaScript that references the control. To specify this property, enter the desired value in the cell to the right of the Options ID property in the Properties dialog.

Preview

The Preview property specifies whether or not to show the Quick View mode in the dtlHTMLEditBox. To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Preview property in the Properties dialog. Select the default value of Yes to specify that the dtlHTMLEditBox control will have the quick view mode. Select No to specify that the control will have only the HTML source mode.

Preview Clause

The Preview Clause property specifies a where clause to retrieve data for the form. WSP uses this where clause to retrieve data to be displayed on the form when it is previewed. If no preview clause is specified, WSP finds the most recently added row in the table associated with the form, and displays that data on the previewed form.

Preview Mode

The Preview Mode property specifies how the form will be previewed during preview mode. To set the Preview Mode of the form, select edit or read-only from the dropdown list to the right of the Preview Mode property. Edit is the default Preview Mode value. If you are previewing the form, in read-only mode, you will not be able to edit any of the control boxes on the form. If the Preview Mode is set to edit, you can edit the control boxes.

Preview URL

The Preview URL property specifies the preview URL. This can be an HTMPL file name, in the form xxxx.htmpl; a CA SDM URL (used unaltered if it begins with “OP=”); or the keyword “no”, indicating the form cannot be previewed. A value not beginning OP= is modified by replacing a reference of the form {factory} or {factory:} with an id or persistent id (respectively) of the most-recently created row from the referenced factory that you are authorized to see.

QBE Condition

The QBE Condition property specifies the SQL select operator used with the QBE Value property of a disabled textbox field on a search filter. The value must be a character string chosen from:

Operator	Description
EQ	equals
NE	not equals
LT	less than
GT	greater than
LE	less than or equals
GE	greater than or equals
IN	LIKE

For example, a value of IN specifies that the search filter should select rows where the attribute associated with the disabled textbox control matches the QBE Value property according to the rules of an SQL LIKE comparison.

To specify this property, enter the desired value in the cell to the right of the QBE Condition property in the Properties dialog.

QBE Display

The QBE Display property specifies the value displayed to the user for a disabled textbox field on a search filter. To specify this property, enter the desired value in the cell to the right of the QBE Display property in the Properties dialog.

QBE Value

The QBE Value specifies the value used for comparison in the portion of an SQL select where clause generated from a disabled textbox field on a search filter. The generated where clause includes a portion selecting rows where the attribute associated with the control compares with the value specified for QBE Value using the operator specified for QBE Condition.

To specify this property, enter the desired value in the cell to the right of the QBE Value property in the Properties dialog.

Read Only

Like all other detail controls in detail form, when you are in read only mode you are not able to edit the control.

Note: This parameter is ignored when Bound is set to Yes.

Rows

The Rows property specifies the number of rows that a text box control or a HTML editor will occupy on a form. To specify this property, enter the desired numeric value in the cell to the right of the Rows property in the Properties dialog.

Note: This property is available only for text boxes on the detail form and not for text boxes in the list forms.

Size

The Size property specifies the width of the control in pixels. If this property is left blank, the control is displayed at whatever width is required to hold its data.

To specify this property, enter the desired numeric value in the cell to the right of the Size property in the Properties dialog.

Spell Check

The Spell Check property specifies whether or not a Textbox control should have Spelling button to the right of its caption to allow the user to spellcheck the contents of the text box. To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Spell Check property in the Properties dialog. Select Yes to specify that a Spelling button should be displayed; select the default value of No to specify no button.

Time

The Time property specifies whether or not the time will be displayed along with the date for the Date and Read Only Date controls. To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Time property in the Properties dialog. Select the default value of Yes to specify that the time should be displayed; select No to specify that only the date should be displayed.

Title

The Title property specifies the title of the element.

To specify this property, enter the desired value in the cell to the right of the Title property in the Properties dialog.

Toolbar

The Toolbar property specifies which toolbar set will be shown in the HTML Editor associated to the dtlHTMLEditBox control.

- **tmpl**
  Displays the toolbar set for document template editor.

- **reportcard**
  Displays the toolbar set for report cards editor.

- **default**
  Displays the default toolbar set.

Tooltip

The Tooltip property specifies the text displayed when the user places the mouse pointer over a control item.

To specify this property, enter the desired value in the cell to the right of the Tooltip property in the Properties dialog.

Where Clause

The Where Clause property specifies a where clause to select the values included in a Dropdown control on a detail form. This property is optional; if left empty, a dropdown on a detail form includes all rows from the table referenced by the attribute associated with the control.

To specify this property, enter the desired value in the cell to the right of the Where Clause property in the Properties dialog.

Wildcard

The Wildcard feature enables a wildcard search for Lookup and Hierarchical Lookup boxes on a List form. A wildcard search is equivalent to adding the "%" symbol around a text string when performing a search. For example, using the string %option% when performing a search on a text field, would retrieve all of the records that contain the word "option" in that text field. To specify this property, select Yes or No from the dropdown displayed when you click in the cell to the right of the Wildcard property in the Properties dialog. Yes means that the control will automatically have the wildcard property enabled. No is the default Wildcard value. If this option is true, the % symbols are no longer required on searches.

Width

The Width property specifies the width of a button control in pixels. If this property is left blank, the control is displayed at whatever width is required to hold its data.

To specify this property, enter the desired numeric value in the cell to the right of the Size property in the Properties dialog.

Menu Designer

Use the Menu Designer dialog in WSP to add a menu bar, menus, submenus, and menu commands to the open form.

Add a Menu Bar

You can add a menu bar to a form.

Follow these steps:

1. Select File, New.
2. On the New Form window, select menubar.template as the File Name.
3. On the menubar.htmpl window, double click to open the Menu Editor dialog. The list box at the top left area of the dialog shows the structure of the menu as you define it.
4. To add the first item, enter its name in the Caption field. To add subsequent items, click Add before entering the caption.

List Designer

This article contains the following topics:

List forms (HTML templates with names of the form list_xxx.htmpl) are used to search the database and display search results. They consist of a search filter at the top of the form, where the user specifies search criteria, and a results list at the bottom of the form, listing records retrieved by the search. Use the drag-and-drop method to design the results list.

Add a Results List

BSVC_r12.1--List

To add the results list control to the List form, use drag-and-drop on the List button to place it on the desired area. This action places a blank frame on the form. Double-click the frame to define the columns and headers.

Modify Results List

To modify the Results List, double-click it and modify the properties. Click OK after making the required changes.

How to Disable Tenant Column Sorting

By default, you can sort the Tenant column on a list form. To disable Tenant column sorting, add the following value to the appropriate list form:

```
tenantSort=no
```

Note: If a form includes a Tenant column, and you do not want it sorted, you can add the following line to the list form:

```
var tenantSort = "no"
```

The Tenant column is disabled on the list form.

Disable the Export Button on a List Form

You can disable the Export button that appears on the list form pages in CA SDM.

Follow these steps:

1. Open a list form, such as list_cr.htmpl (Request List).
2. Double-click the results list.
   The properties dialog appears, showing the existing list definition.
3. On the Source tab, locate the sfStart macro.
4. Change the value to export=no as follows:

   ```
   <pdm_macro name=sfStart factory=nr export=no>
   ```

   The Export button is disabled on the list form.

How to Export Fields Not Included on List Forms

You can include a new field to export but not list.

Follow these steps:

1. Open the Properties dialog and click Add.
2. Select an attribute from the Attribute list, for example, Urgency.
3. Select the Export option.
4. On the Source tab, replace NAME=lsCol with NAME=lsExport as follows:

   ```
   <PDM_MACRO NAME=lsExport hdr="Urgency" attr=urgency justify=left>:
   ```

5. Click OK.
   When a user clicks the Export button on a list form, the Urgency field is exported.

Export the Relative Attribute Value

By default, the common name value of an SREL column is exported. You can export the Relative Attribute value by modifying the lsCol macro.

Follow these steps:

1. Open a list form for editing, for example, list_cr.htmpl.
   The list form opens.

2. Click the Source tab and locate the lsCol macro as follows:

   ```
   <PDM_MACRO NAME=lsCol hdr="Priority/Parent" attr=priority sort="DESC">
   ```

3. Copy the code string to the next line, and do the following:

   - Change the lsCol value to lsExport.
   - Add the common_name= no option.

4. Click OK.
   When a user clicks the Export button on the list form, the Relative Attribute value exports.

PDM Macro Definitions

This article contains the following topics:

- tabBanner (see page 1985)
- tabList (see page 1986)

PDM_Macro

CA SDM builds web forms in a language named HTMPL. HTMPL extends standard HTML with references to server variables and a number of proprietary tags of the form PDM_xxx. One of these tags, PDM_MACRO, copies a named JavaScript code segment from the database into the form. Most PDM_MACRO tags invoke client-side JavaScript that builds the web forms just in time, immediately before they are presented to the user. Most web form controls are built with the PDM_MACRO tag. For example, the PDM_MACRO tag that builds the site field on the Location Detail form is coded as follows:

```
<PDM_MACRO NAME=dtlLookup hdr="Site" attr="site">
```

A PDM_MACRO tag contains one or more keyword parameters (properties). The NAME parameter is required on every PDM_MACRO to specify the name of the macro. Other parameters are required or optional depending on the macro.

Note: Site customization of PDM_MACRO definitions stored in the database is not supported and should not be attempted.

btnEndRow

The btnEndRow macro marks the end of a group of one or more buttons displayed in a horizontal row on a form. The button row starts with either a btnStartRow macro or with a button macro with the NewRow=yes argument. The button row ends with either a btnEndRow macro or with a button macro with the EndRow=yes property. For example:

```
<PDM_MACRO name=btnStartRow . . .>
<PDM_MACRO name=button . . .>
<PDM_MACRO name=button . . .>
. . .
<PDM_MACRO name=btnEndRow>
```

This macro has no properties.

btnStartRow

The btnStartRow macro marks the start of a group of one or more buttons displayed in a horizontal row on a form. The button row starts with either a btnStartRow macro or with a button macro with the NewRow=yes argument. The button row ends with either a btnEndRow macro or with a button macro with the EndRow=yes property. For example:

```
<PDM_MACRO name=btnStartRow . . .>
<PDM_MACRO name=button . . .>
<PDM_MACRO name=button . . .>
. . .
<PDM_MACRO name=btnEndRow>
:
```

This macro has the following properties:

- **centered=true|*false***
  Specifies whether the row of buttons is centered on the form. When you do not specify this property, the row of buttons is left-justified.

- **padding=*0*|*number***
  Specifies the number of hard (nonbreaking) spaces between buttons in the row. When you do not specify this property, buttons are placed as close together as possible.

button

The button macro defines a button that a user of a form can click to invoke an action.

This macro has the following properties:

- **btnType=negative|*positive***
  Specifies whether a button performs a positive action (such as Save) or a negative action (such as Cancel). This specification is for documentation only; specifying a button as positive or negative has no effect on the appearance or use of the button.

- **Caption=*text***
  (Required) Specifies the text for the label of the button. You can optionally end the caption with a hotkey hint enclosed in square brackets, for example, Caption="Save[Sv]". When you provide a hotkey hint, CA SDM selects the hotkey for the button from the characters in the hint. When you do not provide a hotkey hint, CA SDM selects the hotkey from the characters of the entire caption.

- **Disabled=true|*false***
  Specifies whether the button is disabled on the initial display. When you do not specify this property, the button is enabled.

- **EndRow=yes|*no***
  Specifies whether this button is the last of a horizontal row of buttons. If specified as EndRow=yes, CA SDM automatically inserts a btnEndRow macro after this button. When you do not specify this property, CA SDM does not configure the button as the last one in a row.

- **Func=*string***
  (Required) Specifies the JavaScript that is invoked when the user of the form clicks the button.

- **hotkey_name=*string***
  (Required) Specifies the caption for selecting a hotkey. You must specify this property and an ASCII string. CA SDM selects the hotkey for the button from the characters in the hotkey_name string. The hotkey_name macro is ignored in locales using the Latin alphabet; these locales always use the Caption to determine a hotkey.

- **ID=*string***
  (Required) Specifies a JavaScript identifier for the button.

- **NewRow=yes|*no***
  Specifies whether this button is the first of a horizontal row of buttons. When you specify NewRow=yes, the product automatically inserts a btnStartRow macro before this button. When you do not specify this property, the product does not configure the button as the first one in a row.

- **tabIndex=n|*-1***
  Specifies the HTML tabIndex for the button. TabIndex is meaningful only in relation to other HTML elements on the form with a tabIndex. A user of the form tabs from element to element in sequence by the tabIndex values of the element. When you do not specify this property, the button receives a default tabIndex.

- **Tooltip=*string***
  Specifies the tooltip text for the button. When you do not specify this property, the property defaults to the button caption.

- **Width=*0*|*number***
  Specifies the width of the button in pixels. If you omit this property or specify it as 0, the product creates the button exactly wide enough for its caption.

cmdbMetadata

The cmdbMetadata macro provides attribute-level metadata for the versioning, TWA viewer, and CMDBf viewers for use when displaying CI and transaction information. This metadata is used for the following purposes:

- To categorize and provide help information about each attribute.

- To map each MDR provider attribute name with its corresponding CA CMDB attribute name so they are displayed together. This macro does not create a UI control and typically, use it in an HTMPL file. The HTMPL file is then included in a display form, which the versioning, TWA viewer, and CMDBf viewers use.

This macro has the following properties:

- **attr=*attributeName***
  Specifies a CA CMDB attribute name. This property is required in all cases except hiding a provider attribute from the CI displays. All subsequent properties refer to the handling of this attribute. The attribute name specified must be a valid, case sensitive, CI attribute name.

- **category=*attributeCategoryName***
  Specifies the category of this attribute to group-related attributes on the versioning and CMDBf viewer attribute displays. The category is typically the tab that contains the attribute on the CI detail display. Attributes are sorted by category on those forms.

- **common=yes|*no***
  (Deprecated) Specifies whether this attribute is a common attribute (in the nr object). Do not use this property. Do not specify an extension for the metadata for common attributes.

- **currentcivalue=*dottedNotation***
  Explicitly specifies special dotted notation for the current value of the attribute. This property is required when the default dotted notation to access the current CI value is incorrect. For example, this property is required when defining common attributes, and those attributes are not in the extension table.

  
  Note: For dotted notation examples, see the cmdb_metadata_common.htmpl form.

- **dbcolumn=*UAPMcolumnName***
  Specifies a UAPM database column name so that it can be associated with the specified CA CMDB attribute name.

- **extension=*objectName***
  Specifies the extension object name that contains the attribute name. This property is required when defining attributes that are in an extension table.

- **heading=*string***
  Specifies a short label that describes this attribute. Typically, you set this property the default label that the CI detail form displays.

- **help=*string***
  Specifies a brief description of the attribute.

- **hide_provider_attr=yes|*no***
  (For use with the CMDBf viewer only) Hides the provider attribute from the CMDBf viewer display when you specify YES. Requires the specification of provider_attr and either provider_name or provider_name_regexp.

- **provider_attr=*MDRattributeName***
  (For use with the CMDBf viewer only) Specifies the MDR provider attribute name that maps to the current attribute (attr). Requires the specification of attr, and either provider_name or provider_name_regexp.

- **provider_name=*MDRname***
  (For use with the CMDBf viewer only.) Specifies the MDR provider name that is associated with the MDR attribute name (provider_attr). This property specifies an exact match with a particular MDR provider name. Requires the specification of provider_attr. This property is mutually exclusive with provider_name_regexp.

- **provider_name_regexp=*regularExpression***
  (For use with the CMDBf viewer only.) Specifies the MDR provider name regular expression that is associated with the MDR attribute name (provider_attr). This property specifies a regular expression pattern to match with the MDR provider names. Regular expressions use a valid JavaScript RegExp() pattern. Requires the specification of provider_attr. For example, \"MyMdr.*\" matches all provider names starting with \"MyMdr\" such as \"MyMdr1\", \"MyMdrAbcd\", and so on. The characters \".*\" indicate to match all provider names. This property is mutually exclusive with provider_name.

- **standardcivalue=*dottedNotation***
  Explicitly specifies special dotted notation for the corresponding value of the attribute for the standard CI. This property is required when the default dotted notation to access the standard CI value is incorrect. For example, this property is required when defining common attributes, and those attributes are not in the extension table.

dtlCheckbox

The dtlCheckbox macro specifies a check box control on an HTMPL detail form. The control appears as follows:

- A check box on the edit view of the form.
- The text specified by the on or off properties on the read-only view.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1|number***

  Specifies the number of columns on the form.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **off=*0|text***
  Specifies the text displayed on a read-only form when the check box is not selected.

- **on=*1|text***
  Specifies the text displayed on a read-only form when the check box is selected.

- **title=*text***

  Specifies the title for screen reader users.

dtlCheckboxReadonly

The dtlCheckboxReadonly macro specifies a read-only check box control on an HTMPL detail form. The control appears as the text specified by the on or off properties on both the edit and read-only views of the form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1|number***

  Specifies the number of columns on the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **off=*0|text***
  Specifies the text displayed on a read-only form when the check box is not selected.

- **on=*1|text***
  Specifies the text displayed on a read-only form when the check box is selected.

dtlCheckboxWithDesc

The dtlCheckboxWithDesc macro defines a check box control with a description.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **code=*string***
  Specifies the internal value of the check box. This property is not intended for customer use.

- **desc=*text***
  Specifies the text of the description appearing after the check box.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **func=*script***
  Provides the function to select or clear the check box. This property is not intended for customer use.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **title=*text***

  Specifies the title for screen reader users.

- **padding=*0*|*number***
  Specifies the number of spaces before the check box.

- **sameCol=true|*false***
  Specifies that the check box and description are in one column. By default, the check box and description are in two columns.

- **title=*text***

  Specifies the title for screen reader users.

- **value**
  Specifies the value of the attribute in the read-only view.

dtlDate

The dtlDate macro specifies a date control on an HTMPL detail form. A date control contains a date and time that can be edited with a date picker pop-up in the edit view of a detail form.

This macro has the following properties:

- **attr**
  Specifies the name of the attribute.

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **make_required=YES|*NO***
  Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **size=*20*|*number***

  Specifies the width of the input field.

- **time=*yes*|no**
  Specifies whether the field contains both a date and time, or only a date.

dtlDateDropdown

The dtlDateDropdown macro specifies a date control on an HTMPL detail form. When empty, this field displays as a drop-down control on the edit view of the form. The drop-down control includes date selections such as "In One Day" or "In One Week". This control displays date fields with a nonempty value in the same way as the dtlDate control.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **codename=*string***

  Specifies the name of a set of values from the ui_selection object that are displayed in the date drop-down control. The values are those values with code attributes that match the value specified for codename.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **make_required=YES|*NO***

Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **size=*20*|*number***

  Specifies the width of the input field.

dtlDateReadonly

The dtlDateReadonly macro specifies a noneditable date control on an HTMPL detail form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **time=*YES*|NO**
  Specifies whether the field contains both a date and time, or only a date.

dtlDropdown

The dtlDropdown macro specifies a drop-down selection control on an HTMPL detail form. The control appears as a drop-down or lookup on the edit view of the form, and as the text in the read-only view.

Note: The CA SDM administrator can specify the maximum number of entries a drop-down list should contain (default 10); when the size of a drop-down list exceeds this number, CA SDM automatically converts the list to a lookup. You can override this behavior with the lookup property of this macro.

This macro has the following properties:

- **attr*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **autofill=*yes*|no**

  Specifies whether the field allows autofill when it is displayed as a lookup. Autofill lets a user enter a value in the field by typing the first few characters of a value and pressing Tab. These actions cause the product to perform one of the following actions:

  - Request the full value for the field from the server.
  - Pop up a selection form when the specified value is missing or ambiguous.

- **cbwidth=*0*|*number***
  Specifies the width of the drop-down list in pixels. If omitted or specified as zero, the list automatically sizes to the width of its widest entry.

- **codename=*string***

  Specifies the name of a set of values from the ui_selection object that are displayed in the date drop-down control. The values are those values with code attributes that match the value specified for codename.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **default=*text***

  Specifies the default value when the attribute is null.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **extraURL=*string***

  Specifies a where clause predicate in URL format to restrict the contents of the control.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **title=*text***

  Specifies the title for screen reader users.

- **initial=*value***
  Specifies the initial selection in the drop-down list, overriding the value of the attribute in the database.

- **link=*yes*|no**

  Specifies whether the control on the read-only view is a link to detail for the value of the attribute.

- **list_display=*attributeName***
  Specifies the common attribute name of the table. Effective only if use_list_display=1, codename is blank, and the factory, rel_attr_name, and whereclause properties are supplied.

- **list_orderby=*attributeName***
  Specifies the order of the drop-down list. Effective only if use_list_display=1, codename is blank, and the factory, rel_attr_name, and whereclause properties are supplied.

- **lookup=*yes*|no**
  Specifies whether the field should automatically convert to a lookup if the number of entries in the drop-down list exceeds a configured value (typically 10).

- **make_required=YES|*NO***

  Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **rel_attr_name=*attributeName***
  Specifies the attribute from the referenced table that is stored. This property is required when use_list_display=1 is specified, codename is blank, and the factory, list_display, and whereclause properties are supplied.

- **size=*20*|*number***

  Specifies the width of the input field.

- **title=*text***

  Specifies the title for screen reader users.

- **use_list_display=*0*|1**
  Specifies whether the drop-down control should be built from an explicit query instead of from the referenced attribute. When use_list_display=1, the factory, list_display, rel_attr_name, and whereclause properties must also be supplied.

- **whereclause=*string***
  Specifies a where clause.

dtlDropdownWithDesc

The dtlDropdownWithDesc macro specifies a drop-down list on an HTMPL detail form. A caption (header) precedes the drop-down list with a text description following it.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **desc=*text***
  Specifies the description that appears after the drop-down list.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **sel_fac=*factoryName***
  Specifies a factory whose entire contents will display in the drop-down list. This property is effective only if sel_list is empty.

- **sel_list="text@,@value@,…,@text@,@value"**
  Specifies a comma-separated list of values for the drop-down. Values are specified in pairs, with the displayed value followed by the corresponding internal value. At symbols (@) delimit the individual values, except for the first and last value in the list.

- **title=*text***

  Specifies the title for screen reader users.

- **value=*string***
  Specifies the value of the attribute in the read-only view.

dtlEnd

The dtlEnd macro marks the end of the macros that define the contents of a detail form. This macro must be the last macro on the form. You structure all detail forms with the following code:

```
<PDM_MACRO name=dtlForm . . .>
<PDM_MACRO name=dtlStart . . .>
```

```
<PDM_MACRO name=dtlStartRow . . .>
. . .
<PDM_MACRO name=dtlEnd>
```

This macro has no properties.

dtlEndDiv

The dtlEndDiv macro marks the end of a group of detail form macros that JavaScript can show or hide. Pair this macro with a dtlStartDiv macro and use a dtlEndTable macro. For example:

```
<PDM_MACRO name=dtlStartDiv divid="my_div" . . .>
. . .
<PDM_MACRO name=dtlEndTable>
<PDM_MACRO name=dtlEndDiv>
```

This macro has no properties.

dtlEndTable

The dtlEndTable macro marks the end of an HTML table, and is not intended for customer use. No dtlStartTable macro exists; the detail form table automatically starts and ends HTML tables as required for the layout. A dtlEndTable macro is required only when a macro group must be separated into HTML blocks, such as when dtlStartDiv and dtlEndDiv create a division.

dtlEndTable has no properties.

dtlForm

The dtlForm macro marks the beginning of the macros that define the contents of a detail form. This macro must be the first macro on the form. All detail forms must be structured with the following code:

```
<PDM_MACRO name=dtlForm . . .>
<PDM_MACRO name=dtlStart . . .>
<PDM_MACRO name=dtlStartRow . . .>
. . .
<PDM_MACRO name=dtlEnd>
```

This macro has the following properties:

- **button=*true*|false**
  Specifies whether to show the default buttons on the edit view and the Edit button on the read-only view. The default buttons are Save, Cancel, and Reset.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hideeditbtn=true|*false***
  Specifies whether to hide the Edit button in the read-only view.

- **onsubmit=*script***
  Overrides the default form submit handler. The default handler is sufficient for most cases.

- **saveclose=true|*false***
  Specifies whether to show a "Save and Close" button in the edit view.

- **skip_tenant_hdr=yes|*no***
  Specifies whether to suppress the tenant field at the header of the form.

- **skiphdr=yes|*no***
  Specifies whether to skip standard form headers, such as default buttons.

dtlHier

The dtlHier macro specifies a hierarchical lookup control on a detail form. In the edit view, a user can click the caption (header) of the control to pop up a hierarchical selection form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **autofill=*yes*|no**

  Specifies whether the field allows autofill when it is displayed as a lookup. Autofill lets a user enter a value in the field by typing the first few characters of a value and pressing Tab. These actions cause the product to perform one of the following actions:

  - Request the full value for the field from the server.
  - Pop up a selection form when the specified value is missing or ambiguous.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **common_name=*attributeName***
  Specifies the name of the attribute from the referenced table that should be displayed on the detail form. This macro is not intended for customer use.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **factory=*name***

Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **make_required=YES|*NO***

  Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **size=*20*|*number***

  Specifies the width of the input field.

dtlHTMLEditbox

The dtlHTMLEditbox macro defines an HTML edit field in a detail form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **bound=*yes*|no**
  Specifies whether the control is bound to an attribute.

- **className=*value***
  Specifies a style sheet class.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **escape=*JS2*|C|JS|HTML**
  Specifies how data is escaped in the read-only view. This property is not intended for customer use.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **make_required=YES|*NO***

  Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **maxlength=*number***

  Specifies the maximum length of the edit field.

- **optionid=*string***
  Specifies the JavaScript identification of the HTML edit field control. This property is not intended for customer use.

- **persid=*value***
  Specifies the persistent identifier of the object displayed in the edit field. This property is not intended for customer use.

- **preview=*yes*|no**
  Specifies whether the edit field supports Quick View mode.

- **readonly=yes|*no***
  Specifies whether the HTML editor is read-only. This property is ignored unless bound=no.

- **rows=1|number**

  Specifies the number of rows on the form occupied by the textbox.

- **size=*20*|*number***

  Specifies the width of the input field.

- **spellchk=yes|*no***

  Specifies whether to display a Spell button next to the field label in the edit view.

- **tenant=*value***
  Specifies the internal identification (UUID) of the tenant. This property is not intended for customer use.

- **tenantName=*value***
  Specifies the name of the tenant. This property is not intended for customer use.

- **toolbar=*default*|reportcard|tmpl**
  Specifies the set of HTML editing tools displayed in the edit field. This property has the following possible values:

  - default -- the default toolbar set
  - reportcard -- a toolbar set appropriate for the knowledge report card
  - tmpl -- a toolbar set appropriate for the document template editor

dtlLookup

The dtlLookup macro specifies a lookup control on a detail form. In the edit view, a user can click the caption (header) of the control to pop up a selection form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **autofill=*yes*|no**

  Specifies whether the field allows autofill when it is displayed as a lookup. Autofill lets a user enter a value in the field by typing the first few characters of a value and pressing Tab. These actions cause the product to perform one of the following actions:

  - Request the full value for the field from the server.
  - Pop up a selection form when the specified value is missing or ambiguous.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **common_name_attr=*attributeName***
  Specifies the name of the attribute from the referenced table to display on the detail form. This property is not intended for customer use.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

  ```
  evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
  ```

- **extraURL=*string***

  Specifies a where clause predicate in URL format to restrict the contents of the control.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **link=*yes*|no**

  Specifies whether the control on the read-only view is a link to detail for the value of the attribute.

- **make_required=YES|*NO***

  Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **size=*20*|*number***

  Specifies the width of the input field.

dtlLookupReadonly

The dtlLookupReadonly macro specifies a read-only lookup control on an HTMPL detail form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **link=*yes*|no**

Specifies whether the control on the read-only view is a link to detail for the value of the attribute.

dtlLrelMultiselbox

The dtlLrelMultiselbox macro displays a multiselect field (side-by-side selection) control for a many-to-many selection form. This macro displays a set of input controls, including the following:

- A left-side multiselect field and its header
- A right-side multiselect field and its header
- Two select buttons between the multiselect fields
- Pagination text below the multiselect fields if any
- Two Clear Selection buttons at the bottom of the multiselect fields

This macro has the following properties:

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

dtlRadio

The dtlRadio macro displays a group of option button controls with optional text following the control.

This macro has the following properties:

- **actcode=*string***
  Specifies the action code.
- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.
- **codename=*string***
  (Required) Specifies the name of a set of values from the ui_selection object that are displayed in the date drop-down list control. These values have code attributes that match the value specified for codename.
- **dataclass=*string***
  Specifies the CSS class name used for the text of the option button.
- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

```
evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
```

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **title=*text***

  Specifies the title for screen reader users.

- **sameRow=true|*false***
  Specifies whether to display the option buttons on the same row.

- **title=*text***

  Specifies the title for screen reader users.

Example: dtlRadio

NX_ROOT\bopcfg\www\htmpl\web\analyst\detaikl_pri_cal.htmpl file has the following use of the macro:

<PDM_MACRO name=dtlRadio hdr="Duplicate Ticket Action" attr="action" actcode="$args.action" codename="dupActions">

dtlReadonly

The dtlReadonly macro specifies a read-only textbox on an HTMPL detail form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **fmtfunc=*name***
  Specifies the name of a JavaScript function that formats the field for display. The function is passed a single argument containing the value of the attribute, and must return a string that is displayed on the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **hdrclass=*text***
  Specifies the CSS class used to format the caption. This property is not intended for customer use.

- **title=*text***

  Specifies the title for screen reader users.

- **inline=yes|*no***
  Specifies whether the header text and the data are on the same line, separated by a colon (:). Use this property only when attr="n/a".

- **value=*value***
  Specifies the value displayed on the form when attr="n/a".

dtlShowtext

The dtlShowtext macro displays plain text on the form without any label or header that is associated with the text. This macro lets you do the following activities:

- Associate the text to display with an attribute.
- Format and display the text when needed.
- Show a bar image below the text.

This macro has the following properties:

- **argumts=*string***
  Specifies the arguments that are passed to the fmtmsg format function.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **dataclass=pageHeader|hdr|required|alertmsg|className**
  Specifies the CSS class that is applied to displayed text.

- **fmtmsg=*string***
  Specifies the name of the function to format the text for display. The arguments for this function are specified in the argumts parameter. The function must return a text string that is the value displayed.

- **keeplinks=yes|*no***

  Specifies whether HTML links (Action: tags) are displayed as links or formatted as raw text. Preserves HTML links when the text to display contains HTML links. The default value is no.

- **keeptags=yes|*no***

Specifies whether HTML tags are interpreted as HTML links or formatted as raw text. keeptags=yes overrides the keeplinks property.

- **showbarimg=yes|*no***
  Specifies whether to display a bar image below the text.

- **value=*text***
  (Required) Specifies the value to display. The value can be associated to an attribute.

Example: dtlShowtext

NX_ROOT\bopcfg\www\htmpl\web\analyst\detaikl_pri_cal.htmpl file uses the following macro:

<PDM_MACRO name=dtlShowtext colspan=6 dataclass=hdr value="Priority Calculation Options">

- **Colspan**
  Specifies the number of field columns we want to span.

- **Dataclass**
  Specifies the css we want to apply for the text.

- **Value**
  Specifies the displayed text value.

dtlStart

The dtlStart macro begins a detail form, and must be the second macro on the form. Structure all detail forms with the following code:

```
<PDM_MACRO name=dtlForm . . .>
<PDM_MACRO name=dtlStart . . .>
<PDM_MACRO name=dtlStartRow . . .>
. . .
<PDM_MACRO name=dtlEnd>
```

This macro has the following properties:

- **center=true|*false***
  Specifies whether the form is centered.

- **scroll=true|*false***
  Specifies whether the form always has a scroll bar.

dtlStartDiv

The dtlStartDiv macro marks the beginning of a group of detail form macros that JavaScript can show or hide. Pair this macro with a dtlEndDiv macro. For example:

```
<PDM_MACRO name=dtlStartDiv divid="my_div". . .>
. . .
<PDM_MACRO name=dtlEndTable>
<PDM_MACRO name=dtlEndDiv>
```

This macro has the following properties:

- **align=*left*|center|right**
  Specifies the alignment of the DIV.
- **class=*className***
  Specifies the CSS class of the DIV.
- **divid=*string***
  (Required) Specifies the JavaScript identification of the DIV.
- **style=*string***
  Specifies the style of the DIV.

dtlStartExpRow

The dtlStartExpRow macro specifies the start of an expandable row on a detail form. An expandable row lets the user hide the row controls by clicking the title bar of the row.

This macro has the following properties:

- **class=*className***
  Specifies the CSS class of the HTML table containing the controls in the new row.
- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **exp_rows="1,2,..."**
  Specifies the row numbers in the expandable section as a quoted string containing a sequence of numbers from 1 to *N*. *N* represents the number of rows desired in the expandable section. The section includes the controls following dtlStartExpRow, and the next n-1 dtlStartRow macros.
- **form_name=*name***
  Specifies the name of the containing HTMPL file name without the htmpl extension. The name value is the name of the file. When the expandable section is in a tab, this argument specifies the name of the file containing the tab.
- **label=*string***
  Specifies the label shown on the expandable section bar.

dtlStartRow

The dtlStartRow macro marks the start of a row on a detail form.

This macro has the following properties:

- **class=*className***
  Specifies the CSS class of the HTML table containing the controls in the new row.

- **hrClass=*className***
  Specifies the CSS class of an optional dividing line. This property is effective only when hrSpan specifies a nonzero value.

- **hrSpan=*0*|*number***
  Specifies the number of columns spanned by an optional dividing line above the new row. The default value of zero specifies no dividing line.

dtlSurvey

The dtlSurvey macro displays multiple choice answers for each survey question. Survey questions can accept single answers for which option buttons are displayed or can accept multiple answers for which check boxes are displayed. You can use this macro in survey forms like preview risk survey, submit risk survey, and view submitted survey.

This macro has the following properties:

- **answerselected=*number***
  Specifies the index of the selected answer.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **factory=*name***
  Specifies the factory containing the survey, usually risk_svy_atpl.

- **parentid=*number***
  Specifies the database id of the question, usually $question.id.

- **parentmultiflag=*number***
  Specifies whether to display a check box or a option button. This value is usually $question. mult_resp_flag.

- **parentsequence=*number***
  Specifies the question sequence. This value is usually $question.sequence.

- **view=*preview*|doview|viewsubmitted**
  Specifies the survey view to display. You can specify any of the following views:

  - preview -- specifies to display preview survey page

  - doview -- specifies to display survey page which is ready to be submitted

  - viewsubmitted -- specifies to display the previously submitted survey page

dtlTextbox

The dtlTextbox macro specifies a text field on a detail form. In the edit view, the field allows entry of free-form text.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **disp_entities=yes|*no***
  Specifies whether to display HTML entities (for example, & or &#26237) in read-only view. If disp_entities=no, HTML entities are displayed exactly as entered; if disp_entities=yes, HTML entities are converted to their external value.

- **evt=*"eventName='script'"***

  Specifies one or more HTML event handlers in the same way you specify them in an HTML statement, with quotes escaped as required. For example:

  ```
  evt="onclick='myfunc()' onchange=\\\"myfunc2()\\\""
  ```

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **title=*text***

  Specifies the title for screen reader users.

- **JSButton=function()**
  Specifies a JavaScript function that creates a button next to the header of the control.

- **keeplinks=yes|*no***

  Specifies whether HTML links (Action: tags) are displayed as links or formatted as raw text. Preserves HTML links when the text to display contains HTML links. The default value is no.

- **keeptags=yes|*no***

  Specifies whether HTML tags are interpreted as HTML links or formatted as raw text. keeptags=yes overrides the keeplinks property.

- **make_required=YES|*NO***

Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **maxlength=*number***

  Specifies the maximum length of the edit field.

- **password=yes|*no***
  Specifies whether the text field contains a password field. CA SDM replaces passwords with a string of asterisks in both the edit and read-only views.

- **rows=1|number**

  Specifies the number of rows on the form occupied by the textbox.

- **size=*20*|*number***

  Specifies the width of the input field.

- **spellchk=yes|*no***

  Specifies whether to display a Spell button next to the field label in the edit view.

- **srchknow=yes|*no***
  Specifies whether to display a search knowledge button next to the field label.

- **title=*text***

  Specifies the title for screen reader users.

- **value=*text***
  Specifies the value to display when the value cannot be retrieved from the attribute.

dtlWriteproperty

The dtlWriteproperty macro specifies a custom property for a change or issue category, or a request, incident, or problem area. Properties appear on the properties tab of the respective tickets. This macro formats a single property with the label on the left, input field value in the middle, and a sample value on the right. The Input field can be a textbox, drop-down list, or a check box.

This macro has the following properties:

- **label=prop*n*.label**
  Specifies a label for the property, in the form propn.label. n is the property number specified in the propNum argument.

- **make_required=YES|*NO***

  Makes a field required when you specify YES regardless of whether the associated attribute is required at the object level. A required field forces the user to specify a nonblank value.

- **propNum**
  (Required) Specifies a number for the property. Properties are displayed in sequence by property number.

- **sample=prop*n*.sample**
  Specifies an example of a value for the property, in the form propn.sample. n is the property number specified in the propNum argument.

- **validation_rule=prop*n*.validation_rule.id**
  Specifies the validation rule for the property, in the form propn.validation_rule.id. n is the property number specified in the propNum argument.

- **validation_type=prop*n*.validation_type**
  Specifies the validation type for the property, in the form propn.validation_type. n is the property number specified in the propNum argument.

- **value=prop*n*.sample**
  Specifies the value of the property. n is the property number specified in the propNum argument.

ebr_search_filter

The ebr_search_filter macro specifies an Advanced filter for a related knowledge search. This macro is not intended for customer use.

This macro has the following properties:

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **order_by=*true*|false**
  Specifies whether the filter should include an Order by combo box.

- **view=Architect|*Generic*|Knowledge**
  Specifies whether the filter should be displayed in a Knowledge tab, an Architect tab, or generically (any tab except Knowledge or Architect).

elsEditField

The elsEditField macro specifies an editable field for the Edit in List feature of a list form. You specify that a list form has the Edit in List feature by including the elsStartEdit and elsEndEdit macros. You define the fields on the Edit in List form with one or more elsEditField and elsEditReadOnly macros. For example:

```
<PDM_MACRO name=elsStartEdit search_filter="__search_filter">
```

```
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditReadonly . . .>
. . .
<PDM_MACRO name=elseEndEdit>
```

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **datatype=0**
  Specifies the data type for input validation. The only datatype supported is 0, which causes the field to be validated as an integer.

- **EndRow=yes|*no***

  Specifies whether the field is the last one in a row on the Edit in List form. Specifying EndRow=yes causes CA SDM to display the next field on a new line of the form.

- **extraEvt=function()**
  Specifies a JavaScript function that is called as an onchange event handler when a user modifies the field.

- **extraURL=*string***

  Specifies a where clause predicate in URL format to restrict the contents of the control.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **size=*20*|*number***

  Specifies the width of the input field.

- **StartRow=yes|*no***

  Specifies whether the field starts a new row on the Edit in List form.

elsEditReadonly

The elsEditReadonly macro specifies a read-only field for the Edit in List feature of a list form. You specify that a list form has the Edit in List feature by including the elsStartEdit and elsEndEdit macros. You define the fields on the Edit in List form with one or more elsEditField and elsEditReadOnly macros. For example:

```
<PDM_MACRO name=elsStartEdit search_filter="__search_filter">
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditReadonly . . .>
. . .
<PDM_MACRO name=elseEndEdit>
```

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **EndRow=yes|*no***

  Specifies whether the field is the last one in a row on the Edit in List form. Specifying EndRow=yes causes CA SDM to display the next field on a new line of the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **size=*20*|*number***

  Specifies the width of the input field.

- **StartRow=yes|*no***

  Specifies whether the field starts a new row on the Edit in List form.

elsEndEdit

The elsEndEdit macro marks the end of the fields specified for the Edit in List feature of a list form. You specify that a list form has the Edit in List feature by including the elsStartEdit and elsEndEdit macros. You define the fields on the Edit in List form with one or more elsEditField and elsEditReadOnly macros. For example:

```
<PDM_MACRO name=elsStartEdit search_filter="__search_filter">
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditReadonly . . .>
. . .
<PDM_MACRO name=elseEndEdit>
```

This macro has no properties.

elsStartEdit

The elsStartEdit macro activates the Edit in List feature of a list form, and marks the start of the list of fields. You specify that a list form has the Edit in List feature by including the elsStartEdit and elsEndEdit macros. You define the fields on the Edit in List form with one or more elsEditField and elsEditReadOnly macros. For example:

```
<PDM_MACRO name=elsStartEdit search_filter="__search_filter">
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditField . . .>
<PDM_MACRO name=elsEditReadonly . . .>
. . .
<PDM_MACRO name=elseEndEdit>
```

This macro has the following properties:

- **search_filter="__search_filter"**
  (Required) Specifies the JavaScript object name of the search filter. Specify this property exactly as shown.

endFrameset

The endFrameset macro marks the end of a frameset definition. You define a page of the frame with the startFrameset, endFrameset, and frame macros. For example:

```
<PDM_MACRO name=startFrameset. . .>
<PDM_MACRO name=frame. . .>
<PDM_MACRO name=frame. . .>
. . .
<PDM_MACRO name=endFrameset>
```

This macro has no properties.

endMenu

The endMenu macro marks the end of a menu within a menubar definition. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
<PDM_MACRO name=endMenu>
. . .
```

This macro has no properties.

endMenubar

The endMenubar macro marks the end of definition of a menubar, and is followed by the definitions of the menus on the menubar. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
<PDM_MACRO name=endMenu>
. . .
```

This macro has no properties.

endNotebook

The endNotebook macro marks the end of the definition of a notebook on a detail page. Only one notebook can exist on a page and it must be the last item on the page. You define a notebook with the startNotebook, startTabGroup, tab, and endNotebook macros. For example:

```
<PDM_MACRO name=startNotebook. . .>
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=endNotebook>
```

This macro has no properties.

frame

The frame macro specifies a frame on a frameset page. You define a frameset page with the startFrameset, frameab, and endFrameset macros. For example:

```
<PDM_MACRO name=startFrameset. . .>
<PDM_MACRO name=frame . .>
<PDM_MACRO name=frame . .>
. . .
<PDM_MACRO name=endFrameset >
```

This macro has the following properties:

- **extra=*string***
  Specifies a string of keywords in the same way as in an HTML <frame> statement, with quotes escaped as required.

- **frame_name=*name***
  (Required) Specifies a name for the frame (the "name" argument on an HTML <frame> statement).

- **frameborder=*yes*|no**
  Specifies whether the frame has a border (the "frameborder" argument on an HTML <frame> statement).

- **id=*name***
  (Required) Specifies the JavaScript ID of the frame (the "id" argument on an HTML <frame> statement).

- **marginheight=*number***
  Specifies the size of the top and bottom margins (the "marginheight" argument on an HTML <frame> statement).

- **marginwidth=*number***
  Specifies the size of the top and bottom margins (the "marginwidth" argument on an HTML <frame> statement).

- **noresize=true|*false***
  Specifies whether the frame is resizable (the "noresize" keyword on an HTML <frame> statement).

- **scrolling=*auto*|yes|no**
  Specifies whether the frame has a scroll bar (the "scrolling" argument on an HTML <frame> statement).

- **style=*string***
  Specifies CSS style information for the frame (the "style" argument on an HTML <frame> statement).

- **tabindex=*number***
  Specifies the tab index of the frame (the "tabindex" argument on an HTML <frame> statement).

- **title=*text***

  Specifies the title for screen reader users.

- **web_form_name=*string***
  Specifies the code name of an object in the web_form factory where CA SDM can obtain the URL for the form displayed in the frame. This property is effective only when web_form_url is not specified.

- **web_form_url=*string***
  Specifies the URL of the form that displays in the frame.

kt_Categories_Tree

The kt_Categories_Tree macro creates a knowledge category frame.

This macro has the following properties:

- **frameborder=*0*|*number***
  Specifies the size of the border.

- **height=*100px*|*value***
  Specifies the frame height.

- **iframe=*yes*|no**
  Specifies whether to generate an iframe for the tree. Specify iframe=no when you are using a predefined frame.

- **menu=*name***
  Specifies the tree menu type. Specify adm_tree, DOCUMENT_EDITOR, HTML_EDITOR, ATTACHMENTS_IMAGES, ATTACHMENTS_TAB, ATTACHMENTS_ADMIN, ARCHITECT, or FAQ.

- **ParentTenant=*value***
  Specifies the parent tenant. Typically, you code this property as ParentTenant="$args. ParentTenant"

- **tabindex=*number***
  Specifies the tab index of the frame.

- **UseTenant=*0*|1**
  Specifies whether to use a tenant.

- **view=*ArchitectTree*|FAQ**
  Specifies the view: ArchitectTree or FAQ.

- **width=*100px*|*value***
  Specifies the frame width.

lsCol

The lsCol macro specifies a column on a list form. You define the contents of a list form with the lsStart, lsCol, and lsEnd macros. You can optionally include lsWrite and lsExport macros. For example:

```
<PDM_MACRO name=lsStart. . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsWrite . .>
<PDM_MACRO name=lsCol . .>
. . .
<PDM_MACRO name=lsEnd>
```

HTML for the entire list is output by the lsEnd macro. The other list macros save information used by lsEnd to generate the list.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

  Note: This property is not used and is ignored. This property is retained for compatibility with previous releases.

- **common_name_option=*yes*|no**
  Specifies whether the column contains an SREL attribute. The common name of the referenced table when the list is exported replaces the attribute value.

- **disp_entities=yes|*no***
  Specifies whether to display HTML entities (for example, & or &#26237 in read-only view. This property has the following values:

  - **YES** -- HTML entities are converted to their external value.

  - **NO** -- HTML entities are displayed exactly as entered.

- **display_attr=*COMMON_NAME*|attrName**
  Specifies the column from the referenced table that is displayed on the list for columns containing an SREL attribute. This property is ignored for columns that are not SRELs.

- **escape=*C*|HTML|JS|JS2**
  Specifies how the value of the column is escaped. This property has the following values:
  - **C** -- Prefix quotes, backslashes, and newlines with a backslash
  - **HTML** -- Convert quote, backslash, '<', and '>' to HTML entities
  - **JS** -- Convert quote, backslash, and newline to JavaScript hex (%nn)
  - **JS2** -- Same as JS, but also convert '%' to '%25'
- **export=*yes*|no**
  Specifies whether this column is exported when the user clicks the Export button.
- **export_hdr_default**
  Specifies the default header text. The list result export uses this property.
- **exportFmt=*function***
  Specifies the name of a JavaScript function (without parentheses) that returns a string format code which controls formatting the column when it is exported. This property has the following function values:
  - **"YES_NO"** -- Return either "yes" or "no"
  - **"FACTORY_LINK"** -- No formatting (reserved for future use)
  - **"LIST_LOOKUP:v1,v1a,v2,v2a,.."** -- Convert from a list. A value matching the first element in a pair is converted to the second element in the pair.
- **exportHdr=*text*|DISPLAY_NAME**
  Specifies the header for the column when it is exported. You can specify the value as explicit text, or as the keyword value DISPLAY_NAME, which sets the header to the value of export_hdr_default.
- **export_hdr_default=*text***
  Specifies the text of the export column header when exportHdr has the keyword value DISPLAY_NAME. You rarely must specify this property, which defaults to the display name of the attribute for the column.
- **fmtfunc=*function***
  Specifies the name of a JavaScript function that formats the field for display. The function is passed as a single argument containing the value of the attribute, and must return a string that is displayed on the form.
- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **hidden=yes|*no***
  Specifies whether the column is invisible. A hidden column can be useful for Edit in List or export.

- **img=*name***
  Specifies a JavaScript variable containing the URL of an image to display in the column. Set the JavaScript variable with a preceding lsWrite macro.

- **justify=*left*|center|right**
  Specifies the position of content within the columns.

- **keeplinks=yes|*no***

  Specifies whether HTML links (Action: tags) are displayed as links or formatted as raw text. Preserves HTML links when the text to display contains HTML links. The default value is no.

- **keeptags=yes|*no***

  Specifies whether HTML tags are interpreted as HTML links or formatted as raw text. keeptags=yes overrides the keeplinks property.

- **label=*string***

  Specifies text for a label positioned to the left of data.

- **link=*yes*|no**

  Specifies whether the control on the read-only view is a link to detail for the value of the attribute.

- **max_char=*0*|*number***
  Specifies the maximum number of characters to display in column.

- **nowrap=yes|*no***
  Specifies whether to suppress wrapping of text in a call. When you specify nowrap=yes, text for the column is not permitted to wrap to multiple lines.

- **required=yes|*no***
  Specifies whether text must appear in the column. When you specify required=yes and the attribute has no value, its value is replaced with "Not Available."

- **sort=*ASC*|DESC|no**
  Specifies the sort sequence of the list when a user clicks the column as follows:

  - ASC (ascending)
  - DESC (descending)
  - no (column is not a sort column)

- **startrow=yes|*no***
  Specifies whether the column is the first one in the expansion section. This property works as follows:

- Columns defined by lsCol macros prior to one specifying startrow=yes are displayed on the main portion of the list.
- Columns defined by the lsCol macro specifying startrow=yes are included in the expansion section that is hidden from view unless the user clicks the plus sign at the beginning of the list row.
- The startrow property is effective only for the first lsCol macro specifying startcol=yes; it is ignored on subsequent lsCol macros.

- **style=*string***
  Specifies CSS formatting for the column.
- **uid=*string***
  Specifies an additional identifier to distinguish between columns with the same attribute. This property is not intended for customer use.
- **width=*0*|*number***
  Specifies the maximum width of a column.

lsEnd

The lsEnd macro marks the end of a list form specification. You define the contents of a list form with the lsStart, lsCol, and lsEnd macros. You can optionally include lsWrite and lsExport macros. For example:

```
<PDM_MACRO name=lsStart. . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsWrite . .>
<PDM_MACRO name=lsCol . .>
. . .
<PDM_MACRO name=lsEnd>
```

HTML for the entire list is output by the lsEnd macro. The other list macros save information used by lsEnd to generate the list.

This macro has the following properties:

- **alt_data_src=*name***
  Specifies the name of a JavaScript variable containing the contents of the list. This property is used to display data from a source other than the database. For example:

```
var alternative_source = new Array();

var row1 = new Object();

row1. column0 = "column0";

row1. column1 = 4;

alternative_source[0] = row1;

......

<PDM_MACRO name=lsEnd alt_data_src=alternative_source>
```

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **isTicketFactory=*0*|1**
  Specifies a list of tickets (requests, incidents, problems, changes, or issues).

- **list=*name***
  Specifies the source variable of a database list. This property is not intended for customer use.

- **sort=*attributeName***
  Specifies the initial sort sequence of the list.

- **start=*number***
  Specifies the ordinal number of the first row of the list to display. This property is not intended for customer use.

lsExport

Use the lsExport macro in place of lsCol to specify a column for a list form that is not included in the web UI list. However, this column is included in the spreadsheet generated by exporting the list. You define the contents of a list form with the lsStart, lsCol, and lsEnd macros. You can optionally include lsWrite and lsExport macros. For example:

```
<PDM_MACRO name=lsStart. . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsWrite . .>
<PDM_MACRO name=lsCol . .>
. . .
<PDM_MACRO name=lsEnd>
```

HTML for the entire list is output by the lsEnd macro. The other list macros save information used by lsEnd to generate the list.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **common_name_option=*yes*|no**
  Specifies whether the column contains an SREL attribute. The common name of the referenced table replaces this attribute value when the list is exported.

- **export=*yes*|no**
  Specifies whether this column is exported when the user clicks the Export button.

- **export_hdr_default**
  Specifies the text of the header.

- **exportFmt=*function***
  Specifies the name of a JavaScript function (without parentheses) that returns a string format code used to control formatting the column when it is exported. The function can return the following values:

  - "YES_NO" -- Return either "yes" or "no"
  - "FACTORY_LINK" -- No formatting (reserved for future use)
  - "LIST_LOOKUP:v1,v1a,v2,v2a,.." -- Convert from a list. A value matching the first element in a pair is converted to the second element in the pair.

- **exportHdr=*text*|DISPLAY_NAME**
  Specifies the header for the column when it is exported. You can specify the value as explicit text, or as the keyword value DISPLAY_NAME, which sets the header to the value of export_hdr_default.

- **export_hdr_default=*text***
  Specifies the text of the export column header when exportHdr has the keyword value DISPLAY_NAME. You rarely must specify this property, which defaults to the display name of the attribute of the column.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **label=*string***

  Specifies text for a label positioned to the left of data.

lsStart

The lsStart macro marks the beginning of a list form specification. You define the contents of a list form with the lsStart, lsCol, and lsEnd macros, and can optionally include lsWrite and lsExport macros. For example:

```
<PDM_MACRO name=lsStart. . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsWrite . .>
<PDM_MACRO name=lsCol . .>
. . .
<PDM_MACRO name=lsEnd>
```

HTML for the entire list is output by the lsEnd macro. The other list macros save information used by lsEnd to generate the list.

This macro has the following properties:

- **search_type=*DISPLAY*|GET_DOB**
  Specifies how data for the list is retrieved. The default of DISPLAY causes all data to be retrieved directly from the database. The alternate value of GET_DOB causes data to be formatted by the object engine (domsrvr), and may be required if the list includes local attributes not stored in the database. A specification of search_type=GET_DOB reduces the performance of the list form, and only use it when necessary.

lsWrite

The lsWrite macro specifies JavaScript code executed for every row of a list. The text specified by lsWrite is inserted into the HTML form multiple times, once for each row of the list. You define the contents of a list form with the lsStart, lsCol, and lsEnd macros. You can optionally include lsWrite and lsExport macros. For example:

```
<PDM_MACRO name=lsStart. . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsCol . .>
<PDM_MACRO name=lsWrite . .>
<PDM_MACRO name=lsCol . .>
. . .
<PDM_MACRO name=lsEnd>
```

HTML for the entire list is output by the lsEnd macro. The other list macros save information used by lsEnd to generate the list.

This macro has the following properties:

- **both=yes|*no***
  Specifies whether the JavaScript text defined by the macro is inserted before the list and for every row on the list.

- **text=*script***
  Specifies the text to insert.

menubarItem

The menubarItem macro defines an item on a menubar. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
```

```
<PDM_MACRO name=endMenu>
. . .
```

This macro has the following properties:

- **hotkey=*string***

  Provides a hotkey suggestion for this menubar item. CA SDM selects the hotkey for the menubar item from the characters in the string; otherwise, it selects the hotkey from the characters in the label.

- **id=*name***
  (Required) Specifies a JavaScript identifier for the menubar item.

  Note: The startMenu macro references this identifier. The startMenu macro defines the contents of the menu dropped down from the menubar for this item.

- **img=*url***
  Specifies the URL of an image to display on the toolbar section of the menubar.

- **label=*text***
  (Required) Specifies the text of the menu bar item.

- **variable=*name***
  Specifies a JavaScript variable that can be used to reference the menubar item. This property is not intended for customer use.

menuItem

The menubarItem macro defines an item on a menu. The item invokes a JavaScript function in the main CA SDM form, even if the menu is in a pop-up form. Use the menuitemLocal macro to invoke a local function. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
<PDM_MACRO name=endMenu>
. . .
```

This macro has the following properties:

- **extended=*0*|1**
  Specifies whether this item is an extended menu item supporting disabling, hiding, and changing an image.

- **function=*script***
  (Required) Specifies the JavaScript function invoked when the menu item is selected. This function must be available in the main CA SDM form, and not in the pop-up form containing the menu. Menu items invoking functions in the pop-up form should be defined with the menuitemLocal macro.

- **hotkey=*string***

  Provides a hotkey suggestion for this menubar item. CA SDM selects the hotkey for the menubar item from the characters in the string; otherwise, it selects the hotkey from the characters in the label.

- **icon_name=*string***
  Specifies the name of an image file displayed as an icon on the menu next to the menu item.

- **id=*name***
  Specifies a JavaScript ID for the menu item.

- **label=*text***
  (Required) Specifies the text of the menu item.

- **local=*0*|1**
  Specifies whether extended menus use the function in the local frame. This property is not intended for customer use.

- **tooltip=*string***
  Specifies a tooltip for the icon.

menuItemLocal

The menuItemLocal macro defines an item on a menu that invokes a JavaScript function in the form containing the menu. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
<PDM_MACRO name=endMenu>
. . .
```

This macro has the following properties:

- **function=*script***
  (Required) Specifies the JavaScript function invoked when the menu item is selected. This function must be available in the form containing the menu.

- **hotkey=*string***

  Provides a hotkey suggestion for this menubar item. CA SDM selects the hotkey for the menubar item from the characters in the string; otherwise, it selects the hotkey from the characters in the label.

- **icon_name=*string***
  Specifies the name of an image file displayed as an icon on the menu next to the menu item.

- **id=*name***
  Specifies a JavaScript ID for the menu item.

- **label=*text***
  (Required) Specifies the text of the menu item.

- **tooltip=*string***
  Specifies a tooltip for the icon.

priMatrix

The priMatrix macro specifies a priority calculation matrix.

This macro has the following properties:

- **impact_label=*name***
  Specifies an impact label.

- **matrix_name=*name***
  (Required) Specifies the name of this matrix.

- **reset_btn_name=*name***
  Specifies a reset button name.

- **urgency_label=*name***
  Specifies an urgency label.

schedAttr

The schedAttr macro specifies an attribute included on a schedule form, either the change schedule (list_chgsched_config.htmpl) or the knowledge schedule (list_kdsched_config.htmpl). You define a schedule form with the schedConfig, schedAttr, and schedGroup macros. For example:

```
<PDM_MACRO name=schedConfig. . .>
<PDM_MACRO name=schedAttr . .>
<PDM_MACRO name=schedAttr . .>
. . .
```

```
<PDM_MACRO name=schedGroup . .>
<PDM_MACRO name=schedGroup . .>
. . .
```

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **attrRef=*.COMMON_NAME*|attributeName**
  Specifies the attribute in the table referenced by an SREL attribute that should be shown on the schedule.

- **detail=0|*1***
  Specifies whether to include the attribute in the detailed n-day view.

- **fmtfunc=*none*|function**
  Specifies the name of a JavaScript function that formats the field for display. The function is passed a single argument containing the value of the attribute, and must return a string that is displayed on the form.

- **hoverInfo=*0*|1**
  Specifies whether to include the attribute in the monthly view info pop-up.

- **ident=*0*|1**
  Specifies whether to include the group name on the n-day view.

- **label=0|string|*$args.&{attr].DISPLAY_NAME***
  Specifies a label for the attribute. A value of zero signifies no label; the default is the display name of the attribute.

- **summary=*0*|1**
  Specifies whether to include the attribute in the summary n-day view.

schedConfig

The schedConfig macro controls the appearance and contents of a schedule form, either the change schedule (list_chgsched_config.htmpl) or the knowledge schedule (list_kdsched_config.htmpl). You define a schedule form with the schedConfig, schedAttr, and schedGroup macrosle. For example:

```
<PDM_MACRO name=schedConfig. . .>
<PDM_MACRO name=schedAttr . .>
<PDM_MACRO name=schedAttr . .>
. . .
<PDM_MACRO name=schedGroup . .>
<PDM_MACRO name=schedGroup . .>
. . .
```

This macro has the following properties:

- **autoSearch=0|1**
  Specifies whether to reissue a search automatically if necessary.

- **defaultView=0|1|7|*30*|99**
  Specifies the initial view as 1 (day), 7 (week), 30 (month), 99 (*n*day), or 0 (list).

- **export=0|*codename***
  Specifies the iCalendar export template code (0=no export).

- **firstday=*0*|1|2|3|4|5|6**
  Specifies the first weekday from 0 (Sunday) to 6 (Saturday).

- **hoverMax=*35*|number**
  Specifies the maximum number of rows in a hover information pop-up.

- **legend=0|*1*|2**
  Specifies the position of a legend (1=top, 2=bottom, 0=none).

- **maxgroups=*4*|*number***
  Specifies the maximum number of groups per cell in month view.

- **ndays=0|(*3,7,14,28*)|(*n1,n2,..*)**
  Specifies the contents the n-days drop-down list as a comma-separated list of numbers. A value of 0 signifies no n-days drop-down list.

- **round=0|(*0,15*)|(*hh,mm*)**
  Specifies event times in hours and minutes enclosed in parentheses. The default of (0,15) specifies rounding to the nearest 15 minutes. A value of 0 signifies no rounding.

- **timefmt=*24hr*|(*am,pm*)**
  Specifies time format as either 12 or 24 hour. You specify the 12-hour value as two comma-separated strings, the first for am and the second for pm.

- **tzSelect=*string***
  Specifies where clause restrictions on the time zone drop-down list.

schedGroup

The schedGroup macro controls the name and styling of groups of items on a schedule form, either the change schedule (list_chgsched_config.htmpl), or the knowledge schedule (list_kdsched_config.htmpl). You define a schedule form with the schedConfig, schedAttr, and schedGroup macrosle. For example:

```
<PDM_MACRO name=schedConfig. . .>
<PDM_MACRO name=schedAttr . .>
<PDM_MACRO name=schedAttr . .>
. . .
<PDM_MACRO name=schedGroup . .>
<PDM_MACRO name=schedGroup . .>
. . .
```

This macro has the following properties:

- **bgcolor=*white*|color**
  Specifies the background color for the group as any valid web color.

- **color=*black*|color**
  Specifies the foreground (text) color for the group as any valid web color.

- **grpname=*name***
  (Required) Specifies the name of the group.

- **icon=*filename***
  Specifies an icon for the group as the name of a file in $NX_ROOT/bopcfg/www/wwwroot/img.

- **label=*string***
  Specifies a label for the group.

- **legend=0|*string***
  Specifies description of the group for the legend. A value of 0 signifies that group is not in the legend.

- **style=*normal*|bold|italic**
  Specifies the text style for the group.

sfDate

The sfDate macro specifies a date control in the search filter of a list form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

  colspan=*1*|*number*

  Specifies the number of columns on the form.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **qbe_condition=*condition***

  Specifies one of the following conditions for comparing the value in this field to the database value:

  - EQ is equal to the value.
  - NE is not equal to the value.
  - GT is greater than the value.
  - LT is less than the value.
  - GE is greater than or equal to the value.

- LE is less than or equal to the value.
- NU is null
- NN is not null.
- IN matches the SQL LIKE expression.
- KY contains the text entered.

sfDropdown

The sfDropdown macro specifies a drop-down selection control in the search filter of a list form.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **codename=*string***

  Specifies the name of a set of values from the ui_selection object that are displayed in the date drop-down control. The values are those values with code attributes that match the value specified for codename.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **default=*text***

  Specifies the default value when the attribute is null.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **lookup=*yes*|no**
  Specifies whether the field should automatically convert to a lookup when the number of entries in the drop-down list exceeds a configured value (typically 10).

- **Noempty=yes|*no***
  Specifies whether the empty value is included in the drop-down list. Specify Noempty=yes to suppress the empty value.

- **op=QBE.op**
  Specifies one of the following conditions for comparing the value in this field to the database value:

  - EQ is equal to the value.
  - NE is not equal to the value.
  - GT is greater than the value.
  - LT is less than the value.
  - GE is greater than or equal to the value.
  - LE is less than or equal to the value.
  - NU is null
  - NN is not null.
  - IN matches the SQL LIKE expression.
  - KY contains the text entered.

- **win=*windowName***
  Specifies the target window. This property is not intended for customer use.

sfEnd

The sfEnd macro marks the end of the definition of a search filter on a list page. You define a search filter with the sfStart, sfEnd, and other sfxxx macros. For example:

```
<PDM_MACRO name=ssfStart. . .>
<PDM_MACRO name=sfxxx. . .>
<PDM_MACRO name=sfxxx. . .>
. . .
<PDM_MACRO name=sfEnd>
```

The macro has no properties.

sfHier

The sfHier macro specifies a hierarchical lookup control in the search filter of a list form. A hierarchical lookup control allows a user to click the caption (header) of the control to pop up a hierarchical selection form.

This macro has the following properties:

- **addPercent=yes|no**

Specifies whether to allow wildcard character searches. This property defaults to the value of the web_wildcard_search option.

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

sfLookup

The sfLookup macro specifies a lookup control in the search filter of a list form. A lookup control allows a user to click the caption (header) of the control to pop up a selection form.

This macro has the following properties:

- **addPercent=yes|no**

  Specifies whether to allow wildcard character searches. This property defaults to the value of the web_wildcard_search option.

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **extraURL=*string***

  Specifies a where clause predicate in URL format to restrict the contents of the control.

- **factory=*name***

Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

sfMultiLookup

The sfMultiLookup macro specifies a multi-value lookup control in the search filter of a list form. A multi-value lookup control allows a user to selection one or more values for the attribute associated with the control.

This macro has the following properties:

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **size=*20*|*number***

  Specifies the width of the input field.

sfStart

The sfStart macro marks the beginning of the definition of a search filter on a list page. You define a search filter with the sfStart, sfEnd, and other sfxxx macros. For example:

```
<PDM_MACRO name=ssfStart. . .>
<PDM_MACRO name=sfxxx. . .>
<PDM_MACRO name=sfxxx. . .>
. . .
```

```
<PDM_MACRO name=sfEnd>
```

This macro has the following properties:

- **button=*true*|false**
  Specifies whether to show the default search filter buttons: Search, Show Filter, Clear Filter, and Create New.

- **color=*string***
  This property is not used in this release (reserved for future use).

- **create=*true*|false**
  Specifies whether to show the Create New button.

- **export=*yes*|no**
  Specifies whether to show the Export button.

- **extraCreateURL=*string***
  Specifies additional arguments for the URL used to create an object.

- **factory=*name***

  Specifies the name of a Majic factory for the selection list. Defaults to the factory referenced by the associated attributes, and so is not typically required.

- **ForceSearchWithKeywords=true|*false***
  Specifies whether to request a nonempty search text. This property is effective only when KnowledgeSearchText is true.

- **KnowledgeSearchText=true|*false***
  Specifies whether to show the knowledge search text at the top of the filter.

sfStartRow

The sfStartRow macro marks the start of a row on a search filter.

This macro has the following properties:

- **type=Set**
  Specifies that the new row begins a row set that is hidden from view until the user clicks the green filter icon at the end of the previous row.

sfTextbox

The sfTextbox macro specifies a textbox in a search filter.

This macro has the following properties:

- **addPercent=yes|no**

  Specifies whether to allow wildcard character searches. This property defaults to the value of the web_wildcard_search option.

- **attr=*attributeName***

  (Required) Specifies the name of the attribute associated with the control.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **disabled=yes|*no***
  Specifies whether the textbox is disabled for input. If you disable the textbox, you must also specify the value, display_value, and qbe_condition properties.

- **display_value=*text***
  Specifies the human-readable value of a disabled textbox. This property is effective only when disabled=yes.

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **qbe_condition=*condition***

  Specifies one of the following conditions for comparing the value in this field to the database value:

  - EQ is equal to the value.
  - NE is not equal to the value.
  - GT is greater than the value.
  - LT is less than the value.
  - GE is greater than or equal to the value.
  - LE is less than or equal to the value.
  - NU is null
  - NN is not null.
  - IN matches the SQL LIKE expression.
  - KY contains the text entered.

- **size=*20*|*number***

  Specifies the width of the input field.

- **value=*string***
  Specifies the value of a disabled textbox used in the search. This property is effective only when disabled=yes.

startFrameset

The startFrameset macro marks the beginning of a frameset definition. You define a frame page with the startFrameset, endFrameset, and frame macros. For example:

```
<PDM_MACRO name=startFrameset. . .>
<PDM_MACRO name=frame. . .>
<PDM_MACRO name=frame. . .>
. . .
<PDM_MACRO name=endFrameset
```

This macro has the following properties:

- **border**
  Specifies the space between the frames.
- **cols**
  Specifies the quantity and sizes of the columns in the frame set.
- **frameborder=*yes*|no**
  Specifies whether the frame has a border (the "frameborder" argument on an HTML <frame> statement).
- **id=*name***
  (Required) Specifies the JavaScript ID of the frame (the "id" argument on an HTML <frame> statement).
- **onload**
  Specifies the onLoad handler of the frame set.
- **onunload**
  Specifies the onUnload handler of the frame set.
- **rows**
  Specifies the quantity and sizes of the rows in the frame set.

startMenu

The startMenu macro marks the beginning of a menu within a menubar definition. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
```

```
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
<PDM_MACRO name=endMenu>
. . .
```

This macro has the following properties:

- **parentid=*name***
  (Required) Specifies the ID of the menubarItem macro specifying this menu.

startMenubar

The startMenubar macro marks the beginning of a menubar definition. You define a menubar page with the startMenubar, menubarItem, endMenubar, startMenu, menuItem, menuItemLocal, and endMenu macros. For example:

```
<PDM_MACRO name=startMenubar. . .>
<PDM_MACRO name=menubarItem. . .>
<PDM_MACRO name=menubarItem. . .>
. . .
<PDM_MACRO name=endMenubar>
<PDM_MACRO name=startMenu. . .>
<PDM_MACRO name=menuItem. . .>
<PDM_MACRO name=menuItemLocal. . .>
. . .
<PDM_MACRO name=endMenu>
<PDM_MACRO name=startMenu. . .>
. . .
<PDM_MACRO name=endMenu>
. . .
```

This macro has no properties.

startNotebook

The startNotebook macro marks the beginning of the definition of a notebook on a detail page. A page can only have one notebook and it must be the last item on the page. You define a notebook with the startNotebook, startTabGroup, tab, and endNotebook macros. For example:

```
<PDM_MACRO name=startNotebook. . .>
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=endNotebook>
```

This macro has the following properties:

- **hdr=*text***

  Specifies the text of the caption on the control; defaults to the DISPLAY_NAME of the attribute associated with the control.

- **ilayer_height=*number***
  This property is deprecated; not used in this release.

- **nb_height=*number***
  Specifies the height of the notebook in pixels.

startTabGroup

The startTabGroup macro specifies the beginning of a group of tabs in a notebook on a detail page. This macro indicates that the notebook is organized in tab groups. A notebook with tab groups shows the groups as the highest level of tab. Tabs following the group are visible only when the group is selected.

You define a notebook with the startNotebook, startTabGroup, tab, and endNotebook macros. For example:

```
<PDM_MACRO name=startNotebook. . .>
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=endNotebook>.
```

This macro has the following properties:

- **title=*string***
  Specifies the name of the tab group that is shown at the top of the notebook. If you omit this property, CA SDM creates the name of the tab group by concatenating the names of all the tabs within the group.

tab

The tab macro specifies a tab in a notebook on a detail page. You define a notebook with the startNotebook, startTabGroup, tab, and endNotebook macros. For example:

```
<PDM_MACRO name=startNotebook. . .>
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
<PDM_MACRO name=tab . .>
. . .
<PDM_MACRO name=startTabGroup. . .>
<PDM_MACRO name=tab . .>
```

```
. . .
<PDM_MACRO name=endNotebook>
```

This macro has the following properties:

- **accordion_specific_tab=true**
  Specifies that this macro defines an CA SDM Release 12.9 notebook. If present, you must specify this property exactly as shown.

- **file=*filename*.htmpl**
  Specifies an immediate tab. The contents of an immediate tab are part of the form containing it, and are formatted at the same time the containing form is formatted. This property specifies the HTMPL file containing its contents. CA SDM looks for a <PDM_FORM> tag in the referenced file, and includes the contents of this form as the contents of the tab. This property is mutually exclusive with the src property.

- **filename=*string***
  Specifies the value of the $prop.filename server variable that is passed to the tab contents. This property has no relationship to the similarly named file property.

- **height=*number***
  Specifies the height of this tab.

- **id=*string***
  Specifies the JavaScript identification of this tab.

- **new_row=yes|*no***
  (Deprecated) Indicates that the tab starts a new row of tabs. This property is informational only and CA SDM ignores it. The startTabGroup macro handles the grouping of tabs into rows.

- **src=*url***
  Specifies that this tab is a deferred tab. The contents of a deferred tab are independent of the main form and are loaded only when the user selects the tab. This property specifies the URL invoked to load the content of the tab. This property is mutually exclusive with the file property.

- **title=*string***
  Names the tab on the notebook.

- **tooltip=*string***
  Specifies a tooltip for a tab on the notebook.

tabBanner

The tabBanner macro specifies a banner (header) within a tab. You can only use this macro within an immediate tab loaded by the file property of the tab macro. The banner can contain text and one or more buttons.

This macro has the following properties:

- **add_btns=true|*false***
  Specifies whether the tab banner contains buttons. When this property is true, the containing form must include a JavaScript that defines the buttons. The btnfunc property specifies the name of the function and defaults to add_button_to_tab_banner().

- **btnfunc=*add_button_to_tab_banner*|*functionName***
  Specifies the name of the function that creates the buttons in the banner when add_btns=true.

- **btns_in_two_rows=*true*|false**
  Specifies whether to include an additional line in the banner for scrolling in the Internet Explorer browser.

- **show_bar=*true*|false**
  Specifies whether to display a horizontal bar below the tab banner.

- **title=*string***
  The text displayed in the tab banner. The string can be an empty string.

tabList

The tabList macro specifies a list included within an immediate tab loaded by the file property of the tab macro.

This macro has the following properties:

- **brBefore=yes|*no***
  Specifies whether to insert a line break before the list for spacing.

- **btnTitle=*string***
  Specifies a title for the Load button displayed when the Screen Reader preference is active.

- **colspan=*1*|*number***

  Specifies the number of columns on the form.

- **frmName=*string***
  Specifies a JavaScript identification of the HTML iframe that contains the list.

- **height=*number***
  Specifies the height of the generated list.

- **src=*url***
  (Required) Specifies the URL to invoke to generate the list.

Security and Role Management

This article contains the following topics:

Set up security and role management for user authentication, user access level, and the mode of authentication while logging in.

Access Types

Access types define contact roles, contacts authentication, and whether the contacts can modify web forms or the database schema.

Modify the predefined access types and create new ones.

Assign Access Type Using LDAP Groups

Assign AccessTypesvaluestocontactsautomatically with a Lightweight Directory Access Protocol (LDAP) server.

Note: To enable this feature, install the ldap_enable_group and ldap_group_object_class options.

Follow these steps:

1. Select Security and Role Management, Access Types on the Administrator tab.
2. Select the Access Type you want to associate with an LDAP Group. For example, select Administration.
   If the ldap_enable_group option is installed, the LDAP Access Group field appears on the Web Authentication tab.

   Note: If an LDAP Group is already associated with the selected Access Type, a link to the LDAP Group Detail appears. Click the link for a read-only description of the LDAP Group and a listing of its members.

3. Click Edit on the Access Type Detail page to associate an Access Type with an LDAP Group.
4. Click the LDAP Access Group link.
5. (Optional) Enter filter criteria to limit the search to the LDAP groups of interest.
6. Select the LDAP Group that you want to associate with this Access Type.
7. Click Save.
   Association of the selected LDAP Group with the Access Type is complete.

Create an Access Type

Access types define how contacts are authenticated when they log in to the web interface, whether the contacts can modify web forms or the database schema using Web Screen Painter, and which roles are available for the contacts.

You can modify the predefined access types and create new ones.

The access types define all aspects of security. Several predefined access types are included, and you can modify them or can define new ones. Each access type for a user controls the following aspects of system behavior:

- How CA SDM performs the web authentication when the user logs in.
- The access level for the user.
- Whether the user can modify web forms or the database schema using Web Screen Painter.
- What are the roles available to the user.

Follow these steps:

1. Select Security and Role Management, Access Types on the Administration tab.
   The Access Type List page opens.
   Default: 15
2. Click Create New and complete the access type fields (https://wiki.ca.com/display/CASM1401/Data+Partition+Associations#DataPartitionAssociations-AccessTypeFields), as appropriate, on the Create New Access Type page.
3. Use the tabs to complete the following tasks:
   - Configure Web Authentication for an Access Type (https://wiki.ca.com/display/CASM1401/Data+Partition+Associations#DataPartitionAssociations-ConfigureWebAuthenticationforanAccessType)
   - Assign Web Screen Painter Permissions to an Access Type (https://wiki.ca.com/display/CASM1401/Data+Partition+Associations#DataPartitionAssociations-AssignWebScreenPainterPermissionstoanAccessType)
   - Assign Roles to an Access Type (https://wiki.ca.com/display/CASM1401/Data+Partition+Associations#DataPartitionAssociations-AssignRolestoanAccessType)
4. Click Save.
   The access type is created.

Access Type Fields

The following fields appear on the Create Access Type, Access Type Detail, and Update Access Type pages.

- **Symbol**
  Specifies a unique identifier for the access type.

- **Default?**
  Indicates whether this access type is the default that is associated with contacts.

- **Record Status**
  Specifies whether this access type is Active or Inactive.

- **Description**
  Describes the access type. Use this field to help identify the characteristics of the access type.

- **Receive Internal Notification**
  Determines whether the contacts associated with the access type receive internal notification of activities that are related to tickets.

- **Access Level**
  Determines which access types a user can grant to another user. A user can assign an access typeto the contact record of another user only if the access level of the access type they are attempting to assign is ranked the same as or lower than thegrant level for their own access type. The levels are ranked as follows:

  - Admin (highest)
  - Analyst
  - Cust/Emp
  - None (lowest)

  Licensed?
  Determines whether thiscontact is a licensed access type. Contacts assigned to unlicensed access types can only view or update their own personal data.

Configure Web Authentication for an Access Type

You can configure the web authentication and validation type to specify how roles assigned to this access type are authenticated when users attempt to access the CA products. Complete the following fields in the **Web Authentication** tab.

- **Allow External Authentication**
  Select this check box if you want to allow contacts to be authenticated externally, for example by the HTTPD server or the operating system. If you select this option, users with this access type are validated by the appropriate external method as configured during installation.Checks ensure that no external validation has taken place (for example, that the user has not attempted access through a non-secure server) and that the user is defined as a valid contact in the system using the login ID. Then, it uses the access type to determine the correct interface to use.

- **Validation Type**
  Defines how users are authenticated when an external authorization is either not permitted or fails (for example, if the user is attempting access through a non-secure server). The available options are:

  - **No Access**
    Denies access to CA products unless external authentication is allowed and is valid.

  - **Open**
    Access to the CA products are always allowed, with no additional authentication required.

  - **OS**
    Access to the CA products are allowed through operating system user name and password.

  - **PIN / PIN Number**
    Users of this type can access only if they enter the correct value for the PIN field in their contact record. If you select the PIN option, you can choose which field in the contact record stores the PIN by entering the field attribute name in the PIN Field edit box.

  - **CA EEM**
    Access to the CA products are allowed through CA EEM. This option is available only if CA SDM is integrated with CA EEM.

  - **OS-Use Operating System**
    When the Administration Access Type Validation Type drop-down is set to **OS-Use Operating System Authentication** and if you want to login using the CASMAdmin user, you must first create the CASMAdmin user in the Operating System for the login to be successful.

Assign Web Screen Painter Permissions to an Access Type

The Web Screen Painter (WSP) utility allows CA SDM users to build and publish web forms and schemas. The Web Screen Painter tab also controls the database access for Web Screen Painter preview sessions. For the details about WSP, see Using the Web Screen Painter (WSP) (https://wiki.ca.com/pages/viewpage.action?pageId=103915346).

Select the permissions that you want to allow for an access type in the Web Screen Painter tab.

- **Modify Forms**
  Allows the users todo the changes to existing forms withoutdoing the changes available to all users.

- **Modify Schema**
  Allows the users todo the changes to an existing schema withoutdoing the changes available to all users.

- **Publish Forms**
  Allows the users to make their modified forms available to all users.

- **Publish Schema**
  Allows the users to make their modified schema available to all users.

- **Preview Session Can Update Database**
  Allows the users to do the changes to the database during a preview session. By default, database changes are not allowed during a preview session.

Assign Roles to an Access Type

Assign the roles to an access type to limit contacts access to functional areas for assigned roles.

Follow these steps:

1. Select the following roles for this access type:
   - **Reporting Role**
     Defines the reporting access for this type.
   - **REST Web Service API Role**
     Defines the access to the REST web services for this type.
   - **SOAP Web Service API Role**
     Defines the access to the SOAP web services for this type.
   - **Command Line Utility Role**
     Defines the access to the command-line utilities for this type.
2. Click Update Roles.
   The Role Search page opens.
3. Enter any search criteria that you want to limit the list tothe roles of interest, and then click Search.
   The Roles Assigned - Update page opens, listing the roles that matched the search criteria.
4. Select the roles that you want to assign. To select multiple items, hold down the CTRL key while clicking the left mouse button.
5. Click the double right-directional arrows, after you have selected all the roles that you want.
   The selected roles move to the Roles Assigned list on the right.
6. Click OK.
   The Access Type Detail page opens, with the assigned roles listed on the Roles tab.
7. Click Save.
   The Access Type Detail page opens, with a confirmation message that your changes have been saved.
8. Select the role that you want to be the default for this access type upon login. Click Set Default Role.
   Your selection for the default role is saved.

Create Contacts Manually

If you do not want to use an active directory such as LDAP for your contacts information, you can create the contacts manually in CA SDM.

Note: If multi-tenancy is enabled, select the appropriate tenant from the drop-down list.

Follow these steps:

1. Select File, New Contact from the menu bar on the Scoreboard.
   The Create New Contact window opens.

2. Complete the following fields as appropriate for the contact:

Tenant

Specifies the tenant that is associated with the contact (for multi-tenancy installations).

Contact ID

Specifies a unique identifier for the contact. If the default user authentication is being used, the value in this field is used as the password when the user logs in.

User ID

Specifies the user name of the contact. The contact uses this value to log in to the system.

Service Type

Specifies the level of support that is received by the contact.

Data Partition

Specifies the data partition for this contact. This value determines the records that this contact can access.

Access Type

Specifies the access type. The access type determines the system functions the contact can access.

Available

Indicates whether the contact is available for ticket assignments.

Confirm Self-Service Save

Indicates whether the contact receives a confirmation when saving a record from the self-service interface.

Analyst's Tenant Group

(Analyst Contact Type Only) Specifies the tenant group that the analyst is responsible for.
To configure the contact, use the following controls available on the tabs.

Notification

Defines the contact information and method for notifying the contact.

- Select the notification method from the drop-down list (Email, Notification, Pager_Email, xMatters/Email, xMatters/Notification, and xMatters/Pager_Email) that you want to use for each message urgency level for this contact.

  Note: CA SDM supports only one notification method at a time. If you are using Email, then you cannot use Notification at the same time. This applies to all out of the box notification methods like Email, Notification, Pager_Email, xMatters/Email, xMatters /Notification, and xMatters/Pager_Email.

  Note: CA SDM Administrators must update the notification method manually in the contact details page if the xMatters and CA SDM integration is disabled. For more information, see Create a Notification Method (see page 834) and Options Manager xMatters (see page 1303).

- Select the workshift that is valid for each notification urgency level.

For example, you may assign a Regular workshift (five-day week, eight-hours a day) to the normal level notification, but a 24 hour workshift to the emergency level notification.

Address

Specifies the location of the contact.

Organizational Info

Specifies the functional or administrative organization, department, cost center, or vendor information of the contact.

Environment

Specifies the environment of the contact, such as equipment, software, and services.

Groups

Assigns a contact to a group (a collection of contacts with a common area of responsibility).

Roles

Assigns the contact to one or more roles.

Service Contracts

Displays any service contracts that have been associated with the contact.

Special Handling

Lists the special handing contacts and lets you search for and associate a contact to a special handling type, such as a visitor or security risk type.

Event Log

Lists events that are associated with the contact, such as self service and knowledge activities.

Activities

Lists the activity log for the contact.

Click Save.
The contact information is saved.

Building CA Service Catalog

This section contains the following articles:

Guidelines for Modifying Catalog Content

When you modify the catalog content, follow these guidelines, mostly in sequential order, but with iteration as needed:

- Install all content onto a test system, and then browse and understand the default catalog content.
- Review the frequently asked questions. (see page 1995)
- Understand the basic structure of catalog entries. (see page 1996)
- Understand the main parts of a service specification (see page 1999). View the sample service specification (see page 2000) for further details.

- Illustrate the fulfillment of the service as steps in a business process that you can follow logically.
- Create a detailed logical design to help you design the service in the CA Service Catalog.
- Determine what parts of the default catalog you want to modify in your production catalog.
- On subsequent installations, load only those sections of the content that fit into your test catalog.
- Configure all customizations in a test catalog. Test and refine them until you approve them.
- Copy only the approved modifications into your production catalog.
- Consider maintaining a separate development catalog in addition to a test catalog. Keeping the two separate ensures that testing and development can occur in parallel.

Frequently Asked Questions

The following information provides answers to frequently asked questions and includes instructions for managing your catalog content.

- **How do I modify the catalog content?**
  Modify the catalog content by using the standard CA Service Catalog component of the web browser user interface.
- **How do I back up, import, and export catalog content?**
  Use the IXUtil utility to back up the content. You can then export this content from one system, and to import it into another system.
- **How do I make bulk changes to the catalog content?**
  Make bulk changes to the catalog, as follows:

  1. Export the catalog folder or service to be changed, using the IXUTIL utility.
  2. Edit the exported XML file using a text editor.
  3. Delete and reimport the folder into the catalog.

  This process works well for simple changes in descriptions and naming conventions. For example, suppose that your IT organization is named General Information Services (GIS). In that case, consider a bulk change to replace the word "IT" with "GIS" within the catalog.
  You must be familiar with using a text editor for editing the XML files. Be especially careful to use a text editor like Notepad, not a word processor like Microsoft Word.
  Also follow these guidelines:

  - Back up frequently. If referential integrity issues occur, the import process does not always import all content.
  - Review the ixutil.log in the USM_HOME\logs\install folder after each import. Review it for duplicate name errors and other errors that incorrect syntax in the imported data can cause.
- **How do I copy catalog entries from test catalogs to production catalogs?**
  Copy catalog entries from test catalogs to production catalogs, as follows:

1. Use a test catalog to modify the default catalog content.
2. Back up the test catalog.
3. Export the updated catalog content from the test catalog.
4. Import the updated catalog content into your production catalog.

The two entities included in your catalog are the catalog entries and the associated images and URL links.
Use the IXUtil utility to export the catalog entries from the test catalog. Use the same utility to import the exported content into the production catalog.
The catalog entries include folders, services, service option groups, and service option elements. Copy the following entities to the production environment separately: category, class, and subclass definitions (category.xml), images, and status definitions.

Catalog Entries

As an administrator, you use the CA Service Catalog to create and maintain catalog entries. The following types of catalog entries exist:

- Folders (see page 1996)
- Services (see page 1997)
- Service Option Groups (see page 1997)
- Service Options and Service Option Elements (see page 1998)
- Images (see page 1999)
- Category, Class, and Subclass (see page 1999)

Understand these types before you create or modify catalog entries.

Many entries in a single container can be difficult for catalog users to navigate. Therefore, as a general guideline, we recommend that you limit the number of entries in a container to ten. For example, verify that no folder contains more than ten sub-folders or services. Similarly, verify that no service contains more than ten service options.

Note: The out of the box content does *not* add new statuses to the predefined statuses in CA Service Catalog.

Folders

The installation process creates the folders that you select. If you select all folders, then the installation process creates the following top-level folders:

- IT Services
- Telecom Services
- Network Services

- Application Services
- Project Services
- Corporate Services
- Personnel Services
- Facilities Services
- Reservation Services

The names of the folders and services in your catalog must be unique.

If you create your own folders, you can name them any unique name. You can modify the content from the predefined folders. We recommend short descriptive names for folders.

Services

The catalog supports services that contain multiple service option groups. In this starter implementation, however, most services contain one associated service option group. As the catalog designer, you decide to use either one or multiple service option groups per service. In both cases, we recommend that you organize related service option groups in services logically and intuitively.

Focus on the user when designing services and service option groups. A common flaw in catalog design is placing service option groups in a non-intuitive service or folder. When service option groups in a service or folder are unrelated, users have difficulty finding the services that they want. For example, consider a service option group for a network design program. You could place it in a service or folder named Development Tools. However, such a service option group fits better in a service or folder named Miscellaneous Software. A network administrator is more likely to view the latter folder first for this program.

The catalog provides a search tool that can be helpful. This tool supplements thoughtful design, but does not replace it.

Service Option Groups

Most service option groups in the predefined catalog are named the same as the corresponding service, for simplicity. They have multiple service options that are contained within them.

As your catalog becomes more mature, this one-to-one relationship between services and service option groups is likely to decrease. Some examples of having multiple service option groups in a service exist in the "Procure Laptop" and "Procure Desktop" services. The hardware configuration of laptops and desktops have differences. However, the standard and optional software that is bundled with them is typically identical. Therefore, the catalog does not duplicate the service options that are related to software choices in the two services. Instead, both services include service option groups for standard and optional software bundles.

The naming conventions become more important as the number of services and service option groups increases. The naming standards are as follows:

- All folders and services have unique names.

- If a service contains only one service option group, their names are the same.
- If a service contains multiple service option groups, one service option group has the same name as the service, and the others have unique names.

Service Options and Service Option Elements

A service option is the most basic element that users can request or subscribe to in the catalog. A service option consists of one or more service option elements. The service options in the Best Practice content have the following service option elements. Your modified catalog can have more or fewer service option elements, depending on its design.

- **Short Description**
  Specifies a plain text field (not rich text) that describes the service being requested or subscribed to.
  Use this option to describe the service in cases where rich text or HTML is not processed properly. For example, the workflows use this column to title the email.

- **Long Description**
  Specifies a rich text field.
  This text describes the service in detail. This text can also include a hyperlink to an internal web page containing more information about the service.

- **Rate**
  Specifies the cost of the service option.
  Consumers must understand the cost of the service to the corporation, regardless of whether the request is charged back.
  Because the cost structure at your location is unique, all service option elements have been set to a one-time charge. Determining cost and rate structures depends on a number of factors. In some cases, the rate posted in the catalog is only advisory: The rate reminds users that although they are not charged, the service is not free. In other cases, however, the posted rate is linked to a chargeback policy. In these cases, it is designed to recover the cost of the service. Accounting Component is designed for automating the process of tracking service costs.

- **Service Level**
  Describes the level of service the user can expect. The user can click the "More Information" link to get a description of the basic levels of service that they can subscribe to. The sample information that is displayed when you click the "More Info" hyperlink is contained in "sladescription.html" located in the USM_HOME\filestore\images\offerings directory.
  You can change this location, as follows: Use the CA Service Catalog, Service Offerings, Options Group to modify each service option element in your catalog to reference a file in another location.

- **Special Instructions**
  Specifies more instructions for the user. Many services require users to specify more detail information. An example is a "backup production server" service on which you must back up files and must specify the backup interval. The instructions tell users to place this information in the notes that are associated with a request.
  You can use the Form service option element type to present custom forms to gather more information from the requester.

Images

You can optionally associate images with every folder, service, and service option. All images reside in USM_HOME\filestore\images\offerings.

Images whose size is 32x32 pixels fit best in the catalog.

Images can be in any format suitable for a web browser (For example, .jpg, .bmp).

Many predefined images exist in this directory. The Best Practice content does not use all of them. You can optionally use these predefined images and add others to meet the needs of your organization. Use images that help users searching for a service to find the service they need.

Category, Class, and Subclass

The first service option element in a service option determines the Category, Class, and Subclass for the other items in that row. The Best Practice: Foundation catalog uses several Category/Class /Subclasses which are defined in category.xml. If you are building your catalog "from scratch," you can use any Class/Subclass structure. The Category drives associated Workflow processing and other downstream activities. So, do not change the predefined Category corresponding numeric values.

The predefined service option elements reference the predefined category, class, and subclass values in the category.xml file. If you build your catalog on top of the best practices content, do not *change* the predefined settings in the file. Instead, *add* new categories, classes, or subclasses in the file, if necessary.

Service Specification

When you design your catalog, consider the following service specification factors. These attributes help your customers understand the service.

Attribute Name	Definition
Service Description	Brief description of the service which explains what the service includes.
Service Exclusions	Brief description regarding what is not included in the service.
Service Core Dependencies	Listing of the underlying services and processes that are necessary for this service.
Service Options	The various components and options available to users when ordering the service from the catalog.
Service Hours	The time period during which the service is typically available.
Service Maintenance and Planned Down Time	The time period during which the service is typically not available due to scheduled maintenance.
Service Availability	The targeted percentage (of the defined Service Hours) during which service is available for requests.
	The person responsible for the service.

Attribute Name	Definition
Service Owner (Performance Measure Owner)	
Service Users	The intended group of requesters for this service.
Performance Measures /Descriptions	One or more defined performance measurements for the service fulfillment with a base line target.
Key Performance Indicators	The performance measurement which is the primary indicator of the performance of the fulfillment of this service.
Key Goal Indicators	The overall company benefit from this service.
Data Collection Method /Frequency	An overview of the intended data collection method and frequency. If tools and methods are known, specify them in this attribute.
Cost Categorization (to Business Unit)	Definition of the cost categorization of the service regarding the following aspects of costs: direct and indirect, capital and operational, fixed and variable, cost type, cost elements, cost units.
Charging Policies	The charging policy for this service. The template gives examples both for internal and external providers.

Sample Service Specification

This sample server specification illustrates the following costs that are associated with the "Personal Computer (PC)" service:

- Direct (associated costs that are allocated directly to the IT organization) for the request of the other vendor software.
- Capital for the acquisition of the new PC.
- Variable depending on the number of new PC requests.

Charges are based on the following elements:

- Internal Service Provider
- Initial setup of the service at the time of SLA signature plus Hardware
- Fixed subscription per year
- Cost of usage per request
- External Service Provider
- Market Standard

Element	Description
Service Name	Personal Computer

Element	Description
Service Description	New Desktop or Laptop
Service Exclusions	No support, No Equipment Returns
Service Core Dependencies	Architectural standards, including approved server hardware lists Procurement process for IT infrastructure equipment, including appropriate vendor agreements
Service Options	Options, such as Standard Laptop, Deluxe Laptop, Standard Desktop, Deluxe Laptop
Service Hours	24 hours per day, 7 days per week, 365 days per year This value can vary, depending on Service Level that the customer selects.
Service Maintenance and Planned Down Time	Last Sunday of every month from 2AM - 3AM EST This value can vary, depending on Service Level that the customer selects.
Service Availability	Availability Target: 99% of Service Hours This value can vary, depending on Service Level that the customer selects.
Service Owner (Performance Measure Owner)	John Doe - Director, IT Organization
Service Users	Finance, Marketing, Operations, and Customer Service Organizations
Performance Measures and Descriptions	Acknowledgment of order Number of hours that have elapsed between user submitting the request and user receiving acknowledgment of the order. Target: Average less than eight hours Order Fulfillment: Normal Number of days that have elapsed between user submitting the request and user receiving acknowledgment that the requested items are available. Target: Average less than seven days
Key Performance Indicators	Number of days that have elapsed between the time the user submitted the request and the time the vendor notified the user that order was shipped
Key Goal Indicators	Better capacity planning and inventory management through standardized procurement processes Compliance to SLAs by third-party vendors and providers Standardization of computers throughout the organization
Data Collection Method /Frequency	Data is collected for “time of request”, “time of acknowledgment” and “PC available” by feeds. The feeds are available from tools that are used at each event. If the feeds are not available, collect the data daily.
Cost Categorization	Direct and Indirect - Direct cost of service Capital and Operational Capital Fixed and Variable - Fixed based for subscription - variable per request Cost Type - Service + Hardware Cost Elements - Hardware + Services Defined in Service Dependencies Cost Units - Per Request + Hardware
Charging Policies	Internal Service Provider - Fixed Setup Price + Hardware External Service Provider - Market Price

Add Custom Fields to the User Interface

On the CA Service Catalog user interface, you can optionally add custom field that is related to business units, accounts, or users. You can add a new field to meet a custom requirement for your organization or one of your customers. To do so, follow this process:

- Step 1 - Review the Additional Data Fields (see page 2002)
- Step 2 - Review the Sample custom.xml File (see page 2002)
- Step 3 - Expose Additional Data Fields (see page 2002)

Step 1 - Review the Additional Data Fields

The Business Unit, Account, and User schemas in the CA Service Catalog database tables provide extra data fields. By default, these fields do not have labels. The fields do not appear on the CA Service Catalog user interface.

The additional data fields and their data types follow.

- The additional data fields (and their types) for business units in the usm_tenant table follow: data1: nvarchar(32)data2: nvarchar(32)data3: nvarchar(32)data4: nvarchar(64)data5: nvarchar (64)data6: nvarchar(128)data7: nvarchar(128)

- The additional data fields (and their types) for accounts in the usm_account table follow: data1: nvarchar(32)data2: nvarchar(32)data3: nvarchar(32)data4: nvarchar(64)data5: nvarchar (64)data6: nvarchar(64)data7: nvarchar(128)

- The additional data fields (and their types) for users in the usm_contact_extension table follow: data1: nvarchar(512)data2: nvarchar(512)data3: nvarchar(512)data4: nvarchar(512)data5: nvarchar(512)data6: nvarchar(512)data7: nvarchar(512)

Step 2 - Review the Sample custom.xml File

The custom.xml file lists all additional data fields for CA Service Catalog. Optionally expose an extra data field on the CA Service Catalog user interface by adding a label to the field.

The custom.xml file can be different based on the language that is chosen for the system. This file is located in a different folder for each language. For example, for English (icusen), the custom.xml file is located in the USM_HOME\view\webapps\usm\locale\icusen folder.

Step 3 - Expose Additional Data Fields

You can expose the data fields fields to add custom fields to the user interface.

Follow these steps:

1. Edit the custom.xml file for the language of your system. For example, for English, edit the USM_HOME\view\webapps\usm\locale\icusen\custom.xml file.

2. Type the label for the field between the start and end tags for the appropriate field (data1-data7) for the appropriate object: account, business unit (tenant), or user.
   This label appears on the user interface to help users identify the purpose of the field.

3. Save the custom.xml file.

4. Verify that the label appears as specified when you view the related object on the GUI. Examples include the associated add, edit, and profile pages.

Example: Expose Additional Fields in the User Interface

This example configures the account data1 and account data 5 fields in the custom.xml file to expose Cost Center and Department data on the GUI:

```
<account>
        <data1>Cost Center</data1>
        <data2></data2>
        <data3></data3>
        <data4></data4>
        <data5>Department</data5>
        <data6></data6>
        <data7></data7>
</account>
```

Note: To expose a field without specifying a new label on the user interface, specify a space as the value of the label.

Modify the Category, Class, and Subclass Lists

Each service option in the catalog has a category, class, and subclass assigned to it. CA Service Catalog assigns a value to each category, class, and subclass in the category.xml file.

Each <option> section in the category.xml file represents a separate category and contains one or more <class> sections. Each of these sections contains one or more <subclass> sections.

The category.xml file can be different based on the language that is chosen for the system. The file is located in a different folder for each language. For example, for English (icusen), the category.xml file is located in the USM_HOME\view\webapps\usm\locale\icusen\billing folder.

Each service option in the catalog has a predefined category, class, and subclass assigned to it. You can update the existing values or can add new values to meet the needs of your organization or customer.

Note: After you add a category, class or subclass value in the category.xml file, do *not* remove it. Ensure that you do not change the meaning of the category values, because business logic in the product is based on the category values.

Follow these steps:

1. Review the inline comments in the file. Verify that synchronized sections of the file remain synchronized. Verify that you do not use, certain status values.

2. Edit the appropriate category.xml file for the language of your system. For example, for English, edit the USM_HOME\view\webapps\usm\locale\icusen\billing\category.xml file.

3. Add a line or section for the category, class, or subclass you want to add. Select an unused numeric value for the category, class, or subclass you are adding.

   Note: To add a new category, add a new “option” section containing at least one class and subclass. To add a new class, add a new “class” section containing at least one subclass.

   Use a unique numeric value within the list of related objects. For example, suppose you add a new class to the Other category. In that case, you cannot use a value of 10, because the IT class already uses that value.

4. Update any existing values as needed; do *not* use the same value twice.

5. Save the category.xml file and test by using the CA Service Catalog user interface screens.

Example: Add a New Subclass

To add a new subclass named “Mouse” to the IT class of the Hardware category, modify the category.xml file as illustrated in the following example:

```
<option value="1" name="Hardware">
      <class value="10" name="IT">
          <subclass value="10" name="Desktop" />
          <subclass value="20" name="Laptop" />
          <subclass value="30" name="Monitor" />
          <subclass value="40" name="Memory" />
          <subclass value="50" name="Printer" />
          <subclass value="60" name="Server" />
          <subclass value="70" name="Storage" />
          <subclass value="71" name="Mouse" />
          <subclass value="999" name="Other" />
      </class>
    ...
  </option>
```

Modify the User and Service Approval Level List

Each user is assigned an approval level, in its user profile. Each service that requires approval is also assigned an approval level, in its service definition.

When a service uses the “System approval process,” the approver requires an approval level equal to or greater than the approval level of the service. Otherwise, the approver cannot approve or reject the service.

The approval level values are maintained in a file named approval_shared.xml. This file can be different based on the language that is chosen for the system. The file is located in a different folder for each language. For example, for English (icusen), the approval_shared.xml file is located in the USM_HOME\view\webapps\usm\locale\icusen folder.

You maintain the approval levels for users and services in a file named approval_shared.xml. You can add or change the values in this file to meet the needs of your organization.

Note: After you add an approval level to the file, do not remove it.

Follow these steps:

1. Edit the appropriate approval_shared.xml file for the language of your system, using an editor, such as Notepad. For example, for English, edit the approval_shared.xml file in the USM_HOME%\view\webapps\usm\locale\icusen folder.

2. Add a line for the approval level that you want to add. Select an unused numeric value for the approval level you are adding.

3. (Optional) Update an existing name or value in the file.

4. Save the approval_shared.xml file.

5. Verify that the new approval level appears as an option when you edit user profiles and service definitions on the product interface.

You have maintained the approval levels for users and services.

Example: Add a New Approval Level

This example illustrates a new approval level added to approval_shared.xml file. The name of the level is Director. The approval level value is 60.

```
<?xml version="1.0" encoding="UTF-8"?>
<shared>
    <approval_level>
        <option value='0'>Level 0</option>
        <option value='10'>Level 10</option>
        <option value='20'>Level 20</option>
        <option value='30'>Level 30</option>
        <option value='40'>Level 40</option>
        <option value='50'>Level 50</option>
        <option value='60'>Director</option>
    </approval_level>
</shared>
```

Modify the Request Status List

This article contains the following topics:

Each service and service option in a request has a status. In addition, the request has an overall status. CA Service Catalog supplies an extensive list of status values by default. Modify status values for the approval and fulfillment phases of the request life cycle, by editing the requestshared.xml file. You can also change the spelling of existing status values.

You maintain the request status values in the requestshared.xml file. This file can be different based on the language that is chosen for the system. The file is located in a different folder for each language. For example, for English (icusen), the requestshared.xml file is located in the USM_HOME\view\webapps\usm\locale\icusen\request folder.

The request status of the *entire* request is visible on the Pending Actions page. The request statuses of individual items in the request are visible in the Item Status drop-down list on the request-related user interface pages: Request Details, Approve Request, Fulfill Request, and Push Through Request. Updates that you make to the request status values in the requestshared.xml file are reflected in the options that users see on those pages.

Follow these steps:

1. Become familiar with the requestshared.xml file (see page 2007).
2. Back up the original requestshared.xml file and save it for reference.
3. (Optional) Modify existing status values or add additional request statuses (see page 2008).
4. (Optional) Hide request statuses (see page 2010).
5. (Optional) Restrict the status changes available for a request item based on its status (see page 2012).
   By default, all options (all statuses) are available for an item always, until the entire request is completed. In other words, you can change the status of request items to any value at any time. However, your organization can optionally restrict the menu options available for a request item that is based on its status.
6. Test your changes by verifying that they are correctly reflected on the request-related user interface screens.
   In the Item Status drop-down list on the request-related user interface pages, the status is designated with an asterisk (*).

Important! After you have added and used status numeric values to the default list, do *not* remove them.

Review requestshared.xml

Become familiar with the requestshared.xml file, as follows:

- Understand the purpose of the major sections (see page 2007) of the file: request_header, request_item, request_item_approval_action, and request_item_fulfillment_action.
- Understand that the status values in these sections must remain synchronized.
- Understand that the order of the statuses in the status drop-down lists on the GUI matches the order of the statuses in the requestshared.xml file. For example, suppose that the status 800 (Reject) is defined above the status 600 (Approved) in this file. In this case, the Reject status appears above the Approved status in the status drop-down lists on the GUI.
- Review the inline comments and note the *reserved* status values.
- Review the ranges for custom status values (see page 2008) to see which ranges are reserved for specific types of status values.

Important! Do *not* modify or delete the opening and closing lines that define the default statuses in the requestshared.xml file . Even when you modify statuses, these lines must remain as shown. This requirement applies to both the <request_item_approval> and <request_item_fulfillment> sections. These lines help ensure proper status behavior when the customizations are not used or are defined incorrectly.

```
- <custom_menu current_status_value="default">
status lines
</custom_menu>
```

Major Sections

The major sections of the requestshared.xml file are as follows:

- **request_header**
  Maintains all possible status values for the entire request.
- **request_item**
  Maintains all possible status values for a specific item (such as a service option element or service option group) in a request.
- **request_item_approval_action**
  Maintains all possible status values for a specific item in a request, when the request has been submitted but has not been approved or rejected.

- **request_item_fulfillment_action**
  Maintains all possible status values for a specific item in a request, when the request has been approved but has not yet been fulfilled.

The list of possible status values must be synchronized in the request_header and request_item sections: They must have the same values with same meaning.

Every value in the request_item_approval_action and request_item_fulfillment_action sections must have a matching value in both the request_header and request_item sections. The value in the request_item_approval_action and request_item_fulfillment_action sections must be a complete set or a subset of the values in the request_header and request_item sections.

Ranges for Custom Status Values

When adding a new request status in the requestshared.xml file, define it within the range that is specified for the custom statuses:

- 300 to 399 - custom *submit* status
- 500 to 599 - custom *pending approval* status
- 900 to 990 - custom *approved* status

Add an Additional Request Status

You can modify the request status list by adding request statuses. One common purpose is for approval or rejection of a request by a specific department. For example, the Finance department.

Follow these steps:

1. Edit the requestshared.xml file for the language of your system in a text editor. For example, for English, edit the file in the USM_HOME\view\webapps\usm\locale\icusen\request folder.

Add a line, including the number and text for the new status to the following sections: <request_header> and <request_item>.

- Select an unused numeric status value in the appropriate range for custom status values for the status you are adding.

  Note: If possible, limit the text of the status value to 40 characters. Text longer than 40 characters can be truncated in the drop-down status menu lists and request status fields. In such cases, the entire text string is displayed to catalog users *only* in the tooltip text.

- Copy that line to the custom section or sections where you want them to appear. Examples include <request_item_approval>, <request_item_fulfillment>, <request_item_stuck_approval_action>, and <request_item_stuck_fulfillment_action>.
- Delete the text from the line you copied and modify the line to include the statval="*value*" expression.

- Save the requestshared.xml file.
- Verify that the changes are correctly reflected on the request-related user interface screens (the Request Details, Approve Request, and Fulfill Request screens).

Example: Add New Approval Statuses

To add approval statuses 500, 700, and 900, all related to financial approval, add the new lines for these statuses to the request_header, request_item, and request_item_approval_action sections of the requestshared.xml file. Examples follow, in **bold**.

Specify the numeric value and text in the request_header and request_item sections. Specify only the numeric value (without the text) in the request_item_approval_action section.

```
<?xml version="1.0" encoding="UTF-8" ?>
...
- <request_header>
  <!--  status values must be synchronized with the status list in request_item,
request_item_approval_action and/or request_item_fulfillment_action   -->
  <st_1>Pending</st_1>
  <st_2>Completed</st_2>
...
  <!--  400 to 499 are reserved   -->
  <st_400>Pending Approval</st_400>
  <!--  500 to 599 can be used for custom pending approval status   -->
  <st_500>Pending Financial Approval</st_500>
  <!--  600 to 699 are reserved   -->
  <st_600>Rejected</st_600>
  <!--  700 to 799 can be used for custom rejected status   -->
  <st_700>Rejected by Financial Approver</st_700>
  <!--  800 to 899 are reserved   -->
  <st_800>Approved</st_800>
  <st_801>Approval Not Needed</st_801>
  <!--  900 to 990 can be used for custom approved status   -->
  <st_900>Approved by Financial Approver</st_900>
  !--  991 to 999 are reserved   -->
  <st_999>Approval Done</st_999>
...
 </request_header>
- <request_item>
  <!--  status values must be synchronized with the status list in request_header,
request_item_approval_action and/or request_item_fulfillment_action   -->
  <st_1>Pending</st_1>
  <st_2>Completed</st_2>
...
  <!--  400 to 499 are reserved   -->
  <st_400>Pending Approval</st_400>
  <!--  500 to 599 can be used for custom pending approval status   -->
  <st_500>Pending Financial Approval</st_500>
  <!--  600 to 699 are reserved   -->
  <st_600>Rejected</st_600>
  <!--  700 to 799 can be used for custom rejected status   -->
  <st_700>Rejected by Financial Approver</st_700>
```

```
  <!--  800 to 899 are reserved   -->
  <st_800>Approved</st_800>
  <st_801>Approval Not Needed</st_801>
  <!--  900 to 990 can be used for custom approved status   -->
  <st_900>Approved by Financial Approver</st_900>
  <!--  991 to 999 are reserved   -->
  <st_999>Approval Done</st_999>
...
  </request_item>
- <request_item_approval_action>
  <!--  status values must be synchronized with the status list in request_header and
request_item   -->
  <!--  A "default" value for the attribute "current_status_value" indicates these
statuses will be listed by default in the "item status" menu if no other custom
statuses are defined   -->
  <custom_menu current_status_value="default">
  <!--  400 to 499 are reserved   -->
  <!--  500 to 599 can be used for custom pending approval status   -->
    <st_500 statval="500"/>
  <!--  600 to 699 are reserved   -->
  <!--  700 to 799 can be used for custom rejected status   -->
  <st_700 statval="700"/>
  <!--  800 to 899 are reserved   -->
  <st_800 statval="800">Approve</st_800>
  <!--  900 to 999 can be used for custom approved status   -->
   <st_900 statval="900"/>
...
```

Hide Request Statuses

The default list of request statuses can include more options than you need for certain categories. You can hide some of the values in that category. So, users do not see these options on the GUI when they handle requests pending action.

Follow these steps:

1. Edit the requestshared.xml file for the language of your system using a text editor. For example, for English, edit the file in the USM_HOME\view\webapps\usm\locale\icusen\request folder.

2. Edit the line in the <request_header> and <request_item> sections for each status that you want to hide. Enter the comment characters before and after the original expression.

3. Hide the corresponding lines in all other sections that use it, such as the <request_item_approval> or <request_item_fulfillment> section.

   Note: Hide the exact same lines in all relevant sections of the file. Doing so is required for the status to appear correctly in the user interface.

4. Save the requestshared.xml file.

5. Test your changes by verifying that they are correctly reflected on the following request-related pages: Request Details, Approve Request, and Fulfill Request.

Example: Hide Request Statuses

To hide certain default fulfillment-related statuses, enter the comment characters before and after the original expression. Example in **bold**. Enter the comment characters in the request_header, request_item, and request_item_fulfillment_action sections of the requestshared.xml file.

In this example, *before* the comment markers are added, the following statuses are visible on the following request-related pages: Ordered, Shipped, Received, Order Cancelled, Staged, and Configured. *After* the comment markers are added, the following statuses are visible on those pages: Ordered, Shipped, and Configured.

```
- <request_header>
...
  <st_1004>Ordered</st_1004>
  <st_1006>Shipped</st_1006>
   <!--<st_1007>Received</st_1007>-->
   <!--<st_1008>Order Cancelled</st_1008>-->
   <!--<st_1017>Staged</st_1017>-->
  <st_1019>Configured</st_1019>
...
  </request_header>
- <request_item>
...
  <st_1004>Ordered</st_1004>
  <st_1006>Shipped</st_1006>
   <!--<st_1007>Received</st_1007>-->
   <!--<st_1008>Order Cancelled</st_1008>-->
   <!--<st_1017>Staged</st_1017>-->
  <st_1019>Configured</st_1019>
...
  </request_item>
- <request_item_fulfillment_action>
...
  <custom_menu current_status_value="default">
...
  <st_1004 statval="1004"/>
  <st_1006 statval="1006"/>
   <!--<st_1007 statval="1007"/>-->
   <!--<st_1008 statval="1008"/>-->
   <!--<st_1017 statval="1017"/>-->
  <st_1019 statval="1019"/>
...
</shared>
```

Restrict the Status Changes Available for a Request Item

You can restrict the status changes available for a request item that is based on its current status. For example, suppose that when an item is approved (Approved status), you no longer want users to be able to change the status *except* to a fulfillment-related status. You can configure the Item Status drop-down list to display *only* fulfillment-related options for items whose status is approved.

Follow these steps:

1. Edit the requestshared.xml file for the language of your system using a text editor. For example, for English, edit the file in the USM_HOME\view\webapps\usm\locale\icusen\request\requestshared.xml folder.

2. Locate the section of the file in which you want to restrict the available changes for one or more status values.
   You can restrict status changes in any section *except* the <request_item> and <request_header> sections.

3. Decide which status you want to restrict and the statuses to which you permit it to be changed.
   The list of all existing status values appears under the following line:

   ```
   - <custom_menu current_status_value="default">
   ```

4. Add a request status to permit in your list, if necessary. The statuses that you want to permit must exist already.

5. Locate the custom menu section. By default, this section is indented and commented out. Delete the opening and closing comment lines of this section.

   ```
   - <!--
           <custom_menu current_status_value="400">
           <st_400 statval="400"/>
           <st_600 statval="600"/>
           </custom_menu>
     -->
           <custom_menu current_status_value="400">
               <st_400 statval="400">/>
               <st_600 statval="600"/>
           </custom_menu>
           <custom_menu current_status_value="400">
               <st_400 statval="400"/>
               <st_600 statval="600"/>
                    <st_801 statval="801"/>
             </custom_menu>
   ```

6. Verify that the value in the current_status_value="*nnn*" expression in the first line of this section matches the status value that you want to restrict.
   For example, in the previous step, 400 corresponds to the Pending Approval status. Therefore, the status values shown appear on request-related pages when the status value is Pending Approval. If you want to restrict a different status, replace the current value with your new value.

7. Verify that the value in the current_status_value="*nnn*" expression is defined in one of the "<st_*nnn* statval=..." lines, as shown for Pending Approval in the previous example.

8. Copy and paste the additional status or statuses to which you want to allow the status to be changed. You can copy and paste it from the list of status values earlier in the section.
   For example, in the <request_item_approval> section, copy and paste the new "<st_801..." line to the custom_menu section for Pending Approval:

Now Approval Not Needed status is added to the statuses to which items in Pending Approval status can be changed.

- Restrict status changes for another status in the same section of requestshared.xml file, if necessary. Use these guidelines:

  1. Copy the entire custom_menu element and its children.

  2. Paste it after the element that you updated.

  3. Modify the newly copied element.

  4. Modify existing custom_menu element and children, if necessary. For example, in the <request_item_fulfillment> section, suppose you want to restrict items in Pending Fulfillment status to be changed to either Fulfillment Cancelled or Fulfilled. In that case, modify the existing custom_menu element as follows:

```
<custom_menu current_status_value="1000">
    <st_1000 statval="1000"/>
    <st_1999 statval="1999"/>
    <st_2000 statval="2000"/>
</custom_menu>
```

- Save the requestshared.xml file.

- Verify that the changes are correctly reflected on the request-related user interface pages (the Request Details, Approve Request, and Fulfill Request pages).

You have restricted the status changes available for a request item that is based on its current status.

Modify the Request Priority List

This article contains the following topics:

Every request has a priority that is assigned to it. CA Service Catalog supplies predefined priority values in the requestinfoshared.xml file. You can add or change the values in this file. You can also use this file to specify which user roles can assign specific priority values to requests. For example, you can add a new priority value "Immediate" that only the Service Delivery role can assign to a request.

The requestinfoshared.xml file can be different for each language and is located in a different folder for each language. For example, for English (icusen), the requestinfoshared.xml file is located in the USM_HOME\view\webapps\usm\locale\icusen\request folder.

You can modify the predefined priority levels:

- Add a new priority level for a specific role. (see page 2016)
- Add a new priority level for multiple roles. (see page 2015)

Priority Levels

The <priority_levels> section of the request and priority list in the requestinfoshared.xml file defines the numeric and text values for each priority. Each <levels> section defines those priority values that are available to the role code specified in the role attribute. The “default” role specification is used when no section exists for the role of the user.

The priority list appears in the order that is specified in the <priority_levels> section, regardless of role. You can use the defaultSel attribute to specify the default value for a new request according to role. The following table lists the roles and codes:

Role	Code
Catalog User	catalogenduser
Request Manager	requestmanager
Catalog Administrator	catadministrator
End User	enduser
SMA End User	smaenduser
Administrator	administrator
Service Manager	servicemanager
Super Business Unit Administrator	stadministrator
Service Delivery Administrator	spadministrator

You can edit this file to add values or change the spelling of existing values.

Suppose that a request uses a priority value that is *not* available to the role of the user editing the request. In that case, the user sees that priority in the list of priority values. Suppose that the request is set to another priority that *is* available the role of the user editing the request. In that case, the user can see *only* the priorities available to its role.

Example: Customizations for the requestinfoshared.xml File

If the Catalog End User role does not include priority 1 (High), a user who has that role does not see "High" listed in the priority list. Moreover, that user cannot set the priority of a request to High.

Suppose that the following situation occurs:

- A Request Manager who can use all the status values later sets the priority of the request to High.
- A user with the Catalog End User role later edits the request.

In this case, the status of High does appear in the priority list.

Thus, administrators *can* configure the product to prevent a certain role from using a particular priority value. Administrators cannot prevent users in that role from viewing and editing their requests when another user has set the priority.

Add a New Priority Level for Multiple Roles

If necessary for your organization, you can add a new priority level to the predefined priority levels.

Follow these steps:

1. Edit the requestinfoshared.xml file for the language of your system, using an editor, such as Notepad. For example, for English, edit the USM_HOME\view\webapps\usm\locale\icusen\request\ requestinfoshared.xml file.
2. Add a line in the priority_levels section for the priority you want to add. Specify a unique numeric value for the new priority level.
   The priority values are listed in the user interface in the order that they appear in this file section.
3. Perform *one* of the following actions:
   - Add a line in the levels section for each role that you permit to use the new priority.
   - Add a line in the levels section for the role. The line makes the new priority available to all users who do not have a role-specific priority list.
4. Save the file.
5. Log in to CA Service Catalog as a user with the role that you modified. Verify your updates on the request-related pages.

Example: Add a New Priority for All Roles

This example adds the following **bold** line to the requestinfoshared.xml file. This example adds a new priority named “Urgent” and makes it available to all users who do not have a role-specific priority list.

```
<priority_levels>
    <priority_6 propval="6">Urgent</priority_6>
    <priority_1 propval="1">High</priority_1>
    <priority_2 propval="2">Medium-High</priority_2>
```

```
    <priority_3 propval="3">Medium</priority_3>
    <priority_4 propval="4">Medium-Low</priority_4>
    <priority_5 propval="5">Low</priority_5>
    </priority_levels>
    <priority_level_roles>
<levels role="default">
    <level propval="1" />
    <level propval="2" />
    <level propval="3" defaultSel="true"/>
    <level propval="4" />
    <level propval="5" />
    <level propval="6" />
</levels>
</priority_level_roles>
```

Add a New Priority Level for a Specific Role

If necessary for your organization, you can add a new priority level to the predefined priority levels. You can add a new priority level for a specific role only.

Follow these steps:

1. Edit the requestinfoshared.xml file for the language of your system, using an editor such as Notepad. For example, for English, edit the USM_HOME\view\webapps\usm\locale\icusen\request\ requestinfoshared.xml file.

2. Add a level section for the affected role.

3. Perform *all* of the following actions in that section:

   - Specify the role code in the role attribute.

   - Include only the lines from the priority_levels section that you want users in the role to see.

   - Specify the default priority for new requests by using the defaultSel attribute.

4. Save the file.

5. Log in to CA Service Catalog as a user with the role that you modified. Verify your updates on the request-related pages.

Example: Add a New Priority Level for a Specific Role

This example adds a new priority list for users with the Catalog User role. This example sets the default priority to Medium-Low and does *not* allow users to set the priority to High. This example achieves these goals by adding the new section that is shown in **bold**:

```
<priority_levels>
        <priority_1 propval="1">High</priority_1>
        <priority_2 propval="2">Medium-High</priority_2>
        <priority_3 propval="3">Medium</priority_3>
        <priority_4 propval="4">Medium-Low</priority_4>
```

```
        <priority_5 propval="5">Low</priority_5>
    </priority_levels>
    <priority_level_roles>
        <levels role="default">
            <level propval="1" />
            <level propval="2" />
            <level propval="3" defaultSel="true"/>
            <level propval="4" />
            <level propval="5" />
    </levels>
        <levels role="catalogenduser">
            <level propval="2" />
            <level propval="3" />
            <level propval="4" defaultSel="true"/>
            <level propval="5" />
    </levels>
</priority_level_roles>
```

Modify the Typefaces Available for Notes in Requests

Users can add notes to requests by accessing the Request Details page and clicking Add in the Notes section. The Add Notes dialog appears and presents several type faces and type sizes as options. For these notes, the default typeface is Arial, and the default type size is 8-point. In addition, users can apply several formatting and highlighting options to these notes.

By default, all supported type faces are enabled. The Add Notes dialog displays all type faces listed in the <fonts> section of requestshared.xml file. Administrators can optionally limit or expand the typefaces that appear to users in the drop-down list of the dialog.

Users can select a typeface in the drop-down that the local computer being used to display or print the request does not support. In that case, the typeface changes to the default typeface, Arial.

Follow these steps:

1. Open the requestshared.xml file and move to the <fonts> section of the file.

2. Leave the type faces that you want to be available to users for notes in request. Comment out the type faces that you do not want to appear in the dialog.
   Comment the lines whose font you want to exclude from the Add Notes dialog.
   For example, to comment out the Courier New and Bookman Old Style type faces, modify their lines as follows:

   ```
   <!--<courier_new>Courier New</courier_new>-->
   <!--<bookman_old_style>Bookman Old Style</bookman_old_style>-->
   ```

3. Add a new typeface to the list that appears in the drop-down list in the dialog: Enter a new line and specify the new typeface. Use the following convention: If the font name is X Y, use the format <x_y>X Y</x_y>.
   For example, to add a typeface, "my company font", add the following line to the <fonts> section:

   ```
   <my_company_font>my company font</my_company_font>
   ```

The fonts that you added become available to users for notes in requests.

4. Save and close the requestshared.xml file.

Verify that the local computer being used to display or print the request supports the font.

- Verify your changes by adding a note to a request and reviewing the available typefaces.

You have modified the typefaces available to users for notes in requests.

Modify XSL, XML, JavaScript, and Image Files

CA Service Catalog includes several XSL, XML, JavaScript, and image files. Together, they are used to form every page and every page element in the product. Each file represents one page or a part of a page. For example, a dialog, menu option, form field control, message, or picture.

You can optionally modify any of these files to meet your requirements. To modify XSL, XML, JavaScript, and image files, follow this process:

1. Determine the specific page or part of a page that you want to modify.
2. Locate the file whose name matches the element you want to change. For example:
   - To modify the configuration information of any of the integrated products, locate the toolsconfig.xsl file.
   - To modify the states of request life cycle, locate the requestshared.xml file.
   - To modify the messages that appear when a user tests the connection for a new administration configuration setting, locate the toolsconfig.js and toolsconfig.xsl files.
   - To modify the edit button of the Administration, Configuration page, locate the modify.gif and toolsconfig.xsl files.
   - Modify the request status list by editing the requeststatus.xml file.
3. Open the file, review its contents, and verify that it controls the element or behavior that you want to change.
4. Copy the file from its original location to the custom location. Use the table as a reference.
5. Modify the file according to your requirements.
6. If you modified a JavaScript or image file, perform this step. Otherwise, skip it.
   a. Copy the modified JavaScript file to the \FileStore\custom\explorer\scripts folder.
   b. Copy the modified images to the \FileStore\custom\images folder.
   c. Locate the XSL file in the custom location in which the JavaScript or image file is used.

d. Update this XSL file and specify the new custom path name of the JavaScript or image file. To do so, prepend "FileStore/" to the relative path of the JavaScript or image file. Use the following example as a model:

```
<script src="FileStore/custom/explorer/scripts/custom_form_example.js"><
/script>
```

This action is required because the XSL file references the filestore location for the modified script files.

Important! If you are using multiple Catalog Component computers, verify that the filestore is shared among *all* of them.

7. Clear the USM_HOME\view\translets folder on all Catalog Component computers: Delete all files in this folder, but do *not* delete the folder itself.

8. Restart all Catalog Component computers.

9. Verify that the changes are working in CA Service Catalog as you intended.

In the following table, the parent folder is USM_HOME/view/webapps/usm. The filestore folder is % USM_HOME/filestore. The folder entries, such as /explorer and /custom/explorer, are subfolders under the parent and filestore folders.

File Type	Original Location in Parent Folder	Custom Location in Filestore Folder
XSL	/explorer	/custom/explorer
XSL	/explorer/request	/custom/explorer/request
XML	/locale/icusen*	/custom/locale/icusen*
XML	/locale/icusen*/request	/custom/locale/icusen*/request
image	/images	/custom/images
image	/images/billing	/custom/images/billing
JS	/explorer/scripts	/custom/explorer/scripts

*The folder name *icusen* applies to English-language implementations only. If you are using a non-English implementation, your locale-specific folder name is different. In such cases, use your locale-specific folder name instead of *icusen*.

Increase the Number of Values for a Drop-Down Variable

An administrator can add a query runtime variable that appears as a drop-down list to users. The limit for the number of values in the list is 1000. If the report query returns more than 1000 values, the system truncates these additional values. So, the user cannot view them in the drop-down list. You can increase the number of values that appear in the drop-down list to be greater than 1000.

Follow these steps:

1. Verify that your implementation has set up a filestore, a single location for shared files.
2. Copy the reportsgenericgetvariables.xsl file from its *parent* folder (USM_HOME\View\webapps\usm\explorer\reports) to the *filestore* folder.
3. Open the reportsgenericgetvariables.xsl file in the filestore and locate the following line:

   ```
   <input type="hidden" name="Args" value="1000"/> <!---1-->
   ```

4. Increase 1000 to the value you want.
5. Save the file.
6. Restart all Catalog Component computers.
7. Run a report and test the increased limit and verify the results.

You have increased the number of values for a drop-down variable.

Modify the Branding

As an administrator, you can modify the look-and-feel of the CA Service Catalog UI. The following are the main categories of look-and-feel elements that you can modify:

- Logos are image files that uniquely identify a company, business unit, or super business unit. These logos include the login logo (see page), global logo (see page), and business unit logo (see page).
- The login page (see page 2024) enables a user to access the product.
  The same login page (including the login logo) applies to all users in all business units. For example, images and icons (*except for* logos), menus, and tabs. When applicable, these elements include colors, font name and point size, highlighting, and related specifications. You modify these look-and-feel elements by editing the Cascading Style Sheet (CSS) files for the login page.
- *A theme* (see page 2026)specifies the settings for several look-and-feel elements. For example, images and icons (*except for* logos), menus, and tabs. When applicable, these elements include colors, font name and point size, highlighting, and related specifications. You modify these look-and-feel elements by editing the CSS files for the theme.
  The look-and-feel of the UI matches the theme of the business unit that you are logged in to. If theme is not set for a business unit, CA Service Catalog checks the business unit hierarchy and it finds a theme. Thus, if a business unit does not have its own theme, it uses the theme of its closest parent business unit. You can use the same theme for all business units. Alternatively, you can optionally create and use different themes for different business units.
- Global page elements appear on several or all product pages. They include the product name, shopping icon, and footer. Global page elements are always the same, on every product page where they appear.
  Like the elements of the login page, global page elements apply to all users, regardless of their

business unit. You *cannot* override them with business unit-specific settings. The global page elements also apply regardless of whether you have modified the themes of one or more business units.
You modify global page elements (see page 2030) by editing the includes_shared.xml file.

You can modify any, all, or none of the items in this list. This separation provides flexibility.

Important! Verify that the changes you plan to make to each one are compatible with each other. Such consistency helps provide a consistent look-and-feel to users. For example, use similar colors and elements on both the login page and the product pages.

Upgrade Considerations

Depending upon your implementation and if you have customized any of these elements in previous releases, perform *one* of the following actions:

- Verify that the modified files reside in a *custom* subfolder of the USM_HOME\FileStore folder.
- Recreate your changes by following the instructions in this section to:
  - Change the Logos (see page 2021)
  - Modify the Login Page (see page 2024)
  - Modify the Theme (see page 2026)
  - Modify Global Page Elements (see page 2030)

Change the Logos

This article contains the following topics:

Logos are image files that uniquely identify a company, business unit, or super business unit. As a service delivery manager, you can modify the logos that are used on the CA Service Catalog UI. Using custom logos helps reinforce branding or other messaging in your organization.

Note: We recommend that you size your custom logo to be approximately the same size as the predefined logo.

Change the Login Logo

CA Service Catalog includes a predefined login logo that you can optionally replace with a custom login logo. The login logo *always* applies to the login page, regardless of whether you have specified different logos for different business units.

Follow these steps:

1. Determine the custom login logo that you want to use.
2. Access the USM_HOME/FileStore/themes/common/images/logo folder on your filestore computer.
3. Copy and rename the predefined login logo (login_logo.png).
4. Copy the custom logo to the same folder. Rename it to the name of the original logo.
5. Access the login page for CA Service Catalog.
6. Verify that the predefined login logo no longer appears and that the custom login logo appears correctly.

You have changed the login logo.

Change the Global Logo

CA Service Catalog includes a *predefined* global logo that applies to all users. You can optionally replace it with a *custom* global logo. The global logo appears in the heading of all product pages (except the login page) and request emails.

Note: If a business unit has its own logo, users who log in to it see the business unit logo instead of the global logo.

Follow these steps:

1. Determine the custom global logo that you want to use.
2. Access the USM_HOME/FileStore/themes/common/images/logo folder on your filestore computer.
3. Copy and rename the predefined global logo (header_logo.png).
4. Copy your custom logo to the same folder. Rename it to the name of the original logo.
5. Log in to CA Service Catalog.
6. Verify that your custom global logo is legible on the UI and in request emails.

You have changed the global logo.

Change the Business Unit Logo

For each business unit, you can optionally specify a *business unit* logo. If you specify this logo, it replaces the *global* logo in the heading on product pages and request emails for users of the business unit. You can update the logos for every business unit or only for specific business units. For example, you can decide to customize logos only for super tenants directly under the root business unit.

Important! If you have enabled multi-tenancy with CA Service Desk Manager, CA Service Catalog ignores any of its settings for business logos. Instead, CA Service Catalog uses the logo or logos that the CA Service Desk Manager setup specifies, if applicable. If no CA Service Desk Manager logo applies, then each business unit uses the CA Service Catalog global logo.

Follow these steps:

1. Determine the business unit logo that you want to use.
2. (Optional) Perform the following actions:
   - Rename the custom logo file intuitively to match its business unit. For example, for a business unit that is named Vienna_123, name the logo Vienna_123_header_logo.png.
   - Create a subfolder that is named "custom logos" in USM_HOME/FileStore/themes /common/images/logo directory.
3. Copy your custom logo to the USM_HOME/FileStore/themes/common/images/logo folder on your filestore computer.
4. Perform *one* of the following actions, whichever applies to your level of administrative access:
   - Log in to the business unit whose logo you want to change.
   - Log in to the root business unit:
     a. Select Administration, Business Units.
     b. Drill down the tree to the business unit whose logo you want to change.
5. Edit the business unit.
6. Enter the URL of the logo that you copied in the Logo field and save your changes.
7. Refresh your browser.
8. Verify that your business unit logo is legible on the UI and in request emails.
9. (If the business unit has child business units) Verify:

- If the child business unit has its own logo, users who log in to it see the child logo, not the parent logo.
- If the child business unit does not have its own logo, users who log in to it see the global logo.

Thus, users with access to multiple business units can see different header logos when they log in to each business unit.

You have specified a business unit logo.

Modify the Login Page

You can modify the login page, as follows:

- Modify the login logo (see page).
- Modify the *content* or *text* of the Predefined Login Page (see page 2024).
- Modify the *look-and-feel* of several elements of the login page by editing the logon.css file (see page 2024).

You can modify the login page *without* changing the theme for one or more business units. The same login page applies to all users, regardless of whether you have changed any theme. This separation provides greater flexibility to your organization. This separation also enables you to update the login page alone more quickly and efficiently.

As an administrator, ensure that you have expertise in the following areas before modifying the login page:

- UI design, especially look-and-feel elements
- Standard specifications for CSS files
- Customization of the CSS files, using a CSS file editor for your web browser

Predefined Login Page

The following table lists the elements of the login page that you can customize, except for the login logo. When applicable, each row lists the section of the login.css file that affects the look-and-feel of the element.

GUI Element	File Location under USM_HOME*	Section in Logon.css File
Text for the browser window title and title bar	view\webapps\usm\locale\icusen\logon.xml	.loginpage
Text for product name	view\webapps\usm\locale\icusen\logon.xml	. loginproductname
Login input text		.logininputtext

GUI Element	File Location under USM_HOME*	Section in Logon.css File
	view\webapps\usm\locale\icusen\logon.xml **Note:** This text supplies the User Name, Password, and Advanced-Business Unit fields.	
Copyright text and date	view\webapps\usm\locale\icusen\logon.xml	.loginpagecopyright

USM_HOME is the documentation convention that specifies the local CA Service Catalog installation directory. For 32-bit computers, the default path name is C:\Program Files\CA\Service Catalog. For 64-bit computers, the default path name is C:\Program Files (x86)\CA\Service Catalog for 32-bit installations or C:\Program Files\CA\Service Catalog for 64-bit installations.

Note: The favorites icon appears in the browser address bar and the product title bar of every product page, including the login page. The favorites icon is a global page element that you can modify.

Note: For the Text elements, the File Name column displays the folder location for an English system (icusen). For other languages, the location is different.

Edit the logon.css file

Modify the look-and-feel of the login page to reinforce branding or other messaging. The same login page applies to all users, regardless of business unit that they are logging in to.

Follow these steps:

1. Open your web browser and access the login page for CA Service Catalog.
2. Back up the USM_HOME\filestore\themes\common\css\logon.css file. *Always* back up CSS files and other configuration files before editing them.
3. Open the file, using the CSS editor for your web browser.
4. Find the lines that control the look-and-feel specification that you want to update.
   For example, to configure the look-and-feel of the product name, find the following line:

```
.loginproductname {
  text-align: left;
  font-family: CAlibri, Verdana, Arial, Helvetica, sans-serif;
  color: #ffffff;
...
```

   To change the color of the product name from the current color to blue, update the lines:

```
.loginproductname {
  text-align: left;
  font-family: CAlibri, Verdana, Arial, Helvetica, sans-serif;
  color: blue;
...
```

5. Repeat the previous step for other look-and-feel changes that you want to make.
   For example, to configure the background color of the login page, find the following lines:

   ```
   .login_page {
     background-color: #00174A;
     text-align: center;
   ...
   ```

   To change the background color of the login page to yellow and align the affected text to the right, update the lines:

   ```
   .login_page {
     background-color: yellow;
     text-align: right;
   ...
   ```

6. Refresh your browser and verify your updates on the login page.

7. Update the elements of the login page (see page 2024) to meet your requirements. Verify each change by saving the file and refreshing the login page.

You have modified the login page.

Modify the Theme

A theme specifies the settings for the following look-and-feel elements:

- Images and icons (*except for* logos)
- Menus
- Tabs
- Toolbars
- Wizards

When applicable, these elements include the following specifications:

- Colors (especially background colors)
- Font name and point size
- Highlighting, such as bold or underline
- Position on a page or dialog

You modify these look-and-feel elements by editing the Cascading Style Sheet (CSS) files for the theme. Each theme includes the following CSS files:

- logon.css, which applies to the login page *only*
- main.css, which applies to other product pages

A theme is organized in folders, with one top-level folder for each theme. In addition to the CSS files, a theme includes several other supporting files and several folders. You do not need to edit these additional files and folders. However, you copy them as a group when you copy and modify a CSS file.

The look-and-feel of the UI matches the theme of the business unit that you are logged in to. If theme is not set for a business unit, CA Service Catalog checks the business unit hierarchy until it finds a theme. Thus, if a business unit does not have its own theme, it uses the theme of its closest parent business unit. You can use the same theme for all business units. Alternatively, you can optionally create and use different themes for different business units.

As an administrator, edit the theme for one or more business units *only* if you have expertise in:

- UI design, especially look-and-feel elements
- Standard specifications for CSS files
- Customization of CSS files, using a CSS file editor for your web browser

To customize a theme:

- Step 1 - Understand Predefined and Custom Themes (see page 2027)
- Step 2 - Create a Custom Theme (see page 2028)
- Step 3 - Change the New Theme (see page 2029)

Step 1 - Understand Predefined and Custom Themes

A theme is organized in folders, with one top-level folder for each theme. In addition to the CSS files, a theme includes several other supporting files and several folders. You do not need to edit these additional files and folders. However, you copy them as a group when you copy and modify a CSS file.

In the USM_HOME\filestore\themes folder, CA Service Catalog includes the following top-level folders for each predefined theme:

- **CA_Technologies_R7**
  Specifies the predefined look-and-feel elements of CA Service Catalog.
- **common**
  Contains look-and-feel elements that apply to *all* predefined and custom themes.

  Important! Do *not* copy and modify the *common* folder.

If you have already created custom themes, your top-level folders for those themes also appear in the USM_HOME\filestore\themes folder.

To create a custom theme, you copy either a predefined folder (such as CA_Technologies_R7) or a custom folder that you created earlier. Afterwards, you modify the CSS file of interest in the folder that you copied.

You store all custom theme folders under the filestore folder. You store them on the same folder level as the CA_Technologies_R7 folder.

Each top-level folder name becomes the name of an option for a theme. When you edit a business unit, you can select a theme for it.

If you update a theme for a specific business unit, the change affects the users who belong to that business unit. The change also affects any child business units that do not have their own theme specified. Child business units inherit the theme of their parent business unit. However, they can optionally override the inherited theme by specifying their own theme.

Step 2 - Create a Custom Theme

You create a custom theme by copying and modifying an existing theme. You can copy and modify either a predefined CA Service Catalog theme or another existing theme that you created earlier.

Important! As a best practice, do *not* modify a predefined CA Service Catalog theme directly. Instead, copy and modify it, so that you can efficiently return to the original version, if necessary. *Always* back up the CSS files before editing them.

Follow these steps:

1. Access the computer on which the filestore resides.
2. Find and expand the USM_HOME folders. Expand the \filestore\themes folder. Review the organization of the predefined and custom themes (see page) in that folder.

   Note: The name of each top-level folder is an option that you can select when you select a theme for a business unit.

3. Copy the top-level folder of existing theme that you want to use as a starting point for your new theme.
4. Rename the new theme.
   For example, suppose that the existing theme was named Rome_Super_Tenant_A. If the new theme is for a second super tenant, you can name it Rome_Super_Tenant_B. Conversely, if the new theme is for a new child business unit of the parent super tenant, you can name it Rome_Super_Tenant_A--Child-1.
5. Add or edit the business unit for which you want to use this theme. In the Available Branding field, select the new theme that you created.
   For example:

- To apply the theme to all business units that do not have their own theme, edit the root business unit and apply this theme.
- To apply the theme to a specific business unit, add or edit the business unit and apply the theme.
  The theme also applies to all child business units that do not have their own theme.

6. Change the new theme (see page 2026) by editing its main.css file.

The new theme is ready for modifications.

Step 3 - Change the New Theme

After you have created a theme, you can change it, to give it a unique look-and-feel.

Follow these steps:

1. Log in to CA Service Catalog and note the look-and-feel of the home page.
2. Back up the main.css file in the custom theme folder that you created (see page). A sample path name is USM_HOME\filestore\themes*custom_theme*\css\main.css file.
3. Open the main.css file of your custom theme. Use a suitable CSS editor for your web browser.
4. Find the lines that control the look-and-feel specification that you want to update.
   For example, To change the background color globally on product pages, perform the following actions:
   a. Find the following default setting:

      ```
      td.pagebg{background-image:url(../images/grid/page-bg.png);background-repeat:repeat-x;background-color:#D9E2F3;}
      ```

   b. Delete the following phrase:

      ```
      background-image:url(../images/grid/page-bg.png);
      ```

      The line now appears as follows:

      ```
      td.pagebg{background-repeat:repeat-x;background-color:#D9E2F3;}
      ```

   c. Change the background-color:#D9E2F3 to the color of your choice, for example, background-color:red.
   d. Save the file.

> **Note:** The setting in this example *does* affect the background color of the *entire* product page. However, the background colors of specific sections of the page *override* the background color of the entire page.

5. Refresh the CA Service Catalog UI. Verify the changes to the product pages.

6. Update other elements of the theme to meet your requirements. Verify each change by saving the file and refreshing the login page. For example, you can customize the look-and-feel of the top-level menu tabs (Home, Service Builder, Accounting, and Administration).

Modify Global Page Elements

Global page elements include both text and icons. The same global page elements apply to all users, regardless of business unit that they are logging in to. The global page elements also apply regardless of whether you have modified the themes of one or more business units.

Global page elements appear on several or all product pages. They include the product name, shopping icon, and footer.

Follow these steps:

1. Back up the USM_HOME\view\webapps\usm\locale\icusen\ includes_shared.xml. *Always* back up XML files and other configuration files before editing them.

2. Open the includes_shared.xml file, using an XML editor.

   Note: The folder location is for an English system (icusen). For other languages, the location is different.

3. Find the line that controls the text that you want to update. For example,

   - Text for the product name: <product_title> value
     Default: CA Service Catalog

4. Update the lines to the values you want, and save the file.

5. Access the folder that contains the icons that you want to update. For example, USM_HOME\view\webapps\usm\images or USM_HOME\view\webapps\root folders contain icons.

   Note: To view an icon, double-click its file name.

6. Perform the following steps for each icon that you want to change:

   a. Rename the original file to filename_OLD.png.

   b. Copy your new file to the folder, and rename it to the original file name.

7. Log in to CA Service Catalog and verify your updates on the product UI.

8. Copy the icons that you customized to the USM_HOME\filestore\custom\images folder.

Important! This step is required to help ensure that your updates apply to all users in your organization.

You have modified the global page elements.

Add a Custom Time Zone

You select the time zone for a business unit when you create or edit it. The time zone selection determines the date and time settings for the business unit, including the following components: the Scheduler, outage calendars, and business hours, date and time fields in forms, and the availability dates for services. You can also select a time zone for conditions in policies. CA Service Catalog supplies several predefined time zones that you can use in these settings. You can add a custom time zone.

Follow these steps:

1. Verify that you have set up the filestore.
2. Copy the appropriate sharedxml.xml file for the language of your system to the filestore. For example, for English, copy the file USM_HOME% \view\webapps\usm\locale\icusen\sharedxml.xml to the filestore.
3. Edit the sharedxml.xml file in the filestore using a text editor. Locate the <timezones> tag and the existing time zone entries under it.
4. Enter the custom time zone under the existing entries. Use the format that is shown in the following example:

```
<t53>
        <id>GMT-06:00 America/North_Dakota/Center</id>
        <text>(GMT-06:00) Central Time (US&amp;Canada)</text>
</t53>
```

5. Verify that the new custom time zone is implemented, as follows:
   - Edit a business unit and verify that the available time zones include the new custom time zone.
   - Set the business unit to this time zone. Verify that the time zone is used in affected components.
   - Verify that this time zone works accurately in conditions in policies, if applicable.

Note: If You have implemented CA Service Catalog in multiple languages, repeat steps 2 through 5 for all other languages.

You have added a custom time zone.

Customize the Online Help

Service delivery administrators can optionally replace the predefined online help with custom online help, for some or all roles. Here, the predefined online help refers to the *CA Service Management Wiki* . Custom online help appears instead of the predefined online help when users with the specified roles click the **Help** button.

Note: If the user selects Administration, Tools, Links, CA Service Management Wiki, the predefined online help *always* appears. Customization for online help does not affect the menu selection that appears when users click the **Help** button.

Follow these steps:

1. Create your custom online help file files and copy them to the USM_HOME\filestore\custom\help\<***language***> folder.

   - ***language***
     Specifies the language of the operating system on which you installed CA Service Catalog. For example, specify en_US for U.S. English or ja_JP for Japanese.
     For example, the file location for your custom English help files must be USM_HOME\filestore\custom\help\en_US folder.

   Note: The folder must include an index.html file that, when clicked, opens the custom online help.

2. Click **Administration**, **Configuration**, **Filestore**.
3. Select the option that is named **Enable Custom Help**.
4. Specify the roles that must see the custom help rather than the predefined online help.
5. Restart Catalog Component.
6. Verify that CA Service Catalog functions as expected when users with the specified roles click the **Help** button:

   - If applicable, the custom online help opens instead of the predefined online help.
   - If the index.html file does *not* exist in the USM_HOME\filestore\custom\help\<***language***> folder, the index.html file in the USM_HOME\filestore\custom\help\default folder runs. The predefined online help opens.

- If the custom online help is disabled, the predefined online help opens.

Use Web Services to Automate Business Processes

Administrators can use the CA Service Catalog web services to automate business processes and to reduce manual input by catalog users. You can access the web services from any client that uses standard web service protocol.

A web service is any collection of software operations or methods that is available over the Internet. A web service uses a standardized XML messaging system. The web services use XML to encode all communications: A client invokes a web service operation by sending an XML message and then waits for a corresponding XML response.

CA Service Catalog includes several predefined web services. For example, the UserService web service provides a *getUser* method and an *editUser* method that you can use to manage information about users. The BusinessUnitService web service provides similar functionality for business units. This set of web services constitutes an application programming interface (API) for CA Service Catalog.

The web services use Simple Object Access Protocol (SOAP). SOAP is a lightweight, XML-based communication protocol and encoding format for inter-application communication.

The CA Service Catalog implementation of SOAP is Axis-compliant. You can access the web services from any Axis-compliant client. Implementers can use any programming language with which they are familiar to call exposed methods, using method call syntax. Implementers must be skilled users of the web services of the programming language they select.

The web services support the Web Service Description Language (WSDL). You can use WSDL to build stubs to access remote services. You can also use WSDL to export automatically machine-readable descriptions of CA Service Catalog deployed services from Axis.

Important! For more information about how to use the web services, log in to CA Service Catalog and click Administration, Tools, Links, Web Services API. The API documentation is automatically generated Java documentation that is based on the CA Service Catalog web service methods. Alternatively, to access this documentation, click Start, Programs, CA, Service Catalog, Documentation, Web Service API on the Catalog Component computer.

Follow these steps:

Step 1 - Verify the Prerequisites for Clients

Clients must meet the following prerequisites to call CA Service Catalog web services:

- Verify that you are using apache Axis 1 for your web service implementation.
- Axis clients require a Web Service Description Language (WSDL) file for the initialization.
- Verify that a WSDL file is generated for each web service when the Axis server is initialized. The WSDL file for a web service is updated each time when the service is dynamically deployed or undeployed successfully.
  A WSDL file is required for each web service. Typically, when a web service is made available using Axis, a unique URL is associated with that web service. The URL name is typically http://localhost:8080/usm/services/*webservice*. An example is http://localhost:8080/usm /services/UserService for the web service named UserService.
  Name your WSDL files using the convention *webservice*.wsdl, where *webservice* is the name of the web service.
- Verify that each WSDL file contains the information, including method signatures, required to call currently deployed services. The WSDL files help you to differentiate the following parts of a service:
  - Abstract functionality description
  - Concrete details description, such as message format and communication protocol. Examples include SOAP, HTTP, and MIME.

  Thus, you can reuse a WSDL file for different types of clients.
- If you use a Java program to call the methods, verify that the following jar files are in the class path. These files are installed in USM_HOME/webapps/usm/WEB-INF/lib:
  - axis.jar
  - jaxrpc.jar
  - commons-logging.jar
  - commons-discovery.jar
  - wsdl4j.jar
  - mail.jar

Step 2 - Deploy Web Services

To make a web service accessible to a client application, deploy the web service. After you deploy, enable the method on the server. An authenticated user with proper permissions can deploy and undeploy services dynamically when the server starts.

By default, the Catalog system deploys all web services and their methods. With the proper login credentials, a client application has access to all web services functionality. If you decide to undeploy a web service, check if any client applications use it. Therefore, undeploying a web service can affect request approval and fulfillment business processes.

When a web service is deployed or undeployed, the WSDL file for the web service is updated. Each web service has its own WSDL that contains the information about currently deployed services, including method signatures. The URL format for the web service follows:

```
http://hostname:port/usm/services/servicenameService?wsdl
```

- ***hostname*:*port***
  Specifies the Catalog Component server name and port number.

- ***servicename***
  Specifies the web service name.

For example, in your browser address field, you enter:

```
http://prod123:8080/usm/services/UserService?wsdl
```

The results display the following data:

- The WSDL contents for a Catalog Component server named “prod123” on port 8080
- All web service methods and data structures for the User web services, in XML format

Note: You can also remotely invoke methods of the Axis server at runtime through an Axis-compatible client.

Step 3 - Generate the WSDL File

Generating the WSDL file for each web service is required when you call web services with a Java client.

Follow these steps:

1. Access the web service URL in a browser.
   You typically see a message referencing an Axis service and SOAP access.

2. Append **?wsdl** to the URL.
   Axis generates a service description for the deployed service and returns it as XML in the browser, for example:

   ```
   http://localhost:8080/usm/services/AccountService?wsdl
   ```

3. Save the output as a file named *webservice*.wsdl. Record the path name for future reference.

Use the webservice.wsdl file as input to web service calls (proxy-generation) when you generate java stubs for each web service.

Step 4 - Generate Java Stubs

Generating Java stubs for each web service is required when you call web services with a Java client.

Follow these steps:

1. Verify that you are using the Axis WSDL2Java tool for generating the Java stubs.

   Note: You can obtain the Axis tools from the Apache Axis website (apache.org).

2. Open a command prompt and enter the command to generate Java stubs. Use the following command as a model.

   ```
   java org.apache.axis.wsdl.WSDL2Java -o . -ptesting.soap AccountService.wsdl
   ```

   This action generates the following files in the package named testing\soap:

   - *web_service_name*Impl.java
     This new interface file contains the appropriate java.rmi.Remote usages.
   - *web_service_name*ImplService.java
     This file is the Service Interface of the web service. The Service Locator implements this interface.
   - *web_service_name*ImplServiceLocator.java
     This file is the Helper factory to retrieve a handle to the service.
   - *web_service_name*SoapBindingStub.java
     This file is the client-side stub code that encapsulates the client access.
   - Serialized beans
     These beans function as input and return types. They also catch exceptions.

3. Verify that the command generated files like the ones in the previous step.

Step 5 - Call each Web Service

This article contains the following topics:

Use a Java Program to Call a Web Service

The Java-related specifications and parameter-related specifications are specific to your program. For more information, see the Axis and web service related-related sections of apache.org website.

Use a JavaScript Program to Call a Web Service

Developers can access web services directly through JavaScript programs. This ability enables web programmers and system administrators to invoke methods remotely through DHTML or Windows Scripting Host. The ability to call web services through client-side scripting gives web developers greater flexibility to create dynamic web sites.

For more information, see the web service-related portions of the workshop sections of the Microsoft Developer Network (MSDN).

Follow these steps:

1. Review the following sample files and use them as models to create your own programs. These files reside at:
   USM_HOME\ view\webapps\usm\admin
   - soapTest_index.html
   - soapTest_bottom.html
   - soapTest.html. This file contains the JavaScript code to call web service.

   The sample files provide a sample HTML that gets the list of all accounts for a business unit, using synchronous method calls.

   Note: The sample files support both synchronous and asynchronous method calls. When you use asynchronous calls, the web browser does not lock during calls and responds to user input.

2. Open the soapTest_index.html file in your browser.

3. Complete the fields and run the file.
   The file runs and calls the web service. The page dynamically creates an HTML table with the list of accounts.

Step 6 - (Optional) Specify Special Characters

If necessary, your web service calls can include special characters, as explained in the sections that follow.

Select Special Characters

Important! This section applies only if the special character does *not* function as a separator for the parameter in the web service call.

You can use the following XML character entities to specify special characters in web service calls:

- & (ampersand)
- ' (apostrophe)
- " (double quotation mark)
- < (less than)
- > (greater than)

For example, use the following entities to specify the business unit named Smith&Jones Hardware&Software Supplies:

```
Smith&amp;Jones Hardware&amp;Software Supplies
```

Special Characters Other Than Separator Characters

Important! This section applies only if the special character does *not* function as a separator for the parameter in the web service call.

To use CDATA tags to specify special characters in web service calls, use the following format:

```
<![CDATA[...]]>
```

For example, use the following expression to specify the business unit named Smith&Jones Hardware&Software Supplies:

```
<![CDATA[Smith&Jones Hardware&Software Supplies]]>
```

Separator Characters

The following special characters are typically used as separators:

- | (vertical bar)
- ! (exclamation point)

If the special character functions as a separator for the parameter in the web service call, specify the special character as a dynamic variable:

1. On the CA Service Catalog UI, enter the special character or characters in the field that you reference in the web service call. For example, in the Description field for the current business unit, enter !&.

Note: Dynamic variable can also handle other special characters (for example, & and ,) although they are not separators for web service methods.

2. In the web service call, replace the special character with the dynamic variable for the field of previous step. For example, $bu.description$.

The following sample web service call uses the example from the previous steps:

```
<soapenv:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="
http://www.w3.org/2001/XMLSchema" xmlns:soapenv="http://schemas.xmlsoap.org/soap
/envelope/" xmlns:ser="http://services.soap.usm.ca.com">
   <soapenv:Header/>
   <soapenv:Body>
      <ser:saveRequestForm soapenv:encodingStyle="http://schemas.xmlsoap.org/soap
/encoding/">
         <sessionID xsi:type="xsd:string">e2f6b05b85247d35b4d7371edc9c6fe398fba60d<
/sessionID>
         <subscriptionDetailID xsi:type="xsd:int">10009</subscriptionDetailID>
         <formValuesData xsi:type="xsd:string">text1:M$bu.description$<
/formValuesData>
      </ser:saveRequestForm>
   </soapenv:Body>
</soapenv:Envelope>
```

Step 7 - Clients Invoke Login and Logout Methods

When you call web services with a Java client, a required process is clients invoking login and logout methods for each web service. A typical process follows:

1. The client uses a method for login and authentication.
   Each web service has a set of login methods. The client applications can use several login methods for authentication. For example, the *logIn* method takes the same parameters as the Login window: User ID, Password, and Business Unit.
   To view the method parameter information, including signatures, use the following resources:

   - Web Services API documentation.
     To access the Web Services API documentation, log in to CA Service Catalog, click Administration, Tools, Links, Web Services API.

   - SOAP administration interface for deploying or undeploying web services

2. The Catalog system authenticates the user and determines its role.
   Subsequent method calls operate within the scope of the access rights of the user.

3. The client:

   - States the service that it is calling.

   - Provides the method name and its corresponding parameters before initiating the remote procedure call.

   - Checks the WSDL file for this information, if it is unknown.
     Typically, the client already has this information.

4. The web service returns a session ID. This session ID is a required parameter that the client uses for the remaining web service calls. Because the underlying transport protocol can be either HTTP or non-HTTP, the authentication uses a common logIn web service.
   You can share the session ID across web services. For example, you can use the UserService logIn method to obtain a session ID. You can then use the session ID in a call to a Business Unit web service method.

5. This session ends when one of the following events occurs:

   - The client calls the logOut web service method.
     Once you are finished using a session ID, you call the *logOut* web service to terminate the session. The *logOut* web service also invalidates the session ID. Managing the sessions efficiently in this manner helps you obtain the best product performance.

   - The client is idle for a period longer than the session timeout value.
     The client can use the session ID repeatedly within the timeout period. If the session times out, the session ID becomes invalid.
     To change the timeout value, update the administration configuration setting named User Default: Session Timeout.

Step 8 - Add Attachments to Requests

Administrators can use the addRequestAttachmentWithPath web service as an automated, efficient, and reliable mechanism for adding attachments to requests.

Use the following options to use this web service to add attachments to requests:

- Add attachments stored by CA Service Catalog (see page 2040).
- Add attachments stored by a WEBDAV (see page 2042).
- Add attachments using an absolute path (see page 2043)

Add Attachments Stored by CA Service Catalog

You can optionally attach files to requests when the files are stored using the Document Management feature of CA Service Catalog. To do so, follow this process:

1. Enable the Document Management feature.

2. Attach the file.

Enable the Document Management Feature

Perform this procedure once.

Follow these steps:

1. Disable the following policies in CA EEM : ACL_deprecated_features_launchpads and ACL_deprecated_features_guinodes.

Note: For more information about how to disable policies in CA EEM, see your CA EEM documentation.

2. Restart CA Service Catalog.

3. Verify that the Home, Documents menu is enabled.

Note: The following menu options are also enabled when you disable the CA EEM policies: Home, Reports and *both* Offline Data Views *and* Offline Layouts under Administration, Report Builder.

Attach the File

Perform this procedure each time that you want to attach a file to a request using web services.

Follow these steps:

1. Click Home, Documents. Upload the file that you want to use as an attachment.

2. Call the web services that use addRequestAttachmentWithPath and pass the values that you want to the input parameters.
   Use the following format for the attachmentPath parameter:

   ```
   http://username:password@computername:port/usm/documents/pathname
   ```

   - ***username* and *password***
     Specifies one of the following options:

     - The user name and password of the user who uploaded the documents
     - A user with the Service Delivery administrator role

   - ***pathname***
     Specifies the subfolder pathname (under the documents folder) of the file being uploaded, including its extension.

Examples

The following example attaches a file from the Documents folder:

```
http://spadmin:spadmin@computer-abc:8080/usm/documents/test.txt
```

The following example attaches a file from a subfolder of the Documents folder:

```
http://spadmin:spadmin@computer-xyz:8080/usm/documents/WSAttachments/test.txt
```

Add Attachments Stored by a WEBDAV

You can attach files to requests when the files are stored using a third-party web-based distributed authoring and versioning (WEBDAV). A sample WEBDAV is Microsoft Internet Information Server (IIS). To do so, follow this process:

1. Enable WEBDAV functionality.
2. Attach the file.

Enable WEBDAV functionality

Perform this procedure *once*.

Follow these steps:

1. Edit the following section in the web.xml file:

```
<init-param>
  <!-- web dav is disabled as of 12.8 to enable change the flag and restart -->
  <param-name>disableWebDav</param-name>
  <param-value>true</param-value>
</init-param>
```

2. Change the value of the WebDav parameter from *true* to *false*.
3. Restart CA Service Catalog.

Attach the File

Perform this procedure *each time* that you want to attach a file to a request using a WEBDAV.

Follow these steps:

1. Pass the HTTP URL of the attachment.
2. Call the web services that use addRequestAttachmentWithPath and pass the appropriate values to the input parameter.
3. Use the following format for the attachmentPath parameter:

```
http://computername/websharefoldername/filename
```

   - ***computername***
     Specifies the name of the computer from which you are adding the attachments.
   - ***websharefoldername***
     Specifies the name of the new folder.
   - ***filename***
     Specifies the file name of the attachment, including the extension for example, test.txt.

Add Attachments Using An Absolute Path Name

You can optionally attach files to requests by using the absolute path name of the file.

Follow these steps:

1. Verify that the attachment is stored on the CA Service Catalog computer. If necessary, copy or move the attachment to meet this requirement.

2. Call the web services that use addRequestAttachmentWithPath and pass the values that you want to the input parameters. Pass the absolute path name of the attachment, for example: C:\\TEST\\test.txt.

Use API Plug-ins to Load Data into Policies and Forms

This article contains the following topics:

Administrators and service designers work together to write API plug-ins that dynamically load data into policies and forms, as follows:

- For a policy, this data specifies the assignees (approvers) for a request. You use the plug-in instead of specifying assignees manually using the Action Builder. When a user submits a request, the API plug-in dynamically specifies the assignees.

- For a form, this data specifies the value for any of the following fields: dynamic tables, dual lists, or select boxes and their options. For example, when a user completes a form to reserve a virtual computer, the report data object populates the list of available computers. You can also write other report data objects to populate related fields, for example, options for RAM and disk space.

API plug-ins query the MDB or another data source. The API plug-in returns the number of objects that meet the criteria that you specify. You can either write your own API plug-ins or copy and modify the predefined plug-ins to meet your requirements. In both cases, you meet the prerequisites and compile your plug-ins *before* you can use them.

API plug-ins are deployed as jar files in the plugins directory of the filestore. API plug-ins run in the same Java Virtual Machine instance as CA Service Catalog.

Perform the tasks that apply:

- Use API plug-ins for policies (see page)

- Use API plug-ins for forms (see page)

Use API Plug-ins for Policies

To write and use an API plug-in for policies, follow this process:

1. Define the purpose or goal of the plug-in.
   An API plug-in is useful when you query an external system for data to specify the assignees. An API plug-in is also useful when the identities vary according to the data in the request. Based on this data, the plug-in dynamically creates the assignee list and specifies the assignee levels.

2. Meet the prerequisites:

3. Be able to do the following proficiently:

   - Program in Java.
   - Create policies, including conditions, and understand the types of assignees required.

4. Review the API Plug-in documentation, as follows:

   a. Select Administration, Tools, Plug-ins.

   b. Click API Documentation.

   c. Review the com.ca.usm.plugins.apis.policies package.

   The API documentation is automatically generated Java documentation from the Java class methods for the plug-ins. You use the interfaces, classes, methods, and so on, to implement your plug-in.

5. Download and review the sample API plug-in for policies, as follows:

   a. Select Administration, Tools, Plug-ins.

   b. Click the Sample Policy Plug-in, review the details, and download the source code.

   c. Open and review the SamplePolicyPlugin.java file in the \src\java\com\ca\usm\plugins\samples\policy folder. Use this sample policy plug-in as a model.

6. Create a Java class that implements the interface, com.ca.usm.plugins.apis.policies. AssignmentPolicyPlugin. The sample policy plug-in illustrates how to implement this interface.

7. (Optional) If you use content configuration forms, retrieve values from the fields on these forms. Use the forms as needed.

8. Create a properties file for the plug-in. You can use the plugin.properties file in the sample policy plug-in as a model for your properties files.

9. Create a folder to store the properties file and any JAR files that provide the classes and supporting libraries.

Important! Store the properties file at the *top* level of the folder. Do *not* store the properties file in a subfolder.

10. Activate the plug-in:
    a. Stop the CA Service Catalog Windows service.
    b. Copy your folder (including all subfolders, if any) to the USM_HOME\filestore\plugins folder.
11. Start the CA Service Catalog Windows service.
12. Verify that the plug-in was successfully adopted:
    a. Select Administration, Tools, Plug-ins.
    b. Verify that the plug-in is listed and that its details appear properly.
13. Test this plug-in:
    a. Use it to specify assignees for a policy.
    b. Submit a request that activates the policy and verify that the policy assigns approvers dynamically as intended.

Use API Plug-ins for Forms

To write and use an API plug-in for use in a form, follow this process:

1. Define the purpose of the plug-in. For example, to populate a select field with meeting rooms that a user can reserve for a specified time period. Other examples include options for the meeting room, such as projectors, video conferencing units, and microphones.
2. Meet the prerequisites. Be able to do the following proficiently:
   - Program in Java.
   - Create forms using the Form Designer.
   - Create the following fields in Form Designer forms:
     - Single select, multi-select, and dual list fields
     - Dynamic table fields
3. Review the API Plug-in documentation, as follows:
   a. Log in to CA Service Catalog and select Administration, Tools.
   b. Select Links.

c. Click Plug-in Documentation.

The API documentation is automatically generated Java documentation from the Java class methods for the plug-ins. You use the interfaces, classes, methods, and so on, to implement your plug-in.

4. Create a Java class for the type of Form Designer field for which the plug-in applies, as follows:

   - For single select, multiselect, and dual list fields: Create a Java class that implements the com.ca.usm.plugins.apis.forms.FDSelectDataProvider interface. A sample implementation of this interface is provided in the Sample Select Plug-in, with id ca.catalog.samples.select-plugin.

   - For dynamic table fields: Create a Java class that implements the com.ca.usm.plugins.apis.forms.FDTableDataProvider interface. A sample implementation of this interface is provided in the Sample Table Plug-in, with id ca.catalog.samples.table-plugin.

   To access Java documentation for the interfaces, click Administration, Tools, Plug-ins, and click API Documentation.
   To download sample source code, click the sample plug-ins on the same page and click Download Source Code.

5. Create a properties file for the plug-in, as follows:

   - Use the sample plug-ins as models for your properties files. In that case, change the plug-in id property in the plugin.properties file.

   - Use the Java Development Kit 1.6 (or higher) and Apache Ant 1.8 (or higher) to use the included build file to compile the plug-in.

   - Use a private classloader for your plug-ins. To use a private classloader, add the following line to your plugin.properties file:

     ```
     classloader.type=private
     ```

     Note: Custom plug-ins from CA Service Catalog Release 12.7 do *not* require any updates after you upgrade CA Service Catalog. These plug-ins continue to function as they originally did.

6. (Optional) If you use content configuration forms, retrieve values from the fields on these forms. Use the forms as needed.

7. Perform the actions that apply:

   - Configure Pagination Parameters for Select Fields.

   - Configure Attributes for Select Boxes Only.

   - Configure Sorting and Pagination Parameters for Dynamic Tables.

8. Create a folder to store the properties file and any JAR files that provide the classes and supporting libraries.

   Important! Store the properties file at the *top* level of the folder. Do *not* store the properties file in a subfolder.

9. Activate the plug-in:

   a. Copy your folder (including all subfolders, if any) to the plugins folder of the filestore.

   b. Select Administration, Tools, Plug-ins, and click the Reload Plugins method.

10. Verify that the plug-in was successfully adopted:

    a. Log in to CA Service Catalog and select Administration, Tools.

    b. Select Plug-ins.

    c. Verify that the plug-in is listed and that its details appear properly.

You are ready to test this API for use in a form field.

Configure Pagination Parameters for Select Fields

Your plug-in can return a large amount of data in a select field on a form. In that case, you often specify the page size of the results in the select field. An example is displaying ten results per page in the select field. To accomplish this task, configure the parameters for pagination in the related Java class and object.

Follow these steps:

1. Edit the Java class that implements the interface, com.ca.usm.plugins.apis.forms. FDSelectDataProvider. Implement the following method in FDSelectDataProvider:

   ```
   List<FDOption> getOptions(int start, int numToReturn);
   ```

   - **start**
     Specifies the first row to return. This parameter is an integer.

   - **numToReturn**
     Specifies the number of rows to return. This parameter is an integer.

   This method returns a list of FDOption objects:

   - The key value pair (id and value) in a report data object for the options of the select field.

   - Data that complement the key value pair. You can optionally display this additional data in other fields (except the select field) on the form.

The value of the _id attribute of each field must match the one of the keys in the additional data.

2. Also in FDSelectDataProvider, implement the following method:

```
int totalCount();
```

This method returns the total number of rows that exist.

Note: For more information and examples, see the API plug-in documentation.

Configure Attributes for Select Boxes Only

Some HTML Attributes apply to select boxes only. For more information, see the Attributes for Select Boxes Only (see page 2934) section.

Configure Sorting and Pagination Parameters for Dynamic Tables

Your plug-in can return a large amount of data in a dynamic table in a form. In such a scenario, you specify the page size of the results. An example is displaying ten results per page on the form. Similarly, you often want to let users sort the results on each page in ascending or descending order. To accomplish both tasks, configure the parameters for sorting and pagination in the related Java class and object.

Follow these steps:

1. Click Catalog, Forms, and open the form of interest.

2. Open the table and verify that the attribute named Sortable is set to True.
If this attribute is enabled (True), then users can click arrows on the table column headers to sort the results.

3. Edit the Java class that implements the interface, com.ca.usm.plugins.apis.forms.FDTableDataProvider. Implement the following method in FDTableDataProvider:

```
List<FDTableRow> getTableRows(int start, int numToReturn, String sortField,
boolean sortAscending);
```

Users determine these values by interacting with the form, for example, by clicking to view the next page.

- **start**
Specifies the first row to return. This parameter is an integer.

- **numToReturn**
Specifies the number of rows to return. This parameter is an integer.

- **sortField**
  Specifies the rows to sort. When the value is null, no sorting occurs. This parameter is a string.

- **sortAscending**
  Specifies whether to sort the results in ascending or descending order. This parameter is Boolean.

This method returns FDTableRow objects, which are described in a later step.

4. Also in FDTableDataProvider, implement the following method:

```
int totalCount();
```

This method returns the total number of rows that exist.

5. Use the FDTableRow object and its methods to return table row data. You can use the following methods:

- **public void setColumnValue(String columnId, String data)**
  Specifies the following to set the value for a column:
  - String columnid - Specifies "_id" attribute of a component of a table.
  - String data - Specifies a value that you can parse and place into the field on the table.
- **public String getColumnValue(String columnId)**
  Specifies the matching GET function for the previous SET function (public void setColumnValue).
- **public Set getColumns()**
  Returns the set of column IDs stored in this object.

Note: For more information and examples, see the API plug-in documentation.

Using

Audience: IT Analysts, Knowledge Managers, Configuration Administrators, Configuration Managers, Asset Managers, Service Designers

CA Service Desk Manager

CA Service Catalog

CA Asset Portfolio Management

Vendor Management (see page 2457)

Common Capabilities

Reporting (see page 3180)

Mobility (see page 3156)

Self-Service (see page 3244)

Working with Problems

This article contains the following topics:

Problems are difficulties encountered when following normal procedures. Records of problems are recorded, along with the steps taken to correct the problems. If you create a ticket as a copy of another ticket, the Status field displays all Status values.

Important! Unless otherwise noted, all the CA SDM Request features are also available for Incidents and Problems.

Note: Depending on your role, you may not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create records.

Create a Problem

You can create a new problem either using a template or without using a template.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. Do one of the following steps:
   - On the Service Desk tab, select File, New Problem.
   - On the Service Desk tab, select File, New Problem from Template.
2. Complete the Problem Fields (see page 2052) as appropriate for the problem.
3. Use the controls available on the problem tabs (see page) to process the problem as appropriate.
4. Click one of the following buttons:
   - **Use Template** -- Displays a list of available problem templates. Select the template you want to use for creating this problem.
   - **Quick Profile** -- Displays the contact information for the user entered in the Affected End User field. If you are creating a new problem, a list of available users appears. Select the user that is the Affected End User.
   - **Find Similar** -- Opens the Find Similar page to search for similar problems.
   - **Create Change Order** -- Opens the Create New Change Order window so you can create a change order ticket associated with this problem.

Problem Fields

The following fields require explanation to create or update a problem:

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

- **Problem Reference Number**
  This is a unique reference number assigned by CA Service Desk Manager for all problem tickets. This is used by analysts and customers to refer to a particular problem ticket.
- **Requester**
  Specifies the name of the person who initiated the ticket. This person must be a defined contact. You can enter a value directly or click the magnifier to search for the name.
- **Affected End User**
  Specifies the contact name of the person who is affected by the record. If the contact is assigned to a special handling type, special handling indicators are displayed. You can enter a value directly or click the magnifier to search for a contact name.
- **Problem Area**
  Indicates the general area of your IT environment that is affected by the problem (for example, Applications, E-mail, Hardware, and Software). A problem area provides default values that are

entered automatically on all problem tickets that are assigned to the area. In addition to the predefined problem areas, your system administrator can define custom problem areas. You can enter a value directly or click the magnifier to search for a problem area.

Note: Your system administrator has the option of adding custom properties to problem areas. If custom properties have been added, they are displayed on the Properties tab when you create, edit, or view a problem. Some custom properties require that you enter a value.

- **Status**
  Specifies the status code of the record. For example, you can list only the tickets with a status code of Fix in Progress, or can Close Requested. You can enter a value directly or click the magnifier to search for a status. The blue button (on the left side of the Status field) lets you change the current status to the next default status.

- **Priority**
  Specifies the priority ranking of the record. The ranking determines the amount of attention the ticket receives. The predefined priority levels are 1 (highest) through 5 (lowest). Your system administrator or an active priority calculation can generate the appropriate Priority values for various installations and tenants. When priority calculation is enabled, this field updates based on Impact, Urgency, Affected Service, and Affected User settings. When your administrator disables priority calculation and uninstalls the urgency_on_employee option, Self Service Users see the Priority field on the Request Detail page.

Detail Fields

- **Reported By**
  Specifies the name of the person reporting the record.

- **Assignee**
  Specifies the name of the person who is assigned to handle the record. You can enter a value directly or click the magnifier to search for a name. Selecting an assignee populates the groups that the assignee belongs to in the **Group** field.

- **Group**
  Specifies the group that is responsible for this record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, or problems. Any contact who is part of the group can handle the record after it is assigned to the group. You can enter a value directly or click the magnifier to search for a group. Selecting a group populates the **Assignee** field with the corresponding assignee name, which belong to the group.

- **Urgency**
  Specifies the urgency of the record. The urgency is determined by the importance of the user tasks that are affected by the record. Urgency codes indicate the importance of a ticket based on the degree to which it affects user tasks. For example, a network outage is more urgent than a printer failure. Your system administrator can modify the default urgency codes, so they can vary from one installation to another. Urgency values can update automatically based on an active priority calculation.

- **Impact**
  Specifies an impact code, such as 1 - Entire Organization, that indicates how a ticket affects the work being performed. For example, a ticket that requires a network outage for several hours would have a higher impact than a ticket that takes a printer off-line. Your system administrator can modify the default impact codes, so they can vary from one installation to another.

- **Active**
  Indicates whether the record is Active or Inactive. This value applies to the current record only, not the associated template.

- **Configuration Item**
  Specifies the hardware, software, or service that is affected by the record. Your system administrator creates a record that uniquely identifies each configuration item for your organization and indicates its precise location. You can enter a value directly or click the magnifier to search for an item.

- **Charge Back ID**
  Specifies the ID that is charged for the service.

- **Call Back Date/Time**
  Specifies the date and time to follow up on this record. You can enter the date and time in the format mm/dd/yyyy hh:mm am | pm, or click the calendar icon to open a calendar window where you can select the date and time for follow-up.

- **Symptom**
  Specifies a code that describes a primary symptom of the record. For example, Slow Response.

- **Root Cause**
  Identifies the code associated with the core reason why the ticket was opened. Your service desk can use generic root cause codes, such as Hardware Failure or Software Failure, or more specific codes, such as Network.Cable, Network.Card, or Network.Response. You can enter a value directly or click the magnifier to search for a code.

- **Change**
  Specifies the number and name of the change order that is associated with this record. Enter the number or name of the change order directly in this field.

- **Caused by Change Order**
  Specifies only tickets that were opened as a result of a specific change order ticket. You can enter a value directly or click the magnifier to search for a change order ticket.

- **External System Ticket**
  Specifies an identification for a ticket that belongs to an external system that integrates with CA SDM. This field stores hyperlinks and displays functional links in read-only mode.

- **Timer**
  Tracks the incremental amount of the time spent working on various phases of ticket processing. The timer is reset to 00:00:00 each time you open the ticket record for updates. You cannot edit this field.

> **Note:** The amount of time that is spent on each activity is shown on the Activities tab of the ticket record.

- **Action**
  Sets or resets the Actual Date/Time to the current date and time.

- **Target**
  Specifies the current Service Target.

- **Target Date/Time**
  Specifies date and time when this Service Target is due. If the ticket is in a Hold status, this value is blank.

- **Actual Date/Time**
  Specifies the time when the target condition was met. If no value appears, the target condition has not been met.

- **Time Left**
  Specifies the amount of remaining time for the service target when the ticket is on hold. If the Service Target has been met, Time Left shows the unused time. A negative value indicates the time that elapsed since the missed target date.

- **Violation Cost**
  Specifies the incurred cost when the service type time limit is violated.

- **Affected Service**
  Specifies the primary service that affects the problem or incident. The CIs of type Service have a class that is defined in the Enterprise Service Family field. The ticket stores the currently affected service information in the ticket for reporting. You can enter a value directly or click the magnifier to search for a CI.

- **Affected End User**
  Specifies the contact name of the person who is affected by the record. If the contact is assigned to a special handling type, special handling indicators are displayed. You can enter a value directly or click the magnifier to search for a contact name.

- **Priority**
  Specifies the priority ranking of the record. The ranking determines the amount of attention the ticket receives. The predefined priority levels are 1 (highest) through 5 (lowest). Your system administrator or an active priority calculation can generate the appropriate Priority values for various installations and tenants. When priority calculation is enabled, this field updates based on Impact, Urgency, Affected Service, and Affected User settings. When your administrator disables priority calculation and uninstalls the urgency_on_employee option, Self Service Users see the Priority field on the Request Detail page.

- **Summary**
  Provides a brief description of the record.

- **Description**
  Describes the record in detail.

- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.

- **Last Modified By**
  Displays the name of the last person who edited the ticket.

- **Ticket Open Date/Time**
  Displays the date and time the ticket was opened.

- **Ticket Resolved Date/Time**
  Displays the date and time the ticket was resolved.

- **Ticket Closed Date/Time**
  Displays the date and time the ticket was closed.

- **Created Via**
  Specifies the component reporting the record (detail_pr.htmpl).

Problem Tabs

The following tabs are available on the Create New Problem, Problem Detail, and Update Problem pages:

- **Activities:** Displays a log of the activities performed to resolve the problem. For more information, see Add an Activity from the Ticket Management (see page 2308) topic.

- **Event Log:** Displays a record of significant actions that occur regarding the problem.

- **Attachments:** Allows you to attach a document or a link to a URL to the problem.

- **Workflow Tasks:** Lists the process instance and related audit trail messages for a CA Process Automation, or Classic Workflow that is associated with the ticket. The Workflow Tasks tab shows fields that apply to an attached workflow. The workflow may require some of the work items to complete before the ticket can close. The Workflow Tasks tab appears only if your administrator configured workflows for the ticket area or category. For more information, see Define a Category or Area (see page 1054) topic.

- **Service Type:** Allows you to attach a service type event (see page 2313) to indicate the level of support for the ticket.

- **Attached Incidents:** Allows you to view a list of any incident tickets attached to the problem ticket.

- **Knowledge:** Allows you to search for or submit information to the CA SDM Knowledge Base to help resolve problems. The Federated Search capability helps you to get the knowledge search results from multiple sources. For example, Google, SharePoint, CA Open Space, and so on.

- **Solutions:** Allows you to store information about the problem solution with the problem record for future reference.

- **Parent / Child:** Allows you to create a parent/child relationship between the problem and another CA SDM record.

- **Properties:** Your CA SDM administrator can add custom properties to problem areas.
- **Templates:** Allows you to create a template (see page 2315) using the current ticket as a model.

Create a Problem from an Incident

From an incident, you can create an associated problem if necessary.

Follow these steps:

1. From the Incident Detail Page, click Create Problem.
   The Create New Problem page displays. The fields are filled with the values from the original incident, but they can be edited for the problem. See the Problem Fields (see page 2052) as appropriate for the problem.

2. Use the controls available on the problem tabs (see page) to process the problem as appropriate.

3. Click one of the following buttons:

   - **Use Template** -- Displays a list of available problem templates. Select the template you want to use for creating this problem.
   - **Quick Profile** -- Displays the contact information for the user entered in the Affected End User field. If you are creating a new problem, a list of available users appears. Select the user that is the Affected End User. For more information about Quick Profile, see the Ticket Management (see page 2308) topic.
   - **Find Similar** -- Opens the Find Similar page to search for similar problems.
   - **Create Change Order** -- Opens the Create New Change Order window so you can create a change order ticket associated with this problem.

Issue Management

Contents

Issues are entered by customers when they encounter questions or difficulties when following normal procedures. Records of issues are recorded, along with the steps taken to correct the issues. If you create a ticket as a copy of another ticket, the Status field displays all Status values.

Create an Issue

You can either create an issue from scratch or use an existing template.

Important! Depending on your role, you do not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create new ones.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, select File, New Issue.
2. Fill in the issue fields (see page)as appropriate for the ticket.
3. Use the controls available on the tabs (see page)to process the ticket as appropriate.
4. Click one of the following buttons:

   Auto Assign -- Triggers an auto assignment task, and updates the activity log. This button appears only when the ticket specifies a category or area that has auto-assignment enabled.

   Find Similar -- Opens the Find Similar page to search for similar problems.**Quick Profile --** Displays the contact information for the specified user in the **Affected End User** field. You can also view their environment details and their entire ticket history.

   Use Template -- Displays a list of available templates for the selected ticket type. You can select the template that you want to use for creating this ticket.

Note: You can use the Quick Profile to identify a contact to be the affected end user of your new ticket. Quick Profile allows you to search for a contact, and view the history of the issues, requests, change orders, incidents, and problems that are assigned to that contact. When you have identified a contact, you can create the incident ticket directly from the Quick Profile.

Issue Fields

The following fields require explanation:

- **Affected End User**
  Specifies the name of the person affected by the record. You can enter a name directly or click the magnifier to search for a contact.

- **Category**
  Indicates the general category of the issue within your IT environment (for example, Hardware.pc. install and Software.pc.install). Issue categories provide default values that are entered automatically on all issue tickets assigned to the category. In addition to the predefined issue categories, your system administrator may define custom issue categories. You can enter a value directly, or click the Lookup icon to select from the defined categories. When you edit the Category and a CA Process Automation workflow is already running, the workflow cancels.

- **Status**
  Specifies the status of the record. You can enter the status directly or click the magnifier to search for a status.

- **Priority**
  Specifies the priority ranking of the record, determined by the amount of attention it should receive. Your system administrator can modify the default priority codes, so they can vary from one installation to another.

- **Product**
  Indicates the product that is associated with this issue. Select a product from the drop-down list.

Detail Fields

- **Organization**
  Specifies the name of the organization responsible for submitting the issue. You can enter a value directly or click the magnifier to search for an organization.

- **Position**
  Specifies the job title of the contact within the organization that submitted the issue, such as CEO, Director, or Manager.

- **Role**
  Indicates the role of the person submitting the issue to your service desk. For example, the person might be a customer or a potential customer.

- **On**
  Displays the date and time the record was created, in the time zone of the server. This field is read-only and is automatically filled during creation. The date and time display in mm/dd/yyyy hh: mm am | pm format.

- **Reason**
  Identifies the basic reason for opening the issue. For example, the reason might be a complaint, inquiry, or suggestion from a customer. Select a value from the drop-down list.

- **Reporting Method**
  Indicates the reporting method used to submit the current issue. Select a value from the drop-down list.

- **Assignee**
  Specifies the name of the person assigned to handle the record. You can enter the name of the person directly, or click the magnifier to search for a name. Selecting an assignee populates the groups that the assignee belongs to in the **Group** field.

- **Group**
  Specifies the group that is responsible for the record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, or problems. Any individual contact assigned to the group can handle the record once it has been assigned to the group. You can enter the group name directly, or click the magnifier to search for the group. Selecting a group populates the **Assignee** field with the corresponding assignee name, which belong to the group.

- **Service #**
  Specifies an issue number for an on-site service call.

- **Service Date**
  Specifies the date of the last on-site service call. You can enter the date and time in mm/dd/yyyy hh:mm am | pm format or click the calendar to select a date.

- **Need By Date**
  Specifies the date that the issue needs to be completed by. You can enter the date and time in mm/dd/yyyy hh:mm am | pm format or click the calendar to select a date.

- **Call Back Date/Time**
  Specifies the date and time to follow up on this record. You can enter the date and time in the format mm/dd/yyyy hh:mm am | pm, or click the calendar icon to select the date and time for follow up.

- **Root Cause**
  Specifies the code associated with the core reason why the ticket was opened. Your service desk can use generic root cause codes, such as Hardware Failure or Software Failure, or more specific codes, such as Network.Cable, Network.Card or Network.Response. You can enter the root cause directly into the field, or click the Lookup icon to display the defined root causes and select one.

- **External System Ticket**

  Specifies an identification for a ticket that belongs to an external system that integrates with CA SDM. This field stores hyperlinks and displays functional links in read-only mode.

Summary Information Fields

- **Issue Summary**
  Describes the record briefly.

- **Spelling**
  Checks the spelling of the text you enter in the Issue Summary field.

- **Issue Description**
  Describes the record.

- **Spelling**
  Checks the spelling of the text you enter in the Issue Description field.

- **Open Date**
  Displays the date and time when the issue was started in mm/dd/yyyy hh:mm am | pm format.

- **Resolve Date**
  Displays the date and time when the issue was resolved in mm/dd/yyyy hh:mm am | pm format.

- **Close Date**
  Displays the date and time when the issue was closed in mm/dd/yyyy hh:mm am | pm format.

- **Timer**
  Tracks the incremental amount of the time spent working on various phases of ticket processing. The timer is reset to 00:00:00 each time you open the ticket record for updates.

  Note: The amount of time spent on each activity is shown on the Activities tab of the ticket record.

Issue Tabs

The following tabs are available on the Create Issue, Issue Detail, and Update Issue pages:

- **Properties:** Administrators have the option of defining custom properties for issue categories, to provide additional detail on issue tickets assigned to that category. When you select an issue category while creating or editing an issue, if any custom properties have been defined for that category, they appear on the Properties tab.

- **Workflow Tasks:** Lists Workflow tasks associated with the issue. For more information, see Define a Category or Area (see page 1054) topic.

- **Config Items:** Links configuration items (CIs) to an issue or change order in order to give analysts information about the system that is affected by the ticket.

- **Knowledge:** Searches for or submits information to the knowledge base to help resolve issues. The Federated Search capability helps you to get the knowledge search results from multiple sources. For example, Google, SharePoint, CA Open Space, and so on.

- **Solutions:** Stores information about the issue solution with the issue record for future reference.

- **Resolution:** Displays a text description of the resolution to the issue.

- **Related Issues:** Create a parent/child relationship between the issue and another issue.

- **Activities:** Displays a log of the activities performed to resolve the issue. For more information, see Add an Activity from the Ticket Management (see page 2308) topic.

- **Event Log:** Displays a record of significant actions that take place regarding the issue.

- **Attachments:** Attaches a document or a link to a URL to the issue.

- **Service Type:** Attaches a service type event (see page 2313) to indicate the level of support for the ticket.
- **Time / Cost:** Calculates the estimated cost and duration of the entire issue by adding together the estimated cost and duration of each task.
- **Custom Fields:** Defines custom fields for tracking information about the issue.
- **Templates:** Create a template (see page 2315) using the current ticket as a model.
- **Support Automation:** Displays the assistance session log and lets you invite the end user to an assistance session.

Note: If multi-tenancy is installed, the list page displays Tenant and Public Data settings in the search filter. Public Data can be Excluded or Included with Tenant data; Only searches for public objects exclusively. On detail pages, select the appropriate tenant from the list. If you select <empty>, the object is public.

Accumulate Costs and Time to an Issue

The accumulate feature allows you to calculate the estimated cost and duration of the entire issue by adding together the estimated cost and duration of each task. You can also choose to accumulate the issue and all of its children. Children are additional records entered as a result of attempting to resolve the original issue.

Follow these steps:

1. Select Issues, Assigned or Unassigned, and a priority level.
   The Issue List appears.
2. Select the issue of interest.
   The Issue Detail page appears.
3. Select Actions, Accumulate Issue on the menu bar.
   The Accumulate Issue page appears.
4. Click one of the following buttons:
   - **Accumulate this Issue and All Children**
     Calculates the estimated cost and duration of the issue by adding together the estimated cost and duration of tasks for this issue and all of its children.
   - **Accumulate Only this Issue**
     Calculates the estimated cost and duration of the issue by adding together the estimated cost and duration of tasks for only this issue.
   - **Cancel**
     Closes the Accumulate Issue page without accumulating the issue.

The estimated cost and duration are accumulated and you are returned to the Issue Detail page.

5. Select the Time/Cost tab on the Issue Detail page.
   The tab displays the estimated cost and duration for the issue based on the values accumulated.

Expedite an Issue

You can use the Expedite Issue command to change the status of unnecessary tasks to Skip so the issue can be completed quickly.

Note: Skip must be defined as a valid status for the task.

Follow these steps:

1. Select Issues from the Scoreboard.
   The Issues folder expands to reveal nested folders for Assigned, Unassigned, and All Scheduled issues.

2. Select the appropriate folder under Assigned, Unassigned, and All Scheduled for the issue whose children you want to close.
   The Issue List page appears.

3. Click the issue number.
   The Issue Detail page appears.

4. Select Expedite Issue from the Actions menu.
   The Expedite Issue page appears.

5. (Optional) Enter comments in the Remarks field to explain the action.

6. Click OK.
   The Expedite Issue page closes and the Workflow Tasks tab on the Issue Detail page shows all unnecessary tasks with status of Skip.

Status Transitions

You can define a subset of the full status list and determine the next status of the ticket as it continues through its lifecycle. You can also specify how strictly the system enforces status transition policies by configuring the Status Policy Violations option in Options Manager (General Options).

Note: Because status transitions can be shared between integrations such as Events and Macros, do not inactivate predefined status transitions unless explicitly requested.

Follow these steps:

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, and specify one of the following:

   - Incident Transitions
   - Problem Transitions
     Request Transitions

   The Transition List page appears.

2. Click Create.
   The Update Status Transitions page appears.

3. Complete the fields as appropriate. The following fields require explanation:

   - **From Status**
     Defines the current status of the ticket, for example, Open.
   - **To Status**
     Specifies a valid next status of the ticket, for example, Assigned.
   - **Default Transition**
     Specifies the default status transition. CA SDM uses the default transition when a user clicks the default transition button on the ticket detail page, or when a user (including a web services user) updates the status to a <d> value. You can only configure one default transition for each status (or one for each tenant in a multi-tenanted system).
   - **Must Comment**
     Indicates that a comment for the transition must be supplied. Specifying this option indicates that an analyst must supply an activity log comment when changing the status on a request.
   - **Condition**
     Specifies the condition by which the transition is allowed. For example, when the condition "nonprty 1&2 assigned req" is associated with the Request Transition of Acknowledged to Hold, the condition verifies if the transition to move the status from Acknowledged to Hold is allowed.
   - **Transition Type**
     Links a transition type to this transition. Transition types and their corresponding statuses control when employees can close and reopen Incidents and Requests using self-service. This field only displays for Incident and Request status transitions.
   - **Condition Error Message**
     Specifies the message returned to the user if the transition is rejected.

The transition is defined.

4. Click Save, Close Window.
   The transition appears in the Transition List when you refresh the page.

Status Transitions and Dependent Attribute Controls

This article contains the following topics:

You can use the following configurable controls to restrict ticket status flows for change orders, issues, incidents/problems/requests, and determine which fields are shown or required for each ticket status:

- **Transitions**
  Controls how users select available statuses on the incident/problem/request, issue, or change order form. For example, a problem is in a status of Open, and the transition flow only allows the analyst to update the status to Closed. In this example, the analyst has no other status options, which reinforces the problem management process.
  Transitions let you define a subset of the full status list and specify the default new (or next) status of a ticket based on the current status. You can define unique status transitions for each ticket type. Consider using transitions when you want to restrict status workflows for your end users.

- **Dependent Attributes**
  Controls how attributes are designated as required (must supply) or locked (cannot update) depending on ticket status. For example, the Change Manager can prevent an analyst from editing the Summary attribute after a change order is approved. Consider using attribute controls when you want to restrict certain attributes based on the status.

Note: You can specify how strictly the system enforces Status policies by configuring the Status Policy Violations option in Options Manager (General Options). This option only applies to automated system processes, such as integrations and macros.

Work with Status Transitions and Dependent Attribute Controls

To work with status transitions and dependent attribute controls, do the following:

1. On the Administration tab, configure the appropriate tenants, contacts, and roles for your environment.

2. On the Service Desk node, specify a ticket type (Change Order, for example), and select Status. The Status List page displays active status codes.

3. Edit the appropriate status code (Acknowledged, for example) and use the controls available on the tabs at the bottom of the ticket's status detail page to do the following:

   - Configure Status Transitions (see page 2066)

   - Configure Dependent Attribute Controls (see page 2067)

Note: You can configure unique transitions and dependent attribute controls for each ticket type.

Configure Status Transitions

You can configure a subset of the full status list and specify the default next status of a ticket based on the current status. Transitions are enforced when the status is changed on the ticket detail form.

To configure status transitions

1. Click the Transitions tab at the bottom of the ticket's status detail page.
   The Transitions List page shows all valid transitions for the status.

Note: When configured, linked transition types appear on the Incident and Request Transition list.

2. Click the Update Transitions button.
   The Update Ticket Status Transitions page appears.

3. Configure the following check boxes as appropriate:

   - **Allowed**
     Specifies a valid transition for the status. Use this option to restrict status workflows.

   - **Default**
     (Optional) Specifies the default status transition. CA SDM applies the default transition when a user clicks the default transition button on the ticket detail form, or when a user (including a web services user) updates the status to a <d> value. There is only one default transition for each status (or one for each tenant in a multi-tenanted system).

- **Must Comment**
  (Optional) Specifies that an activity log comment for the transition is required when changing the status on a ticket.

  Note: This option applies to CA SDM tickets only. It does not apply to other areas, such as web services or the edit in list functionality.

4. (Optional) Select a status code in the Name column to update its details.

5. Click Save.
   The list of transitions configured for the new status appears on the Transition list. When the analyst selects the Status drop-down on the ticket form, the new status list appears.

Configure Dependent Attribute Controls

You can determine which fields are shown or required for the ticket status.

Note: Before you configure dependent attributes as "required" for the ticket status, be aware that the Edit in List option that appears on the ticket's list page may not display the attribute field values that are required. If the required attribute field value is not already part of the saved ticket, and if it is not presented in the Edit In List format, then the ticket is not saved. Consequently, the analyst must edit the required dependent attribute field values on the ticket's detail page instead of using the Edit in List option.

To configure a dependent attribute control

1. On the ticket's status detail page, select the Dependent Attribute Control tab at the bottom of the page.
   The Attribute Control List appears.

2. Click Create.
   The Update Status Dependent Attribute Control page appears.

3. Complete the following fields:

   - **Tenant**
     (Optional) In a system with multi-tenancy installed, specifies an optional tenant name. If a tenant is specified, the dependency applies only to that tenant and to its sub-tenants.

   - **Attribute**
     Specifies the name of the attribute you want to control, for example, Summary.

   - **Locked**
     Specifies the attribute as locked. A locked attribute associated with a status cannot be updated in a ticket with the same status. The attribute is unlocked when the status is changed.

- **Required**
  Specifies the attribute as required. A required attribute for the status cannot use a null value in a ticket with the same status.

4. Click Save.
   The new attribute control for the status appears in the Attribute Controls List when you redisplay the page. When a user updates the ticket status, the system retrieves the list of required attributes corresponding to the new status, and updates the ticket form as appropriate. An error message appears at the top of the ticket form when a user attempts to close the ticket without filling in a required field.

Web Services Methods

You can configure the following status transition and dependent attribute control SOAP web services methods:

- **getValidTransitions**
  Lists the transitions for a ticket. This method is modeled on the existing getValidTaskTransitions method, except that the argument can be a ticket or a status.

- **getDependentAttrControls**
  Lists the locked and required attributes for an attribute of an object that persistent id specified. The Status attribute is supported at this time.

Predefined Transition Flows

For each ticket type, you can use the predefined status transitions provided with the product and modify them to accommodate your desired transition flow.

To view the list of predefined transitions, do the following:

On the Administration tab, expand the Service Desk node, and select one of the following:

- Change Order Transitions
- Issue Transitions
- Request/Incident/Problem Transitions

The Transitions List displays the predefined transitions that let you control how a ticket (incident /request/problem, change order, and issue) continues through its lifecycle.

Incident Transition Flow

The following table shows the predefined Incident transition flow:

Current Status	Default Transition	Available Next Statuses
Acknowledged	In Progress <d>	Avoided, Awaiting Vendor, Cancelled, Closed, Closed Unresolved, In Progress, Open, Pending Change, Resolved
Avoided		

Current Status	Default Transition	Available Next Statuses
		Acknowledged, Avoided, Awaiting End User Response, Closed, Closed Unresolved, In Progress, Reject Solution, Researching, Resolved
Awaiting End User Response	Researching <d>	Closed, Closed Unresolved, In Progress, Open, Researching, Resolved
Awaiting Vendor	Researching <d>	Acknowledged, Closed, Closed Unresolved, In Progress, Open, Pending Change, Researching, Resolved
Cancelled		Closed
Closed		Open
Closed Unresolved		Acknowledged
Closed Unresolved		Closed
Closed Unresolved		Open
Hold		Acknowledged, Closed, In Progress, Open, Pending Change, Resolved
In Progress	Researching <d>	Acknowledged, Awaiting End User Response, Awaiting Vendor, Closed, Closed Unresolved, Open, Pending Change, Researching, Resolved
Pending Change	Researching <d>	Acknowledged, Closed, In Progress, Open, Resolved
Researching	Resolved <d>	Closed, Open, Resolved
Resolved	Closed <d>	Awaiting End User Response, Closed, Open

Problem Transition Flow

The following table shows the predefined Problem transition flow:

Current Status	Default Transition	Available Next Statuses
Acknowledged	In Progress <d>	Acknowledged, Approved, Cancelled, Closed, Fix in Progress, Open, Rejected, Researching
Analysis Complete	Approved <d>	Acknowledged, Cancelled, Closed, Fix in Progress
Approved	Fix in Progress <d>	Closed, Fixed, Pending Change
Awaiting Vendor	Researching <d>	Acknowledged, Closed, Closed Unresolved, Fixed, In Progress, Open, Pending Change, Researching
Cancelled	Closed <d>	Closed, Closed Unresolved, Open
Closed Unresolved		Acknowledged, Closed, Open
	Fixed <d>	Approved, Cancelled, Fixed, Fix in Progress, Researching, Rejected

Current Status	Default Transition	Available Next Statuses
Fix in Progress		
Fixed	Closed <d>	Closed
Hold	Researching <d>	Acknowledged, Closed, Fixed, In Progress, Open, Pending Change, Researching
In Progress	Researching <d>	Acknowledged, Approved, Cancelled, Closed, Fix in Progress, Pending Change, Rejected, Researching
Known Error	Fix in Progress <d>	Closed, Fix in Progress, Fixed
Open	Acknowledged <d>	Acknowledged, Approved, Cancelled, Closed, Fix in Progress, In Progress, Rejected, Researching
Pending Change	Fixed <d>	Closed, Fixed, Researching
Rejected	Closed <d>	Closed, Closed Unresolved, Open
Researching	Analysis Complete <d>	Acknowledged, Analysis Complete, Approved, Cancelled, Closed, fix in Progress, Fixed, Rejected

Issue Transition Flow

The following table shows the predefined Issue transition flow:

Current Status	Default Transition	Available Next Statuses
Acknowledged	In Progress <d>	Awaiting End User Response, Awaiting Vendor, Closed, Closed Unresolved, In Progress, Open, Pending Change, Resolved
Awaiting End User Response	Researching <d>	Acknowledged, Closed, Closed Unresolved, In Progress, Open, Researching, Resolved
Awaiting Vendor	Researching <d>	Acknowledged, Closed, In Progress, Open, Pending Change, Researching, Resolved
Cancelled	Closed <d>	Closed
Closed		Acknowledged, Open
Closed Unresolved		Acknowledged, Closed, Open
Hold		Acknowledged, Closed, In Progress, Open, Pending Change, Resolved
In Progress	Researching <d>	Acknowledged, Awaiting End User Response, Awaiting Vendor, Closed, Closed Unresolved, Open, Pending Change, Researching, Resolved
Open	Acknowledged <d>	Acknowledged, Avoided by Self Service, Awaiting End User Response, Awaiting Vendor, Closed, Closed Unresolved, In Progress, Pending Change, Resolved

Current Status	Default Transition	Available Next Statuses
Pending Change	Researching <d>	Acknowledged, Closed, In Progress, Open, Researching, Resolved
Researching	Resolved <d>	Closed, Open, Resolved, Awaiting End User Response, Closed, Open

Change Order Transition Flow

The following table shows the change order transition flow:

Current Status	Default Transition	Available Next Statuses
Approval in Progress	Approved <d>	Approved, Cancelled, Closed
Approved	Scheduled <d>	Cancelled, Closed, Implementation in Progress, Scheduled
Backed Out		Approval in Progress, Closed, Open, RFC
Cancelled		Closed
Customer Hold		Cancelled, Closed, Implementation in Progress, Rejected, Scheduled, Verification in Progress
Hold		Cancelled, Closed, Implementation in Progress, Scheduled
Implementation in Progress		Backed Out, Cancelled, Closed, Customer Hold, Rejected, Scheduled, Vendor Hold, Verification in Progress
Open	RFC <d>	Approval in Progress, Cancelled, Closed, Customer Hold, Implementation in Progress, Rejected, RFC, Scheduled, Vendor Hold
Rejected	Closed <d>	Approval in Progress, Cancelled, Closed
RFC	Approval in Progress <d>	Approval in Progress, Cancelled, Closed, Customer Hold, Implementation in Progress, Open, Rejected, Scheduled, Vendor Hold
Scheduled	Implementation in Progress <d>	Cancelled, Closed, Customer Hold, Implementation in Progress, Vendor Hold, Verification in Progress, Cancelled, Closed, Implementation in Progress, Scheduled, Backed Out, Closed

Best Practice Predefined Status Transitions

The predefined status transitions delivered with the product are Active in a new installation and Inactive after the upgrade. For every status listed on the Transitions List page, there is a default status transition (or next status). The path taken by the default status transition reflects the best practice. The additional status transitions listed on the Transitions List page are provided to fulfill

various ticket management workflows. However, only Active status transitions that use this best practice can ensure that the proper workflow for managing Requests, Incidents, Problems, and Change Orders occurs. This best practice helps promote the movement of tickets to resolution and closure within the IT environment.

For example, the following predefined incident transitions listed on the Incident Transition list page are set to Inactive to help promote the resolution and closure of incidents:

Status	New Status	Default	Status Description	Record Status
Acknowledged	Closed	No	Acknowledged to Closed Status Transition	Inactive
Acknowledged	Closed Unresolved	No	Acknowledged to Close Unresolved Status Transition	Inactive
Acknowledged	Open	Yes	Acknowledged to Open Status Transition	Inactive
Awaiting End User Response	Acknowledged	No	Awaiting End User Response to Acknowledged Status Transition	Inactive
Awaiting End User Response	Open	No	Awaiting End User Response to Open Status Transition	Inactive
Awaiting Vendor	Acknowledged	No	Awaiting Vendor to Acknowledged Status Transition	Inactive
Awaiting Vendor	Closed	No	Awaiting Vendor to Closed Status Transition	Inactive
Awaiting Vendor	Open	No	Awaiting Vendor to Open Status Transition	Inactive
Closed	Acknowledged	No	Closed to Acknowledged Status Transition	Inactive
Closed Unresolved	Acknowledged	No	Closed Unresolved to Acknowledged Status Transition	Inactive
Closed Unresolved	Closed	No	Closed Unresolved to Closed Status Transition	Inactive
Hold	Acknowledged	No	Hold to Acknowledged Status Transition	Inactive
Hold	Closed	No	Hold to Closed Status Transition	Inactive
Hold	Open	No	Hold to Open Status Transition	Inactive
In Progress	Acknowledged	No	In Progress to Acknowledged Status Transition	Inactive
In Progress	Closed	No	In Progress to Closed Status Transition	Inactive
In Progress	Open	No	In Progress to Open Status Transition	Inactive
Open	Closed	No	Open to Closed Status Transition	Inactive
Pending Change	Acknowledged	No	Pending Change to Acknowledged Status Transition	Inactive
Pending Change	Closed	No	Pending Change to Closed Status Transition	Inactive
Pending Change	Open	No	Pending Change to Open Status Transition	Inactive
Researching	Open	No	Researching to Open Status Transition	Inactive

Status Transitions for Self-Service

This article contains the following topics:

Status transitions let you control the movement of a ticket from one discrete state to another (for example, from Open to Closed). For employees using self-service, you can include buttons on the Incident and Request detail forms to represent any status transition (see page 2065).

Status transition buttons for incident and request process workflows appear in the employee interface when incident or request transitions are linked to active transition types. A transition type defines the button text and controls the behavior of the ticket detail form. When buttons are defined, the legacy Close Incident (or Request) and Reopen Incident (or Request) buttons are not displayed on the ticket detail forms. Instead, the employee can only change the status of the Incident or Request using the status transition buttons configured by the administrator.

By default, all predefined transition types delivered with the product are inactive, so status transition buttons are not in effect. As a system administrator, you can activate and modify predefined transition types or create transition types to accommodate your status transition workflows. After you create or modify a transition type, you can link them to any incident or request status transition.

How Transitions for Self-Service Work

Transition types and their corresponding statuses control when employees can close and reopen tickets as follows:

1. Active transition types are linked to incident (or request) status transitions by the administrator.
2. The employee creates an incident using self-service.
3. The analyst assigned to the incident finds a solution and moves the ticket to the Resolved status.
4. When the ticket is in a Resolved status, the employee detail form displays status transition buttons to Accept or Reject the resolution.
   - If the employee accepts the resolution, the Resolved to Closed transition occurs.
   - If the employee rejects the resolution, the Resolved to Open transition occurs.
5. After the employee clicks a button, they can add their remarks in the resolution form that appears.

How to Create or Update Transition Types for Transitions

As a system administrator, you can create new or update existing transition types for incident and request status transition workflows on the Transition Types List page.

To create a transition type for a status transition, do the following:

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Transition Types.

2. Click Create on the list page.

3. Edit the fields as appropriate on the detail page.
   The transition type for the status transition is created.

4. Click Save.
   The new transition type appears in the Transitions Type List when you redisplay the page.

To update a transition type, do the following:

1. Open the desired transition type for editing on the Transition Types List page.

2. Edit the fields as appropriate.

3. Click Save.
   The updated transition type appears on the Transition Type list.

How to Link Transition Types to Transitions

When status transitions are linked to transition types, the employee ticket detail form displays status transition buttons to Accept or Reject the resolution. To link a transition type with a status transition, do the following:

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Incident (or Request) Transitions.

2. Open the desired status transition for editing on the Request or Incident Transition List page.

3. Specify the desired transition type in the Transition Type field.

4. Click Save.
   The transition type is linked to the status transition.

Activate Predefined Transition Types

By default, all predefined transition types that are delivered with the product are Inactive, so status transition buttons are not in effect. You can activate and modify these transition types to accommodate your desired status transition flow.

To activate a predefined transition type

1. Select Show Filter on the Transition Type List page.
   The top portion of the page reveals additional search fields.

2. Select Inactive in the Record Status field and click Search.
   The Transition Type List displays all inactive transition types.

3. Right-click the desired transition type and select Edit from the menu.

4. Select Active in the Record Status field.

5. Click Save, Close window.

6. Click Search.
   The Transition Type List displays the active transition type.

Predefined Transition Types for Incident Status Transitions

The following table describes the predefined transition types for incident status transitions:

Symbol	Button Text	Form Header Text	Incident Status Transition
Accept incident resolution button	Accept	Accept Resolution	Resolved to Closed
Reject incident resolution button	Reject	Reject Resolution	Resolved to Open
Reject Closure incident button	Request Closure	Request Closure	To Closed Unresolved from Open Awaiting End User Response Awaiting Vendor In Progress Acknowledged

Predefined Transition Types for Request Status Transitions

The following table describes the predefined transition types for request status transitions:

Note: The Closed Requested status for Requests is the equivalent of the Resolved status for Incidents.

Symbol	Button Text	Form Header Text	Request Status Transition
Accept request resolution button	Accept	Accept Resolution	Close Requested to Closed
Reject request resolution button	Reject	Reject Resolution	Close Requested to Open
Request Closure request button	Request Closure	Request Closure	

Symbol	Button Text	Form Header Text	Request Status Transition
			To Canceled from Open Awaiting End User Response Awaiting Vendor Approval In Progress Acknowledged
Close request button	Close	Close Requested	From In Progress to Closed

Define Issue Transitions

Issue status transitions control the movement of a issue from one discrete state to another (for example, from Open to Closed). With transitions, you can define a subset of the full status list and determine the next status of the ticket as it continues through its lifecycle. You can use the predefined transitions (listed on the Issue Transitions List page), modify the transitions, or create transitions.

Note: You can specify how strictly the system enforces Status policies by configuring the Status Policy Violations option in Options Manager (General Options). This option only applies to automated system processes, such as integrations and macros.

You can define a subset of the full status list and determine the next status of the ticket as it continues through its lifecycle.

Note: Because status transitions can be shared between integrations such as Events and Macros, do not inactivate predefined status transitions unless explicitly requested.

Follow these steps:

1. On the Administration tab, select Service Desk, Issues.
   The Issue Transition List page appears.

2. Click Create.
   The Update Status Transitions page appears.

3. Complete the fields as appropriate. The following fields require explanation:

   - **From Status**
     Defines the current status of the ticket, for example, Open.

   - **To Status**
     Specifies a valid next status of the ticket, for example, Assigned.

- **Default Transition**
  Specifies the default status transition. CA SDM applies the default transition when a user clicks the default transition button on the ticket detail page, or when a user (including a web services user) updates the status to a <d> value. You can only configure one default transition for each status (or one for each tenant in a multi-tenanted system).

- **Must Comment**
  Indicates that a comment for the transition must be supplied. Specifying this option indicates that an analyst must supply an activity log comment when changing the status on a request.

- **Condition**
  Specifies the condition by which the transition is allowed. For example, when the condition "nonprty 1&2 assigned req" is associated with the Request Transition of Acknowledged to Hold, the condition verifies if the transition to move the status from Acknowledged to Hold is allowed.

- **Condition Error Message**
  Specifies the message returned to the user if the transition is rejected.

- **Description**
  Specifies the message returned to the user if the transition is rejected.

The transition is defined.

4. Click Save, Close Window.
   The new transition appears in the Issue Transition List when you refresh the page.

Define Transition Types

This article contains the following topics:

For employees using self-service, you can modify incident and request process flows by including buttons to represent any *status transition*. Status transition buttons for incident and request process workflows are configured through *transition types*. A transition type lets you define the button text, form header text, and control the behavior of the Incident and Request detail page. You can link a transition type to any incident or request status transition.

To define a transition type

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Transition Types.
   The Transitions Type List page appears.

2. Click Create.
   The Update Transition Types page appears.

3. Complete the fields as appropriate.
   The transition type for the status transition is created.

4. Click Save, Close Window.
   The new transition type appears in the Transitions Type List when you refresh the page.

Link Transition Types to Incident/Request Status Transitions

You can link a transition type to any incident or request status transition.

To link a transition type to an incident or request status transition

1. On the Administration tab, select Service Desk, Requests/Incidents/Problems, Request (or Incident) Transitions.
   The Transition List page appears.

2. Open the desired status transition.
   The Transition Details page appears.

3. Click Edit.
   The Update Transition page appears.

4. Specify the transition type that you want to link to in the Transition Type field. You can enter a value directly or click the magnifying glass to search for a service type.
   The transition type is associated with the status transition.

5. Click Save, Close Window.
   The transition type appears on the Status Transition list when you redisplay the list.

Activate Predefined Transition Types

By default, all predefined transition types delivered with the product are inactive, so status transition buttons are not in effect. You can activate and modify these transition types to accommodate your desired status transition flow.

To activate a predefined transition type

1. Select Show Filter on the Transition Type List page.
   The top portion of the page reveals additional search fields.

2. Select Inactive in the Record Status field and click Search.
   The Transition Type List displays all inactive transition types.

3. Right-click the title of the transition type and select Edit from the menu.

4. Select Active in the Record Status drop-down list.

5. Click Save, Close Window.

6. Click Search.
   The Transition Type List displays the active transition type.

Issue Workflows

Contents

A *workflow* is an automated or partially automated business process that specifies the sequence of tasks that must be performed to resolve a ticket.

Two workflow solutions are supported for issues:

- **CA SDM "classic" workflow** -- internal workflow automation features provided as a standard CA SDM component.
- **CA Process Automation** -- workflow with task-based steps that run remotely on the CA Process Automation web service.

Your administrator can configure issue categories to use either type of workflow. When an issue ticket is assigned to a category with an associated workflow, a series of tasks appear on the ticket's Workflow Tasks tab.

Some workflow tasks may be optional, which allows you to delete them from the task list.

You must complete all mandatory workflow tasks before you can close the ticket. The only exception is that if the ticket status is set to Cancelled, the workflow process terminates automatically.

If a ticket is removed from a category with an attached workflow, or assigned to a different category, the workflow process terminates automatically. If the new category has an attached workflow, its process starts automatically.

Process CA Process Automation Workflow Items

You can use CA Process Automation to manage required tasks for requests, incidents, problems, issues, and change orders. From CA SDM, you can view the status for a workflow. You can log in to the CA Process Automation server to view, update, or approve tasks, When you log in, CA Process Automation shows more details about each workflow task.

Note: For information about using CA Process Automation, see the CA Process Automation documentation.

Follow these steps:

1. On the CA SDM tab, select one of the following item:
   - Incidents, Assigned, or Unassigned, and the Priority
   - Problems, Assigned, or Unassigned, and the Priority
   - Requests, Assigned, or Unassigned, and the Priority
   - Change Orders, Assigned, or Unassigned, and the Priority

- Issues, Assigned, or Unassigned, and the Priority

The ticket List appears.

2. Select the ticket.
   The ticket Detail page appears.

3. Select the Workflow Tasks tab.
   When a CA Process Automation workflow is attached, a list of workflow tasks appears on the tab.

4. Click View Process or select a Process Instance Name.
   The CA IT Process Automation Manager log in page appears.

5. Enter your CA Process Automation user login and password.
   CA Process Automation launches a graphical snapshot of the workflow or a Task List for the process instance. After you close CA Process Automation, the CA SDM Workflow Tasks tab updates. During the same browser session, you do not have to re-enter your credentials to access CA Process Automation.

Incident Management

This article contains the following topics:

Incidents are events outside of normal operations. When an incident occurs, it disrupts the normal operational processes of an organization.

Important! Unless otherwise noted, all the CA SDM Request features are also available for Incidents and Problems.

Note: Depending on your role, you may not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create records.

Create an Incident

You can either create an incident from scratch or use an existing template.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type that you want to create. For example: To create a request from scratch, click File, New Request. To create a request from a template, click File, New Request from Template.

2. Fill in the incident fields (see page) as appropriate. Use the controls available on the issue tabs (see page 2080) to process the ticket as appropriate.

3. Click one of the following buttons:

   Auto Assign -- Triggers an auto assignment task, and updates the activity log. This button appears only when the ticket specifies a category or area that has auto-assignment enabled.

   Create Change Order -- Opens the Create New Change Order page. You can create a change order ticket that is associated with this incident. This button appears only when you create incidents, problems, and requests.

   Create Problem -- Opens the Create New Problem page so you can create a problem ticket associated with this incident. This button appears only when you create incidents and requests.

   Find Similar -- Opens the Find Similar page to search for similar problems.**Quick Profile --** Displays the contact information for the specified user in the **Affected End User** field. You can also view their environment details and their entire ticket history.

   Use Template -- Displays a list of available templates for the selected ticket type. You can select the template that you want to use for creating this ticket.

Note: You can use Quick Profile to identify a contact to be the affected end user of your new ticket. Quick Profile allows you to search for a contact, and view the history of the issues, requests, change orders, incidents, and problems that are assigned to that contact. When you have identified a contact, you can create the incident ticket directly from Quick Profile.

Incident Fields

The following fields are required to create or update an incident:

- **Incident Reference Number**
  This is a unique reference number assigned by CA Service Desk Manager for all incident tickets. This is used by analysts and customers to refer to a particular incident ticket.

- **Requester**
  Specifies the name of the person who initiated the ticket. This person must be a defined contact. You can enter a value directly or click the magnifier to search for the name.

- **Affected End User**
  Specifies the contact name of the person who is affected by the record. If the contact is assigned to a special handling type, special handling indicators are displayed. You can enter a value directly or click on the magnifier icon to search for a contact name.

- **Incident Area**
  Indicates the general area of your IT environment that is affected by the incident. For example, Applications, E-mail, Hardware, and Software. An incident area provides default values that are automatically entered on all the incident tickets pertaining to that area. In addition to the predefined incident areas, your system administrator can define custom incident areas. You can enter a value directly, or you can expand the node to display the defined incident areas and select one.

  Note: Your system administrator has the option of adding custom properties to incident areas. The custom properties are available on the Properties tab when you create, edit, or view an incident ticket. Some custom properties require that you enter a value.

- **Status**
  Specifies the status code of the record. For example, you can list only the tickets with a status code of Fix in Progress, or Close Requested. You can enter a value directly or click on the magnifier icon to search for a status. The blue button (on the left side of the Status field) lets you change the current status to the next default status.

- **Priority**
  Specifies the priority ranking of the record. The ranking determines the amount of attention the ticket receives. The predefined priority levels are 1 (highest) through 5 (lowest). Your system administrator or an active priority calculation can generate the appropriate priority values for various installations and tenants. When priority calculation is enabled, this field is updated based on Impact, Urgency, Affected Service, and Affected User settings. When your administrator disables priority calculation and uninstalls the urgency_on_employee option, Self Service Users see the Priority field on the Request Detail page.

- **Active**
  Indicates whether the record is Active or Inactive. This value applies to the current record only and not the associated template.

Detail Fields

- **Reported By**
  Specifies the name of the person reporting the record.

- **Assignee**
  Specifies the name of the person who is assigned to handle the record. You can enter a value directly or click on the magnifier icon to search for a name. Selecting an assignee populates the groups that the assignee belongs to in the **Group** field.

- **Group**
  Specifies the group that is responsible for this record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, or problems. Any contact who is part of the group can handle the record after it is assigned to the group. You can enter a value directly or click on the magnifier icon to search for a group. Selecting a group populates the **Assignee** field with the corresponding assignee name that belongs to the group.

- **Affected Service**
  Specifies the primary service that affects the problem or incident. The CIs of type Service have a class that is defined in the Enterprise Service Family field. The ticket stores the currently affected service information for reporting. You can enter a value directly or click on the magnifier icon to search for a CI.

- **Urgency**
  Specifies the urgency of the record. The urgency is determined by the importance of the user tasks that are affected by the record. Urgency codes indicate the importance of a ticket based on the degree to which it affects user tasks. For example, a network outage is more urgent than a printer failure. Your system administrator can modify the default urgency codes, so they can vary from one installation to another. Urgency values can update automatically based on an active priority calculation.

- **Impact**
  Specifies an impact code, such as 1 -- Entire Organization, that indicates how a ticket affects the work being performed. For example, a ticket that requires a network outage for several hours would have a higher impact than a ticket that takes a printer off-line. Your system administrator can modify the default impact codes, so they can vary from one installation to another.

- **Major Incident**
  Specifies that the incident is major or significant. Because of its importance, changes to this value on a ticket generate an activity log entry.

  Note: When you copy an incident, the value of this field is cleared. In addition, related tickets (child incidents) do not include the Major Incident value.

- **Configuration Item**
  Specifies the hardware, software, or service that is affected by the record. Your system administrator creates a record that uniquely identifies each configuration item for your organization and indicates its precise location. You can enter a value directly or click on the magnifier icon to search for an item.

- **Problem**
  Provides the number and name of the problem that is associated with this record. Enter the number or name of the problem directly into this field or click the search icon to search for the problem.

- **Symptom**
  Specifies a code that describes a primary symptom of the incident. For example, Slow Response.

- **Resolution Code**
  Indicates the action that the analyst had taken to resolve an incident or request. Resolution codes specify the general resolution of the ticket. For example, an Applied Patch resolution code indicates that the analyst used a software patch to address an incident.

- **Resolution Method**
  Indicates *how* an analyst implemented the resolution. For example, a Chat Session resolution method indicates that an analyst used a chat session to address an incident.

- **Call Back Date/Time**
  Specifies the date and time to follow up on this record. You can enter the date and time, in the format *mm/dd/yyyy hh:mm am | pm*, or click the calendar icon to open a calendar window where you can select the date and time for follow-up.

- **Change**
  Specifies the number and name of the change order that is associated with this record. You can enter the number or name of the change order directly in this field. Or, click the search icon to search for the change order.

- **Caused by Change Order**
  Specifies the change order number when the Incident ticket is the result of changes that are implemented from a change order.

- **External System Ticket**
  Specifies an identification for a ticket that belongs to an external system that integrates with CA SDM. This field stores hyperlinks and displays functional links in read-only mode.

Summary Information Fields

- **Summary**
  Provides a brief description of the record.

- **Spelling**
  Checks the spelling of the text that you enter in the Summary field.

- **Search Knowledge**
  Searches the CA SDM knowledge base to help resolve tickets. If you do not find any relevant knowledge base articles, you can submit your own knowledge base article after the ticket is resolved.

- **Total Activity Time**
  Displays a running total of the overall amount of time that is spent on the ticket. This value is updated each time a change is made to the ticket record. You cannot edit this field.

- **Timer**
  Tracks the incremental amount of the time spent working on various phases of ticket processing. The timer is reset to 00:00:00 each time you open the ticket record for updates. You cannot edit this field.

Note: The amount of time that is spent on each activity is shown on the Activities tab of the ticket record.

- **Description**
  Describes the record in detail.
- **Created via**
  Specifies the component reporting the record (Form Name: detail_in.htmpl)
- **Ticket Open Date/Time**
  Displays the date and time the ticket was opened.
- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.
- **Ticket Resolved Date/Time**
  Displays the date and time the ticket was resolved.
- **Ticket Closed Date/Time**
  Displays the date and time the ticket was closed.
- **Last Modified By**
  Displays the name of the last person who edited the ticket.

Incident Tabs

The following tabs are available on the Create New Incident, Incident Detail, and Update Incident pages:

- **Activities:** Displays a log of the activities performed to resolve the incident. For more information, see Ticket Management (see page 2308).
- **Event Log:** Displays a record of significant actions that occur regarding the incident.
- **Verification Log:** Displays the change verification activity history for this Incident. The log shows details about the policy and actions taken during the change verification operations involved in this Incident. For example, this log identifies the policy, CI, and managed attribute values that caused a change specification to create the Incident.

Note: This tab only appears if a CACF policy created the Incident.

- **Attachments:** Attaches a document or a link to a URL to the incident.
- **Service Type:** Attaches a service type event (see page 2313) to indicate the level of support for the ticket.

- **Workflow Tasks:** Lists the process instance and related audit trail messages for CA Process Automation or Classic Workflow that is associated with the ticket. The Workflow Tasks tab shows fields that apply to an attached workflow. The workflow may require some of the work items to complete before the ticket can close. The Workflow Tasks tab appears only if your administrator configured workflows for the ticket area or category. For more information, see Define a Category or Area (see page 1054) topic.

- **Efficiency Tracking:** You can specify criteria to track incidents. The information that you specify provides your organization with metrics about incidents for reports. For example, you can indicate that an incident was assigned incorrectly. When a large percentage of incorrectly assigned incidents appears in a report, your organization is aware that assignments must be adjusted. Efficiency tracking options appear only when the efficiency_tracking Options Manager option is installed. For more information about installing efficiency_tracking, see Install Incident Tracking (see page 1072). Complete the following fields as appropriate:

  - **Resolvable at a Lower Level**
    Flags incidents that are resolvable at a lower level.

  - **Incorrectly Assigned**
    Flags incidents that are assigned incorrectly.

  - **Remote Control was Used**
    Flags incidents in which remote control was used.

  - **Action**
    Sets or resets the Actual Date/Time to the current date and time.

  - **Target**
    Specifies the current Service Target. Service Targets measure whether the required service or repair is completed within the required time frame.

  - **Target Date/Time**
    Specifies date and time when this Service Target is due. If the ticket is in Hold status, this value is blank.

  - **Actual Date/Time**
    Specifies the time when the target condition was met. If no value appears, the target condition has not been met.

  - **Time Left**
    Specifies the amount of remaining time for the service target when the ticket is on hold. If the Service Target has been met, Time Left shows the unused time. A negative value indicates the amount of time that elapsed since the missed target date.

  - **Violation Cost**
    Specifies the incurred cost when the service type time limit is violated.

- **Parent / Child:** Create a parent/child relationship between the incident and another CA SDM record.

- **Knowledge:** Searches for or submits information to the knowledge base to help resolve incidents. The Federated Search capability helps you to get the knowledge search results from multiple sources. For example, Google, SharePoint, CA Open Space, and so on.

- **Solutions:** Stores information about the incident solution with the incident record for future reference.

- **Properties:** Adds custom properties to incident areas.

- **Outage:** Specifies information about service outages for an incident. Complete the Service Outage fields as appropriate:

  - **Start Time**
    Specifies the start date and time for an outage period related to the subject of the incident ticket. This value, together with the End Time, lets you track incident outages with the tickets that are opened relative to the outage. You can click the calendar icon to open the Date Helper window to select a date.

  - **End Time**
    Specifies the end date and time for an outage period related to the subject of the incident ticket. This value, together with the Start Time, lets you track incident outages with the tickets that are opened relative to the outage. You can click the calendar icon to open the Date Helper window so you can select a date.

  - **Type**
    Specifies the type of outage, such as a network outage. You can use the predefined outage types or create outage types.

  - **Return to Service**
    Indicates that service was restored.

  - **Percent of Service Restored**
    Specifies the percentage of service that was restored.

- **Template:** Allows you to create a Problem template (see page 2315) using the current ticket as a model.

- **Support Automation:** Displays the assistance session log and lets you invite the end user to an assistance session.

Request Management

Request Management Using CA IT Asset Manager

You can automate the request of IT assets through a repeatable service offering that is accessible through a service catalog. This function can increase customer satisfaction and can standardize your asset base to improve response times and service levels.

To automate request fulfillment, use the CA APM integration with CA Service Catalog.

Request Fulfillment

When CA APM and CA Service Catalog are integrated, you can perform request fulfillment using the two products. Use request fulfillment to associate requested items from a CA Service Catalog service request with CA APM assets. During the fulfillment process, you can perform the following tasks:

- View the assets that are assigned to a request.
- Assign the assets to a request.
- Remove the assets from a request.
- Deny the fulfillment of a request for assets.

For information about creating and managing requests in CA Service Catalog, see Integrate with CA Service Catalog Manually (see page 3470).

How to Fulfill Requests from Inventory

When you integrate CA Service Catalog with CA APM, you can associate assets with items requested from the catalog during request fulfillment. To fulfill requests from inventory, complete the following steps:

1. In CA APM, verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled.

   Note: For more information about creating user roles, see User Roles (see page 1574).

2. In CA Service Catalog, create a request for an asset.
   The request contains information about the requester and the type of hardware or software asset being requested.

3. In CA Service Catalog, open the request and click the gold brick action icon that is associated with the request.
   CA APM opens and the CA APM Fulfillment page appears.

Note: For information about creating and managing requests, see Integrate with CA Service Catalog Manually (see page 3470).

4. In CA APM, complete the following steps:
   a. Search for the assets from the inventory request that you want to fulfill.
   b. Complete any of the following steps:
      - Fulfill the inventory request for a hardware asset (see page 2090).
      - Fulfill the inventory request for a software asset (see page 2090).
      - (Optional) Deny an inventory request (see page 2089).
      - Display the list of assigned assets (see page 2089) to verify that they match the request.
      - (Optional) Remove an assigned hardware asset from an inventory request (see page 2091).
      - (Optional) Remove an assigned software asset from an inventory request (see page 2092).
5. In CA Service Catalog, verify the status of the fulfilled inventory request.

Deny an Inventory Request

You can deny an inventory request to indicate that none of the assets that are requested are fulfilled. When you open CA APM from a CA Service Catalog request, the CA APM Fulfillment page appears with a list of all assets available in CA APM.

Note: Verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled. For more information about creating user roles, see User Roles (see page 1574).

On the CA APM Fulfillment page, click Not Fulfilled from Inventory. The inventory request is denied, and the status of the request is updated in CA Service Catalog.

Display Assets Assigned to a Request

CA APM lets you display all assets that are currently assigned to a CA Service Catalog request. The enables you to manage the request fulfillment. When you open CA APM from a CA Service Catalog request, the CA APM Fulfillment page appears with a list of all assets available in CA APM.

Note: Verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled. For more information about creating user roles, see User Roles (see page 1574).

To display assets that are assigned to an inventory request, click Assigned Asset in the menu on the left of the CA APM Fulfillment page. A list of all assets that are assigned to the request appears in the search results.

Fulfill an Inventory Request for a Hardware Asset

You can fulfill a CA Service Catalog inventory request so that hardware assets are correctly assigned and fulfilled. When you open CA APM from a CA Service Catalog request, the CA APM Fulfillment page appears with a list of all hardware assets available in CA APM.

Note: Verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled. For more information about creating user roles, see User Roles (see page 1574).

Follow these steps:

1. On the CA APM Fulfillment page, complete one of the following steps to search for an asset:
   a. Scroll through the list of all available hardware assets that appear in the search results.
   b. Specify the search criteria and click Go.
      A list of matching hardware assets appears in the search results.
2. In the search results, select the assets that you want to fulfill.
3. (Optional) In the Fulfillment Changes area of the page, make field-level changes to all selected assets. For example, you can change the department, cost center, general ledger (GL) code, contact, and location for all selected assets.
4. Click Fulfill.
   The request is fulfilled, the request status is updated in CA Service Catalog. The asset information is updated in CA APM.

Fulfill an Inventory Request for a Software Asset

You can fulfill a CA Service Catalog inventory request so that a software asset is correctly assigned and fulfilled. When you open CA APM from a CA Service Catalog request, the CA APM Fulfillment page appears with a list of all software assets available in CA APM.

Important! If you have a CA SAM implementation, we do not recommend that you fulfill software asset requests in CA APM. We recommend that you use CA SAM to manage your software assets and licenses.

Note: Verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled. For more information about creating user roles, see User Roles (see page 1574).

Follow these steps:

1. On the CA APM Fulfillment page, complete one of the following steps to search for a software asset:

    a. Scroll through the list of all available assets that appear in the search results.

    b. Specify the search criteria and click Go.
    A list of matching software assets appears in the search results.

2. In the search results, click the software asset that you want to fulfill.
The Asset Details page for the selected software asset appears.

3. Define or update software internal allocations for the software asset by clicking Asset Allocation in the Relationships menu.

4. Click New and select the hardware asset that you want to associate with the software asset.

5. Click Fulfill and Save.
The software request is fulfilled, the internal allocations are saved, the request status is updated in CA Service Catalog. The asset information is updated in CA APM.

Remove an Assigned Hardware Asset from an Inventory Request

CA APM lets you remove an assigned hardware asset from an inventory request. For example, you have a laptop that was mistakenly added to a request and you want to remove it. When you open CA APM from a CA Service Catalog request, the CA APM Fulfillment page appears with a list of all hardware assets available in CA APM.

Note: Verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled. For more information about creating user roles, see User Roles (see page 1574)

Follow these steps:

1. On the left of the CA APM Fulfillment page, click Assigned Asset.
   A list of all hardware assets that are assigned to the request appears in the search results.

2. In the search results, select the hardware assets that you want to remove from the request.

3. (Optional) In the Fulfillment Changes area of the page, make field-level changes to all selected assets. For example, you can change the general ledger (GL) code, cost center, department, contact, location.

4. Click Remove Assignment.
   The hardware asset is removed from the request, the status of the request is updated in CA Service Catalog. The asset information is updated in CA APM.

Remove an Assigned Software Asset from an Inventory Request

CA APM lets you remove an assigned software asset from an inventory request. For example, a graphics software package was mistakenly added to a request and you remove the software from the request. When you open CA APM from a CA Service Catalog request, the CA APM Fulfillment page appears with a list of all software assets available in CA APM.

Note: Verify that the user fulfilling the request belongs to a role in which asset fulfillment access is enabled. For more information about creating user roles, see User Roles (see page 1574).

Follow these steps:

1. On the left of the CA APM Fulfillment page, click Assigned Asset.
   A list of all software assets that are assigned to the request appears in the search results.

2. In the search results, click the software asset that you want to remove from the request.
   The Asset Details page for the selected software asset appears.

3. Remove or update software internal allocations for the software asset by clicking Asset Allocation in the Relationships menu.

4. Click the Delete icon next to your selected asset.

5. Click Remove Fulfillment and Save.
   The asset is removed from the request, the internal allocations are saved. The status of the request is updated in CA Service Catalog and the asset information is updated in CA APM.

Request Management Using CA SDM

This article contains the following topics:

- Request Tabs (see page 2097)

Requests are records of reports made to the help desk and the activities performed to resolve the requests. If you create a ticket as a copy of another ticket, the Status field displays all Status values.

Important! Depending on your role, you do not have access to all the functionality described in this section. For example, some predefined roles can edit records but cannot create new ones.

Create a Request

You can either create a request from scratch or use an existing template.

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

Follow these steps:

1. On the Service Desk tab, click the File menu and select the ticket type that you want to create. For example, to create a request from scratch, click File, New Request. To create a request from a template, Click File, New Request from Template.

2. Fill in the request fields (see page) as appropriate.
   Use the controls available on the tabs (see page) to process the ticket as appropriate.

3. Click one of the following buttons:

   Auto Assign -- Triggers an auto assignment task, and updates the activity log. This button appears only when the ticket specifies a category or area that has auto-assignment enabled.

   Create Change Order -- Opens the Create New Change Order page. You can create a change order ticket that is associated with this incident. This button appears only when you create incidents, problems, and requests.

   Create Problem -- Opens the Create New Problem page so you can create a problem ticket associated with this incident. This button appears only when you create incidents and requests.

   Create Incident – Opens the Create New Incident page so you can create an associated incident ticket. This button appears only when you create change orders and requests.

   Find Similar -- Opens the Find Similar page to search for similar problems.**Quick Profile --** Displays the contact information for the specified user in the **Affected End User** field. You can also view their environment details and their entire ticket history.

Use Template -- Displays a list of available templates for the selected ticket type. You can select the template that you want to use for creating this ticket.

Note: You can use the Quick Profile to identify a contact to be the affected end user of your new ticket. Quick Profile allows you to search for a contact, and view the history of the issues, requests, change orders, incidents, and problems that are assigned to that contact. When you have identified a contact, you can create the incident ticket directly from the Quick Profile.

Request Fields

The following fields are required to create or update a request:

Note: If multi-tenancy is installed, select the appropriate tenant from the drop-down list. The public (shared) option creates the object for all tenants.

- **Request Reference Number**
  This is a unique reference number assigned by CA Service Desk Manager for all request tickets. This is used by analysts and customers to refer to a particular request ticket.

- **Requester**
  Specifies the name of the person who initiated the ticket. This person must be a defined contact. You can enter a value directly or click the magnifier to search for the name.

- **Affected End User**
  Specifies the contact name of the person who is affected by the record. If the contact is assigned to a special handling type, special handling indicators are displayed. You can enter a value directly or click the magnifier to search for a contact name.

- **Request Area**
  Indicates the general area of your IT environment affected by the request (for example, Applications, E-mail, Hardware, and Software). Request areas provide default values that are entered automatically on all requests assigned to the area. In addition to the predefined request areas provided, your system administrator can define custom request areas.
  You can enter the request area directly into the field, or click the Lookup icon to select from the defined request areas.

  Your system administrator has the option of adding custom properties to request areas. If custom properties have been added, they are displayed on the Properties tab when you create, edit, or view a request. Some custom properties require that you enter a value. For details, see Request Properties.

- **Status**
  Specifies the status code of the record. For example, you can list only the tickets with a status code of Fix in Progress, or can Close Requested. You can enter a value directly or click the magnifier to search for a status. The blue button (on the left side of the Status field) lets you change the current status to the next default status.

- **Priority**
  Specifies the priority ranking of the record. The ranking determines the amount of attention the ticket receives. The predefined priority levels are 1 (highest) through 5 (lowest). Your system administrator or an active priority calculation can generate the appropriate priority values for various installations and tenants. When priority calculation is enabled, this field is updated based on Impact, Urgency, Affected Service, and Affected User settings. When your administrator disables priority calculation and uninstalls the urgency_on_employee option, Self Service Users see the Priority field on the Request Detail page.

Detail Fields

- **Reported By**
  Specifies the name of the person reporting the record.

- **Assignee**
  Specifies the name of the person who is assigned to handle the record. You can enter a value directly or click the magnifier to search for a name. Selecting an assignee populates the groups that the assignee belongs to in the **Group** field.

- **Group**
  Specifies the group that is responsible for this record. Your system administrator defines groups of contacts that are responsible for different types of issues, requests, incidents, or problems. Any contact who is part of the group can handle the record after it is assigned to the group. You can enter a value directly or click the magnifier to search for a group. Selecting a group populates the **Assignee** field with the corresponding assignee name, which belong to the group.

- **Configuration Item**
  Specifies the hardware, software, or service that is affected by the record. Your system administrator creates a record that uniquely identifies each configuration item for your organization and indicates its precise location. You can enter a value directly or click the magnifier to search for an item.

- **Severity**
  Specifies the severity of the record, determined by the effect on people. Your system administrator can modify the default severity codes, so they can vary from one installation to another.

- **Urgency**
  Specifies the urgency of the record. The urgency is determined by the importance of the user tasks that are affected by the record. Urgency codes indicate the importance of a ticket based on the degree to which it affects user tasks. For example, a network outage is more urgent than a printer failure. Your system administrator can modify the default urgency codes, so they can vary from one installation to another. Urgency values can update automatically based on an active priority calculation.

- **Impact**
  Specifies an impact code, such as 1 -- Entire Organization, that indicates how a ticket affects work being performed. For example, a ticket that requires a network outage for several hours would have a higher impact than a ticket that takes a printer off-line. Your system administrator can modify the default impact codes, so they can vary from one installation to another

- **Active**
  Indicates whether the record is Active or Inactive. This value applies to the current record only, not the associated template.

- **Charge Back ID**
  Identifies the ID that is charged for service.

- **Call Back Date/Time**
  Identifies the date and time to follow up on this record. Enter the date and time in the format mm/dd/yyyy hh:mm am | pm, or click the calendar icon to select the date and time for follow-up.

- **Resolution Code**
  Indicates the action that the analyst had taken to resolve an incident or request. Resolution codes specify the general resolution of the ticket. For example, an Applied Patch resolution code indicates that the analyst used a software patch to address an incident.

- **Resolution Method**
  Indicates *how* an analyst implemented the resolution. For example, a Chat Session resolution method indicates that an analyst used a chat session to address an incident.

- **Change**
  Specifies the number and name of the change order associated with this record. You can enter a value directly or click the magnifier to search for a change order.

- **Caused by Change Order**
  Specifies only tickets that were opened as a result of a specific change order ticket. You can enter a value directly or click the magnifier to search for a change order ticket.

- **External System Ticket**
  Specifies an identification for a ticket that belongs to an external system that integrates with CA SDM. This field stores hyperlinks and displays functional links in read-only mode.

Summary Information Fields

- **Summary**
  Provides a brief description of the record.

- **Spelling**
  Checks the spelling of the text you enter in the Summary field.

- **Total Activity Time**
  Displays a running total of the overall amount of time spent working on the ticket. This value is updated each time a change is made to the ticket record. You cannot edit this field.

- **Timer**
  Tracks the incremental amount of the time spent working on various phases of ticket processing. The timer is reset to 00:00:00 each time you open the ticket record for updates. You cannot edit this field.

  Note: The amount of time spent on each activity is shown on the Activities tab of the ticket record.

- **Search Knowledge**
  Searches for or submits information to the CA SDM Knowledge Base to help resolve tickets.

- **Description**
  Describes the record in detail.

- **Ticket Open Date/Time**
  Displays the date and time the ticket was opened.

- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.

- **Ticket Resolved Date/Time**
  Displays the date and time the ticket was resolved.

- **Ticket Closed Date/Time**
  Displays the date and time the ticket was closed.

Request Tabs

The following tabs are available on the Create Request, Request Detail, and Update Request pages:

- **Activities:** Displays a log of the activities performed to resolve the request. For more information, see Add an Activity from the Ticket Management (see page 2308) topic.
- **Event Log:** Displays a record of significant actions that take place regarding the request.
- **Attachments:** Attaches a document or a link to a URL to the request.
- **Workflow Tasks:** Lists the process instance and related audit trail messages for CA Process Automation or Classic Workflow that is associated with the ticket. The Workflow Tasks tab shows fields that apply to an attached workflow. The workflow may require some of the work items to complete before the ticket can close. The Workflow Tasks tab appears only if your administrator configured workflows for the ticket area or category. For more information, see Define a Category or Area (see page 1054) topic.
- **Service Type:** Allows you to attach a service type event (see page 2313) to indicate the level of support for the ticket.
- **Parent / Child:** Allows you to create a parent/child relationship between the request and another CA SDM record.

- **Knowledge:** Searches for or submit information to the CA SDM Knowledge base to help resolve requests. The Federated Search capability helps you to get the knowledge search results from multiple sources. For example, Google, SharePoint, CA Open Space, and so on.
- **Solutions:** Stores information about the request solution with the request record for future reference.
- **Properties:** Adds custom properties to request areas.
- **Templates:** Allows you to create a template (see page 2315) using the current ticket as a model.
- **Support Automation:** Displays the assistance session log and lets you invite the end user to an assistance session.

Edit Service Targets for a Request

This article contains the following topics:

Service targets determine whether Service Level Agreements (SLA) have been met within the required time frame. If a service type has a set of service targets, you can view the status and deadlines for completing each target on the ticket. If necessary, you can update or override service target values such as Workshift.

Follow these steps:

1. On the Service Desk tab, select Incidents, Problems, Requests, Change Orders, or Issues.
   The ticket detail page appears.
2. Click the Service Type tab.
   Additional Service Type information appears at the bottom of the ticket.

   Note: Service targets appear on tickets that meet the conditions that the Administrator sets up. Priority calculation can be a factor in how target information calculates and displays.
3. In the Target column, click the target.
   The Service Target Detail page appears.
4. Click Edit.
   The Update Service Target page appears.
5. Complete the following fields as appropriate:
   - **Name**
     Identifies the service target.

- **Target Duration**
  Specifies the amount of allotted time to perform the service target. You can only override this value by editing the ticket.

- **Workshift**
  Displays the schedule to use for service target time calculations.

- **Condition**
  Specifies the name of the condition or site-defined condition. The condition evaluates the ticket data to determine whether the service target is met.

- **Required Outcome**
  Displays the required result of the condition or site-defined condition Macro.

- **Cost**
  Specifies the penalty that incurs for missing the target. This information also displays on the ticket.

- **Target Date/Time**
  Specifies the deadline for completing the target. If the ticket is in a Hold status or the target has been met, this field is blank.

- **Actual Date/Time**
  Specifies the date and time that the condition was satisfied or the user clicked Set Actual.

- **Time Left**
  Specifies the amount of remaining time for the service target. A negative value indicates the amount of time that exceeded the target time frame.

- **Allow Set Actual**
  Lets the users set the date and time of a service target.

- **Allow Reset Actual**
  Lets the users reset the service target.

- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.

- **Service Type**
  Displays the Service Type that is attached to this service target.

- **Service Target Template**
  Specifies the name of the service target template to link to the service type.

- **Last Modified By**
  Displays the name of the last person who edited the ticket.

- **Lock Target Date/Time From Hold Recalculations**
  Prevents automatic target date and time updates when the ticket goes on hold or when the ticket is delayed.

6. Click Save.
   The system saves and updates the service target.

View Ticket Counters and Timers for Service Targets

If an analyst assigned a set of service targets to a ticket, you can view the status and deadlines for completing each target.

Follow these steps:

1. On the Service Desk tab, display a list of Incidents, Problems, Requests, Change Orders, or Issues.
   The ticket detail page appears.

2. Click the Service Type tab.
   Additional Service Type information appears at the bottom of the ticket.

3. In the Target column, click the Service Target for additional information.
   The Ticket Counters and Timers section appears near the bottom of the Assigned Service Target Detail page. The Assigned Service Target Detail page displays the following fields:

   - **Name**
     Displays the name of the service target.

   - **Target Duration**
     Displays the amount of allotted time to perform the service target. You can only override this value by editing the ticket.

   - **Workshift**
     Displays the schedule used for time calculations for the service target.

   - **Condition**
     Displays the condition or site-defined condition macro that evaluates the ticket data to determine whether the work can complete within the target time frame.

   - **Required Outcome**
     Displays the required result of the condition or site-defined condition Macro.

   - **Cost**
     Displays the penalty that incurs for missing the target. This information also displays on the ticket.

   - **Target Date/Time**
     Displays the deadline for completing the target. If the ticket is in a Hold status or the service target has been met, this field is blank.

   - **Actual Date/Time**
     Specifies the date and time that the condition was satisfied or the user clicked Set Actual.

   - **Time Left**
     Displays the amount of remaining time for the service target. A negative value indicates the amount of time that exceeded the target time frame.

- **Allow Set Actual**
  Displays whether you can set the actual time. Yes indicates that you can set the Actual Date/Time of a Service Target. No indicates that you cannot override the Actual Date /Time.

- **Allow Reset Actual**
  Displays whether you can restart the time. Yes indicates that you can reset the Actual Date /Time of a Service Target. No indicates that you cannot reset the Actual Date/Time.

- **Last Modified Date/Time**
  Displays the date that this ticket was last modified.

- **Last Modified By**
  Displays the name of the last person who edited the ticket.

- **Service Type**
  Displays the name of the service type that attached this service target.

- **Service Target Template**
  Displays the name of the service target template that was linked to the service type that was used to create this Service Target.

- **Lock Target Date/Time From Hold Recalculations**
  Locks the Target Date/Time from being automatically updated when the ticket goes on hold or is delayed.

- **Last Start Date/Time**
  Displays the last time the service target timer was started.

- **Ticket Status**
  Displays the value of the Status field of the ticket.

- **Hold Status**
  Displays whether the ticket status has placed the ticket on hold.

- **Last Hold Date/Time**
  Displays the last time that the ticket was placed on hold.

- **Hold Count**
  Displays the number of times the ticket was placed on hold.

- **Last Resolved Date/Time**
  Displays the last time that the ticket transitioned to a resolved status.

- **Resolved Count**
  Displays the number of times that the ticket changed to resolved status.

- **Last Closed Date/Time**
  Displays the last time the ticket was changed to a closed status.

- **Closed Count**
  Displays the number of times the ticket was changed to a closed status.

- **Ticket Open Date/Time**
  Displays the date and time the ticket was opened.

- **Ticket Resolved Date/Time**
  Displays the date and time the ticket was resolved.

- **Ticket Closed Date/Time**
  Displays the date and time the ticket was closed.

View Service Target Status

On an open ticket, you can view the status for each service target. Status information such as Time Left and Violation Cost help you prioritize your work.

Follow these steps:

1. On the Service Desk tab, display a list of Incidents, Problems, Requests, Change Orders, or Issues.
   The respective ticket list displays with the following Service Target information:

   - **Service Target**
     Displays the time that the next service target is due.

   - **Projected Violation**
     Displays the incurred cost when the service type time limit is violated.

2. Select the ticket that you want from the list page.
   The ticket detail page appears.

3. Select the Service Type tab.

   Note: Service targets appear on tickets that meet the conditions that the administrator sets up. Priority calculation can be a factor in how target information calculates and displays.

   If the ticket meets predefined target conditions, the Service Targets List the following information about service targets:

   - **Action**
     Sets or resets the Actual Date/Time to the current date and time.

   - **Target**
     Specifies the current service target for the ticket.

   - **Target Date/Time**
     Specifies date and time when this service target is due. If the ticket is in a Hold status, this value is blank.

- **Actual Date/Time**
  Specifies the time when the target condition was met. If no value appears, the target condition has not been met.

- **Time Left**
  Specifies the amount of remaining time for the service target when the ticket is on hold. If the service target has been met, the Time Left field shows the unused time. A negative value indicates the amount of time that elapsed since the missed target date.

- **Violation Cost**
  Displays the penalty that incurs for missing the target. This information also displays on the ticket.

Create a Parent/Child Relationship for Requests

This article contains the following topics:

Records that are entered in the CA SDM system can be related to other records that are entered into the system. For example, a problem could result in two more problems when you attempt to resolve the original problem. The original record is referred to as the *parent*, and the additional records are referred to as *children*.

You can record such relationships in the CA SDM system for future references. The Parent/Child tab on the ticket detail page lists the parent and children tickets of a ticket.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.

2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.

3. Open the desired ticket from the list that appears.

4. Select the Parent/Child tab and click Update Children.
   The search page opens.

5. Complete one or more of the search fields for related ticket records, and click Search.
   A list of tickets matching the search criteria are displayed.

6. Select the related tickets from the list on the left, and click  .
   The selected tickets are added to the list on the right.

7. When all related tickets are in the list on the right, click OK.
   The detail page displays with the selected tickets listed on the Parent/Child tab.

Close All Children

You can close all the children tickets before closing the parent ticket.

Follow these steps:

1. Select the appropriate ticket type from the Scoreboard. For example, select Requests.
2. Open the parent ticket.
3. Click the Action menu and select Close All Children.

Use Knowledge to Resolve a Request

This article contains the following topics:

You can search the CA SDM Knowledge Base to help resolve a ticket, such as an incident, problem, request, issue, or change order.

Follow these steps:

1. On the Service Desk tab, browse to the ticket type such as, Incidents, Problems, Requests, Change Orders, or Issues.
2. Navigate to Assigned or Unassigned, and select the priority for the desired ticket.
3. Open the desired ticket from the list that appears.
4. Select the **Knowledge Management** tab.
5. Enter text in the search field to describe the problem, or copy text from the **Summary** or **Description** fields of the ticket.
6. From the drop-down list, select where you want to search.
7. Click **Search**.
   A list of documents matching the search criteria displays.
8. Look for the document that provides the solution to your ticket.
9. Right-click the document and select **Accept as Solution**.
   The knowledge document information is copied into the **Summary** and **Description** fields.

Submit a Knowledge Document

When you log a solution activity for a ticket, you can submit the solution to the knowledge base administrator as a candidate for publication.

Follow these steps:

1. Open a ticket, such as an Incident.
   The ticket detail page appears.
2. On the Knowledge tab, click Submit Knowledge.
   The Create New Document page displays.

For more information on creating knowledge documents, refer to Create Knowledge Documents (see page 2732).

After you submit a solution to the knowledge base, it becomes a candidate for publication in the knowledge base. A Knowledge Management administrator reviews the information and publishes it if it is deemed appropriate and accurate. After it is published, the information becomes available to other users.

Request Management Using CA Service Catalog

This section contains the following articles:

Approval Processes and Fulfillment Processes

Approval Processes

When a user submits a request, approvers must approve or reject each service in the request. For each service, the administrator specifies one of the following approval processes on the Service Details tab:

- **No Approval**
  Requires no approval. When a request containing the service is submitted, the status is changed to Approval Done.

- **System Approval Process**
  Determines the approver and the number of approval levels by using a combination of the following parameters:

  - The management hierarchy.
  - The authorization level of each user in the hierarchy.
  - The approval level that is specified for the service.

  When a request containing the service is submitted and the Requested For value is a user, not an account, the Catalog system:

  1. Finds the Requested For authorization level of the user in the user profile.
  2. Compares it with the approval level of the service.

If the authorization level of the user matches or exceeds the approval level that the service specifies, then no further approval is required. The system moves the request to the next status, typically Pending Fulfillment, or Completed.
Otherwise, then the system determines an approver, as follows:

- The Requested For value is a user. In this case, the system determines the manager of the user and assigns the request to that manager for approval.
- The user does not have a manager or the Requested For value is an account. The system assigns the approval task to the user-specified in the configuration option that is named Default User For Request Actions.

After the manager or other approver approves the service, the system uses similar logic to determine whether another level of approval is required. If yes, then the system routes the request to a request manager whose authorization level matches or exceeds the approval level of the service.

- **Workflow Driven Approval Process**
  Uses a CA Process Automation process to determine the approval process.
  The process includes the business logic to determine the approver and the number of approval levels. CA Service Catalog provides sample processes and process definitions, including default ones for a single level of manager approval.
  For any service, if you use this approval process with a CA Process Automation process, you can optionally use policies. In that case, the approval process proceeds the same as with Policy driven approval process, except as follows:
  - The Workflow driven approval process uses the CA Process Automation workflow engine to evaluate and implement policies.
  - Policy driven approval process uses the Catalog Policy Engine to evaluate and implement policies. This option is typically more efficient for an approval process because this engine is internal. Verify that the rules and actions are enabled (see page) for the option that you specify.
- **Policy driven approval**
  Uses a policy to determine the approval process for requests. You specify conditions in policies, which are based on the attributes of service options, services, requested items, and users. If a policy is active and a submitted request meets the condition in the policy, then the assignees in the policy receive a request pending action to approve, reject, or fulfill a service option, service, or request.

Policy driven approval and system approval use a few common terms. For example, in both methods, the *level of approval* refers to the authority of an approver in numeric terms: the higher the number, the greater the authority of the approver. However, in policy driven approval, the administrator assigns each approver and authority level uniquely, with no relation to system approval.

If a policy does not apply to a request, the Catalog system uses the approval flow as defined in the workflow driven approval process. For example, you are using the predefined workflow approval process. Also, no predefined sample policy applies to a request pending action. In that case, the Catalog system assigns request pending action to the manager of the Requested For user. If the user has no manager, then the system assigns the request pending action to the Default User for Request Actions. This user is specified in the Catalog Configuration.

Fulfillment Processes

Fulfillment is required for each service option included in the services in a request. When the status of a service option is set to Pending Fulfillment, it enters the fulfillment phase. When the status is set to Fulfilled or Fulfillment Cancelled, the service option leaves the fulfillment phase. For each service Approval Process setting, the fulfillment phase of the requested service options can be managed separately.

- No Approval and System Approval Process: After approval, the status of the service options for the service is set to either Fulfilled or Pending Fulfillment.
- Workflow Driven Approval Process: After approval, the status of the service options for the service is set to Pending Fulfillment.

When you set the requested service options status to Pending Fulfillment, a Workflow process definition manages the fulfillment process. Several process definitions manage the fulfillment process. These process definitions and associated event rules support three different approaches to fulfillment.

Generally, fulfillment options do not fit your business processes. More commonly, alter the distributed components to more accurately fit your business processes. Before altering the existing components or adding to them, it is important to understand what they do.

Note: Enabling all the rules that are related to all the options is not recommended, because the fulfillment options overlap.

- **Complex Fulfillment**
  This process considers the current status value of the service option and new status being assigned to determine the next step in the fulfillment process. The Complex Fulfillment process supports major fulfillment phases that are related to:
  - Checking availability of the requested service option when initially requested or when the service option status is Received.
  - (Optional) Opening a CA Service Desk Manager Change Order (for Hardware or Software) or notifying appropriate fulfillment personnel when the service option is found in the available inventory.
  - Notifying Procurement of the requested service option when it is not found in available inventory. In this case, the service option is ordered and marked as Received when it arrives.
- **Simple Fulfillment**
  This process notifies the appropriate fulfillment personnel that the item must be fulfilled with no special regard for fulfillment phases.
- **CA Service Desk Manager Request Fulfillment**
  This process:
  - Opens a CA Service Desk Manager request.

- Notifies the appropriate fulfillment personnel that the service option must be fulfilled.
- Lays responsibility of the fulfillment process on the CA Service Desk Manager request logic.

Status Values

On a viewed request, the name of the current status displays in the Status column or Status drop-down list. To display other available statuses, click the list. Optionally, change the request to a new status, such as Approved, Cancelled, or Fulfilled. To change the request, click its status.

The following table shows the number, name, and meaning of the default statuses of Service Accounting Component and CA Service Catalog. The number of a status does not appear in the drop-down list. However, the number is used in the requeststatus.xml file. This file contains specifications for all default statuses and any customized statuses. Optionally, create new statuses and customize the statuses in the drop-down list by editing the requeststatus.xml file.

Some text in this table refers to the two request fulfillment models: simple and complex. In certain situations, the request flow differs for each model. These differences, when applicable, are noted in the following table.

Number	Name	Meaning
2	Completed	Catalog system-assigned status. When a request finishes with approval and fulfillment cycles, it reaches a Completed status. Once completed, the underlying request subscription reaches an active subscription status.
3	Pending Cancellation	This status applies when: ▪ CA Service Catalog is installed. ▪ Service is not subscribed. ▪ The default Cancellation status under Accounting, Configuration is set to Pending Cancellation. On cancellation, a request first attains the Pending Cancellation status. Then, after an invoice is run, it attains Cancelled status. If a request attains the complete state and is cancelled, then the request stays in pending cancellation state until the invoice is run.
4	Cancelled	A request attains this status on cancellation. A request does not attain Cancelled status when the Service Accounting Component is installed and the default Cancellation status is Pending Cancellation. The default Cancellation status is set under Accounting, Configuration.
6	Pending Resource Assignment	This status applies only when: ▪ CA Business Service Insight is integrated. ▪ A request that includes a service option of type application or agreement reaches Fulfilled status. Such a service option requires provisioning; therefore, the request is moved to Pending Resource Assignment status.
7	Resource Assigned	This status applies only when a request is at Pending Resource Assignment status. Once the service option in such a request is provisioned, the request moves to Resource Assigned status.

Number	Name	Meaning
100	Not Submitted	This status is user-initiated. When creating a request, optionally, click Save as Request to save the request in Not Submitted status. This option is an alternative to submitting the request.
101	Not Submitted - Cart	This status is Catalog system-assigned. This status is attained when a request item is added to the cart. **Note:** This status appears only in reports, not on the GUI.
103	Not Submitted - Rejected	This status is system-assigned. After a service in a request is rejected, the request eventually reaches a Not Submitted - Rejected status. The request is returned to the open queue of the requestor for review, modification, and resubmission.
104	Not Submitted - Approved	This status is catalog system-assigned. When the same request contains both approved and rejected services, the approved services eventually reach a Not Submitted - Approved status. This status helps the user to differentiate between a previously rejected request items and approved request items. In this case, the entire request is in Not Submitted - Rejected status.
200	Submitted	This status is user-initiated. A request reaches this status when a requestor submits the request. For each service in the request, the configured approval process type drives three scenarios: ▪ For the Workflow driven approval process, a rule action is triggered to activate the approval process. This process determines the approver for the service and changes the status to Pending Approval. ▪ For the System Approval process, the Catalog system determines the next action and status. This determination is based on: ▪ The approval level that is assigned to the service. ▪ The management hierarchy of the user for whom the service is requested. ▪ For the No approval process, if the service is configured for fulfillment, then the status eventually changes to Pending Fulfillment. If the service is not configured for fulfillment, then the status eventually changes to Fulfilled. When all services in the request reach the Fulfilled status, the request reaches the Completed status.
201	Re-submitted	This status is User-initiated. When a rejected request is submitted, it reaches a Re-submitted status. The eventual flow is similar to Submitted status.
400	Pending Approval	This status is Catalog system-assigned. A request reaches this status when one or more services in a request require approval. For each service in the request, the configured approval process type drives two scenarios: ▪ For the Workflow driven approval process, a rule action is triggered to activate the approval process. This process determines the approver for the service and changes the status to Pending Approval. By default, all Catalog Content services use the Workflow driven approval process. ▪ For the System Approval process, the Catalog system determines the next action and status. This determination is based on: ▪ The approval level that is assigned to the service. ▪ The management hierarchy of the user for whom the service is requested.
600		

Number	Name	Meaning
	Rejected	This status is User-assigned. If a service in the request is configured for approval, a pending action is assigned to the approver. The approver can optionally either approve or reject each service in the request. The entire request is rejected when a service is rejected. Then, the request is returned to the queue of the requestor for review, modification, and resubmission.
800	Approved	This status is User-assigned. If a service in the request is configured for approval, a pending action is assigned to the approver. The approver can either approve or reject each service in the request. When you approve a service, the status can either: ▪ Attain Approval Done status ▪ The status can get reassigned to Pending Approval status, when further approval is required. When all services in the request have received all required approvals, the request reaches the Approval Done status.
801	Approval Not Needed	This status is Catalog system-assigned. If a service in the request is configured for no approval, then the service reaches this status after the request is submitted. The service eventually reaches Approval Done status.
999	Approval Done	This status is Catalog system-assigned or workflow-assigned. When all required approvers approve a service in a request, that service attains Approval Done status. When all services in a request attain Approval Done status, the entire request is approved. The request eventually reaches Approval Done status. The next status after Approval Done is either Pending Fulfillment or Fulfilled. ▪ Using Pending Fulfillment allows for more fulfillment business processes to be followed by using CA Process Automation processes. ▪ If the request does not require fulfillment, then it reaches a state of Fulfilled.
1000	Pending Fulfillment	This status is Catalog system-assigned or workflow-assigned. In a request containing multiple services, the services can belong to any or all of the following categories: ▪ If a service in the request is configured for fulfillment, then a fulfillment process is triggered. This process determines the fulfiller for the service option and changes its status to Pending Fulfillment. Using Pending Fulfillment allows for more fulfillment business processes to be followed. If the request does not require fulfillment, then it reaches a state of Fulfilled. Once the service is configured for Pending Fulfillment, one of the following actions occurs: ▪ If a service option in the request is configured for simple fulfillment, then a fulfillment process is triggered. The status is set to Pending Fulfillment. ▪ If a service in the request is configured for complex fulfillment, then a fulfillment process is triggered. The status is set to Check Availability.
1001	Check Availability	This status is Workflow-assigned. This status applies when the Catalog system is configured for complex fulfillment. If a service option in the request is configured for fulfillment and it belongs to a hardware or software category, then an associated rule action triggers a fulfillment process definition. The process definition typically assigns a pending action to an IT Services User (that is, a fulfiller). The fulfiller can:

Number	Name	Meaning
		▪ Choose between Filled from Inventory and Not Filled from Inventory. ▪ Bypass fulfillment completely by selecting Fulfillment Cancelled or Fulfilled.
1002	Filled From Inventory	This status is User-assigned. This status applies when the Catalog system is configured for complex fulfillment. If an IT Services user is assigned a service option that is in Check Availability status, then the fulfiller can choose between Filled from Inventory and Not Filled from Inventory. This status is set in one of the following ways: ▪ If CA APM is integrated with CA Service Management, then this status is set when a CA APM user assigns an asset. ▪ If CA APM is not integrated with CA Service Catalog, then the IT Services user: ▪ Verifies that the requested items are available. ▪ Sets manually the status to Filled from Inventory.
1003	Not Filled From Inventory	This status is User-assigned. This status applies when the Catalog system is configured for complex fulfillment. If an IT Services user is assigned a service option that is in Check Availability status, then the fulfiller can choose between Filled from Inventory and Not Filled from Inventory. This status is set in one of the following ways: ▪ If CA APM is integrated with CA Service Catalog, then this status is set when an asset is not available in CA APM. ▪ If CA APM is not integrated with CA Service Catalog, then the IT Services user sets manually the status to Not Filled from Inventory when one or more requested items are not available. When the status of the service option is set to Not Filled From Inventory, then the status eventually reaches Pending Procurement. The requested hardware or software must then be ordered.
1004	Ordered	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Pending Procurement, then the IT Services user sets its status to the actual status of the ordered item, such as Ordered.
1005	Backordered	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Pending Procurement, then the IT Services user sets its status to the actual status of the ordered item, such as Backordered.
1006	Shipped	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Pending Procurement, then the IT Services user sets its status to the actual status of the ordered item, such as Shipped.
1007	Received	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Pending Procurement, then the IT Services user sets its status to the actual status of the ordered item, such as Received. If the status of the service option is set to Received, then it eventually reaches a status of Check Availability for re-assignment. This re-assignment is performed by an IT Services user or by a CA APM user (if CA APM is integrated with CA Service Catalog).

Number	Name	Meaning
1008	Order Cancelled	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Pending Procurement, then the IT Services user sets its status to the actual status of the ordered item, such as Order Cancelled. If the status of the service option is set to Order Cancelled, then it eventually reaches a status of Check Availability for re-assignment. This re-assignment is performed by an IT Services or user or by a CA APM user (if CA APM is integrated with CA Service Catalog).
1012	Pending Procurement	This status is User-assigned. This status applies when the Catalog system is configured for complex fulfillment. If the status of the service option is set to Not Filled From Inventory, then it eventually reaches a status of Pending Procurement. The requested hardware or software must then be ordered.
1013	CA SDM Change Order Opened	This status is Workflow-assigned. This status applies when the Catalog system is configured for complex fulfillment and a rule action for creating a CA Service Desk Manager change order is enabled. A status change occurs when the following actions occur: ▪ An IT Services user is assigned a service option in Check Availability status. ▪ The IT Services user then sets the status of the service option to Filled from Inventory. ▪ The CA Service Desk Manager is integrated with CA Service Catalog The status is then set to CA SDM Change Order Opened and a Change Order is created in the CA Service Desk Manager.
1015	Notified IT Services	This status is Workflow-assigned. This status applies when the Catalog system is configured for complex fulfillment. A status change occurs when the following conditions apply: ▪ An IT Services user is assigned a service option in Check Availability status. ▪ The IT Services user sets the status of the service option to Filled from Inventory. ▪ The CA Service Desk Manager is not integrated with CA Service Catalog. A process definition is triggered which assigns a pending action to an IT Services User and sets the status to Notified IT Services.
1016	Being Staged	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Notified IT Services, then the IT Services user sets its status to the actual status of the requested service option, such as Being Staged.
1017	Staged	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Notified IT Services, then the IT Services user sets its status to the actual status of the requested service option, such as Staged.
1018	Being Configured	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Notified IT Services, then the IT Services user sets its status to the actual status of the requested service option, such as Being Configured.
1019		

Number	Name	Meaning
	Configured	This status is User-assigned. This service option status applies when the Catalog system is configured for complex fulfillment. Once the status is set to Notified IT Services, then the IT Services user sets its status to the actual status of the requested service option, such as Configured.
1020	CA SDM Request Opened	This status is Workflow-assigned. This service option status applies when the Catalog system is configured for simple fulfillment and a rule action for creating a CA Service Desk Manager change order is enabled. A status change occurs when the following conditions apply: ▪ An IT Services user is assigned a service option in Pending Fulfillment status. ▪ The CA Service Desk Manager is integrated with CA Service Management. The status is then set to CA SDM Request Opened and a request is created in CA Service Desk Manager.
1999	Fulfillment Cancelled	This status is User-assigned or Catalog system-assigned. This status applies when one of the following actions is true: ▪ The IT Services user sets the status to Fulfillment Cancelled when the service option does not require fulfillment. ▪ The Catalog system sets the status to Fulfillment Cancelled when a user cancels a request that has been approved but has not been fulfilled. If all services are set to Fulfillment Cancelled, then the request eventually reaches Cancelled status. If the request contains services with both Fulfilled and Fulfillment Cancelled status, then the request eventually reaches Completed status.
2000	Fulfilled	This status is User-assigned. This status applies when one of the following actions is true: ▪ The IT Services user sets the status of the service option to Fulfilled. ▪ The CA Service Desk Manager is integrated and the process definition in CA Service Desk Manager sets the status to Fulfilled. This occurs when an associated change order is closed in the CA Service Desk Manager. When all services are set to Fulfilled, the request eventually reaches Completed status. If the request contains services with both Fulfilled and Fulfillment Cancelled status, then the request eventually reaches Completed status.
3000	Hold	This status is User-assigned. This status applies when either an administrator or the Catalog system sets the status of the service option to Held. When an item is held, no status changes can occur to it until you change its status to Resume. If a service option is held, then the monitoring of time is stopped for any request SLAs attached to the service option. This stoppage prevents related SLA warnings and SLA violations from being issued inordinately.
4000	Resume	This status is User-assigned. This status applies when an administrator sets the status of a previously held service option to Resume. When resumed, service options that were formerly held move to a temporary Resume status before automatically moving back to their previous status before being put on Hold. When you resume a previously held service or service option, the monitoring of time is resumed for any request SLAs attached to the service or service option.

Subscriptions and Requests

You use the same service catalog for both subscriptions and requests. CA Service Catalog enables catalog users to request services. Service Accounting Component enables accounts in the catalog to have subscriptions.

Requests have a Requested For value. When you add services to your cart, the Requested For value is set to your user ID by default. As an administrator, you can change the Requested For value to be a user or account within your business unit scope. When you set the Requested For value to a user, you are also setting the value to the *user account* associated with the user.

Subscriptions apply to an account. You can optionally associate an account with a user. However, an account is not required to be associated with a user. As an administrator, you can manage subscriptions for an account within your business unit scope. Users who are not administrators can view subscriptions for their user account but cannot manage these subscriptions.

Request Service Levels and Reports

Three phases of the request life cycle are monitored: Approval, Fulfillment, and Completion. Each phase represents the time that is taken for a requested service option to move from one status to another.

- Approval - The duration of moving from **Submitted** to **Approval Done**.
- Fulfillment - The duration of moving from **Approval Done** to **Completed**.
- Completion - The duration of moving from **Submitted** to **Completed**.

For each service option, service providers can establish SLA warning and violation thresholds for each phase.

Example

This example uses the Standard Desktop service option. The fulfillment phase warning time is five days and the violation time is seven days. Therefore, the service provider expects that a standard desktop be fulfilled (configured, delivered, and set up) within five days. A violation occurs if the time frame exceeds seven days.

The violation setting for a service option displays in the catalog as the *estimated time to fulfill*. In this example, the estimated time to fulfill the Standard Desktop service is seven days.

Note: (optional) Set up reports to monitor other request life cycles phases by altering the STATUS_RANGES value that is used in a report data object.

Several report data views and underlying data objects enable you to monitor request service levels.

- **Request Fulfillment Data View**

This report accepts a date range and business unit. Each row represents one request. The columns represent the duration in days, hours and minutes to approve, fulfill, and complete the requests. The date range filters for requests whose initial creation is within the range specified. The business unit value filters for requests for a user or account from a business unit.

Display the Request Item Fulfillment subreport for the service options that are contained in the request by clicking the Request ID field.

- Yellow = Time durations that exceed the warning duration for the service option.
- Red = Time durations that exceed the violation duration for the service option.

- **Request Item Fulfillment Averages Data View**

  This report accepts a date range and business unit. Each row represents one service option. The columns represent the average duration in days, hours, and minutes to approve, fulfill, and complete the requests. The date range filters for requests whose initial creation date is within the range. The business unit value filters for requests for a user or account from a business unit.

  - Yellow = Average time duration exceeds the warning duration for the service option.
  - Red = Average time duration exceeds the violation duration for the service option.

Click the Service Option field to display the Request Item Fulfillment report. This sub-report displays requests containing the service option.

- Yellow = Time durations that exceed the warning duration for the service option.
- Red = Time durations that exceed the violation duration for the service option.

Request Management from an Administrator Perspective

Requests have a life cycle reflected in their status. The status of a request falls into one of the following several phases:

- Not Submitted
- Submitted
- Approval
- Fulfillment
- Completed

For the request and its services and service options to move through the request life cycle, its status must change.

The requesting user controls the **Not Submitted** phase. A request is in the Not Submitted phase when one of the following conditions is true:

- The request is in the user's cart.

- The user has saved the cart as an unsubmitted request.
- The submitted request has been rejected.

> **Note:** The user must submit the request or cart before the request can exit the **Not Submitted** phase.

The **Submitted** phase is brief and controlled by the system. Each service option in the request has a specified approval process. The submitted phase is used only until the approval process begins.

An approving user or the system controls the **Approval** phase. This control depends on the approval process for each service in the request. All services in the request must be approved (or not require approval) before the request enters the Fulfillment phase. If any services are rejected, the entire request is returned to the Not Submitted phase for the requesting user to manage.

A fulfilling user or the system controls the **Fulfillment** phase. This control depends on the fulfillment process for each service option in the request. Set the status of all service options in the request to either Fulfilled or Fulfillment Cancelled before the request enters the Completed phase.

An administrator or the system controls the **Completed** phase. This control depends on the type of service option elements requested.

- If CA Business Service Insight is integrated and the request includes an Agreement service option element that depends on resource metering, then:
  - The status of the service option is changed to Pending Resource Assignment.
  - When a resource is assigned, the status changes to Completed.
- For other types of service options elements, the status is set to Completed. After the status is set to Completed and if Service Accounting Component is installed, invoices then include the service option.

Enable Approval and Rejection of Multiple Items Simultaneously

Administrators enable *multi-item approval* so that request managers can simultaneously approve and reject multiple items in a request. Examples include all services in a request or all service options in a service. Multi-item approval lets request managers process requests quickly and efficiently, especially when they are already familiar with the requests:

- Request managers access their requests pending action, select the services that they want to act on. Then, they click Approve or Reject. Multi-item approval provides this ability *regardless* of whether discrete approval (see page 2120) is implemented.
  Without multi-item approval, request managers must approve or reject every service *individually* by updating its status in the Status drop-down list.
- If discrete approval is implemented, request managers approve or reject multiple *service options* in a service simultaneously, as follows: Request managers access their requests pending action and open the services. In each service, they select the service options that they want to act on, and click Approve or Reject.

- If discrete approval is implemented *without* multi-item approval, request managers can approve or reject each service option *individually* by updating its status in the Status drop-down list.

The benefits of multi-item approval are more pronounced as the number of services or service options in a request increases. Multi-item approval is especially helpful for mobile users, who have limited space and typically have limited time.

Follow these steps:

1. Click Catalog, Configuration, Request Management, and verify that the following option is enabled: Allow Multi Service/Service Option Approval.
2. Verify whether you have implemented discrete approval.
3. Inform request managers of the new approval option for your implementation:
   - Multi-item approval only
   - Multi-item approval and discrete approval
4. Verify that multi-item approval functions as you intended.

Requests with Multiple Approval or Rejection Statuses

The default statuses of the request life cycle (see page 2108) include these statuses: Approved and Rejected. When request managers approve or reject a service option or service, the status of the item changes accordingly. The changed status is displayed to request managers before they confirm their approval or rejection of services or service options. If an approval or rejection changes change the default status, the Catalog system highlights the service or option in green.

Catalog administrators can optionally create custom approval and rejection statuses, such as Approved - Manager, Approved - Finance, Rejected - No Budget. To define custom statuses, edit the requeststatus.xml file. For more information, see the Modify the Request Status List (see page 2006) section.

If one or more custom statuses exist for this service or service option, the Catalog system performs the following actions:

- Displays an informational message that multiple statuses exist.
- Selects the first custom status that is defined in requeststatus.xml file.
- Highlights the service or option in orange.

For all status changes (custom or default), before confirming the approval or rejection, request managers can choose one of these options:

- Accept the status changes
- Update one or more statuses, for example, from a custom status to a default status

Services or options that are not selected are not highlighted and do not change status. They remain as pending items in the request until they are either approved or rejected.

Implement Discrete Request Life Cycle

This article contains the following topics:

The predefined CA Process Automation processes supplied for use with CA Service Catalog require *no* additional configuration to support the discrete request life cycle. However, verify that they work efficiently with the discrete request life cycle after you implement it.

Minimize impact on requests in progress by following the best option for introducing the use of discrete life cycle.

- Instruct the users to stop creating requests in your organization temporarily. When most or all of the requests in progress are completed, begin using a discrete life cycle by setting the related configuration parameters.

- In-progress requests may become stuck as a result of the configuration changes. If the requests become stuck, retry or override (push-through) the alerts (see page 2218) to complete the requests.
  Retries and overrides may be required when you use the configuration setting Allow Discrete Handling of Service Options After.

- Give special attention to canceled items, rejected items, and items pending fulfillment while others are still in pending approval, when one or both of the following are true:

  - You expect some requests to reach pending fulfillment after all the items are approved.

  - You expect to reject the entire request if one item is rejected.

  In these cases, take special care before changing the configuration to support the discrete request life cycle. Verify that such requests have completed before you make the configuration changes.

- Review the following important considerations:

  - Overall status of the request
    The service option with the lowest status value (see page 2108) determines the overall status of the request. To see the status of a request, click Home, Requests, and, if applicable, use the My Requests drop-down list to display requests. Open the request, and view the status.
    When the request contains services and service options having different status values, the lowest status value appears with asterisk (*) next to it, indicating that at least one service or service option in the same request has a higher status. When determining the overall status of the request, the Catalog system ignores services and service options that are rejected, completed, deleted, cancelled, pending cancellation, or on hold.

  - Billing
    If you are using Service Accounting Component, the invoices you generate (see page 3114) *do* include completed services and service options, even if other services and service options in the same request are not completed. The uncompleted services and service options are *not* included in the same billing run as the completed ones.

- Request SLAs
  This point is relevant only if you use request SLAs. The monitoring and recording of request SLA data is not affected when you use a discrete request life cycle. The Catalog system monitors and records the status changes of service options that have request SLAs the same way, regardless of your discrete request life cycle configuration settings.

- CA Business Service Insight-related metrics
  This point is relevant only if you are integrating CA Service Catalog with CA Business Service Insight. Your discrete request life cycle configuration settings do not affect the monitoring and recording of any CA Business Service Insight contract-related metrics that are associated with service options in the Catalog system.

Understand the Discrete Settings

The following table shows whether the request manager acts on a service, service option, or either one, based on the settings for Allow Discrete Handling of Service Options After (ADHSOA).

The table applies to all settings of Allow Discrete Request Life Cycle After.

Request Manager Action	ADHSOA=Submitted	ADHSOA=Pending Fulfillment	ADHSOA=Completed
Approve or Reject	service option	service	service
Hold or Resume	either	either	either
Transfer or Delegate	service option	**A**-service **B**-service option	service
Override	service option	**A**-service **B**-service option	service
Take or Return	service option	**A**-service **B**-service option	service
Pus-Through	service option	**A**-service **B**-service option	service
Cancel	service	service	service
Fulfillment Cancelled	service option	service option	service
Fulfill	service option	service option	service
CA Service Desk Manager Change Order	service option	service option	service

A-service, from Submitted status through Approval Done -service option, from Pending Fulfillment status through Fulfilled status.status.**B**

Set the Configuration Parameters

To enable the discrete handling of requests pending action, set the related configuration parameters. You can use these configuration parameters individually. However, they are most effective when you use them together to achieve the desired request processing.

Follow these steps:

1. Click Catalog, Configuration, Options, Request Management Configuration.

2. Set the following parameters:

- **Allow Discrete Handling of Service Options After**
  Specifies the status at which request managers can discretely (individually) approve, reject, or fulfill each service option in every service in the request. Use this parameter to specify that pending actions are assigned at the service option level, rather than the service level.
  The setting that you specify applies to the request *from* the starting status that you specify *through* the remainder of the request life cycle.
  Valid values: Submitted, Pending Fulfillment, or Completed
  Default: Pending Fulfillment

- **Allow Discrete Request Life Cycle After**
  Specifies the status at which individual service options in a service and individual services in a request advance to further statuses in the request life cycle independently. When the request reaches the specified status, the service options that you approve or fulfill can complete the remainder of the request life cycle. These service options complete the remainder of the request life cycle even if other service options in the same service are not acted on.
  When the request reaches the status that you specify, the services that you approve or fulfill can complete the remainder request life cycle, even if other services in the same request are rejected or not acted on.
  Valid values: Submitted, Pending Fulfillment, or Completed
  Default: Completed

- **Allow Discrete Handling for Reject**
  This parameter specifies the effect of the rejection of a single service or service option upon other services and service options in the same request:

  - **Yes**: When rejecting a service or service option, the remaining services or service options can advance if they are approved. Other services in the same request can advance in the request life cycle if they are approved. Similarly, other service options in the same service can advance in the request life cycle if they are approved.

  - **No**: When you reject a service or service option, the entire request is rejected. All services in the same request are rejected and cannot advance in the request life cycle, even if they were previously approved. All service options in the same service are rejected and cannot advance in the request life cycle, even if they were previously approved.
    Default: No

Discrete Request Life Cycle Parameters

This article contains the following topics:

Administrators can implement a discrete request life cycle to enable services and service options to advance to higher request statuses *without waiting* for all other services and service options to reach the same statuses. Consequently, services and service options can reach Fulfilled and Completed statuses, and can be invoiced earlier than without a discrete life cycle, even if a request manager rejects one or more services or service options in the same request.

An administrator can optionally specify discrete settings for the request life cycle for individual business units, as follows:

- Depending on the configuration you choose, you can specify when the request managers (approvers and fulfillers) can discretely (individually) approve, reject, or fulfill each service option in every service in the request. The setting applies to the request *from* the starting status that you specify *through* the remainder of the request life cycle.
- The status of individual service options in a service and individual services in a request advance to further statuses in the request life cycle independently. Here, *independently* means *without* requiring or waiting for any other service options in the same service or any other services in the same request to advance to any further statuses. The setting applies to the request *from* the starting status that you specify *through* the remainder of the request life cycle.
- The effect of the rejection of a single service or service option upon other services and service options in the same request:
  - If this setting is Yes, when you reject a service or service option, the remaining services or service options can advance if they are approved.
  - If this setting is No, when you reject a service or service option, the entire request is rejected. Even other services or service options that were previously approved change to Rejected status and can not advance in the request life cycle.

Sample Settings and Their Meanings

For all examples, if the request manager rejects one or more services or services options in a request that includes other services and service options, the setting of Allow Discreet Handling for Reject configuration (see page 2119) determines effect of the rejection on the other service options and services in the request.

Examples for Allow Discrete Handling of Service Options After

The *Allow Discrete Handling of Service Options After* parameter specifies the status at which request managers (approvers and fulfillers) can handle requests pending action (approval, rejection, or fulfillment) discretely. When the request reaches the status you specify, request managers can discretely (individually) approve, reject, or fulfill each service option in every service in the request.

Example 1--Submitted

In this example, you want *both* discrete approval and discrete fulfillment. Thus, you want to approve or reject service options individually, rather than approve or reject *all* service options in the service in one action. Similarly, you want to fulfill service options individually, rather than fulfill *all* service options in the service in one action.

To achieve this goal, specify Submitted as the value for this parameter. When the user submits the request, approvers can approve or reject each service option in a service individually. Moreover, fulfillers can fulfill each approved service option individually.

To ensure that the request managers receive notification emails when they address pending actions:

- Set the *Allow Discrete Handling of Service Options After* parameter to Submitted.
- Keep the setting of Yes (predefined) for the parameter named *Notify users when they complete their own pending actions*.

For example, if a service has five service options and the request manager approves each option, the request manager receives five confirmation emails.

Example 2-- Pending Fulfillment

In this example, you do *not* want discrete approval but want discrete fulfillment. Thus, you do *not* want to approve or reject service options individually but rather want to approve or reject all service options in the service in one action. However, once the entire request is approved, you want to *fulfill* service options individually.

To achieve this goal, specify Pending Fulfillment as the value for this parameter. So, as soon as the entire request is approved, fulfillers can fulfill each approved service option in every service individually.

Example 3--Completed

In this example, you do *not* want discrete approval or discrete fulfillment. You do *not* want to approve, reject, or fulfill service options individually at any point during the request life cycle. Instead, you always want to approve, reject, or fulfill all services in the request as a single unit. To achieve this goal, specify Completed as the value for this parameter.

Essentially, this setting "turns off" discrete handling of approval and fulfillment activities. So, request managers must approve, reject, and fulfill all services in the request at once.

Examples for Allow Discrete Request Life Cycle After

The *Allow Request Life Cycle to Continue After* parameter specifies the status at which individual service options in a service and individual services in a request advance to further statuses in the request life cycle independently. Here, *independently* means *without* requiring or waiting for any other service options in the same service or any other services in the same request to advance to any further statuses.

Example 1--Submitted

For example, suppose that you want each service option in a service to advance to the remaining statuses in the request life cycle independently after being approved rather than requiring or waiting for any other service options in the same service to be approved. To achieve this goal, you specify Submitted as the value for this parameter.

As soon as the user submits a request, each service option in all services can advance independently to the remaining statuses in the request life cycle as soon as it (the service option) is approved, *without* waiting for any others to be approved or rejected.

Similarly, as soon as the user submits a request, each service in all requests can advance independently to the remaining statuses in the request life cycle as soon as it (each service) is approved *without* waiting for any others to be approved.

If an approver does not act on one or more service options, the approved service options in the same service can advance to the remaining statuses in the request life cycle. If an approver does not act on one or more services, the approved services in the same request can advance to the remaining statuses in the request life cycle.

Thus, with Submitted as the value for this parameter, the following results occur in a service that has two options: one approved and one no action, as follows:

Service Option	Approver's Action	Resulting Status
Option-1	Approve	Pending Fulfillment
Options-2	No action	Pending Approval

After all service options in the same service are approved, the service reaches Pending Fulfillment status.

After all services in the same request are approved, the request reaches Pending Fulfillment status.

Example 2--Pending Fulfillment

For example, suppose you want each service option in a service to be able to advance to the remaining statuses in the request life cycle independently after all services in the request are approved. To achieve this goal, you specify Pending Fulfillment as the value for this parameter.

So, as soon as the service is approved, it reaches Pending Fulfillment. Each service option in the service can advance independently to the remaining statuses in the request life cycle independently. Similarly, as soon as the request is approved, it reaches Pending Fulfillment, and each service in the request can advance independently to the remaining statuses in the request life cycle independently.

A setting of Pending Fulfillment as the value for this parameter differs from a setting of Submitted in these ways:

- Approved service options *cannot* advance to the remaining statuses in the request life cycle *until* all other service options in the same service are approved.
- Approved services *cannot* advance to the remaining statuses in the request life cycle *until* all other services in the same request are approved.

Thus, with Pending Fulfillment as the value for this parameter, the following results occur in a service having two options. The two are approved sequentially, as follows:

Service Option	Approver's Action	Resulting Status
Option-1	Approve	Approval Done
Option-2	Approve	Pending Fulfillment
Option-1	Fulfilled	Completed
Option-2	Fulfilled	Completed

After all service options in the same service are approved, the service reaches Pending Fulfillment status.

After all services in the same request are approved, the request reaches Pending Fulfillment status.

Example 3--Completed

In this example, you do *not* want individual service options in a service or individual services in a request to be able to change statuses independently of each other at any point in the request life cycle.

Instead, you always want complete services and complete requests to change statuses *only* as a single unit, not independently. To achieve this goal, specify Completed the value for this parameter.

Essentially, this setting "turns off" any possibility of service options in a service or services in a request changing statuses independently of each other at any point in the request life cycle.

Common Settings

The following points apply to all combinations of the *Allow Discrete Handling of Service Options After* and *Allow Discrete Request Life Cycle After:*

- If *Allow Discrete Handling for Reject* is No and you reject any service or service option, the entire request is rejected. The request life cycle stops immediately. After the rejection, the following status changes occur:
  - The status for the entire request changes to Not Submitted - Rejected.
  - Previously approved service options change to Not Submitted - Approved status.
  - All other service options move to Not Submitted - Rejected status.

  The requestor can optionally modify and resubmit the request.
  However, if this setting is Yes and you reject any service or service option, the remaining services or service options continue their request life cycle according to settings for the *Allow Discrete Handling of Service Options After* and *Allow Discrete Request Life Cycle After* parameters, as specified in the tables.
- If the request manager rejects one or more services or services options in a request that includes other services and service options, the setting of *Allow Discreet Handling for Reject* determines effect on the other service options and services in the request, regardless of whether the other services and service options were previously approved.
- The Perform Action icon or button appears on the GUI in all cases, except when *Allow Discrete Handling of Service Options After* is set to Pending Fulfillment and *Allow Discrete Request Life Cycle After* is set to Completed.
  When you click the Perform Action, a new page opens, enabling you to perform all applicable actions for each service or service option in the request, such as approve, reject, fulfill, transfer, delegate, take, return.

Use Policies to Manage Requests

This article contains the following topics:

CA Service Catalog administrators can create policies. Policies define conditions for automatically designating specific users as the assignees for a task during the request life cycle. The most common use is to define conditions for automatically assigning specific approvers for services and service options in a request pending action.

Policies provide the flexibility to assign tasks (such as approval or rejection of requests pending action) to users *other than* the managers of the requestor. However, you can optionally include these managers in your list of assignees.

The policy that you create consists of the following main components:

- The condition under which the policy applies
- The assignment to occur if the condition is met.
  If the condition is met, the user or users you specify are assigned to perform a pending action. You can specify the list of assignees according to any of several attributes, including but not limited to:
  - User name (first name and last name)
  - Membership in a user group
  - Management hierarchy, meaning the manager of the user, the manager of that manager
- An active-or-inactive setting
- Description and priority fields

You create *global* policies and global actions for general use with any service. In contrast, you create *attached* policies and actions for use with a specific service option only. You can create an attached policy or action *only* from the Policies & Actions tab (see page 3018) of that service option.

Comparison to Events, Rules, and Actions

The conditions and actions that you specify in policies are similar to the rules and actions (see page 3040) that CA Service Catalog supplies in events. You can view and edit these events, rules, and actions by selecting Administration, Tools.

In both the cases, you specify conditions that become part of the request life cycle workflow in CA Service Catalog. In both cases, when a request meets the specified conditions, CA Service Catalog assigns the users that are specified in the policy. For example, suppose you create a policy that applies only to requests with cost greater than $100. When a user submits a request that meets this condition, the assignees that are specified in the policy are assigned a pending action to approve, reject, or fulfill the request.

The major difference is that events, rules, and actions are system wide. But, you can optionally specify policies to be either system wide or specific to a business unit.

Step 1 - Review the Criteria to Apply Policies to Individual Requests

CA Service Catalog matches policies to individual requests according to priority and business unit (tenant) level in the following order.

1. High-priority policies at the lowest level business unit (farthest from the root)
2. High-priority policies at the next lowest level business unit
3. High-priority policies at the remaining business unit levels, from the lowest though the highest (the root)
4. Low-priority policies at the lowest level business unit
5. Low-priority policies at the next lowest level business unit
6. Low-priority policies at the remaining business unit levels, from the lowest though the highest
7. When CA Service Catalog matches a policy to a request, it considers other policies *only* if they are at the same priority and business unit level.
8. If CA Service Catalog finds two or more policies at the same priority and business unit level, it assigns requests pending action to *all* applicable assignees from *all* applicable policies.

The Catalog system requires *all* approvals from these assignees to advance the request pending action to the next status in the request life cycle. To help avoid situations in which multiple policies and approvers apply to a single request pending action, create and maintain conditions to use specific criteria.

Step 2 - Create Folders for Policies

You can create and maintain folders (as needed) to store your policies. Organize policies in folders according to the business units and child business units to which they apply, using intuitive names. Similarly, suppose that the policies apply to all business units. In that case, you can organize them according to categories under a folder that is named For All Business Units.

Follow these steps:

1. Click Catalog, Policies.
2. Add a folder, as follows:
   a. Select the folder to which you want to add the new folder and click Add, Folder.
   For example, to add a folder to the root folder (the Policies folder), select it and click Add Folder.
   b. Enter the name of the new folder and click OK.
   The folder is created and appears under the parent folder.

You can create, rename, move, copy, and delete folders.

Note: The names of folders are case-aware, but not case-sensitive. Thus, when you rename a folder, change more than the case. For example, you cannot rename an existing folder from spg policies to Spg Policies or SPG POLICIES.

Step 3 - Enable Rules and Actions for Policies

Policies require an engine. The rules and actions that you enable depend on the engine you use. On the Details Tab (see page 2997) for any service that wants to associate with a policy, you specify the approval process as *one* of the following options:

- Enable policy rules and actions for CA Process Automation (see page 2127).
  Perform this task if any services in the catalog specify the Workflow driven approval process to apply policies. If your implementation uses CA Process Automation for approving and fulfilling requests, you can use CA Process Automation as the engine for policies.
- Enable policy rules and actions for the Catalog Policy Engine (see page 2128).
  Perform this task if any services in the catalog specify the Policy driven approval process to apply policies. The Catalog Policy Engine is part of the Policy Builder, and is available to all CA Service Catalog implementations. The Catalog Policy Engine does not require CA Process Automation. This approach is typically more efficient and therefore is typically preferred.

If necessary, copy and modify a predefined rule or action to specify a custom rule or action. If both options apply, then you can use either option as the policy engine for any service.

Enable Policy Rules and Actions for CA Process Automation

If any services in your catalog specify the Workflow driven approval process, enable the required rules and actions. If necessary, also enable the policy rules and actions for the Catalog Policy Engine.

Follow these steps:

1. Click Administration, Events-Rules-Actions.
2. Click the Event Type named *Request/Subscription Item Change*.

3. Select the rule *When Status is Submitted and Approval Process is driven by Workflow*.
   The Rule Details page for this rule appears. This rule is enabled by default. If it has been disabled, click the Enable button. This button appears on the Rules bar.

4. Select the action that is named Launch Policy Driven Approval SRF and click the Enable button.
   The Enable button appears on the Actions bar.

5. Click Done.
   The Event Details page appears.

6. To configure CA Service Catalog so that you can use policies to fulfill requests, using *simple* fulfillment, perform the following actions:

   a. Open the *When Status is Pending Fulfillment* rule. Do not exit the Event Type named Request/Subscription Item Change.

   b. Create a CA Process Automation action and select the Policy_Approval Start Request Form.

   c. Complete the parameters that appear.

   d. Specify the following parameters as indicated:

   e. **RequestStatusUponAssignment =1000**
      Specifies that the requested item is set to this status (Pending Fulfillment) when the request pending action is assigned.

   f. **RequestStatusUponSuccess =2000**
      Specifies that the requested item is set to this status (Fulfilled) when the request pending action is completed.

   The Policy_Approval Start Request Form supports *simple* fulfillment but does *not* support multilevel fulfillment and complex fulfillment. However, you can optionally create a CA Process Automation process that *does* support multilevel fulfillment and complex fulfillment. To do so, use the assignPolicyBasedPendingActions method in the web service named RequestService.

The rules and actions are enabled.

Enable Policy Rules and Actions for Catalog Policy Engine

If any services in your catalog specify the Policy driven approval process, enable the required rules and actions.

Follow these steps:

1. Click Administration, Events-Rules-Actions.

2. Click the Event Type named Request/Subscription Item Change.

3. Locate the rule *When Status is Submitted and Approval Process is driven by Policy*.
   This rule is enabled by default. If the rule is disabled, select its check box. Click Enable, and click OK.

4. Click the rule name.

5. Click the Edit icon for the action *Evaluates Policy Driven Approval Process*.
   The Edit Action page appears. This action is disabled by default.

6. Select Enabled in the Status drop-down list, and click OK.
   This action checks the policy setting on the Policies and Actions tab of each service option that triggers the action. According to that setting, the action evaluates global policies, attached policies, or both for the service option.

The rules and actions are enabled.

Step 4 - (Optional) Export and Import Policies

The IXUTIL command-line utility is an importing and exporting command-line utility that allows the preservation and migration of CA Service Catalog data between computers. You can use IXUTIL to export and import new and updated objects, including policies, from one computer to another. You can export and import policies in the following cases:

- When you upgrade or migrate CA Service Catalog.
- When you upgrade your computer.
- When the server fails.

Note: You can also use the Import Export Utility on the product UI to import and export policies.

Follow these steps:

1. Open the CA Service Catalog command prompt on any Catalog Component computer.

2. Enter one or more of the following commands:

   - To export all policies in all business units, enter the following command:

     ```
     ixutil export policy -f file
     ```

   - To export all policies in a business unit, enter the following command:

     ```
     ixutil export policy -f file - businessunit businessunit id
     ```

   - To export a single policy, use the following command:

     ```
     ixutil export policy -f file -policy name -businessunit id
     ```

     If the name contains spaces, enclose the name in double quotation marks.

```
ixutil export policy -policy "Mobile Device Policy--Tier 1" ...
```

- To export multiple policies, enclose the names in double quotation marks, and separate the names with commas.

```
ixutil export policy -policy "Mobile Device Policy--Tier 1,Mobile Device Policy--Tier 2,Mobile Device
Policy--Tier 3" ...
```

- To export a folder containing one or more policies, enter the following command:

```
ixutil export policy -f file -folder name -businessunit id
```

  To export multiple folders, enclose the names in double quotation marks, and separate the names with commas. Use the previous command for multiple polices as a model.

- To import a previously exported file containing one or more policies, enter the following command:

```
ixutil import policy -f file -businessunit id
```

  The -businessunit *businessunit id* option is optional when you import the policy file. However, consider the important factors explained in the description of this option later in this topic.

- To import a previously exported file containing one or more policies in disabled status, enter the following command:

```
ixutil import policy -f file -businessunit businessunit id -disable
```

3. Log in to CA Service Catalog on the computer where you imported the policies. If you had imported policies into a specific business unit, log in to the respective business unit.
4. Click Catalog, Policies.
5. Expand the policy folders. Verify that the Catalog system imported the policy or policies as you want.
6. Close the CA Service Catalog command prompt.

Step 5 - Create a Policy

Administrators create policies to assign approvers automatically for services and service options in a request pending action. In this way, you use policies to manage requests.

Follow these steps:

1. Click Catalog, Policies.
2. Select the folder to which you want to add the new policy and click Add, Policy.
3. Enter an intuitive name for the policy and click OK.

4. Enter meaningful descriptions in the policy fields for the policy that is created under the parent folder.

5. Select either High or Low in the Priority drop-down list.

> **Note:** When a user submits a request, CA Service Catalog checks for and the system applies any matching *high-priority* policies. Only if no high-priority policy applies to the request, the system checks for and applies any matching *low-priority* policies.

6. Select either Active (ready to use the policy) or Inactive in the Status drop-down list.

7. Save the policy.

Step 6 - Create Conditions for a Policy

Administrators create the condition as the major decision point of the policy. If the condition is met, the Catalog system automatically assigns the pending action to the assignees. You specify the condition using the attributes of CA Service Catalog elements such as users, requests, services, business units. In addition, you can use match functions for creating conditions that are based on service options and service option elements.

Create simple conditions that are based on known attributes, such as category, external_id, code, item type, cost, status. Specify the criteria that the value of the specified attribute must meet to assign the pending action.

The condition builder is the tool in the Condition field that helps you specify valid conditions, one segment at a time. When you initially move the cursor to the field, the condition builder prompts you with valid options for the first part of the condition. These options appear in a drop-down list under the Condition field. Select the option that you want from the list. As you complete each part of the condition, the condition builder continues to prompt you with valid options for the next part. This process continues until the condition is finished, typically with a closing parenthesis.

The condition must be a valid JavaScript expression. Typically specify one condition per policy, using the following format:

$(_.*group.attribute operator 'value'*)

- ***group***
  Specifies service, request, business unit, or any other group that is illustrated in the types of conditions (see page 2137).

- ***attribute***
  Specifies any attribute of that group

- ***operator***
  Specifies one of the following options:
  == (equal to)
  != (not equal to)

> (greater than)
< (less than)
>= (greater than or equal to)
<= (greater than or equal to)

- ***value***
  Specifies a literal value, typically the name of a business unit, request, service, service option group, or user.
  Enter numeric values without quotation marks, for example: $(_.request.bu.status==0).
  Enclose string values in single quotation mark; for example: $(_.request.bu.taxRegion =='South').
  If a string value includes a single or double quotation mark, precede that mark with a backslash (\) as the "escape" character. For example, if the service name is Demandes d'IP Statique, then specify the condition as follows:

  ```
  $(_.service.name=='Demandes d\'IP statique')
  ```

  As you construct an expression in the Condition Builder, the data type (string or numeric) of the attribute appears on the right, letting you know whether to use quotation marks around the value.

  ```
  $(_.service.name=='Procure Server')
  ```

  This condition means that when the name of the service is Procure Server, the users you specify are assigned as actors, typically approvers, or fulfillers.
  For example: $(_.request.estimatedCost >==1000)
  This condition assigns the pending action to the specified approvers or fulfillers when the estimated cost of the total request is greater than or equal to $1,000.

Step 7 - Specify Assignees for a Policy

Administrators specify assignees for a policy to configure the Catalog system to assign automatically the request pending action that triggered the policy. If the condition of the policy is met, the Catalog system automatically assigns the request to the specified assignees. The assignees typically process the request by approving, rejecting, or fulfilling it.

To specify assignees for a policy, follow this process:

1. Review Information about Assignees for Policies (see page 2132)
2. Decide how to Specify Assignees (see page 2133)

The Catalog system searches for and assigns approvers and fulfillers in the following order:

1. A relevant policy
2. The management hierarchy of the requestor
3. The Service Provider administrator (spadmin)

Review Information about Assignees for Policies

Assignees are typically request managers or other administrators who act on the requests pending action. The Catalog system assigns these requests, either to the assignees personally or to an administrative group to which they belong.

For example, suppose that the condition specifies that the pending action is triggered when both of the following conditions are true:

- The name of the requested service is Procure Laptop.
- The status is Submitted (by default, 200).

In this example, the assignee can be any of the following conditions, depending on the size and scope of the organization:

- The person or group that approves hardware requests.
- The manager of the requestor or another manager.
- The IT Finance Group.
- The Purchasing department.

You can assign only one approver or several approvers. Thus, you can assign either of the following levels:

- Only one *level* of approval, such as the manager only.
- Several levels of approval, such as the manager first, followed in succession by an IT approver and a financial officer.

When you are creating a policy or editing one, you *decide* how many approvers and how many levels of approval to specify. Examples follow:

- For requests to purchase third-party software, the following conditions apply:
  - First, both the immediate manager and the next-level manager must approve the request, in succession.
  - Next, a member of the Software Purchasing department must approve the request.
- If the Requested For user or the Requested By user is a delegate, include the manager of that user in the list of assignees.
- If the Requested For user belongs to a specific business unit, specify the approvers or fulfillers for that business unit in the list of assignees.

Decide How to Specify Assignees

Use the following use cases as guidelines:

- One known user is the assignee. Use either the Action Builder or an API plug-in.
- Multiple known users at specific levels comprise the list of assignees. Use either the Action Builder or an API plug-in.
- You query an external system for data to specify the assignees. Use the API plug-in.

- The identities and number of assignees vary, depending on the data in the request. Use the API plug-in.

Use the Action Builder to Specify Assignees

The Action Builder lets you manually find and select one or more assignees for one or more levels of approval.

Follow these steps:

1. Click Catalog, Policies, and open the policy.
2. Add the first assignee by clicking the plus sign (+) in the Action Builder (the box under the Condition field).
3. Complete the first Requirement field (the one next to the Level 1 column), as follows:
   In the drop-down list, select ANY or ALL.
   - **ANY**
     - The first approval or fulfillment for a requested item changes the status of the item and closes any remaining pending actions for the item. (*Item* means a service or service option.)
     - If all users reject or cancel an item, then the item is rejected or canceled.
   - **ALL**
     - Every assignee must approve or fulfill the requested item.
     - If any assignees are groups, then one member of each assigned group must act on the item.
     - If any assignee cancels or rejects the item, then all pending actions for the item are rejected or canceled.
4. Complete the first Assignees field (the one next to the first Requirement field) by clicking the magnifying lens:

   Note: In the Find Approvers dialog, if you select User or Group, the name of the next field remains Name Filter. If you select Manager, the name of the next field changes to Manager Level.

   The assignees you selected are recorded. The Find Approvers dialog closes. You return to the Action Builder page.
5. Click OK under the first row of approvers, and click Save (above the Policy tree).

6. Specify one or more assignees, as follows:
   If you specify multiple assignees, specify whether the pending actions are to be sequential or parallel.
   Parallel actions occur at the same time and at the same level of approval.
   Sequential actions occur in order, one after the other, and at different levels of approval.

7. To specify a complex (OR) or compound (AND) expression for the first-level approval, click the first row.
   The Operation field and the second Requirement and Assignees fields open for input.

   a. Complete the second Assignees field and second Requirement fields.

   b. Specify AND to require that *both* the first and second assignees you specify must approve (or fulfill) the pending action. Otherwise, the pending action is rejected (or is not fulfilled). Specify OR to require that *only one* of the first and second assignees you specify must approve (or fulfill) the pending action. Otherwise, the pending action is rejected (or is not fulfilled).

   c. Click OK under the first row of approvers, and click Save (above the Policy tree).

   If you are finished specifying approval levels and approvers, navigate away from this window.

8. To specify a second level of approval, go to the next step.
   Optionally complete the steps for the previous bullet (if applicable) before going to the next step.

9. If you are finished specifying approval levels and approvers, navigate away from this window.

10. (Optional) Click the plus sign (+) in the Action Builder to add a second level of approval.
    A second approval row appears, with the fields open for input.

    a. Complete the first Assignees and Requirement fields in this row.

    b. If applicable, specify a complex (either-or) or compound (both-and) expression for this row.

11. (Optional) Specify a third or more level of approval, until you are finished specifying approvers for this policy.

You have specified the assignees for this policy.

Use an API Plug-in to Specify Assignees

An API plug-in is most useful when you query an external system for data to specify the assignees. An API plug-in is also useful when the identities and number of assignees vary, depending on the data that is supplied in the request. Based on this data, the plug-in dynamically creates the assignee list and specifies the assignee levels.

Follow these steps:

1. Click Catalog, Policies, and open the policy.

2. Select Use Plug-in for Assignees. This check box appears under the Condition field.

3. Complete the fields:

   - **Plug-in Id**
     Specifies the ID of your custom plug-in for dynamically populating the list of assignees. You or another administrator must have previously written, tested, and loaded this plug-in. To view the list of plug-ins, select Administration, Tools, Plug-ins.

   - **(Optional) Variables**
     Specify the list of variables for the plug-in, if necessary.
     If applicable, open the plug-in that you selected to display its details, including variables. On the details page, the Inputs section lists the ID values and descriptions of the input variables for the plug-in. Copy the ID values of the variables that you want from that page and paste them into the value of the Variables attribute. Enter the variables as a JSON expression.

You have specified assignees for this policy.

Example: Use of Variables

$({'form_field_value':_.sog['sog1'].serviceoption[2].form['form1'].txt1, 'est_service_cost':_.service.estimatedCost, 'est_sog_cost':_.sog['sog1'].estimatedCost, 'req_status':_.request.status})

These variables return data to the plug-in, as follows:

- form_field_value hold the value of the field named txt1. This field is in the form whose ID is form1. This form is in the service option in row 2 of the service option group whose ID is sog1.
- If necessary, use the product UI to find the row number of a service option. (The linked topic references policy *conditions* but the row number has the same value in this context. The row number is an object property that remains constant, whether you reference it in a policy condition, a JSON expression, or another type of code.)
- est_service_cost holds the estimatedCost property for the service.
- est_sog_cost holds the estimatedCost property for the service option group.
- req_status holds the request status.

The data from the variables populates the list of assignees and the levels of approval, according to the code specified in the plug-in. For example, you can write a plug-in to specify that if the following *conditions* are true, then trigger the following *action*:

Conditions:

- If The txt field in form_field_value equals Deluxe.
- If est_service_cost is greater than 5,000.
- If est_sog_cost is greater than 500.
- If req_status equals 200 (Submitted).

Action: Create the following assignment table:

- Level 1 Assignee is the manager of the IT department.
- Level 2 Assignee is the manager of the Purchasing department.
- Level 3 Assignee is the Vice President of the business unit of the requested-for user.

Types of Conditions

When a condition you specify is met, CA Service Catalog assigns the related pending actions. The pending action is typically to approve, reject, or fulfill a requested item.

Specify one of the following types of conditions:

- Conditions based on the attributes of requests (see page 2137)
- Conditions based on the attributes of users (see page 2139)
- Conditions based on the attributes of the business unit (see page 2145)
- Conditions based on the attributes of services (see page 2148)
- Conditions based on the attributes of service option groups (see page 2150)
- Conditions based on the attributes of service options (see page 2151)
- Conditions based on the attributes of service option elements (see page 2156)
- Match functions for service options and service option elements (see page 2162)
- Conditions based on the fields of Form Designer forms (see page 2163)
- Conditions based on the attributes of the location (see page 2165)

Conditions Based on the Attributes of Requests

You can specify conditions that are based on the following attributes of the request that the policy affects:

- **completionDate**
- **dateCreated**
- **dateRequired**
- **description**
- **estimatedCost**
  Specifies the total estimated cost of all services (including all service options) in the request. The Catalog system calculates this cost when the request is submitted.

> **Note:** To find the cost of the request, click Home, Requests. If applicable, use the My Requests drop-down list to display requests. Find the request and view the details.

- **id**
- **lastModified**
- **name**
- **priority**
  Specifies the priority of the request as a number, using one of the following values:
  1 = high
  2 = medium_high
  3 = medium
  4 = medium_low
  5 = low
- **requestedBy**
- **requestedByAccountId**
- **requestedFor**
- **requestedForAccountId**
- **status**
  Specifies the numeric value of the status of the request.
  To use request status as a condition for *approval*, specify this attribute in your condition, using the *approval range*, by default, less than 800. For example, the following condition is met when the service is named "Procure Laptop" and the request status is approved:

  ```
  $(_.service.name=='Procure Laptop' && _.request.status < 800)
  ```

  To use request status as a condition for *fulfillment*, specify this attribute in your condition, using the *fulfillment range*, by default, greater than or equal to 999. For example, the following condition is met when the service is named "Procure Laptop" and the request status is fulfilled:

  ```
  $(_.service.name=='Procure Laptop' && _.request.status >= 999)
  ```

  If your organization is *not* using custom statuses, you can specify the default status values (see page 2108).
  If your organization *is* using custom statuses, find all *actual* status values (both default and custom). Open the requestshared.xml file. Record the values that you want to use in your conditions.
- **other attributes**
  You can view most of the other attributes when you view the request list pages. Otherwise, open a request to view its additional details.

Examples

- To assign a pending action when the estimatedCost of the request equals 100 monetary units (by default, dollars):

```
$(_.request.estimatedCost == 100)
```

- To assign a pending action when the priority of the request equals 1, meaning high priority, use this condition:

  ```
  $(_.request.priority==1)
  ```

- To assign a pending action when a request item has not been approved (status 800) and the Requested For user has a manager:

  ```
  $(anySoWith('status', lt, 800) &&_.request.requestedForUser.manager != '')
  ```

- To assign a pending action when a request item has been approved or when the Requested For user does not have a manager:

  ```
  $(anySoWith('status', gteq, 800) || _.request.requestedForUser.manager == '')
  ```

  The assignee list for this example can specify the default user (spadmin) or another suitable user.

- To assign a pending action when the request status is greater than 200 (submitted) and the business unit of the assignee is ca.com:

  ```
  $(_.request.status>200 && _.request.bu.id=='ca.com')
  ```

Conditions Based on the Attributes of Users

You can specify conditions that are based on the attributes of users, as follows:

- Conditions that are based on the attributes of the Requested For user (see page 2143)
  The Requested For user is the user who receives the requested services.

- Conditions that are based on the attributes of the Requested By user (see page 2144)
  The Requested By user is the user who created and submitted the request.
  The Requested For user and Requested By user can be the same user or different users. If you submit a request for yourself, you are both the Requested For user and the Requested By user. If you submit a request for another user, you are the Requested By user, and the other user is the Requested For user.

- Conditions that are based on the attributes of the assigner (see page 2144)
  Typically, the assigner is a workflow process utilizing an automated user like CERT-Service Delivery. Relatively few conditions are likely to use these attributes.

You can use the following attributes in conditions based on the attributes of users:

- **alias**

- **commonName**

- **defaultDomain**
  Each user has a default domain (business unit) in the user profile. Administrators set this default business unit when they add or edit the user.
  Specifies different values for different parameters, as follows:

  - For the Requested For user parameter, specifies the default business unit of the Requested For user.

- For the Requested By user parameter, specifies the business unit of the request.

Enter the ID of the business unit you want from the usm_tenant_ext table.
For example, to list the values of all business unit IDs in that table, run the following query on the MDB from your database client:

```
select tenant_id from usm_tenant_ext
```

To list the default business unit of a user, run the following query on the MDB from your database client:

```
select domain from usm_contact_domain_role where user_id=userid and default_domain=1
```

- ***userid***
  Specifies the user ID whose default business unit you want to find.

- **default_domain=1**
  Specifies the default business unit of the user.

- **defaultRole**
  Specifies the default role of a user in a domain.
  Enter the ID of the role ID you want from the usm_role table.
  For example, to list the IDs of all roles in that table, run the following query on the MDB from your database client:

```
select role_id from usm_role
```

To list the default role of a user in a domain, run the following query on the MDB from your database client:

```
select role_id from usm_contact_domain_role where user_id=userid and default_domain=1
```

- ***userid***
  Specifies the user ID whose default domain you want to find. For example:

```
select role...where user_id='john smith'...
```

  If the user ID includes one or more spaces, enclose it with single quotation marks, as shown in the example on the previous line.

- **default_domain=1**
  Specifies that the role is for the default domain of the user.

- **delegate**
  Specifies the user ID of a delegate for auto-delegation of the requests pending action of the user. Such delegates appear in the user profile in the Request Auto Delegation section. Users and their administrators can specify such delegates in the profile.
  If any delegate specified in the condition matches any delegate of the Requested For user, the

Catalog system assigns the pending action.
Enter the user ID of the delegate you want from the MDB.
For example, to list the delegates for a user ID, run the following query on the MDB from your database client:

```
select delegate_id from usm_request_Auto_delegation where delegator_id=userid and
delegation_type=0
```

- ***userid***
  Specifies the user ID of the delegator.

- **delegation_type=0**
  Specifies that the type of delegation is auto-delegation.

Contains all the CA EEM groups to which the user belongs. You can, for example, create a policy condition to assign a request pending action that is based on whether a user belongs to a specific CA EEM user group.
To find the names of CA EEM user groups, query CA EEM. Log in to CA EEM and review the group names.
Use the groups property to check if the requested by user is a member of a CA EEM group. For example, you can create a policy that requires all requests that are created by developers to be assigned to architects. To do so, use the following permission to check the requested by user group membership in the developers group:

```
_.request.requestedByUser.groups.indexOf('developers') >= 0
```

In contrast, you can also create a policy for users who are not members of a CA EEM group. To do so, specify the following expression:

```
_.request.requestedForUser.groups.indexOf('developers') < 0
```

- **description**
- **email**
- **fax**
- **firstName**
- **groups (user groups)**
- **id**
- **lastName**
- **localeCountry**

Specifies the ISO 3166 two-letter country code of the logged in user.
Commonly used ISO 3166 two-letter country codes include the following country codes:

- - Brazil - BR
  - China - CN

- France - FR
- Germany - DE
- Italy - IT
- Japan - JP
- Spain - ES
- United Kingdom - GB
- United States - US

Note: The *localeCountry* attribute uses different values than the *country* attribute (from the ca_country table) used in several other conditions.

- **localeLanguage**
- **manager**

Enter the value of the manager user ID you want from the ca_contact table.
For example, to list the values of all manager user IDs in that table, run the following query on the MDB from your database client:

```
select supervisor_contact_uuid from ca_contact
```

- **middleName**
- **mobile**
- **pager**
- **phone**
- **roles**
- **status**

Specifies the status of the Requested For user.
Values:

- 0 - Active
- 1 - inactive (deleted)

- **timezone**

Specifies the code for the time zone for the business unit.

Examples:

- Eastern USA
- Greenwich Mean Time
- Amazon Time

Enter the time_zone_code from the ca_time_zone table.
For example, run the following query on the MDB from your database client:

```
select contact_uuid from ca_contact
```

- **title**
- **uuid**
  Enter the value of the contact_uuid you want from the ca_contact table.For example, run the following query on the MDB from your database client:

  ```
  select contact_uuid from ca_contact
  ```

- **Title**
  Enter the value of the job title for the user. The ca_contact table stores the job title of each user. For example, list the job title of a specific user (here, Omar PE Patel) in that table. To do so, run the following query on the MDB from your database client:

  ```
  Select job_title from ca_contact where userid='Omar PE Patel'
  ```

  To list the values of all job titles available in CA Service Catalog, run the following query:

  ```
  select id from ca_job_title
  ```

Conditions Based on the Attributes of the Requested For User

To specify conditions that are based on the attributes of the Requested For user that is affected by the policy, use the following format:

`$(_.request.requestedForUser.`*`attribute operator 'value'`*`'')`

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not enter spaces.

Examples

Sample conditions follow:

- To assign a pending action when the country of the business unit of the Requested For User is Brazil, use this condition:

  ```
  $(_.request.requestedForUser.localeCountry==BR)
  ```

  Note: BR is the ISO 3166 two-letter country code (see page 2139) for Brazil.

- To assign a pending action when the role of the Requested For user is request manager, use this condition:

  ```
  $(_.request.requestedForUser.role=='request manager')
  ```

- To assign a pending action when the title of the Requested For user is Procurement Officer, use this condition:

  ```
  $(_.request.requestedForUser.title=='Procurement Officer')
  ```

Conditions Based on the Attributes of the Requested By User

To specify conditions that are based on the attributes of the requested by user the policy affects, use the following format:

```
$(_.request.requestedByUser.attribute operator 'value'')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not enter spaces.

Examples

Sample conditions follow:

- To assign a pending action when the local language of the requested by user is Arabic, use this condition:

  ```
  $(_.request.requestedByUser.localeLanguage='Arabic')
  ```

- To assign a pending action when the time zone of the requested by user is GMT-11:00 MIT, use this condition:

  ```
  $(_.request.requestedByUser.timezone=='GMT-11:00 MIT')
  ```

  The time zone code for each user is specified in the user profile. To retrieve the time zone code that is associated with a specific user (Isabella Lauderos), run the following query:

  ```
  select time_zone_code from usm_contact_extension where user_id='Isabella Lauderos'
  ```

Conditions Based on the Attributes of the Assigner

To specify conditions that are based on the attributes of the assigner, using the following format:

```
$(_.user.attribute operator 'value')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not enter spaces.

Examples

Sample conditions follow:

- To assign the pending action when the title of the assignee is Purchasing Officer, use this condition:

  ```
  $(_.user.title=='Purchasing Officer')
  ```

- To assign the pending action when the default role of the user in the business unit is either Service Delivery Administrator (spadmin) or the Super Business Unit Administrator (stadmin), use this condition:

  ```
  $(_.user.defaultRole=='spadmin' || _.user.defaultRole=='stadmin')
  ```

Conditions Based on the Attributes of the Business Unit

You can specify conditions that are based on the attributes of the business unit, as follows:

- Conditions that are based on the attributes of the business unit of the request (see page 2147); that is, on the business unit of the Requested For user
- Conditions that are based on the attributes of the business unit of the assignee (see page 2148) The assignee is the logged in user attempting to complete the pending action triggered by the policy condition being met. Typically, the assignee performs an approval or fulfillment task.

In both of these types of conditions, you can use the following attributes:

- **Business unit type**
  Specifies the code for the type of the business unit.
  V**alues:**
  - TE - Tenant
  - ST - Super Tenant
  - SP -Service Provider
- **country**
  Specifies the country code for the business unit.
  Enter the code for the country you want from the ca_country table.
  An example follows: To list the code of a specific country (here, India) in that table, run the following query on the MDB from your database client:

  ```
  Select id from ca_country where country='India'
  ```

  The results show that the country code for India is 114.
  To list all country codes for CA Service Catalog, run the following query on the MDB from your database client:

  ```
  select id from ca_country
  ```

- **currency**
  Specifies the code for the currency unit for the business unit.

  Enter the value of the currency_type_code you want from the ca_currency_type table.
  For example, run the following query on the MDB from your database client:

  ```
  select currency_type_code from ca_currency_type
  ```

- **dateFormat**
  Specifies the date format for the business unit.
  Values:
  - M/d/yyyy
  - M-d-yyyy
  - d/M/yyyy
  - d-M-yyyy
  - yyyy/M/d
  - yyyy-M-d
  - dd.MM.yyyy
- **decimalFormat**

Specifies the decimal symbol for the business unit.

Values:

- 1 implies that the decimal symbol is a comma (,)
- 0 implies that the decimal symbol is a dot (.)

- **description**
- **email**
- **federalTaxId**
- **id**
- **name**
- **loginId**
- **openedDate**
- **parent**

Specifies the tenant_id of the parent business unit.
Enter the parent_tenant_id of the usm_tenant_ext table.
For example, run the following query on the MDB from your database client:

```
select parent_tenant_id from usm_tenant_ext
```

- **primaryContact**

- **Single account mode**
  Specifies whether the business unit contains a single account only.
  Values:
  - 0 - The business unit users can have multiple accounts.
  - 1- The business unit can have only a single account.
- stateTaxId
- **status**
  Specifies the status of the business unit (not the request).
  Values:
  - 0 = Inactive (Deleted)
  - 1= Active (Open)
- taxRegion
- **timeformat**
  Specifies the time format for the business unit.
  Values:
  - HH:mm:ss
  - HH.mm.ss
- **Timezone**
  Specifies the code for the time zone for the business unit.
  Enter the time_zone_code from the ca_time_zone table.

For example, run the following query on the MDB from your database client:

```
select time_zone_code from ca_time_zone
```

- **type**
- **website**
- **data1, data2, data3...**
  Specify custom data fields, if applicable, that you have created and use.

Conditions Based on the Attributes of the Business Unit of the Request

To specify conditions that are based on the attributes of the business unit of the request, using the following format:

```
$(_.request.bu.attribute operator 'value')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not enter spaces.

Examples

Sample conditions follow:

- To assign the pending action that is based on the status of the business unit, use this condition:

  ```
  $(_.request.bu.status==0)
  ```

  Note: The value of 0 specifies that the business unit is inactive. You can, for example, use a policy to assign all requests from an inactive business unit to a specific user.

- To assign the pending action when the tax region of the business unit of the request is named South, use this condition:

  ```
  $(_.request.bu.taxRegion =='South')
  ```

- To assign the pending action when the currency of the business unit of the request is named Euro, use this condition:

  ```
  $(_.request.bu.currency =='Euro')
  ```

Conditions Based on the Attributes of the Business Unit of the Assignee

To specify conditions that are based on the attributes of the business unit of the assignee, use the following format:

```
$(_.user.bu.attribute operator 'value')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not enter spaces.

Examples

Sample conditions follow:

- To assign the request pending action when the name of the business unit of the assignee is Western Regional Sales, use this condition:

  ```
  $(_.user.bu.name==‘Western Regional Sales’)
  ```

- You can assign the request pending action when the value of the singleAccountMode attribute of the assignee's business unit is 1 (meaning Yes). To do so, use this condition:

  ```
  $(_.user.bu.singleAccountMode==1)
  ```

- To assign the pending action when the business unit of the assignee is located in India, use this condition:

  ```
  $(_.user.bu.location.country==114)
  ```

  This condition uses 114, because 114 is the ID number for India in the ca_country table.

Conditions Based on the Attributes of Services

You can specify conditions that are based on the following attributes of the service that the policy affects:

- **bu**

- **code**
- **dateAvailable**
- **dateUnavailable**
- **dateCreated**
- **dateCancelled**
- **description**
- **estimatedCost**

Specifies the total estimated cost of a service in a request. The Catalog system calculates this cost when the request is submitted.

Note: To find the cost of the service, click Home, Requests. If applicable, use the My Requests drop-down list to display requests. Find the request that contains the service and view the details.

- **id**
- **name**
- **status**

Specifies the numeric value of the status of the service (*not* the request), as follows:

- 0 - Deleted
- 1 - Available
- 2 - Unavailable
- 3 - Created
- 4 - Canceled

- **website**
- **version**

You can view most of the attributes when you add or edit a service (see page 2996).

Use the following format:

```
$(_.service.attrbute operator 'value')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not enter spaces.

Examples

Sample conditions follow:

- You can assign a pending action that is based on the service name. For example, if the service name is Knowledge Management Tools, use this condition:

  ```
  $(_.service.name=='Knowledge Management Tools')
  ```

- You can assign a pending action that is based on the estimated cost of the service being greater than or equal to 100 monetary units. (The default unit is dollars). To do so, use this condition:

  ```
  $(_.service.estimatedCost<=100.0)
  ```

- You can assign a pending action for any service option (requested item) whose status is greater than 1000 when the service ID is 9999. To do so, use this condition:

  ```
  anySoWith('status', gt, 1000) || _.service.id==9999
  ```

  By default, 1000 is the value for a status of Pending Fulfillment.

Conditions Based on the Attributes of Service Option Groups

You can specify conditions that are based on the following attributes of the service option group that is affected by the policy. Use the following format:

```
$(_.sog['sogname'].serviceoption[rownumber].attribute operator 'value')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not use spaces.

The service option group has the following attributes:

- **bu**
- **code**
- **dateAvailable**
- **dateUnavailable**
- **dateCreated**
- **dateCancelled**
- **description**
- **estimatedCost**
  Specifies the total estimated cost of a service option group in a service in a request. The Catalog system calculates this cost when the request is submitted.

> **Note:** To find the cost of the service option group, click Home, Requests. If applicable, use the My Requests drop-down list to display requests. Find the request that contains the service option group and view the details. Add the costs of all service options that belong to the service option group.

You can verify the service options that belong to a specific service option group by clicking Catalog, Service Offerings, Option Groups. Review the details for the service option group.

- **id**
- **name**
- **status**

Specifies the numeric value of the status of the service option group. The status of the service option group is the same as the status of the service (*not* the request).

Values:

- 0 - Deleted
- 1 - Available
- 2 - Unavailable
- 3 - Created
- 4 - Canceled

Examples

Sample conditions follow:

- You can assign a pending action that is based on a service option group being named Procure Server and having an estimated cost greater than 1,000 monetary units. (The default unit is dollars). To do so, use this condition:

  ```
  sog['Procure Server'].estimatedCost>1000
  ```

- You can assign a pending action that is based on a service option group being named Create email Account and having an estimated cost greater than or equal to 200 monetary units. To do so, use this condition:

  ```
  $(_.sog['Create email Account'].estimatedCost >=200)
  ```

- You can assign a pending action that is based on a service option group being named New Hire Onboarding and being contained in a business unit named Eastern District. To do so, use this condition:

  ```
  sog['New Hire Onboarding'].bu=='Eastern District'
  ```

Conditions Based on the Attributes of Service Options

Conditions that are based on service options can apply to either global or attached policies (see page 3018).

Formats

Use the following format for conditions *with* a match function (see page 2162):

```
$(anySoWith('attribute',operator,'value'))
```

Use the following format (without spaces) for conditions *without* a match function:

- For global policies, you specify conditions that begin with the service option group to which the service option belongs. Use the following format:

  ```
  $(_.sog['sogname'].serviceoption[rownumber] operator 'value' )
  ```

  To find the row number of a service option (see page 2155), use the product UI. Row numbers apply to global policies *only*.

- For attached policies, you specify conditions *without* the service option group name and row number. Use the following format:

  ```
  $(_.serviceoption operator 'value' )
  ```

  Note: Attached policies let you specify a policy that you can share among multiple service options efficiently, using a simple condition. When you specify a global policy for a service option, you must find its row number and must use that number in the condition.

For all formats, enclose string values in single quotation marks, and enter numeric values without quotation marks.

To specify conditions that are based on service options, use the following attributes:

category	external_id
category_class	keywords
category_subclass	status
estimatedCost	track_as_asset

1. For service options and service option elements, you can specify conditions that use match functions (see page 2162).

- **category, category class, and category subclass**
  Specifies the values for category, category class, and category subclass from the category.xml file. View this file and record the values that you want to use in your conditions. This file is located in a different folder for each localized version of CA Service Catalog. For example, for English (icusen), the category.xml file is located in the USM_HOME\view\webapps\usm\locale\icusen\billing folder.

- **estimatedCost**
  Specifies the estimated cost of a service option in a service in a request. The Catalog system calculates this cost when the request is submitted.

Note: To find the cost of the service option, click Home, Requests. If applicable, use the My Requests drop-down list to display requests. Find the request that contains the service option and view the details.

- **external_id and keywords**
  Specifies the values for the attributes that are named external_id and keywords.
  Service builders specify these values when defining the service options of a service option group.
  Service builders typically use these attributes to add meta information about services, especially for categorizing services.
  You can find the values of these attributes and can record them for use in this condition.

- **status**
  Specifies the request status of the service option.

- **track_as_asset**
  Specifies a numeric value indicating whether to track this service option as an asset in CA APM, as follows:
  0 - No
  1 - Yes

  Note: This attribute is relevant *only* when CA Service Catalog is integrated with CA APM.

  You can verify whether a service option uses this attribute (see page 2156), as follows: View the value of the Track as an Asset field on the Service Option Element Options window--Options tab (see page 3019).
  You identify service options in conditions by their row number in the service option group. On the CA Service Catalog GUI, you can find this row number by selecting Catalog, Service Offerings, Option Groups. Click the service option group on left pane, and click the Definition tab on right pane.
  When you do so, each service option in the group appears in a table; each row contains one service option. In the condition, specify the row number of the service option of interest. For example, suppose row 2 contains a service option named Windows server. In that case, specify the following conditions to include this service option.
  For a global policy:

  ```
  $(_.sog['sogname'].serviceoption[2]
  ```

  For an attached policy:

  ```
  $(_.serviceoption
  ```

Examples

Consider the following examples.

- You can specify the assignee when the name of the service option group is Procure Laptop and the category of the first service option is 1. To do so, use this condition:
  For a global policy:

  ```
  $(_.sog[‘Procure Laptop’].serviceoption[1].category==1)
  ```

This policy applies to the service option in row 1 of the service option group.
For an attached policy:

```
$(_.serviceoption.category==1)
```

This condition specifies that the pending action is assigned to the approver or fulfiller when the service option group is named Procure Laptop and the first service option in it belongs to Category 1. By default, Category 1 signifies hardware.

- You can specify the assignee when both of the following conditions are true:
  - The name of the service option group is New Hire Onboarding.
  - The estimated cost of the third service option is 30 monetary units. A sample unit is Euros.

  To do so, use this condition:
  For a global policy:

  ```
  $(_.sog['New Hire Onboarding'].serviceoption[3].estimatedCost==30.0)
  ```

  This policy applies to the service option in row 3 of the service option group.
  For an attached policy:

  ```
  $(_.serviceoption.estimatedCost==30.0)
  ```

- You can specify the assignee when both of the following conditions are true:
  - The name of the service option group is Handheld Devices.
  - The estimated cost of the service option in the third row of the group is 300 monetary units.

  To do so, use this condition:
  For a global policy:

  ```
  $(_.sog[‘Handheld Devices’].serviceoption[3].estimatedCost==300)
  ```

  This policy applies to the service option in row 3 of the service option group.
  For an attached policy:

  ```
  $(_.serviceoption.estimatedCost==300)
  ```

Examples with the Match Function

Consider the following examples:

- You can specify the assignee when the service option group includes a service option (in any row) with a category class greater than 10. To do so, use this condition:

  ```
  $(anySoWith('category_subclass',gt,10))
  ```

  This condition specifies that the pending action is assigned to the approver or fulfiller when any service option belongs to a category class greater than 10. By default, a category class greater than 10 signifies that the request is not related to any IT category, such as hardware or software.

- To specify the assignee when any service option in the request includes a category subclass greater than 10, use this condition:

  ```
  anySoWith('category_subclass',gt,10)
  ```

- To specify the assignee when the external_id (a string) of any service option ends with the string "MB," use this condition:

  ```
  $(anySoWith('external_id',endsWith,'MB'))
  ```

- You can specify the assignee when the category of any service option in the request is greater than 10 but less than 30. To do so, use this condition:

  ```
  $(anySoWith('category',gt,10) && anySoWith('category',lt,30))
  ```

- You can specify the assignee when *both* of the following are true:

  - The value of the external_id attribute of any service option in the request begins with the case-sensitive word "Memory"
  - The request contains a service option group that is named Procure Server. The category attribute of its first service option (row 1) has a value of 1, signifying hardware

  To do so, use this condition:

  ```
  $(anySoWith('external_id',startsWith,'Memory') && _.sog['Procure Server'].
  serviceoption[1].category==1)
  ```

- To specify the assignee when any service option in the request is tracked as an asset in CA APM, use this condition:

  ```
  $(anySoWith('track_as_asset',eq,1))
  ```

  Note: This attribute is relevant only when CA Service Catalog is integrated with CA APM.

Find the Row Number of a Service Option

When you specify a condition that is based on the attributes of a service option (see page 2151), specify the row number of the service option. This row number is the position of the service option in its service option group. Row numbers apply to global policies (see page 3018) *only*.

Follow these steps:

1. Click Catalog, Service Offerings.
2. Click the Option Groups tab.
3. Click the service option group of interest.
4. Click the Definition tab.
5. Find the service option of interest and click its Edit icon.
   The Service Option Details page opens. The row number appears under the image, near the Description field.
6. Record the row number.

> **Note:** Row numbers start at 1 and increase sequentially by 1 as you add service options to a service option group.

You have found and recorded the row number of the service option. You can now use the row number in a condition that is based on the attributes of this service option.

Examples

For example, a service option group contains these service options: Small, Medium, and Large. The Small service option is in row 1. The Medium service option is in row 2, and the Large service option is in row 3.

To specify a condition for the Small service option in a global policy, use the following format:

```
$(_.sog['sogname'].serviceoption[1] operator 'value' )
```

Similarly, to specify a condition for the Medium service option in a global policy, use the following format:

```
$(_.sog['sogname'].serviceoption[2] operator 'value' )
```

Find the Values of the Attributes of a Service Option

You can find the values of the attributes of a service option when required. For example, you can create conditions that are based on the attributes of service options (see page 2151). In that case, you can specify the values of the external_id, code, and keyword attributes as part of the condition.

Follow these steps:

1. Click Catalog, Service Offerings, Option Groups.
2. Click the service option group that you want to open.
3. To display the service options, click the Definition tab.
4. Open the service option of interest and view its details, including its service option elements.
5. Find and optionally record the values of the attributes you want, for example, the external_id, code, and keywords.

You have found and optionally recorded the values of the attributes of a service option.

Conditions Based on the Attributes of Service Option Elements

Conditions that are based on service option elements can apply to either global or attached policies (see page 3018).

For service options and service option elements, you can specify conditions that use match functions (see page 2162).

You can specify conditions that are based on the following attributes of service option elements:

- code item_type
- estimatedCost status
- item_text

The following attributes require explanation:

- **Code**
  Is a user-specified text value to represent the product code, subscription code, SKU # or any other applicable code.
  To find the value of this attribute for a service option element, click Catalog, Services Offerings, Option Groups. View the service option and service option element of interest. On the Service Option Element Definition dialog, click the Options tab and find the value of the Code field.

- **estimatedCost**
  Specifies the estimated cost of a service option element in a service option in a service in a request. The Catalog system includes the cost of all service option elements in the cost of the service option to which they belong. The Catalog system calculates this cost when the request is submitted.

  Note: To find the cost of the service option, click Home, Requests. If applicable, use the My Requests drop-down list to display requests. Find the request that contains the service option and view the details.

- **item_type**
  Specifies a valid value (see page 2161) for the item type, as specified in the Type label of the service option element. For example, if the type of the service option element is CA BSI contract (for CA Business Service Insight contract), the value of item_type is 5. Similarly, if the type is Form, the value of item_type is 14.

- **item_text**
  Specifies the value of the Display Text field on the service option element definition page. You can specify the condition to require either an exact match or an approximate match, as follows:

  - To require an exact match, specify the condition as follows:
    For global policies:

    ```
    $(_.sog['ab'].serviceoption[1].soe[2].item_text=='abc')
    ```

    For attached policies:

    ```
    $(_.serviceoption.soe[2].item_text=='abc')
    ```

    In this format, the text must match exactly, including case and spaces. For example, suppose "Premium Laptop" is the value of the Display Text field. In that case, the value of item_text must also be 'Premium Laptop': The value *cannot* be 'premium laptop' or 'Premium laptop'; the value *cannot* be any value except an exact match.

  - To require an approximate match, specify the condition as follows:

    ```
    $(anySoeWith('item_text',contains,'abc'))
    ```

In this format, the string that is specified must be either the same as the Display Text or a substring of Display Text. The string is not required to match exactly and is case-sensitive. For example, if "Premium Laptop" is the value of the Display Text field, then the string that is specified can be any of the following options:

- 'Premium Laptop'
- 'Laptop'
- 'Premium'

- **status**
  Specifies the request status of the service option that contains this service option element.

Formats

For all formats, enclose string values in single quotation marks, and enter numeric values without quotation marks.

Use the following format for conditions *with* a match function (see page 2162):

```
$(anySoeWith('attribute',operator,'value'))
```

Use the following formats (without spaces) for conditions *without* a match function.

- For global policies, conditions for service option elements use this format:

  ```
  $(_.sog[sogname].serviceoption[rownum].soe[colnum].attribute operator 'value')
  ```

  - ***sogname***
    Specifies the name of the service option group.
  - ***rownum***
    Specifies the row number of the service option.
    To find the row number of the service option (see page 2155) in the service option group, use the product UI.
    Row numbers apply to global policies *only*.
  - ***colnum***

  Specifies the column number of the service option element in its service option.
  To find the column number of the service option element (see page 2160) in the service option, use the product UI.

- For attached policies, conditions for service option elements use this format:

  ```
  $(_.serviceoption.soe[colnum].attribute operator 'value')
  ```

  The same *colnum* attribute as for global policies also applies to attached policies.

Examples

Consider the following examples:

- You can specify the assignee for the request pending action when all of the following conditions are true:
  - The service option group is named Reserve Virtual Machine. This condition applies to global policies only.
  - The service option is in row 2. This condition applies to global policies only.
  - The service option element is in column 3. This condition applies to both global and attached policies.
  - The item type of the service option element is 15 (for reservation). This condition applies to both global and attached policies.

  To do so, use this condition:
  For global policies:

  ```
  $(_.sog['Reserve Virtual Machine'].serviceoption[2].soe[3].item_type==15)
  ```

  For attached policies:

  ```
  $(_.serviceoption.soe[3].item_type==15)
  ```

  Thus, this condition is met when a service option for creating or extending a reservation meets the specified criteria.

- You can specify the assignee for the request pending action when all of the following conditions are true:
  - The service option group is named Increase Mailbox Size. This condition applies to global policies only.
  - The service option is in row 3 of the service option group. This condition applies to global policies only.
  - The estimated cost for the service option element is greater than 200 monetary units. The default unit is dollars. This condition applies to both global and attached policies.
  - The service option element is in column 2 of the service option. This condition applies to both global and attached policies.

  To do so, use this condition:
  For global policies:

  ```
  $(_.sog['Increase Mailbox Size'].serviceoption[3].soe[2].estimatedCost >200)
  ```

  For attached policies:

  ```
  $(_.serviceoption.soe[2].estimatedCost >200)
  ```

  Thus, this condition is especially useful to specify approvers or fulfillers for service option elements costing more than a specified amount.

- You can specify the assignee for the request pending action when all of the following conditions are true:

- The service option group is named Application Hosting.
- The estimated cost is greater than or equal to 2500 monetary units for the sixth service option element in the fifth service option.

To do so, use this condition:
For global policies:

```
$(_.sog['Application Hosting'].serviceoption[5].soe[6].estimatedCost>=2500)
```

For attached policies:

```
$(_.serviceoption.soe[6].estimatedCost>=2500)
```

Examples with the Match Function

Consider the following examples:

- You can specify the assignee for the request pending action when the following condition is true: Any service option element in the request has an estimated cost greater than 30.0 monetary units (for example, pounds). To do so, use this condition:

  ```
  $(anySoeWith('estimatedCost',gt,30.0))
  ```

- You can specify the assignee for the request pending action when the following is true: The value of the item_text attribute of any service option element in the request contains the 'share' text string. To do so, use this condition:

  ```
  $(anySoeWith('item_text',contains,'share'))
  ```

Find the Column Number of a Service Option Element

When you specify conditions that are based on the attributes of service option elements (see page 2156), you include the column number. This column number is the position of the service option element in its service option. This requirement applies to both global and attached policies (see page 3018). For global policies *only*, you also specify the row number of the service option in its service option group (see page 2155).

Follow these steps:

1. Click Catalog, Service Offerings.
2. Click the Option Groups tab.
3. Click the service option group of interest.
4. Click the Definition tab.
5. Edit the service option of interest.
6. Edit or add the service option element of interest, for example, a rate or text element.
   The Service Option Element Definition dialog appears.
7. Click the Options tab and view the Column field near the top of the dialog. Record the number for use in conditions.

Note: Column numbers start at 1 and increase sequentially by 1 as you add service option elements to a service option.

You have found the column number of the service option element. You can use the column number in a condition that is based on the attributes of a service option element.

Examples

For example, a service option group lists these service options, in sequential order: Gold, Silver, and Bronze. The Gold service option is in row 1. The Silver service option is in row 2, and the Bronze service option is in row 3. Each service option has a rate service option element in column 5.

The following examples apply to global policies *only*:

To specify a condition for the Gold service option, use the following format:

```
$(_.sog['sogname'].serviceoption[1].soe[5].attribute operator 'value')
```

Similarly, to specify a condition for the Silver service option, use the following format:

```
$(_.sog['sogname'].serviceoption[2].soe[5].attribute operator 'value')
```

The following example applies to attached policies *only*:

To specify a condition for any of the three options, use the following format:

```
$(_.serviceoption.soe[5].attribute operator 'value')
```

Valid values for item_type

The valid values for item_type and their meanings follow:

item_type	Meaning
0	Text
1	Header
2	Numeric range
3	Rate
4	Usage based price
5	CA Business Service Insight contract
6	Numeric
7	Boolean
8	Adjustment
9	Date
10	Date range
11	Day of billing

item_type	Meaning
12	Allocation
14	Form Designer form
15	Reservation

Service designers specify the item type when they complete the Service Option Element Definition window--Definition tab (see page 3021). They do so as part of the process of creating or editing a service option.

Match Functions for Service Options and Service Option Elements

Use match functions when defining conditions for service options and service option elements. To specify an attribute, value, and relationship in a condition *without* specifying any other elements that are required in other conditions, use a match function.

Elements that are required in other conditions but *not* in match functions include the following elements:

- The name of the request, service, or service option group
- The row number of a service option or service option element

Match functions thus provide flexibility by enabling you to specify the attribute condition across multiple components of a request.

To specify a match function for a service option, use the following format:

```
$(anySoWith('attribute',operator,'value'))
```

To specify a match function for a service option element, use the following format:

```
$(anySoeWith('attribute',operator,'value'))
```

For both formats, enclose string values in single quotation marks, and enter numeric values without quotation marks.

- ***attribute***
  For service options, you can use all the same attributes that are used (see page 2151) in conditions for service options without a match function.
  For service option elements, you can use all the same attributes that are used (see page 2156) in conditions for other service option elements without a match function.

- ***operator***
  For both service options and service option elements, *operator* can be any of the following values:

Operator	Meaning
eq	equal to
neq	not equal to
lt	less than

Operator	Meaning
gt	greater than
lteq	less than or equal to
gteq	greater than or equal to
startsWith	starts with
contains	contains
endsWith	ends with

- ***value***
  Specifies a string or numeric value for the attribute.
  For more information, see the examples of conditions that use the match function for service options (see page 2151) and service option elements (see page 2156).

Conditions Based on the Fields of Form Designer Forms

You can specify conditions that are based on the values of fields of Form Designer forms. Use the following format to specify such conditions:

```
$(_.sog[sogname].serviceoption[rownum].form[form-name].value of _id attribute string-operator'value of value attribute')
```

- ***rownum***
  Specifies the row number of the service option that includes the Form Designer form.

- ***form-name***
  Specifies the name of the Form Designer forms, from the Form Designer tree. Do *not* use the value of name attribute for the form.

- ***value of _id attribute string-operator 'value of value attribute'***
  Specifies the attribute operator value portion of the conditions, using the same format as other conditions (see page). For forms, the following requirements apply:

  - The *attribute* specification must be the value of the _id attribute of the field you want.

  - The *value* specification must be based on the value of the value attribute of the same field.

  Typically, the *value* specification is an option that is based on user input or user selection.

  Important! The Form Designer stores the values for all fields in string format. Even the fields that contain numeric input that users or the Catalog system specify are stored in string format. Therefore, conditions that are based on Form Designer fields can use *only* the comparison operators suitable for strings: equal (==) and not equal (!=). Moreover, always enclose these values in quotation marks, because they are always strings.

  If necessary, you can combine two or more expressions that use these comparison operators. Use operators for specifying complex or compound conditions (see page).
  See the following examples for details about specifying conditions that are based on Form Designer fields.

Examples Using a Predefined Form for Product Information

This example is based on a fictitious service option group that is named Insider Products. The service option group contains an actual predefined form named Product Info. To see this form, select Form Designer, expand the Forms tree, and select Product Info.

Users complete this form while requesting services to obtain services from Insider Products. This form includes a Discount Program Code field with an _id attribute whose value is discount_code and a value attribute whose default value is null. However, users can change this value by entering their discount code, if applicable.

You can specify the assignee for the request pending action, which is based on which of the following actions the user performs:

- User leaves the Discount Program Code field empty.
- User enters a discount code.

To meet each specification, use the following conditions, respectively:

- For an empty field:

```
$(_.sog['Insider Products'].serviceoption[1].form['Product Info'].discount_code==’
null’)
```

- For a field with user input:

```
$(_.sog['Insider Products'].serviceoption[1].form['Product Info'].discount_code!=’
null’)
```

Examples Using a Predefined Form with Radio Buttons

This example is based on a fictitious service option group that is named File Shares. The service option group contains an actual predefined form named File Share Access. To see this form, select Form Designer, expand the Forms tree, and select File Share Access. This form is useful for services that users use to request access to a network file share.

The sample conditions are based on the following options for access levels to the share and the values of their _id attributes:

- None: Permits no access.
- Read: Allows viewing of contained files and directories, loading of files, and executing software.
- Change: Provides all read permissions plus creating, deleting, and changing the directories and files.
- Full Control: Provides all change permissions, including file system changes and ownership.

For all these examples, both of the following conditions apply: The service option group is named File Shares, and the third service option includes a form that is named File Share Access.

The field is a select box that forces the user to select an option (using a radio button) on the form. Therefore, the form fieldportion of the condition uses the following format:

`id_attribute of parent field=='value attribute of child field'`

- **id_*attribute of parent field***
  Specifies the value of the id_attribute of parent field; here, the field that defines the select box. In this example, on the File Share Access form, the value is access_level. The select box appears as a radio button box on the form. Users must select one of the options by clicking its adjacent radio button.

- **'*value attribute of child field*'**
  Specifies the value of the value attribute (*not* the _id attribute) for the child attribute (the radio button option) that the user selected.
  In this example, on the File Share Access form, the valid values of these fields are none, read, change, and full. These values represent the options for each level of access to the file share.

View these form attributes on the Form Designer together with the following conditions to help gain a complete understanding of the relationship between them.

The following sample conditions are based on the radio button that the user selects on the File Share Access form:

- To specify the assignee for the pending action when the user selects No Access, use this condition:

  ```
  $(_.sog['File Shares'].serviceoption[3].form['File Share Access'].access_level
  =='none')
  ```

- To specify the assignee for the pending action when the user selects Read (for read-only access rights), use this condition:

```
$(_.sog['File Shares'].serviceoption[3].form['File Share Access'].access_level
=='read')
```

- To specify the assignee for the pending action when the user selects Change (for read and update access rights), use this condition:

```
$(_.sog['File Shares'].serviceoption[3].form['File Share Access'].access_level
=='change')
```

- To specify the assignee for the pending action when the user selects Full Control. Full Control provides access rights for read, update, create, delete, and so forth, use this condition.

  ```
  $(_.sog['File Shares'].serviceoption[3].form['File Share Access'].access_level
  =='full')
  ```

Conditions Based on the Attributes of the Location

You can specify conditions that are based on the attributes of the location, as follows:

- Conditions that are based on the attributes of the location of the assignee. (see page 2167)
  The assignee is the logged in user attempting to complete the pending action. When the policy condition is met, it triggers the pending action. Typically, the assignee performs an approval or fulfillment task.

- Conditions that are based on the attributes of the location of the business unit of the assignee. (see page 2168)

In both of these types of conditions, you can use the following attributes:

- **address**
- **city**
  Specifies the code for the city for the business unit of the assignee. Users enter their own values, rather than run a database query. This data is user-defined, and the MDB does not store this data.
- **country**
  Specifies the country code for the business unit.
  Enter the code for the country you want from the ca_country table.
  For example, to list the code of India in that table, run the following query on the MDB from your database client:

  ```
  Select id from ca_country where name="India"
  ```

  The results show that the country code for India is 114.
  To list all country codes for CA Service Catalog, run the following query on the MDB from your database client:

  ```
  select id from ca_country
  ```

- **county**
  Specifies the *user-specified* value, such as a name or code, for a county. Examples include a county in a state of the United States or in another country that has counties.
  Values for this attribute are user-specified. The CA Service Catalog and the MDB do not validate or maintain them.
- **description**
- **fax**
- **name**
- **state**
  Specifies the 50 states in the United States, and some but not all of the United States territories, such as American Samoa. Also applies to all provinces in Canada. This attribute is null for other countries and territories.
  This attribute specifies the ID for the applicable state, territory, or province for the business unit of the assigner. Examples include 7404 for California and 7434 for New York.
  Enter the ID you want from the ca_state_province table.
  To list the IDs for all states, territories, and provinces, run this query on the MDB from your database client:

  ```
  select id from ca_state_province
  ```

  Verify the two-letter symbol for the state, territory, or province from the United States Postal Service (www.usps.com (http://www.usps.com)). You can use that symbol to find the ID. For example, the symbol for the state of New York is NY. Therefore, to list the ID for New York, run the following query on the MDB from your database client:

```
select id from ca_state_province where symbol='NY'
```

This query returns a value of 7434, which you use in your condition to assign the pending action based on the user's location being the state of New York. For details, see the sample state attributes in the conditions that are based on the attributes of the location of the business unit of the assignee (see page 2168).
To list the IDs, symbols, and names for all applicable states, territories, and provinces, run the following query:

```
Select id,symbol,description from ca_state_province
```

The results appear similar to the following output:

```
7400 AK  Alaska

7401 AL  Alabama

...
```

- **phone**
- **postalCode**
- **uuid**

Conditions Based on the Attributes of the Location of the Assignee

To specify conditions that are based on the attributes of the location of the assignee, use the following format:

`$(_.user.location.`*`attribute operator 'value'`*`)`

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not use spaces.

Examples

Sample conditions follow:

- To assign the pending action when the name of the location of the user is Home, use this condition:

  `$(_.user.location.name==‘Home’)`

- To assign the pending action when the country of the user's location is India, use this condition:

  `$(_.user.location.country==114)`

  Note: The code for India in the ca_country table is 114.

- To assign the pending action when the city of the location of the user is Hamburg, use this condition:

  `$(_.user.location.city==‘Hamburg’)`

Conditions Based on the Attributes of the Location of the Business Unit of the Assignee

To specify conditions that are based on the attributes of the location of the business unit of the assignee, use the following format:

```
$(_.bu.location.attribute operator 'value')
```

Enclose string values in single quotation marks. Enter numeric values without quotation marks. Do not use spaces.

Examples

Sample conditions follow:

- To assign the request pending action when the business unit is in the state of New York in the United States, use this condition:

  ```
  $(_. bu.location.state==7434)
  ```

  7434 is the code for New York in the ca_state_province table.

- To assign the request pending action when the business unit is in the country of Mozambique, use this condition:

  ```
  $(_. bu.location.country==169)
  ```

  169 is the code for the country of Mozambique in the ca_country table.

Manage Request SLAs

CA Service Catalog administrators can create request SLAs to monitor whether service options in a request are processed within the time period that you specify for each monitored state. Your SLAs specify time to warning and time to violation for the selected service option. A single request SLA specifies the amount of time that is permitted between specified statuses. For example, the time that is taken to move from Submitted to Approved or from Approved to Completed.

For each request SLA, you specify the starting and ending statuses to monitor. You also specify the length of time to reach warning and violation thresholds, the expected level of compliance, and related settings.

Setting SLA warning and violation thresholds helps service providers to track the progress of a request. The request SLA data is stored in the CA Service Catalog database so that it can be included in reports.

The monitoring of time for an SLA warning or violation (SLA time) is started and stopped according to the service hours that both the outage calendars and the business hours specifications that are associated to the service determine. Administrators optionally associate one outage calendar and one business hours specification to each service. Only during service hours, the SLA time is monitored.

You can optionally specify automated actions to be initiated when a request SLA reaches warning status or violation status. These actions include a predefined action for sending email alert messages. For more information, see Configure Automated Email Alerts for SLA Warnings and Violations (see page 2172) section.

Note: Request Service Level Agreements (SLAs) are a feature of CA Service Catalog. Quality of Service (QoS) SLAs are available only if CA Service Catalog is integrated with CA Business Service Insight.

Create Request SLAs

Request SLAs are processed according to both the fixed rules specified by CA Service Catalog and the Maximum Delay for Request SLA Alerts setting that you specify.

Fixed Rules

Request SLAs are processed according to the following fixed rules specified by CA Service Catalog:

- After a request containing one or more SLAs is submitted, the SLA clock for each SLA instance starts tracking time when the request reaches the starting status that is specified for the SLA. For example, if an SLA monitors the period from Pending Approval to Approved, the SLA clock for this SLA instance starts tracking time when the request status changes to Pending Approval.
- An SLA instance completes when either of the following situations occur:
  - The request reaches the ending status of the SLA before the SLA violation time expires. In this case, the SLA instance completes successfully. The SLA violation time is the maximum length of time that is permitted for the request reach the ending status of the SLA.
  - The SLA violation time expires before the request reaches the ending status of the SLA. In this case, the SLA instance completes unsuccessfully, causing an SLA violation to occur.
- The SLA clock tracks time for each active SLA instance and alerts the Catalog system if the SLA warning or violation time expires. The SLA clock is paused and resumed *only* when a CA Service Catalog user holds or resumes the request containing the SLA instance. If a user changes a request with an active SLA instance to Hold status, then the SLA clock is paused. When a user changes such a request to Resume status, the SLA clock is resumed.

  Note: If the user of another product that is integrated with CA Service Catalog puts a request on hold in that product, the CA Service Catalog request, the SLA instance remains active. To pause the SLA clock, hold the request in CA Service Catalog.

- The SLA clock is stopped immediately when a request is canceled.
- The SLA clock is never restarted (reset to zero) under any circumstances, even if the request is rejected and resubmitted.
  For example, consider an SLA named “Approved within 1 Day SLA.” This SLA monitors from “Submitted” status to “Approved” status with a one day SLA violation time. In this example, the approval process also follows this request status cycle, in the following order:
  1. Submitted
  2. Pending Approval

3. Approved
4. Approval Done or Submitted
5. Pending Approval
6. Rejected

In this example, if an end user requests a service, a day passes, and an approver rejects the request, then the SLA "Approved within 1 Day SLA" is violated. After the rejection, if the affected end user updates the request detail and submits it again, the request approval process is repeated, but the SLA instance is not monitored again because it has already been monitored once and completed with a violation.

- If an SLA instance completes, successfully or with a violation, that same instance is never monitored again under any circumstances.
- Once a monitored request SLA instance is violated, the violation is included in SLA-related BusinessObjects Enterprise reports, even if the related request is canceled or rejected after the violation occurs. To exclude such records from a report, customize the report.

Request SLA Processor

The request SLA processor is part of Catalog Component and:

- Listens for status changes for requests that have active SLA instances.
- Sends alert messages when SLA warnings or SLA violations occur.
- Tracks time for the SLA clock.

Maximum Delay for Request SLA Alerts

The request SLA processor checks for SLA instances to be processed at these times:

- When the SLA clock for an active SLA instance alerts the Catalog system that the SLA warning or violation time has expired.
- When it receives a message of a change in the status of a request with an active SLA instance.
- When the time period specified in the Maximum Delay for Request SLA Alerts setting expires. To access this setting, select Administration, Configuration, Request SLA. This setting specifies how frequently the request SLA processor checks for SLA warnings or violations. This setting applies to all SLA instances managed by a Catalog Component computer.

In a Catalog Component-clustered environment, if a clustered computer fails, then event notifications, including SLA alert messages, can be delayed until the failed computer is restored or until other computers in the cluster begin doing the work of the failed computer. So, SLA warning and violation messages may not be issued on time.

To minimize this possible delay in SLA processing time when a Catalog Component- clustered computer fails, you can configure the Maximum Delay for Request SLA Alerts to meet your needs. The smaller the value you set, the greater the frequency with which the request SLA processor checks

the SLA clock for warning and violation times. Therefore, set a less frequent time period, such as one hour, to be informed of SLA warnings and violations quickly. Otherwise, set a larger time period, such as one day, to be notified about SLA warnings and violations later, when the failed clustered computer is restored.

Setting the Maximum Delay for Request SLA Alerts helps reduce any delay of SLA processing in case the clustered computer that started the SLA clock becomes unavailable for a length of time longer than a warning or violation period. In such cases, other active clustered computers take over SLA processing from the failed computer, when one of the following events occurs:

- The Maximum Delay for Request SLA Alerts time period expires.
- An SLA warning or violation is issued.
- A status change occurs in a request with an active SLA instance.

The following criteria can help CA Service Catalog administrators determine which service options to monitor with SLAs:

- Check whether any *critical* business rules, business needs, or contractual obligations with service consumers affect any service options. Indicate that such service options require SLAs.
- Check whether it is expected that *all* service options in your implementation are monitored with SLAs.

Request SLAs monitor whether service options in a service option group are processed within the specified time period. Your SLAs specify time to warning and time to violation for the selected service option.

Follow these steps:

1. Select Catalog, Service Offerings.
2. Expand the tree and select the service to which you want to add the SLA.
3. Click the Definition tab of the service.
4. Click the expand sign on the header next to the service option group name.
5. Locate the service option to which you want to add the SLA.
6. Click the SLA icon and click Add to create the SLA.
7. Specify the values for each SLA.
8. If you create multiple SLAs, select one of them as the primary SLA. To do so, click the option button in the Primary column. If a service option contains only one SLA, then that SLA is the primary SLA.
   When a service option has multiple SLAs, the status of the primary SLA determines the status of the service option as a whole, regardless of the status of the other SLAs. For example, suppose you create four SLAs for a service option. If the primary SLA has not reached a warning or violation when the request containing the service option is completed, then the SLA for that service option is satisfied, even if all of the other three SLAs *did* reach a warning

or violation.
Conversely, if three of the four SLAs have no warning or violation, but the primary SLA has a warning or violation, then the service option as a whole has a warning or violation.
Both warnings and violations are reflected in SLA Reports.

(Optional) Configure Automated Email Alerts for SLA Warnings and Violations

As an administrator, you can create automated actions to be initiated when a request SLA reaches warning status or violation status. Such actions can include using the predefined actions for sending email alerts and running your own custom actions, such as running command-line commands. Using automated actions can help you find the root cause of a problem sooner and correct it earlier. So, you can reduce the number of any additional related SLA warnings or violations.

To create automated email alerts for SLA warnings and violations, follow this process:

1. Select Home, Administration, Events-Rules-Actions.
2. Click the Event Type named Request SLA Alerts.
3. Decide whether to enable one or both of the predefined SLA-related rules: they are *When a Request SLA Instance is Warned* and *When a Request SLA Instance is Violated*.
4. Click Enable to enable one or both of these rules.
5. Click Enable to enable the matching action or actions for each rule that you enabled.
   The predefined (built-in) action for the SLA instance warning is named Email Alert for Warned Request SLA. Similarly, the predefined action for the SLA instance violation is named Email Alert for Violated Request SLA.
6. Click the Edit icon in the Edit column of the action. Specify the information.

   Note: The type is preset to Email. The Subject and Message fields are also preset.

7. Test the action. Submit a request with at least one SLA and letting the SLA reach warn status, violation status, or both.
8. Ensure that both actions (Email Alert for Warned Request SLA and Email Alert for Violated Request SLA) are configured

(Optional) Save SLA History and Reset SLAs

One likely reason to change your SLA definition is a change in service agreement or contract that arises after the monitoring of SLAs has already started. To handle such cases, CA Service Catalog enables you to save your current SLAs as history and reset SLAs. SLA history is *not* accessible using the GUI but *is* reflected in SLA reports.

For example, suppose that you created SLAs for a service on the first day of the month but later change the SLAs. At the end of the month, the SLA report for the entire month shows the different warning and violation settings that are used for the SLAs before and after the changes.

Important! When you change SLA settings for a service option, the change takes effect for *future* requests that include the service in which the service option resides. Requests that are in-progress are *not* affected.

Follow these steps:

1. Select Catalog, Service Offerings.
2. Expand the tree and select the service to which you want to add the SLA.
3. Click the Definition tab of the service.
4. Click the expand sign on the header next to the service option group name.
5. Locate the service option to which you want to add the SLA.
6. Click the SLA icon.
7. Click Save as History. This button is enabled *only* if the defined SLA exists.
8. When prompted, specify a reason for saving as history and resetting the SLAs.
9. Confirm the action.
   The existing SLAs are made inactive. Inactive SLAs are saved for use in both reports and in-progress requests, However, inactive SLAs are *not* applied to any future requests.
   Inactive SLAs are removed from the service and are no longer accessible through the CA Service Catalog GUI.
10. As needed, create request SLAs for use in future requests, to replace the inactive SLAs.

Note: Inactive SLAs are reflected in the SLA reports for related requests.

SLA Reports

In both the Report Builder and BusinessObjects Enterprise, you can create, configure, and view reports concerning SLA-related data. This data covers both current SLAs and inactive SLAs that have been saved as history (see page 2172).

Review the following information when you check SLA reports for warnings and violations:

- If a key SLA is warned or violated, then the service option that is associated with that SLA is warned or violated.
- If any service option in a service is warned or violated, then the service containing that service option is warned or violated.

- If any service in a request is warned or violated, then that request is warned or violated.
- For a violation, the Whole Violated Mark appears, at both the service and request levels.

Create Advanced Searches for Requests

Administrators can define the scope of user searches by clicking **Administration**, **Configuration**, **User Default**. They can specify the User Search Scope as either the business unit of the user or the entire Catalog system.

Follow these steps to create an advanced search query:

1. Click Home, Requests.
2. Click the advanced search icon.
